To obtain a bookmark for the most recently written event, call `audit_log_read_bookmark()`.

`arg`: The argument is optional. If omitted, the function reads events from the current position. If present, the argument can be a `JSON null` value to close the read sequence, or a `JSON` hash. Within a hash argument, items are optional and control aspects of the read operation such as the position at which to begin reading or how many events to read. The following items are significant (other items are ignored):

- `start`: The position within the audit log of the first event to read. The position is given as a timestamp and the read starts from the first event that occurs on or after the timestamp value. The `start` item has this format, where `value` is a literal timestamp value:

```
"start": { "timestamp": "value" }
```

- `timestamp, id`: The position within the audit log of the first event to read. The `timestamp` and `id` items together comprise a bookmark that uniquely identify a particular event. If an

`audit_log_read()` argument includes either item, it must include both to completely specify a position or an error occurs.

- `max_array_length`: The maximum number of events to read from the log. If this item is omitted, the default is to read to the end of the log or until the read buffer is full, whichever comes first.

To specify a starting position to `audit_log_read()`, pass a hash argument that includes either a `start` item or a bookmark consisting of `timestamp` and `id` items. If a hash argument includes both a `start` item and a bookmark, an error occurs.

If a hash argument specifies no starting position, reading continues from the current position.

If a timestamp value includes no time part, a time part of `00:00:00` is assumed.

Return value:

If the call succeeds, the return value is a `JSON` string containing an array of audit events, or a `JSON null` value if that was passed as the argument to close the read sequence. If the call fails, the return value is `NULL` and an error occurs.

Example:

```
mysql> SELECT audit_log_read(audit_log_read_bookmark());
+-----+
| audit_log_read(audit_log_read_bookmark()) |
+-----+
| [{ "timestamp": "2020-05-18 22:41:24", "id": 0, "class": "connection", ... } |
+-----+
mysql> SELECT audit_log_read('null');
+-----+
| audit_log_read('null') |
+-----+
| null |
+-----+
```

Notes:

Prior to MySQL 9.1, string return values could be binary `JSON` strings. For information about converting such values to nonbinary strings, see [Section 8.4.5.6, “Reading Audit Log Files”](#).

- `audit_log_read_bookmark()`

Returns a `JSON` string representing a bookmark for the most recently written audit log event. If the audit log format is not `JSON`, an error occurs.

The bookmark is a `JSON` hash with `timestamp` and `id` items that uniquely identify the position of an event within the audit log. It is suitable for passing to `audit_log_read()` to indicate to that function the position at which to begin reading.

For additional details about the audit log-reading process, see [Section 8.4.5.6, “Reading Audit Log Files”](#).

Arguments:

None.

Return value:

A `JSON` string containing a bookmark for success, or `NULL` and an error for failure.

Example:

```
mysql> SELECT audit_log_read_bookmark();
+-----+
| audit_log_read_bookmark() |
+-----+
| { "timestamp": "2019-10-03 21:03:44", "id": 0 } |
+-----+
```

Notes:

Prior to MySQL 9.1, string return values could be binary `JSON` strings. For information about converting such values to nonbinary strings, see [Section 8.4.5.6, “Reading Audit Log Files”](#).

- `audit_log_rotate()`

Arguments:

None.

Return value:

The renamed file name.

Example:

```
mysql> SELECT audit_log_rotate();
```

Using `audit_log_rotate()` requires the `AUDIT_ADMIN` privilege.

## Audit Log Option and Variable Reference

**Table 8.44 Audit Log Option and Variable Reference**

Name	Cmd-Line	Option File	System Var	Status Var	Var Scope	Dynamic
<code>audit-log</code>	Yes	Yes				
<code>audit_log_buffer_size</code>	Yes	Yes	Yes		Global	No
<code>audit_log_compression</code>	Yes	Yes	Yes		Global	No

<a href="#">Audit_log_write_waits</a>				Yes	Global	No

## Audit Log Options and Variables

This section describes the command options and system variables that configure operation of MySQL Enterprise Audit. If values specified at startup time are incorrect, the [audit\\_log](#) plugin may fail to initialize properly and the server does not load it. In this case, the server may also produce error messages for other audit log settings because it does not recognize them.

To configure activation of the audit log plugin, use this option:

- `--audit-log[=value]`

Command-Line Format	<code>--audit-log[=value]</code>
Type	Enumeration

Default Value	ON
Valid Values	ON  OFF  FORCE  FORCE_PLUS_PERMANENT

This option controls how the server loads the `audit_log` plugin at startup. It is available only if the plugin has been previously registered with `INSTALL PLUGIN` or is loaded with `--plugin-load` or `--plugin-load-add`. See [Section 8.4.5.2, “Installing or Uninstalling MySQL Enterprise Audit”](#).

The option value should be one of those available for plugin-loading options, as described in [Section 7.6.1, “Installing and Uninstalling Plugins”](#). For example, `--audit-log=FORCE_PLUS_PERMANENT` tells the server to load the plugin and prevent it from being removed while the server is running.

If the audit log plugin is enabled, it exposes several system variables that permit control over logging:

```
mysql> SHOW VARIABLES LIKE 'audit_log%';
```

Variable_name	Value
audit_log_buffer_size	1048576
audit_log_compression	NONE
audit_log_connection_policy	ALL
audit_log_current_session	OFF
audit_log_database	mysql
audit_log_disable	OFF
audit_log_encryption	NONE
audit_log_exclude_accounts	
audit_log_file	audit.log
audit_log_filter_id	0
audit_log_flush	OFF
audit_log_flush_interval_seconds	0
audit_log_format	NEW
audit_log_format_unix_timestamp	OFF
audit_log_include_accounts	
audit_log_max_size	0
audit_log_password_history_keep_days	0
audit_log_policy	ALL
audit_log_prune_seconds	0
audit_log_read_buffer_size	32768
audit_log_rotate_on_size	0
audit_log_statement_policy	ALL
audit_log_strategy	ASYNCHRONOUS

You can set any of these variables at server startup, and some of them at runtime. Those that are available only for legacy mode audit log filtering are so noted.

- `audit_log_buffer_size`

Command-Line Format	<code>--audit-log-buffer-size=#</code>
System Variable	<code>audit_log_buffer_size</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No

Type	Integer
Default Value	1048576
Minimum Value	4096
Maximum Value (64-bit platforms)	18446744073709547520
Maximum Value (32-bit platforms)	4294967295
Unit	bytes
Block Size	4096

When the audit log plugin writes events to the log asynchronously, it uses a buffer to store event contents prior to writing them. This variable controls the size of that buffer, in bytes. The server adjusts the value to a multiple of 4096. The plugin uses a single buffer, which it allocates when it initializes and removes when it terminates. The plugin allocates this buffer only if logging is asynchronous.

- [audit\\_log\\_compression](#)

Command-Line Format	<code>--audit-log-compression=value</code>
System Variable	<a href="#">audit_log_compression</a>
Scope	Global
Dynamic	No
<a href="#">SET_VAR</a> Hint Applies	No
Type	Enumeration
Default Value	<a href="#">NONE</a>
Valid Values	<a href="#">NONE</a> <a href="#">GZIP</a>

The type of compression for the audit log file. Permitted values are [NONE](#) (no compression; the default) and [GZIP](#) (GNU Zip compression). For more information, see [Compressing Audit Log Files](#).

- [audit\\_log\\_connection\\_policy](#)

Command-Line Format	<code>--audit-log-connection-policy=value</code>
Deprecated	Yes
System Variable	<a href="#">audit_log_connection_policy</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Enumeration
Default Value	<a href="#">ALL</a>
Valid Values	<a href="#">ALL</a> <a href="#">ERRORS</a>

NONE

**Note**

This deprecated variable applies only to legacy mode audit log filtering (see [Section 8.4.5.10, “Legacy Mode Audit Log Filtering”](#)).

The policy controlling how the audit log plugin writes connection events to its log file. The following table shows the permitted values.

Value	Description
ALL	Log all connection events
ERRORS	Log only failed connection events
NONE	Do not log connection events

**Note**

At server startup, any explicit value given for `audit_log_connection_policy` may be overridden if `audit_log_policy` is also specified, as described in [Section 8.4.5.5, “Configuring Audit Logging Characteristics”](#).

- `audit_log_current_session`

System Variable	<code>audit_log_current_session</code>
Scope	Global, Session
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value	depends on filtering policy

Whether audit logging is enabled for the current session. The session value of this variable is read only. It is set when the session begins based on the values of the `audit_log_include_accounts` and `audit_log_exclude_accounts` system variables. The audit log plugin uses the session value to determine whether to audit events for the session. (There is a global value, but the plugin does not use it.)

- `audit_log_database`

Command-Line Format	<code>--audit-log-database=value</code>
System Variable	<code>audit_log_database</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	String
Default Value	<code>mysql</code>

Specifies which database the `audit_log` plugin uses to find its tables. This variable is read only. For more information, see [Section 8.4.5.2, “Installing or Uninstalling MySQL Enterprise Audit”](#).

- `audit_log_disable`

Command-Line Format	<code>--audit-log-disable[={OFF ON}]</code>
System Variable	<code>audit_log_disable</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Permits disabling audit logging for all connecting and connected sessions. In addition to the `SYSTEM_VARIABLES_ADMIN` privilege, disabling audit logging requires the `AUDIT_ADMIN` privilege. See [Section 8.4.5.9, “Disabling Audit Logging”](#).

- `audit_log_encryption`

Command-Line Format	<code>--audit-log-encryption=value</code>
System Variable	<code>audit_log_encryption</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Enumeration
Default Value	<code>NONE</code>
Valid Values	<code>NONE</code>  <code>AES</code>

The type of encryption for the audit log file. Permitted values are `NONE` (no encryption; the default) and `AES` (AES-256-CBC cipher encryption). For more information, see [Encrypting Audit Log Files](#).

- `audit_log_exclude_accounts`

Command-Line Format	<code>--audit-log-exclude-accounts=value</code>
Deprecated	Yes
System Variable	<code>audit_log_exclude_accounts</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String

Default Value	NULL
---------------	------

**Note**

This deprecated variable applies only to legacy mode audit log filtering (see [Section 8.4.5.10, “Legacy Mode Audit Log Filtering”](#)).

The accounts for which events should not be logged. The value should be `NULL` or a string containing a list of one or more comma-separated account names. For more information, see [Section 8.4.5.7, “Audit Log Filtering”](#).

Modifications to `audit_log_exclude_accounts` affect only connections created subsequent to the modification, not existing connections.

- `audit_log_file`

Command-Line Format	<code>--audit-log-file=file_name</code>
System Variable	<code>audit_log_file</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	File name
Default Value	<code>audit.log</code>

The base name and suffix of the file to which the audit log plugin writes events. The default value is `audit.log`, regardless of logging format. To have the name suffix correspond to the format, set the name explicitly, choosing a different suffix (for example, `audit.xml` for XML format, `audit.json` for JSON format).

If the value of `audit_log_file` is a relative path name, the plugin interprets it relative to the data directory. If the value is a full path name, the plugin uses the value as is. A full path name may be useful if it is desirable to locate audit files on a separate file system or directory. For security reasons, write the audit log file to a directory accessible only to the MySQL server and to users with a legitimate reason to view the log.

For details about how the audit log plugin interprets the `audit_log_file` value and the rules for file renaming that occurs at plugin initialization and termination, see [Naming Conventions for Audit Log Files](#).

The audit log plugin uses the directory containing the audit log file (determined from the `audit_log_file` value) as the location to search for readable audit log files. From these log files and the current file, the plugin constructs a list of the ones that are subject to use with the audit log bookmarking and reading functions. See [Section 8.4.5.6, “Reading Audit Log Files”](#).

- `audit_log_filter_id`

System Variable	<code>audit_log_filter_id</code>
Scope	Global, Session
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	1

Minimum Value	0
Maximum Value	4294967295

The session value of this variable indicates the internally maintained ID of the audit filter for the current session. A value of 0 means that the session has no filter assigned.

- `audit_log_flush`

System Variable	<code>audit_log_flush</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

#### Note

The `audit_log_flush` variable is deprecated; expect support for it to be removed in a future version of MySQL. It is superseded by the `audit_log_rotate()` function.

If `audit_log_rotate_on_size` is 0, automatic audit log file rotation is disabled and rotation occurs only when performed manually. In that case, enabling `audit_log_flush` by setting it to 1 or `ON` causes the audit log plugin to close and reopen its log file to flush it. (The variable value remains `OFF` so that you need not disable it explicitly before enabling it again to perform another flush.) For more information, see [Section 8.4.5.5, “Configuring Audit Logging Characteristics”](#).

- `audit_log_flush_interval_seconds`

Command-Line Format	<code>--audit-log-flush-interval-seconds[=value]</code>
System Variable	<code>audit_log_flush_interval_seconds</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Unsigned Long
Default Value	0
Maximum Value (Windows)	4294967295
Maximum Value (Other)	18446744073709551615
Unit	seconds

This system variable depends on the `scheduler` component, which must be installed and enabled (see [Section 7.5.5, “Scheduler Component”](#)). To check the status of the component:

```
SHOW VARIABLES LIKE 'component_scheduler%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| component_scheduler.enabled | On |
```

When `audit_log_flush_interval_seconds` has a value of zero (the default), no automatic refresh of the privileges occurs, even if the `scheduler` component is enabled (`ON`).

Values between 0 and 60 (1 to 59) are not acknowledged; instead, these values adjust to 60 automatically and the server emits a warning. Values greater than 60 define the number of seconds the `scheduler` component waits from startup, or from the beginning of the previous execution, until it attempts to schedule another execution.

To persist this global system variable to the `mysqld-auto.cnf` file without setting the global variable runtime value, precede the variable name by the `PERSIST_ONLY` keyword or the `@@PERSIST_ONLY` qualifier.

- `audit_log_format`

Command-Line Format	<code>--audit-log-format=value</code>
System Variable	<code>audit_log_format</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Enumeration
Default Value	<code>NEW</code>
Valid Values	<code>OLD</code>  <code>NEW</code>  <code>JSON</code>

The audit log file format. Permitted values are `OLD` (old-style XML), `NEW` (new-style XML; the default), and `JSON`. For details about each format, see [Section 8.4.5.4, “Audit Log File Formats”](#).

- `audit_log_format_unix_timestamp`

Command-Line Format	<code>--audit-log-format-unix-timestamp[={OFF ON}]</code>
System Variable	<code>audit_log_format_unix_timestamp</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean

Default Value	OFF
---------------	-----

This variable applies only for JSON-format audit log output. When that is true, enabling this variable causes each log file record to include a `time` field. The field value is an integer that represents the UNIX timestamp value indicating the date and time when the audit event was generated.

Changing the value of this variable at runtime causes log file rotation so that, for a given JSON-format log file, all records in the file either do or do not include the `time` field.

Setting the runtime value of `audit_log_format_unix_timestamp` requires the `AUDIT_ADMIN` privilege, in addition to the `SYSTEM_VARIABLES_ADMIN` privilege (or the deprecated `SUPER` privilege) normally required to set a global system variable runtime value.

- `audit_log_include_accounts`

Command-Line Format	<code>--audit-log-include-accounts=value</code>
Deprecated	Yes
System Variable	<code>audit_log_include_accounts</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value	NULL

#### Note

This deprecated variable applies only to legacy mode audit log filtering (see [Section 8.4.5.10, “Legacy Mode Audit Log Filtering”](#)).

The accounts for which events should be logged. The value should be `NULL` or a string containing a list of one or more comma-separated account names. For more information, see [Section 8.4.5.7, “Audit Log Filtering”](#).

Modifications to `audit_log_include_accounts` affect only connections created subsequent to the modification, not existing connections.

- `audit_log_max_size`

Command-Line Format	<code>--audit-log-max-size=#</code>
System Variable	<code>audit_log_max_size</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value (Windows)	4294967295
Maximum Value (Other)	18446744073709551615

Unit	bytes
Block Size	4096

`audit_log_max_size` pertains to audit log file pruning, which is supported for JSON-format log files only. It controls pruning based on combined log file size:

- A value of 0 (the default) disables size-based pruning. No size limit is enforced.
- A value greater than 0 enables size-based pruning. The value is the combined size above which audit log files become subject to pruning.

If you set `audit_log_max_size` to a value that is not a multiple of 4096, it is truncated to the nearest multiple. In particular, setting it to a value less than 4096 sets it to 0 and no size-based pruning occurs.

If both `audit_log_max_size` and `audit_log_rotate_on_size` are greater than 0, `audit_log_max_size` should be more than 7 times the value of `audit_log_rotate_on_size`. Otherwise, a warning is written to the server error log because in this case the “granularity” of size-based pruning may be insufficient to prevent removal of all or most rotated log files each time it occurs.

#### Note

Setting `audit_log_max_size` by itself is not sufficient to cause log file pruning to occur because the pruning algorithm uses `audit_log_rotate_on_size`, `audit_log_max_size`, and `audit_log_prune_seconds` in conjunction. For details, see [Space Management of Audit Log Files](#).

- `audit_log_password_history_keep_days`

Command-Line Format	<code>--audit-log-password-history-keep-days=#</code>
System Variable	<code>audit_log_password_history_keep_days</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	4294967295
Unit	days

The audit log plugin implements log file encryption using encryption passwords stored in the MySQL keyring (see [Encrypting Audit Log Files](#)). The plugin also implements password history, which includes password archiving and expiration (removal).

When the audit log plugin creates a new encryption password, it archives the previous password, if one exists, for later use. The `audit_log_password_history_keep_days` variable controls automatic removal of expired archived passwords. Its value indicates the number of days after which archived audit

log encryption passwords are removed. The default of 0 disables password expiration: the password retention period is forever.

New audit log encryption passwords are created under these circumstances:

- During plugin initialization, if the plugin finds that log file encryption is enabled, it checks whether the keyring contains an audit log encryption password. If not, the plugin automatically generates a random initial encryption password.
- When the `audit_log_encryption_password_set()` function is called to set a specific password.

In each case, the plugin stores the new password in the key ring and uses it to encrypt new log files.

Removal of expired audit log encryption passwords occurs under these circumstances:

- During plugin initialization.
- When the `audit_log_encryption_password_set()` function is called.
- When the runtime value of `audit_log_password_history_keep_days` is changed from its current value to a value greater than 0. Runtime value changes occur for `SET` statements that use the `GLOBAL` or `PERSIST` keyword, but not the `PERSIST_ONLY` keyword. `PERSIST_ONLY` writes the variable setting to `mysqld-auto.cnf`, but has no effect on the runtime value.

When password removal occurs, the current value of `audit_log_password_history_keep_days` determines which passwords to remove:

- If the value is 0, the plugin removes no passwords.
- If the value is `N > 0`, the plugin removes passwords more than `N` days old.

#### Note

Take care not to expire old passwords that are still needed to read archived encrypted log files.

If you normally leave password expiration disabled (that is, `audit_log_password_history_keep_days` has a value of 0), it is possible to perform an on-demand cleanup operation by temporarily assigning the variable a value greater than zero. For example, to expire passwords older than 365 days, do this:

```
SET GLOBAL audit_log_password_history_keep_days = 365;
SET GLOBAL audit_log_password_history_keep_days = 0;
```

Setting the runtime value of `audit_log_password_history_keep_days` requires the `AUDIT_ADMIN` privilege, in addition to the `SYSTEM_VARIABLES_ADMIN` privilege (or the deprecated `SUPER` privilege) normally required to set a global system variable runtime value.

- `audit_log_policy`

Command-Line Format	<code>--audit-log-policy=value</code>
Deprecated	Yes
System Variable	<code>audit_log_policy</code>
Scope	Global
Dynamic	No

<code>SET_VAR</code> Hint Applies	No
Type	Enumeration
Default Value	<code>ALL</code>
Valid Values	<code>ALL</code>  <code>LOGINS</code>  <code>QUERIES</code>  <code>NONE</code>

**Note**

This deprecated variable applies only to legacy mode audit log filtering (see [Section 8.4.5.10, “Legacy Mode Audit Log Filtering”](#)).

The policy controlling how the audit log plugin writes events to its log file. The following table shows the permitted values.

Value	Description
<code>ALL</code>	Log all events
<code>LOGINS</code>	Log only login events
<code>QUERIES</code>	Log only query events
<code>NONE</code>	Log nothing (disable the audit stream)

`audit_log_policy` can be set only at server startup. At runtime, it is a read-only variable. Two other system variables, `audit_log_connection_policy` and `audit_log_statement_policy`, provide finer control over logging policy and can be set either at startup or at runtime. If you use `audit_log_policy` at startup instead of the other two variables, the server uses its value to set those variables. For more information about the policy variables and their interaction, see [Section 8.4.5.5, “Configuring Audit Logging Characteristics”](#).

- `audit_log_prune_seconds`

Command-Line Format	<code>--audit-log-prune-seconds=#</code>
System Variable	<code>audit_log_prune_seconds</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value (Windows)	4294967295
Maximum Value (Other)	18446744073709551615

Unit	bytes
------	-------

`audit_log_prune_seconds` pertains to audit log file pruning, which is supported for JSON-format log files only. It controls pruning based on log file age:

- A value of 0 (the default) disables age-based pruning. No age limit is enforced.
- A value greater than 0 enables age-based pruning. The value is the number of seconds after which audit log files become subject to pruning.

#### Note

Setting `audit_log_prune_seconds` by itself is not sufficient to cause log file pruning to occur because the pruning algorithm uses `audit_log_rotate_on_size`, `audit_log_max_size`, and `audit_log_prune_seconds` in conjunction. For details, see [Space Management of Audit Log Files](#).

- `audit_log_read_buffer_size`

Command-Line Format	<code>--audit-log-read-buffer-size=#</code>
System Variable	<code>audit_log_read_buffer_size</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	32768
Minimum Value	32768
Maximum Value	4194304
Unit	bytes

The buffer size for reading from the audit log file, in bytes. The `audit_log_read()` function reads no more than this many bytes. Log file reading is supported only for JSON log format. For more information, see [Section 8.4.5.6, “Reading Audit Log Files”](#).

This variable has a default of 32KB and can be set at runtime. Each client should set its session value of `audit_log_read_buffer_size` appropriately for its use of `audit_log_read()`.

- `audit_log_rotate_on_size`

Command-Line Format	<code>--audit-log-rotate-on-size=#</code>
System Variable	<code>audit_log_rotate_on_size</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0

Maximum Value	18446744073709551615
Unit	bytes
Block Size	4096

If `audit_log_rotate_on_size` is 0, the audit log plugin does not perform automatic size-based log file rotation. If rotation is to occur, you must perform it manually; see [Manual Audit Log File Rotation](#).

If `audit_log_rotate_on_size` is greater than 0, automatic size-based log file rotation occurs. Whenever a write to the log file causes its size to exceed the `audit_log_rotate_on_size` value, the audit log plugin renames the current log file and opens a new current log file using the original name.

If you set `audit_log_rotate_on_size` to a value that is not a multiple of 4096, it is truncated to the nearest multiple. In particular, setting it to a value less than 4096 sets it to 0 and no rotation occurs, except manually.

#### Note

`audit_log_rotate_on_size` controls whether audit log file rotation occurs. It can also be used in conjunction with `audit_log_max_size` and `audit_log_prune_seconds` to configure pruning of rotated JSON-format log files. For details, see [Space Management of Audit Log Files](#).

- `audit_log_statement_policy`

Command-Line Format	<code>--audit-log-statement-policy=value</code>
Deprecated	Yes
System Variable	<code>audit_log_statement_policy</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Enumeration
Default Value	<code>ALL</code>
Valid Values	<code>ALL</code>  <code>ERRORS</code>  <code>NONE</code>

#### Note

This deprecated variable applies only to legacy mode audit log filtering (see [Section 8.4.5.10, “Legacy Mode Audit Log Filtering”](#)).

The policy controlling how the audit log plugin writes statement events to its log file. The following table shows the permitted values.

Value	Description
<code>ALL</code>	Log all statement events
<code>ERRORS</code>	Log only failed statement events

Value	Description
NONE	Do not log statement events

**Note**

At server startup, any explicit value given for `audit_log_statement_policy` may be overridden if `audit_log_policy` is also specified, as described in [Section 8.4.5.5, “Configuring Audit Logging Characteristics”](#).

- `audit_log_strategy`

Command-Line Format	<code>--audit-log-strategy=value</code>
System Variable	<code>audit_log_strategy</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	ASYNCHRONOUS
Valid Values	ASYNCHRONOUS  PERFORMANCE  SEMISYNCHRONOUS  SYNCHRONOUS

The logging method used by the audit log plugin. These strategy values are permitted:

- **ASYNCHRONOUS**: Log asynchronously. Wait for space in the output buffer.
- **PERFORMANCE**: Log asynchronously. Drop requests for which there is insufficient space in the output buffer.
- **SEMISYNCHRONOUS**: Log synchronously. Permit caching by the operating system.
- **SYNCHRONOUS**: Log synchronously. Call `sync()` after each request.

## Audit Log Status Variables

If the audit log plugin is enabled, it exposes several status variables that provide operational information. These variables are available for legacy mode audit filtering (deprecated) and JSON mode audit filtering.

- `Audit_log_current_size`

The size of the current audit log file. The value increases when an event is written to the log and is reset to 0 when the log is rotated.

- `Audit_log_direct_writes`

When the audit log plugin writes events to the JSON-format audit log, it uses a buffer to store event contents prior to writing them. If the query length is greater than the size of the buffer, then the plugin writes the event directly to the log, bypassing the buffer. This variable shows the number

of direct writes. The plugin determines the count based on the current write strategy in use (see [audit\\_log\\_strategy](#)).

**Table 8.45 Write-Strategy Effect on the Direct Write Count**

Write Strategy	Description
<a href="#">ASYNCHRONOUS</a>	Incremented if the event size does not fit into the internal buffer ( <a href="#">audit_log_buffer_size</a> server system variable).
<a href="#">PERFORMANCE</a>	Not incremented. The plugin discards events larger than internal buffer.
<a href="#">SEMISYNCHRONOUS</a>	Always incremented.
<a href="#">SYNCHRONOUS</a>	Always incremented.

- [Audit\\_log\\_event\\_max\\_drop\\_size](#)

The size of the largest dropped event in performance logging mode. For a description of logging modes, see [Section 8.4.5.5, “Configuring Audit Logging Characteristics”](#).

- [Audit\\_log\\_events](#)

The number of events handled by the audit log plugin, whether or not they were written to the log based on filtering policy (see [Section 8.4.5.5, “Configuring Audit Logging Characteristics”](#)).

- [Audit\\_log\\_events\\_filtered](#)

The number of events handled by the audit log plugin that were filtered (not written to the log) based on filtering policy (see [Section 8.4.5.5, “Configuring Audit Logging Characteristics”](#)).

- [Audit\\_log\\_events\\_lost](#)

The number of events lost in performance logging mode because an event was larger than the available audit log buffer space. This value may be useful for assessing how to set [audit\\_log\\_buffer\\_size](#) to size the buffer for performance mode. For a description of logging modes, see [Section 8.4.5.5, “Configuring Audit Logging Characteristics”](#).

- [Audit\\_log\\_events\\_written](#)

The number of events written to the audit log.

- [Audit\\_log\\_total\\_size](#)

The total size of events written to all audit log files. Unlike [Audit\\_log\\_current\\_size](#), the value of [Audit\\_log\\_total\\_size](#) increases even when the log is rotated.

- [Audit\\_log\\_write\\_waits](#)

The number of times an event had to wait for space in the audit log buffer in asynchronous logging mode. For a description of logging modes, see [Section 8.4.5.5, “Configuring Audit Logging Characteristics”](#).

### 8.4.5.12 Audit Log Restrictions

MySQL Enterprise Audit is subject to these general restrictions:

- Only SQL statements are logged. Changes made by no-SQL APIs, such as memcached, Node.JS, and the NDB API, are not logged.

- Only top-level statements are logged, not statements within stored programs such as triggers or stored procedures.
- Contents of files referenced by statements such as `LOAD DATA` are not logged.

**NDB Cluster.** It is possible to use MySQL Enterprise Audit with MySQL NDB Cluster, subject to the following conditions:

- All changes to be logged must be done using the SQL interface. Changes using no-SQL interfaces, such as those provided by the NDB API, memcached, or ClusterJ, are not logged.
- The plugin must be installed on each MySQL server that is used to execute SQL on the cluster.
- Audit plugin data must be aggregated amongst all MySQL servers used with the cluster. This aggregation is the responsibility of the application or user.

## 8.4.6 The Audit Message Component

The `audit_api_message_emit` component enables applications to add their own message events to the audit log, using the `audit_api_message_emit_udf()` function.

The `audit_api_message_emit` component cooperates with all plugins of audit type. For concreteness, examples use the `audit_log` plugin described in [Section 8.4.5, “MySQL Enterprise Audit”](#).

- [Installing or Uninstalling the Audit Message Component](#)
- [Audit Message Function](#)

### Installing or Uninstalling the Audit Message Component

To be usable by the server, the component library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

To install the `audit_api_message_emit` component, use this statement:

```
INSTALL COMPONENT "file://component_audit_api_message_emit";
```

Component installation is a one-time operation that need not be done per server startup. `INSTALL COMPONENT` loads the component, and also registers it in the `mysql.component` system table to cause it to be loaded during subsequent server startups.

To uninstall the `audit_api_message_emit` component, use this statement:

```
UNINSTALL COMPONENT "file://component_audit_api_message_emit";
```

`UNINSTALL COMPONENT` unloads the component, and unregisters it from the `mysql.component` system table to cause it not to be loaded during subsequent server startups.

Because installing and uninstalling the `audit_api_message_emit` component installs and uninstalls the `audit_api_message_emit_udf()` function that the component implements, it is not necessary to use `CREATE FUNCTION` or `DROP FUNCTION` to do so.

### Audit Message Function

This section describes the `audit_api_message_emit_udf()` function implemented by the `audit_api_message_emit` component.

Before using the audit message function, install the audit message component according to the instructions provided at [Installing or Uninstalling the Audit Message Component](#).

- `audit_api_message_emit_udf(component, producer, message[, key, value] ...)`

Adds a message event to the audit log. Message events include component, producer, and message strings of the caller's choosing, and optionally a set of key-value pairs.

An event posted by this function is sent to all enabled plugins of audit type, each of which handles the event according to its own rules. If no plugin of audit type is enabled, posting the event has no effect.

Arguments:

- `component`: A string that specifies a component name.
- `producer`: A string that specifies a producer name.
- `message`: A string that specifies the event message.
- `key, value`: Events may include 0 or more key-value pairs that specify an arbitrary application-provided data map. Each `key` argument is a string that specifies a name for its immediately following `value` argument. Each `value` argument specifies a value for its immediately following `key` argument. Each `value` can be a string or numeric value, or `NULL`.

Return value:

The string `OK` to indicate success. An error occurs if the function fails.

Example:

```
mysql> SELECT audit_api_message_emit_udf('component_text',
 'producer_text',
 'message_text',
 'key1', 'value1',
 'key2', 123,
 'key3', NULL) AS 'Message';

+-----+
| Message |
+-----+
| OK |
+-----+
```

Additional information:

Each audit plugin that receives an event posted by `audit_api_message_emit_udf()` logs the event in plugin-specific format. For example, the `audit_log` plugin (see [Section 8.4.5, "MySQL Enterprise Audit"](#)) logs message values as follows, depending on the log format configured by the `audit_log_format` system variable:

- JSON format (`audit_log_format=JSON`):

```
{
 ...
 "class": "message",
 "event": "user",
 ...
 "message_data": {
 "component": "component_text",
 "producer": "producer_text",
 "message": "message_text",
 "map": {
```

```

 "key1": "value1",
 "key2": 123,
 "key3": null
 }
}

```

- New-style XML format (`audit_log_format=NEW`):

```

<AUDIT_RECORD>
...
<NAME>Message</NAME>
...
<COMMAND_CLASS>user</COMMAND_CLASS>
<COMPONENT>component_text</COMPONENT>
<PRODUCER>producer_text</PRODUCER>
<MESSAGE>message_text</MESSAGE>
<MAP>
 <ELEMENT>
 <KEY>key1</KEY>
 <VALUE>value1</VALUE>
 </ELEMENT>
 <ELEMENT>
 <KEY>key2</KEY>
 <VALUE>123</VALUE>
 </ELEMENT>
 <ELEMENT>
 <KEY>key3</KEY>
 <VALUE/>
 </ELEMENT>
</MAP>
</AUDIT_RECORD>

```

- Old-style XML format (`audit_log_format=OLD`):

```

<AUDIT_RECORD
...
 NAME="Message"
...
 COMMAND_CLASS="user"
 COMPONENT="component_text"
 PRODUCER="producer_text"
 MESSAGE="message_text"/>

```

### Note

Message events logged in old-style XML format do not include the key-value map due to representational constraints imposed by this format.

Messages posted by `audit_api_message_emit_udf()` have an event class of `MYSQL_AUDIT_MESSAGE_CLASS` and a subclass of `MYSQL_AUDIT_MESSAGE_USER`. (Internally generated audit messages have the same class and a subclass of `MYSQL_AUDIT_MESSAGE_INTERNAL`; this subclass currently is unused.) To refer to such events in `audit_log` filtering rules, use a `class` element with a `name` value of `message`. For example:

```

{
 "filter": {
 "class": {
 "name": "message"
 }
 }
}

```

```
}
```

Should it be necessary to distinguish user-generated and internally generated message events, test the `subclass` value against `user` or `internal`.

Filtering based on the contents of the key-value map is not supported.

For information about writing filtering rules, see [Section 8.4.5.7, “Audit Log Filtering”](#).

## 8.4.7 MySQL Enterprise Firewall

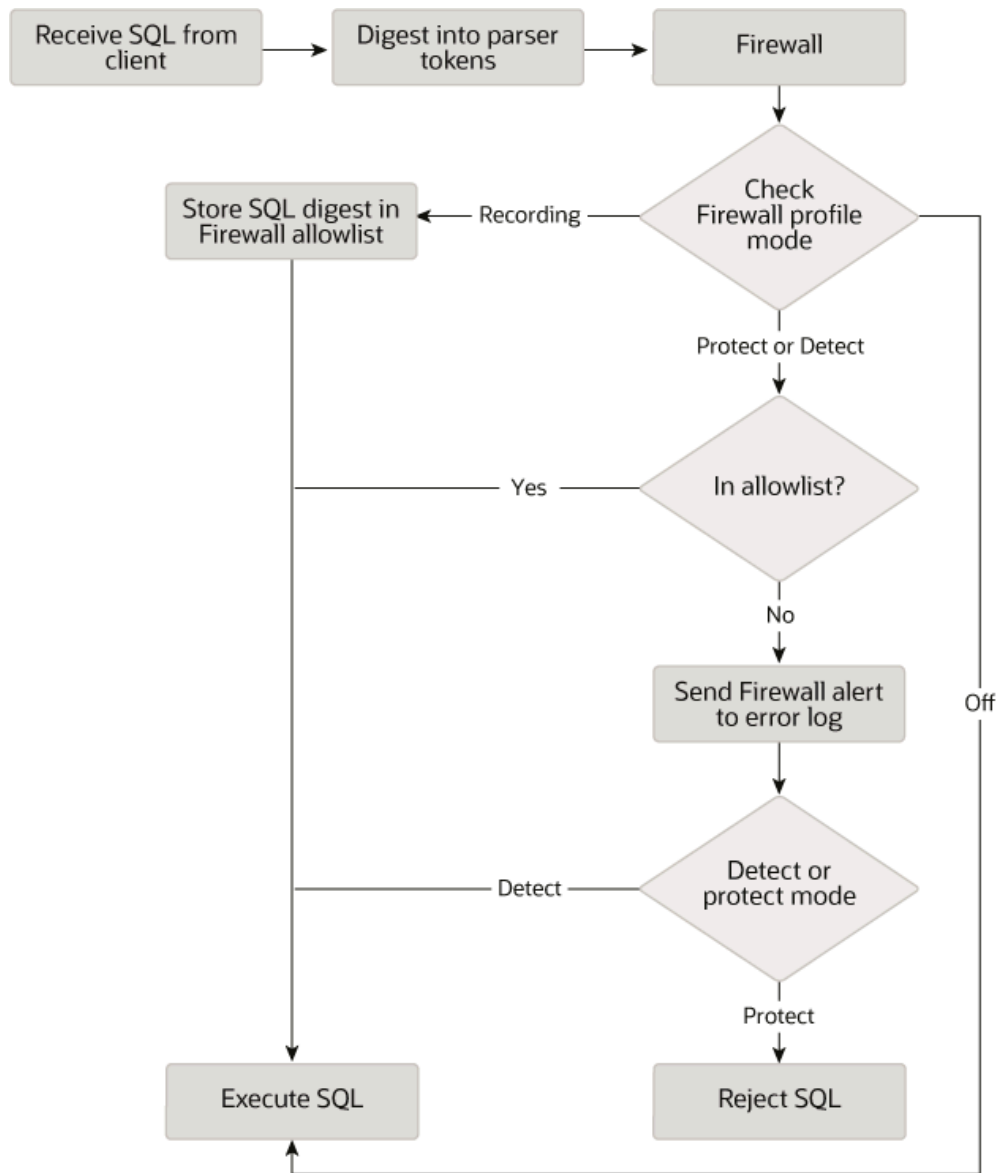

### Note

MySQL Enterprise Firewall is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see <https://www.mysql.com/products/>.

MySQL Enterprise Edition includes MySQL Enterprise Firewall, an application-level firewall that enables database administrators to permit or deny SQL statement execution based on matching against lists of accepted statement patterns. This helps harden MySQL Server against attacks such as SQL injection or attempts to exploit applications by using them outside of their legitimate query workload characteristics.

Each MySQL account registered with the firewall has its own statement allowlist, enabling protection to be tailored per account. For a given account, the firewall can operate in recording, protecting, or detecting mode, for training in the accepted statement patterns, active protection against unacceptable statements, or passive detection of unacceptable statements. The diagram illustrates how the firewall processes incoming statements in each mode.

**Figure 8.1 MySQL Enterprise Firewall Operation**

The following sections describe the elements of MySQL Enterprise Firewall, discuss how to install and use it, and provide reference information for its elements.

#### 8.4.7.1 Elements of MySQL Enterprise Firewall

MySQL Enterprise Firewall is based on a plugin library that includes these elements:

- A server-side plugin named `MYSQLENTERPRISE_FIREWALL` examines SQL statements before they execute and, based on the registered firewall profiles, renders a decision whether to execute or reject each statement.
- The `MYSQLENTERPRISE_FIREWALL` plugin, along with server-side plugins named `MYSQLENTERPRISE_FIREWALL_USERS` and `MYSQLENTERPRISE_FIREWALL_WHITELIST` implement Performance Schema and `INFORMATION_SCHEMA` tables that provide views into the registered profiles.

- Profiles are cached in memory for better performance. Tables in the firewall database provide backing storage of firewall data for persistence of profiles across server restarts. The firewall database can be the `mysql` system database or a custom schema (see [Installing MySQL Enterprise Firewall](#)).
- Stored procedures perform tasks such as registering firewall profiles, establishing their operational mode, and managing transfer of firewall data between the cache and persistent storage.
- Administrative functions provide an API for lower-level tasks such as synchronizing the cache with persistent storage.
- System variables enable firewall configuration and status variables provide runtime operational information.
- The `FIREWALL_ADMIN` and `FIREWALL_USER` privileges enable users to administer firewall rules for any user, and their own firewall rules, respectively.
- The `FIREWALL_EXEMPT` privilege exempts a user from firewall restrictions. This is useful, for example, for any database administrator who configures the firewall, to avoid the possibility of a misconfiguration causing even the administrator to be locked out and unable to execute statements.

### 8.4.7.2 Installing or Uninstalling MySQL Enterprise Firewall

MySQL Enterprise Firewall installation is a one-time operation that installs the elements described in [Section 8.4.7.1, “Elements of MySQL Enterprise Firewall”](#). Installation can be performed using a graphical interface or manually:

- On Windows, MySQL Configurator includes an option to enable MySQL Enterprise Firewall for you.
- MySQL Workbench 6.3.4 or higher can install MySQL Enterprise Firewall, enable or disable an installed firewall, or uninstall the firewall.
- Manual MySQL Enterprise Firewall installation involves running a script located in the `share` directory of your MySQL installation.

#### Important

Read this entire section before following its instructions. Parts of the procedure differ depending on your environment.

#### Note

If installed, MySQL Enterprise Firewall involves some minimal overhead even when disabled. To avoid this overhead, do not install the firewall unless you plan to use it.

For usage instructions, see [Section 8.4.7.3, “Using MySQL Enterprise Firewall”](#). For reference information, see [Section 8.4.7.4, “MySQL Enterprise Firewall Reference”](#).

- [Installing MySQL Enterprise Firewall](#)
- [Uninstalling MySQL Enterprise Firewall](#)

### Installing MySQL Enterprise Firewall

If MySQL Enterprise Firewall is already installed from an older version of MySQL, uninstall it using the instructions given later in this section and then restart your server before installing the current version. In this case, it is also necessary to register your configuration again.

On Windows, you can use [Section 2.3.2, “Configuration: Using MySQL Configurator”](#) to install MySQL Enterprise Firewall by checking the **Enable MySQL Enterprise Firewall** check box from the [Type and](#)

[Networking](#) tab. (**Open Firewall port for network access** has a different purpose. It refers to Windows Firewall and controls whether Windows blocks the TCP/IP port on which the MySQL server listens for client connections.)

To install MySQL Enterprise Firewall using MySQL Workbench, see [MySQL Enterprise Firewall Interface](#).

To install MySQL Enterprise Firewall manually, look in the [share](#) directory of your MySQL installation and choose the script that is appropriate for your platform. The available scripts differ in the file name used to refer to the script:

- [win\\_install\\_firewall.sql](#)
- [linux\\_install\\_firewall.sql](#)

The installation script creates stored procedures and tables in the firewall database you specify when you run the script. The `mysql` system database is the traditional storage option, however, it is preferred that you create and use a custom schema for this purpose.

To use the `mysql` system database, run the script as follows from the command line. The example here uses the Linux installation script. Make the appropriate substitutions for your system.

```
$> mysql -u root -p -D mysql < linux_install_firewall.sql
Enter password: (enter root password here)
```

To create and use a custom schema with the script, do the following:

1. Start the server with the `--loose-mysql-firewall-database=database-name` option. Insert the name of the custom schema to be used as the firewall database.

By prefixing the option with `--loose`, the program does not emit an error and exit, but instead issues only a warning.

2. Invoke the MySQL client program and create the custom schema on the server.

```
mysql> CREATE DATABASE IF NOT EXISTS database-name;
```

3. Run the script, naming the custom schema as the database for MySQL Enterprise Firewall.

```
$> mysql -u root -p -D database-name < linux_install_firewall.sql
Enter password: (enter root password here)
```

Installing MySQL Enterprise Firewall either using a graphical interface or manually should enable the firewall. To verify that, connect to the server and execute this statement:

```
mysql> SHOW GLOBAL VARIABLES LIKE 'mysql_firewall_mode';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| mysql_firewall_mode | ON |
+-----+-----+
```

If the plugin fails to initialize, check the server error log for diagnostic messages.

#### Note

To use MySQL Enterprise Firewall in the context of source/replica replication, Group Replication, or InnoDB Cluster, you must prepare the replica nodes prior to running the installation script on the source node. This is necessary because the `INSTALL PLUGIN` statements in the script are not replicated.

1. On each replica node, extract the `INSTALL PLUGIN` statements from the installation script and execute them manually.
2. On the source node, run the installation script as described previously.

## Uninstalling MySQL Enterprise Firewall

MySQL Enterprise Firewall can be uninstalled using MySQL Workbench or manually.

To uninstall MySQL Enterprise Firewall using MySQL Workbench 6.3.4 or higher, see [MySQL Enterprise Firewall Interface](#), in [Chapter 33, MySQL Workbench](#).

To uninstall MySQL Enterprise Firewall at the command line, run the uninstall script located in the `share` directory of your MySQL installation. The example here specifies the system database, `mysql`.

```
$> mysql -u root -p -D mysql < uninstall_firewall.sql
Enter password: (enter root password here)
```

If you created a custom schema when you installed MySQL Enterprise Firewall, make the appropriate substitution for your system.

```
$> mysql -u root -p -D database-name < uninstall_firewall.sql
Enter password: (enter root password here)
```

This script removes the plugins, tables, functions, and stored procedures for MySQL Enterprise Firewall.

### 8.4.7.3 Using MySQL Enterprise Firewall

Before using MySQL Enterprise Firewall, install it according to the instructions provided in [Section 8.4.7.2, “Installing or Uninstalling MySQL Enterprise Firewall”](#).

This section describes how to configure MySQL Enterprise Firewall using SQL statements. Alternatively, MySQL Workbench 6.3.4 or higher provides a graphical interface for firewall control. See [MySQL Enterprise Firewall Interface](#).

- [Enabling or Disabling the Firewall](#)
- [Scheduling Firewall Cache Reloads](#)
- [Assigning Firewall Privileges](#)
- [Firewall Concepts](#)
- [Registering Firewall Group Profiles](#)
- [Registering Firewall Account Profiles](#)
- [Monitoring the Firewall](#)
- [Migrating Account Profiles to Group Profiles](#)

#### Enabling or Disabling the Firewall

To enable or disable the firewall, set the `mysql_firewall_mode` system variable. By default, this variable is enabled when the firewall is installed. To control the initial firewall state explicitly, you can set the variable at server startup. For example, to enable the firewall in an option file, use these lines:

```
[mysqld]
mysql_firewall_mode=ON
```

After modifying `my.cnf`, restart the server to cause the new setting to take effect.

Alternatively, to set and persist the firewall setting at runtime:

```
SET PERSIST mysql_firewall_mode = OFF;
SET PERSIST mysql_firewall_mode = ON;
```

`SET PERSIST` sets a value for the running MySQL instance. It also saves the value, causing it to carry over to subsequent server restarts. To change a value for the running MySQL instance without having it carry over to subsequent restarts, use the `GLOBAL` keyword rather than `PERSIST`. See [Section 15.7.6.1, “SET Syntax for Variable Assignment”](#).

## Scheduling Firewall Cache Reloads

Each time the `MYSQL_FIREWALL` server-side plugin initializes, it loads data from these tables to its internal cache:

- `firewall_whitelist`
- `firewall_group_allowlist`
- `firewall_users`
- `firewall_groups`
- `firewall_membership`

Without restarting the server or reinstalling the server-side plugin, modification of data outside of the plugin is not reflected internally. The `mysql_firewall_reload_interval_seconds` system variable makes it possible to force memory cache reloads from tables at specified intervals. By default, the periodic interval value is set to zero, which disables reloads.

To schedule regular cache reloads, first ensure that the `scheduler` component is installed and enabled (see [Section 7.5.5, “Scheduler Component”](#)). To check the status of the component:

```
SHOW VARIABLES LIKE 'component_scheduler%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| component_scheduler.enabled | On |
+-----+-----+
```

With the firewall installed, set the `mysql_firewall_reload_interval_seconds` global system variable at server startup to a number between 60 and the `INT_MAX` macro value of the platform hosting the server. Values between zero and 60 (1 through 59) reset to 60. For example:

```
$> mysqld [server-options] --mysql-firewall-reload-interval-seconds=40
...
2023-08-31T17:46:35.043468Z 0 [Warning] [MY-015031] [Server] Plugin MYSQL_FIREWALL
reported: 'Invalid reload interval specified: 40. Valid values are 0 (off) or
greater than or equal to 60. Adjusting to 60.'
```

Alternatively, to set and persist the firewall setting at startup, precede the read-only variable name by the `PERSIST_ONLY` keyword or the `@@PERSIST_ONLY.` qualifier:

```
SET PERSIST_ONLY mysql_firewall_reload_interval_seconds = 120;
SET @@PERSIST_ONLY.mysql_firewall_reload_interval_seconds = 120;
```

After modifying the variable, restart the server to cause the new setting to take effect.

## Assigning Firewall Privileges

With the firewall installed, grant the appropriate privileges to the MySQL account or accounts to be used for administering it. The privileges depend on which firewall operations an account should be permitted to perform:

- Grant the `FIREWALL_EXEMPT` privilege to any account that should be exempt from firewall restrictions. This is useful, for example, for a database administrator who configures the firewall, to avoid the possibility of a misconfiguration causing even the administrator to be locked out and unable to execute statements.
- Grant the `FIREWALL_ADMIN` privilege to any account that should have full administrative firewall access. (Some administrative firewall functions can be invoked by accounts that have `FIREWALL_ADMIN` or the deprecated `SUPER` privilege, as indicated in the individual function descriptions.)
- Grant the `FIREWALL_USER` privilege to any account that should have administrative access only for its own firewall rules.
- Grant the `EXECUTE` privilege for the firewall stored procedures in the firewall database. These may invoke administrative functions, so stored procedure access also requires the privileges indicated earlier that are needed for those functions. The firewall database can be the `mysql` system database or a custom schema (see [Installing MySQL Enterprise Firewall](#)).

### Note

The `FIREWALL_EXEMPT`, `FIREWALL_ADMIN`, and `FIREWALL_USER` privileges can be granted only while the firewall is installed because the `MYSQL_FIREWALL` plugin defines those privileges.

## Firewall Concepts

The MySQL server permits clients to connect and receives from them SQL statements to be executed. If the firewall is enabled, the server passes to it each incoming statement that does not immediately fail with a syntax error. Based on whether the firewall accepts the statement, the server executes it or returns an error to the client. This section describes how the firewall accomplishes the task of accepting or rejecting statements.

- [Firewall Profiles](#)
- [Firewall Statement Matching](#)
- [Profile Operational Modes](#)
- [Firewall Statement Handling When Multiple Profiles Apply](#)

## Firewall Profiles

The firewall uses a registry of profiles that determine whether to permit statement execution. Profiles have these attributes:

- An allowlist. The allowlist is the set of rules that defines which statements are acceptable to the profile.
- A current operational mode. The mode enables the profile to be used in different ways. For example: the profile can be placed in training mode to establish the allowlist; the allowlist can be used for restricting statement execution or intrusion detection; the profile can be disabled entirely.
- A scope of applicability. The scope indicates which client connections the profile applies to:

- The firewall supports account-based profiles such that each profile matches a particular client account (client user name and host name combination). For example, you can register one account profile for which the allowlist applies to connections originating from `admin@localhost` and another account profile for which the allowlist applies to connections originating from `myapp@apphost.example.com`.
- The firewall supports group profiles that can have multiple accounts as members, with the profile allowlist applying equally to all members. Group profiles enable easier administration and greater flexibility for deployments that require applying a given set of allowlist rules to multiple accounts.

Initially, no profiles exist, so by default, the firewall accepts all statements and has no effect on which statements MySQL accounts can execute. To apply firewall protective capabilities, explicit action is required:

- Register one or more profiles with the firewall.
- Train the firewall by establishing the allowlist for each profile; that is, the types of statements the profile permits clients to execute.
- Place the trained profiles in protecting mode to harden MySQL against unauthorized statement execution:
  - MySQL associates each client session with a specific user name and host name combination. This combination is the *session account*.
  - For each client connection, the firewall uses the session account to determine which profiles apply to handling incoming statements from the client.

The firewall accepts only statements permitted by the applicable profile allowlists.

Most firewall principles apply identically to group profiles and account profiles. The two types of profiles differ in these respects:

- An account profile allowlist applies only to a single account. A group profile allowlist applies when the session account matches any account that is a member of the group.
- To apply an allowlist to multiple accounts using account profiles, it is necessary to register one profile per account and duplicate the allowlist across each profile. This entails training each account profile individually because each one must be trained using the single account to which it applies.

A group profile allowlist applies to multiple accounts, with no need to duplicate it for each account. A group profile can be trained using any or all of the group member accounts, or training can be limited to any single member. Either way, the allowlist applies to all members.

- Account profile names are based on specific user name and host name combinations that depend on which clients connect to the MySQL server. Group profile names are chosen by the firewall administrator with no constraints other than that their length must be from 1 to 288 characters.

**Note**

Due to the advantages of group profiles over account profiles, and because a group profile with a single member account is logically equivalent to an account profile for that account, it is recommended that all new firewall profiles be created as group profiles. Account profiles are deprecated, and subject to removal in a future MySQL version. For assistance converting existing account profiles, see [Migrating Account Profiles to Group Profiles](#).

The profile-based protection afforded by the firewall enables implementation of strategies such as these:

- If an application has unique protection requirements, configure it to use an account not used for any other purpose and set up a group profile or account profile for that account.
- If related applications share protection requirements, associate each application with its own account, then add these application accounts as members of the same group profile. Alternatively, configure all the applications to use the same account and associate them with an account profile for that account.

## Firewall Statement Matching

Statement matching performed by the firewall does not use SQL statements as received from clients. Instead, the server converts incoming statements to normalized digest form and firewall operation uses these digests. The benefit of statement normalization is that it enables similar statements to be grouped and recognized using a single pattern. For example, these statements are distinct from each other:

```
SELECT first_name, last_name FROM customer WHERE customer_id = 1;
select first_name, last_name from customer where customer_id = 99;
SELECT first_name, last_name FROM customer WHERE customer_id = 143;
```

But all of them have the same normalized digest form:

```
SELECT `first_name` , `last_name` FROM `customer` WHERE `customer_id` = ?
```

By using normalization, firewall allowlists can store digests that each match many different statements received from clients. For more information about normalization and digests, see [Section 29.10, “Performance Schema Statement Digests and Sampling”](#).

### Warning

Setting the `max_digest_length` system variable to zero disables digest production, which also disables server functionality that requires digests, such as MySQL Enterprise Firewall.

## Profile Operational Modes

Each profile registered with the firewall has its own operational mode, chosen from these values:

- **OFF**: This mode disables the profile. The firewall considers it inactive and ignores it.
- **RECORDING**: This is the firewall training mode. Incoming statements received from a client that matches the profile are considered acceptable for the profile and become part of its “fingerprint.” The firewall records the normalized digest form of each statement to learn the acceptable statement patterns for the profile. Each pattern is a rule, and the union of the rules is the profile allowlist.

A difference between group and account profiles is that statement recording for a group profile can be limited to statements received from a single group member (the training member).

- **PROTECTING**: In this mode, the profile allows or prevents statement execution. The firewall matches incoming statements against the profile allowlist, accepting only statements that match and rejecting those that do not. After training a profile in **RECORDING** mode, switch it to **PROTECTING** mode to harden MySQL against access by statements that deviate from the allowlist. If the `mysql_firewall_trace` system variable is enabled, the firewall also writes rejected statements to the error log.
- **DETECTING**: This mode detects but does not block intrusions (statements that are suspicious because they match nothing in the profile allowlist). In **DETECTING** mode, the firewall writes suspicious statements to the error log but accepts them without denying access.

When a profile is assigned any of the preceding mode values, the firewall stores the mode in the profile. Firewall mode-setting operations also permit a mode value of **RESET**, but this value is not stored: setting a profile to **RESET** mode causes the firewall to delete all rules for the profile and set its mode to **OFF**.

**Note**

Messages written to the error log in `DETECTING` mode or because `mysql_firewall_trace` is enabled are written as Notes, which are information messages. To ensure that such messages appear in the error log and are not discarded, make sure that error-logging verbosity is sufficient to include information messages. For example, if you are using priority-based log filtering, as described in [Section 7.4.2.5, “Priority-Based Error Log Filtering \(log\\_filter\\_internal\)”](#), set the `log_error_verbosity` system variable to a value of 3.

**Firewall Statement Handling When Multiple Profiles Apply**

For simplicity, later sections that describe how to set up profiles take the perspective that the firewall matches incoming statements from a client against only a single profile, either a group profile or account profile. But firewall operation can be more complex:

- A group profile can include multiple accounts as members.
- An account can be a member of multiple group profiles.
- Multiple profiles can match a given client.

The following description covers the general case of how the firewall operates, when potentially multiple profiles apply to incoming statements.

As previously mentioned, MySQL associates each client session with a specific user name and host name combination known as the *session account*. The firewall matches the session account against registered profiles to determine which profiles apply to handling incoming statements from the session:

- The firewall ignores inactive profiles (profiles with a mode of `OFF`).
- The session account matches every active group profile that includes a member having the same user and host. There can be more than one such group profile.
- The session account matches an active account profile having the same user and host, if there is one. There is at most one such account profile.

In other words, the session account can match 0 or more active group profiles, and 0 or 1 active account profiles. This means that 0, 1, or multiple firewall profiles are applicable to a given session, for which the firewall handles each incoming statement as follows:

- If there is no applicable profile, the firewall imposes no restrictions and accepts the statement.
- If there are applicable profiles, their modes determine statement handling:
  - The firewall records the statement in the allowlist of each applicable profile that is in `RECORDING` mode.
  - The firewall writes the statement to the error log for each applicable profile in `DETECTING` mode for which the statement is suspicious (does not match the profile allowlist).
  - The firewall accepts the statement if at least one applicable profile is in `RECORDING` or `DETECTING` mode (those modes accept all statements), or if the statement matches the allowlist of at least one applicable profile in `PROTECTING` mode. Otherwise, the firewall rejects the statement (and writes it to the error log if the `mysql_firewall_trace` system variable is enabled).

With that description in mind, the next sections revert to the simplicity of the situations when a single group profile or a single account profile apply, and cover how to set up each type of profile.

## Registering Firewall Group Profiles

MySQL Enterprise Firewall supports registration of group profiles. A group profile can have multiple accounts as its members. To use a firewall group profile to protect MySQL against incoming statements from a given account, follow these steps:

1. Register the group profile and put it in **RECORDING** mode.
2. Add a member account to the group profile.
3. Connect to the MySQL server using the member account and execute statements to be learned. This trains the group profile and establishes the rules that form the profile allowlist.
4. Add to the group profile any other accounts that are to be group members.
5. Switch the group profile to **PROTECTING** mode. When a client connects to the server using any account that is a member of the group profile, the profile allowlist restricts statement execution.
6. Should additional training be necessary, switch the group profile to **RECORDING** mode again, update its allowlist with new statement patterns, then switch it back to **PROTECTING** mode.

Observe these guidelines for firewall-related account references:

- Take note of the context in which account references occur. To name an account for firewall operations, specify it as a single quoted string ('*user\_name@host\_name*'). This differs from the usual MySQL convention for statements such as **CREATE USER** and **GRANT**, for which you quote the user and host parts of an account name separately ('*user\_name*'@'*host\_name*').

The requirement for naming accounts as a single quoted string for firewall operations means that you cannot use accounts that have embedded @ characters in the user name.

- The firewall assesses statements against accounts represented by actual user and host names as authenticated by the server. When registering accounts in profiles, do not use wildcard characters or netmasks:
  - Suppose that an account named `me@%.example.org` exists and a client uses it to connect to the server from the host `abc.example.org`.
  - The account name contains a % wildcard character, but the server authenticates the client as having a user name of `me` and host name of `abc.example.com`, and that is what the firewall sees.
  - Consequently, the account name to use for firewall operations is `me@abc.example.org` rather than `me@%.example.org`.

The following procedure shows how to register a group profile with the firewall, train the firewall to know the acceptable statements for that profile (its allowlist), use the profile to protect MySQL against execution of unacceptable statements, and add and remove group members. The example uses a group profile name of `fwgrp`. The example profile is presumed for use by clients of an application that accesses tables in the `sakila` database (available at <https://dev.mysql.com/doc/index-other.html>).

Use an administrative MySQL account to perform the steps in this procedure, except those steps designated for execution by member accounts of the firewall group profile. For statements executed by member accounts, the default database should be `sakila`. (You can use a different database by adjusting the instructions accordingly.)

1. If necessary, create the accounts that are to be members of the `fwgrp` group profile and grant them appropriate access privileges. Statements for one member are shown here (choose an appropriate password):

```
CREATE USER 'member1'@'localhost' IDENTIFIED BY 'password';
GRANT ALL ON sakila.* TO 'member1'@'localhost';
```

2. Use the `sp_set_firewall_group_mode()` stored procedure to register the group profile with the firewall and place the profile in `RECORDING` (training) mode:

```
CALL mysql.sp_set_firewall_group_mode('fwgrp', 'RECORDING');
```

#### Note

If you have installed MySQL Enterprise Firewall in a custom schema, then make appropriate substitution for your system. For example, if the firewall is installed in the `fwdb` schema, then execute the stored procedures like this:

```
CALL fwdb.sp_set_firewall_group_mode('fwgrp', 'RECORDING');
```

3. Use the `sp_firewall_group_enlist()` stored procedure to add an initial member account for use in training the group profile allowlist:

```
CALL mysql.sp_firewall_group_enlist('fwgrp', 'member1@localhost');
```

4. To train the group profile using the initial member account, connect to the server as `member1` from the server host so that the firewall sees a session account of `member1@localhost`. Then execute some statements to be considered legitimate for the profile. For example:

```
SELECT title, release_year FROM film WHERE film_id = 1;
UPDATE actor SET last_update = NOW() WHERE actor_id = 1;
SELECT store_id, COUNT(*) FROM inventory GROUP BY store_id;
```

The firewall receives the statements from the `member1@localhost` account. Because that account is a member of the `fwgrp` profile, which is in `RECORDING` mode, the firewall interprets the statements as applicable to `fwgrp` and records the normalized digest form of the statements as rules in the `fwgrp` allowlist. Those rules then apply to all accounts that are members of `fwgrp`.

#### Note

Until the `fwgrp` group profile receives statements in `RECORDING` mode, its allowlist is empty, which is equivalent to “deny all.” No statement can match an empty allowlist, which has these implications:

- The group profile cannot be switched to `PROTECTING` mode. It would reject every statement, effectively prohibiting the accounts that are group members from executing any statement.
- The group profile can be switched to `DETECTING` mode. In this case, the profile accepts every statement but logs it as suspicious.

5. At this point, the group profile information is cached, including its name, membership, and allowlist. To see this information, query the Performance Schema firewall tables:

```
mysql> SELECT MODE FROM performance_schema.firewall_groups
 WHERE NAME = 'fwgrp';
+-----+
| MODE |
+-----+
| RECORDING |
+-----+
mysql> SELECT * FROM performance_schema.firewall_membership
 WHERE GROUP_ID = 'fwgrp' ORDER BY MEMBER_ID;
+-----+-----+-----+-----+-----+-----+
| MEMBER_ID | GROUP_ID | MODE | STATE | LAST_UPDATE |
```

```

+-----+-----+
| GROUP_ID | MEMBER_ID |
+-----+-----+
| fwgrp | member1@localhost |
+-----+-----+
mysql> SELECT RULE FROM performance_schema.firewall_group_allowlist
 WHERE NAME = 'fwgrp';
+-----+-----+
| RULE |
+-----+-----+
| SELECT @@`version_comment` LIMIT ? |
| UPDATE `actor` SET `last_update` = NOW () WHERE `actor_id` = ? |
| SELECT `title` , `release_year` FROM `film` WHERE `film_id` = ? |
| SELECT `store_id` , COUNT (*) FROM `inventory` GROUP BY `store_id` |
+-----+-----+

```

**Note**

The @@[version\\_comment](#) rule comes from a statement sent automatically by the `mysql` client when you connect to the server.

**Important**

Train the firewall under conditions matching application use. For example, to determine server characteristics and capabilities, a given MySQL connector might send statements to the server at the beginning of each session. If an application normally is used through that connector, train the firewall using the connector, too. That enables those initial statements to become part of the allowlist for the group profile associated with the application.

- Invoke `sp_set_firewall_group_mode()` again to switch the group profile to `PROTECTING` mode:

```
CALL mysql.sp_set_firewall_group_mode('fwgrp', 'PROTECTING');
```

**Important**

Switching the group profile out of `RECORDING` mode synchronizes its cached data to the firewall database tables that provide persistent underlying storage. If you do not switch the mode for a profile that is being recorded, the cached data is not written to persistent storage and is lost when the server is restarted. The firewall database can be the `mysql` system database or a custom schema (see [Installing MySQL Enterprise Firewall](#)).

- Add to the group profile any other accounts that should be members:

```
CALL mysql.sp_firewall_group_enlist('fwgrp', 'member2@localhost');
CALL mysql.sp_firewall_group_enlist('fwgrp', 'member3@localhost');
CALL mysql.sp_firewall_group_enlist('fwgrp', 'member4@localhost');
```

The profile allowlist trained using the `member1@localhost` account now also applies to the additional accounts.

- To verify the updated group membership, query the `firewall_membership` table again:

```

mysql> SELECT * FROM performance_schema.firewall_membership
 WHERE GROUP_ID = 'fwgrp' ORDER BY MEMBER_ID;
+-----+-----+
| GROUP_ID | MEMBER_ID |
+-----+-----+
| fwgrp | member1@localhost |
| fwgrp | member2@localhost |
| fwgrp | member3@localhost |
| fwgrp | member4@localhost |
+-----+-----+

```

9. Test the group profile against the firewall by using any account in the group to execute some acceptable and unacceptable statements. The firewall matches each statement from the account against the profile allowlist and accepts or rejects it:

- This statement is not identical to a training statement but produces the same normalized statement as one of them, so the firewall accepts it:

```
mysql> SELECT title, release_year FROM film WHERE film_id = 98;
+-----+-----+
| title | release_year |
+-----+-----+
| BRIGHT ENCOUNTERS | 2006 |
+-----+-----+
```

- These statements match nothing in the allowlist, so the firewall rejects each with an error:

```
mysql> SELECT title, release_year FROM film WHERE film_id = 98 OR TRUE;
ERROR 1045 (28000): Statement was blocked by Firewall
mysql> SHOW TABLES LIKE 'customer%';
ERROR 1045 (28000): Statement was blocked by Firewall
mysql> TRUNCATE TABLE mysql.slow_log;
ERROR 1045 (28000): Statement was blocked by Firewall
```

- If the `mysql_firewall_trace` system variable is enabled, the firewall also writes rejected statements to the error log. For example:

```
[Note] Plugin MYSQL_FIREWALL reported:
'ACCESS DENIED for 'member1@localhost'. Reason: No match in allowlist.
Statement: TRUNCATE TABLE `mysql` . `slow_log`'
```

These log messages may be helpful in identifying the source of attacks, should that be necessary.

10. Should members need to be removed from the group profile, use the

`sp_firewall_group_delist()` stored procedure rather than `sp_firewall_group_enlist()`:

```
CALL mysql.sp_firewall_group_delist('fwgrp', 'member3@localhost');
```

The firewall group profile now is trained for member accounts. When clients connect using any account in the group and attempt to execute statements, the profile protects MySQL against statements not matched by the profile allowlist.

The procedure just shown added only one member to the group profile before training its allowlist. Doing so provides better control over the training period by limiting which accounts can add new acceptable statements to the allowlist. Should additional training be necessary, you can switch the profile back to **RECORDING** mode:

```
CALL mysql.sp_set_firewall_group_mode('fwgrp', 'RECORDING');
```

However, that enables any member of the group to execute statements and add them to the allowlist. To limit the additional training to a single group member, call `sp_set_firewall_group_mode_and_user()`, which is like `sp_set_firewall_group_mode()` but takes one more argument specifying which account is permitted to train the profile in **RECORDING** mode. For example, to enable training only by `member4@localhost`, do this:

```
CALL mysql.sp_set_firewall_group_mode_and_user('fwgrp', 'RECORDING', 'member4@localhost');
```

That enables additional training by the specified account without having to remove the other group members. They can execute statements, but the statements are not added to the allowlist. (Remember, however, that in **RECORDING** mode the other members can execute *any* statement.)

**Note**

To avoid unexpected behavior when a particular account is specified as the training account for a group profile, always ensure that account is a member of the group.

After the additional training, set the group profile back to **PROTECTING** mode:

```
CALL mysql.sp_set_firewall_group_mode('fwgrp', 'PROTECTING');
```

The training account established by `sp_set_firewall_group_mode_and_user()` is saved in the group profile, so the firewall remembers it in case more training is needed later. Thus, if you call `sp_set_firewall_group_mode()` (which takes no training account argument), the current profile training account, `member4@localhost`, remains unchanged.

To clear the training account if it actually is desired to enable all group members to perform training in **RECORDING** mode, call `sp_set_firewall_group_mode_and_user()` and pass a **NULL** value for the account argument:

```
CALL mysql.sp_set_firewall_group_mode_and_user('fwgrp', 'RECORDING', NULL);
```

It is possible to detect intrusions by logging nonmatching statements as suspicious without denying access. First, put the group profile in **DETECTING** mode:

```
CALL mysql.sp_set_firewall_group_mode('fwgrp', 'DETECTING');
```

Then, using a member account, execute a statement that does not match the group profile allowlist. In **DETECTING** mode, the firewall permits the nonmatching statement to execute:

```
mysql> SHOW TABLES LIKE 'customer%';
+-----+
| Tables_in_sakila (customer%) |
+-----+
| customer |
| customer_list |
+-----+
```

In addition, the firewall writes a message to the error log:

```
[Note] Plugin MYSQL_FIREWALL reported:
'SUSPICIOUS STATEMENT from 'member1@localhost'. Reason: No match in allowlist.
Statement: SHOW TABLES LIKE ?'
```

To disable a group profile, change its mode to **OFF**:

```
CALL mysql.sp_set_firewall_group_mode(group, 'OFF');
```

To forget all training for a profile and disable it, reset it:

```
CALL mysql.sp_set_firewall_group_mode(group, 'RESET');
```

The reset operation causes the firewall to delete all rules for the profile and set its mode to **OFF**.

## Registering Firewall Account Profiles

MySQL Enterprise Firewall enables profiles to be registered that correspond to individual accounts. To use a firewall account profile to protect MySQL against incoming statements from a given account, follow these steps:

1. Register the account profile and put it in **RECORDING** mode.
2. Connect to the MySQL server using the account and execute statements to be learned. This trains the account profile and establishes the rules that form the profile allowlist.

3. Switch the account profile to `PROTECTING` mode. When a client connects to the server using the account, the account profile allowlist restricts statement execution.
4. Should additional training be necessary, switch the account profile to `RECORDING` mode again, update its allowlist with new statement patterns, then switch it back to `PROTECTING` mode.

Observe these guidelines for firewall-related account references:

- Take note of the context in which account references occur. To name an account for firewall operations, specify it as a single quoted string (`'user_name@host_name'`). This differs from the usual MySQL convention for statements such as `CREATE USER` and `GRANT`, for which you quote the user and host parts of an account name separately (`'user_name'@'host_name'`).

The requirement for naming accounts as a single quoted string for firewall operations means that you cannot use accounts that have embedded `@` characters in the user name.

- The firewall assesses statements against accounts represented by actual user and host names as authenticated by the server. When registering accounts in profiles, do not use wildcard characters or netmasks:
  - Suppose that an account named `me@%.example.org` exists and a client uses it to connect to the server from the host `abc.example.org`.
  - The account name contains a `%` wildcard character, but the server authenticates the client as having a user name of `me` and host name of `abc.example.com`, and that is what the firewall sees.
  - Consequently, the account name to use for firewall operations is `me@abc.example.org` rather than `me@%.example.org`.

The following procedure shows how to register an account profile with the firewall, train the firewall to know the acceptable statements for that profile (its allowlist), and use the profile to protect MySQL against execution of unacceptable statements by the account. The example account, `fwuser@localhost`, is presumed for use by an application that accesses tables in the `sakila` database (available at <https://dev.mysql.com/doc/index-other.html>).

Use an administrative MySQL account to perform the steps in this procedure, except those steps designated for execution by the `fwuser@localhost` account that corresponds to the account profile registered with the firewall. For statements executed using this account, the default database should be `sakila`. (You can use a different database by adjusting the instructions accordingly.)

1. If necessary, create the account to use for executing statements (choose an appropriate password) and grant it privileges for the `sakila` database:

```
CREATE USER 'fwuser'@'localhost' IDENTIFIED BY 'password';
GRANT ALL ON sakila.* TO 'fwuser'@'localhost';
```

2. Use the `sp_set_firewall_mode()` stored procedure to register the account profile with the firewall and place the profile in `RECORDING` (training) mode:

```
CALL mysql.sp_set_firewall_mode('fwuser@localhost', 'RECORDING');
```

#### Note

If you have installed MySQL Enterprise Firewall in a custom schema, then make appropriate substitution for your system. For example, if the firewall is installed in the `fwdb` schema, then execute the stored procedures like this:

```
CALL fwdb.sp_set_firewall_mode('fwuser@localhost', 'RECORDING');
```

3. To train the registered account profile, connect to the server as `fwuser` from the server host so that the firewall sees a session account of `fwuser@localhost`. Then use the account to execute some statements to be considered legitimate for the profile. For example:

```
SELECT first_name, last_name FROM customer WHERE customer_id = 1;
UPDATE rental SET return_date = NOW() WHERE rental_id = 1;
SELECT get_customer_balance(1, NOW());
```

Because the profile is in `RECORDING` mode, the firewall records the normalized digest form of the statements as rules in the profile allowlist.

#### Note

Until the `fwuser@localhost` account profile receives statements in `RECORDING` mode, its allowlist is empty, which is equivalent to “deny all.” No statement can match an empty allowlist, which has these implications:

- The account profile cannot be switched to `PROTECTING` mode. It would reject every statement, effectively prohibiting the account from executing any statement.
- The account profile can be switched to `DETECTING` mode. In this case, the profile accepts every statement but logs it as suspicious.

4. At this point, the account profile information is cached. To see this information, query the `INFORMATION_SCHEMA` firewall tables:

```
mysql> SELECT MODE FROM INFORMATION_SCHEMA.MYSQL_FIREWALL_USERS
 WHERE USERHOST = 'fwuser@localhost';
+-----+
| MODE |
+-----+
| RECORDING |
+-----+
mysql> SELECT RULE FROM INFORMATION_SCHEMA.MYSQL_FIREWALL_WHITELIST
 WHERE USERHOST = 'fwuser@localhost';
+-----+
| RULE |
+-----+
| SELECT `first_name` , `last_name` FROM `customer` WHERE `customer_id` = ? |
| SELECT `get_customer_balance` (? , NOW ()) |
| UPDATE `rental` SET `return_date` = NOW () WHERE `rental_id` = ? |
| SELECT @@`version_comment` LIMIT ? |
+-----+
```

#### Note

The `@@version_comment` rule comes from a statement sent automatically by the `mysql` client when you connect to the server.

#### Important

Train the firewall under conditions matching application use. For example, to determine server characteristics and capabilities, a given MySQL connector might send statements to the server at the beginning of each session. If an application normally is used through that connector, train the firewall using the connector, too. That enables those initial statements to become part of the allowlist for the account profile associated with the application.

- Invoke `sp_set_firewall_mode()` again, this time switching the account profile to `PROTECTING` mode:

```
CALL mysql.sp_set_firewall_mode('fwuser@localhost', 'PROTECTING');
```

### Important

Switching the account profile out of `RECORDING` mode synchronizes its cached data to the firewall database tables that provide persistent underlying storage. If you do not switch the mode for a profile that is being recorded, the cached data is not written to persistent storage and is lost when the server is restarted. The firewall database can be the `mysql` system database or a custom schema (see [Installing MySQL Enterprise Firewall](#)).

- Test the account profile by using the account to execute some acceptable and unacceptable statements. The firewall matches each statement from the account against the profile allowlist and accepts or rejects it:

- This statement is not identical to a training statement but produces the same normalized statement as one of them, so the firewall accepts it:

```
mysql> SELECT first_name, last_name FROM customer WHERE customer_id = '48';
+-----+-----+
| first_name | last_name |
+-----+-----+
| ANN | EVANS |
+-----+-----+
```

- These statements match nothing in the allowlist, so the firewall rejects each with an error:

```
mysql> SELECT first_name, last_name FROM customer WHERE customer_id = 1 OR TRUE;
ERROR 1045 (28000): Statement was blocked by Firewall
mysql> SHOW TABLES LIKE 'customer%';
ERROR 1045 (28000): Statement was blocked by Firewall
mysql> TRUNCATE TABLE mysql.slow_log;
ERROR 1045 (28000): Statement was blocked by Firewall
```

- If the `mysql_firewall_trace` system variable is enabled, the firewall also writes rejected statements to the error log. For example:

```
[Note] Plugin MYSQL_FIREWALL reported:
'ACCESS DENIED for fwuser@localhost. Reason: No match in allowlist.
Statement: TRUNCATE TABLE `mysql`.`slow_log`'
```

These log messages may be helpful in identifying the source of attacks, should that be necessary.

The firewall account profile now is trained for the `fwuser@localhost` account. When clients connect using that account and attempt to execute statements, the profile protects MySQL against statements not matched by the profile allowlist.

It is possible to detect intrusions by logging nonmatching statements as suspicious without denying access. First, put the account profile in `DETECTING` mode:

```
CALL mysql.sp_set_firewall_mode('fwuser@localhost', 'DETECTING');
```

Then, using the account, execute a statement that does not match the account profile allowlist. In `DETECTING` mode, the firewall permits the nonmatching statement to execute:

```
mysql> SHOW TABLES LIKE 'customer%';
+-----+-----+
```

```
| Tables_in_sakila (customer%) |
+-----+
| customer |
| customer_list |
+-----+
```

In addition, the firewall writes a message to the error log:

```
[Note] Plugin MYSQL_FIREWALL reported:
'SUSPICIOUS STATEMENT from 'fwuser@localhost'. Reason: No match in allowlist.
Statement: SHOW TABLES LIKE ?'
```

To disable an account profile, change its mode to `OFF`:

```
CALL mysql.sp_set_firewall_mode(user, 'OFF');
```

To forget all training for a profile and disable it, reset it:

```
CALL mysql.sp_set_firewall_mode(user, 'RESET');
```

The reset operation causes the firewall to delete all rules for the profile and set its mode to `OFF`.

## Monitoring the Firewall

To assess firewall activity, examine its status variables. For example, after performing the procedure shown earlier to train and protect the `fwgrp` group profile, the variables look like this:

```
mysql> SHOW GLOBAL STATUS LIKE 'Firewall%';
+-----+
| Variable_name | Value |
+-----+
| Firewall_access_denied | 3 |
| Firewall_access_granted | 4 |
| Firewall_access_suspicious | 1 |
| Firewall_cached_entries | 4 |
+-----+
```

The variables indicate the number of statements rejected, accepted, logged as suspicious, and added to the cache, respectively. The `Firewall_access_granted` count is 4 because of the `@@version_comment` statement sent by the `mysql` client each of the three times you connected using the registered account, plus the `SHOW TABLES` statement that was not blocked in `DETECTING` mode.

## Migrating Account Profiles to Group Profiles

MySQL Enterprise Firewall supports account profiles that each apply to a single account and also group profiles that each can apply to multiple accounts. A group profile enables easier administration when the same allowlist is to be applied to multiple accounts: instead of creating one account profile per account and duplicating the allowlist across all those profiles, create a single group profile and make the accounts members of it. The group allowlist then applies to all the accounts.

A group profile with a single member account is logically equivalent to an account profile for that account, so it is possible to administer the firewall using group profiles exclusively, rather than a mix of account and group profiles. For new firewall installations, that is accomplished by uniformly creating new profiles as group profiles and avoiding account profiles.

Due to the greater flexibility offered by group profiles, it is recommended that all new firewall profiles be created as group profiles. Account profiles are deprecated, and subject to removal in a future MySQL version. For upgrades from firewall installations that already contain account profiles, MySQL Enterprise

Firewall includes a stored procedure named `sp_migrate_firewall_user_to_group()` to help you convert account profiles to group profiles. To use it, perform the following procedure as a user who has the `FIREWALL_ADMIN` privilege:

1. Run the `firewall_profile_migration.sql` script to install the `sp_migrate_firewall_user_to_group()` stored procedure. The script is located in the `share` directory of your MySQL installation.

Specify the same firewall database name on the command line that you previously defined for your firewall installation. The example here specifies the system database, `mysql`.

```
$> mysql -u root -p -D mysql < firewall_profile_migration.sql
Enter password: (enter root password here)
```

If you installed MySQL Enterprise Firewall in a custom schema, make the appropriate substitution for your system.

2. Identify which account profiles exist by querying the Information Schema `MYSQL_FIREWALL_USERS` table. For example:

```
mysql> SELECT USERHOST FROM INFORMATION_SCHEMA.MYSQL_FIREWALL_USERS;
+-----+
| USERHOST |
+-----+
| admin@localhost |
| local_client@localhost |
| remote_client@abc.example.com |
+-----+
```

3. For each account profile identified by the previous step, convert it to a group profile. Replace the `mysql.` prefix with the actual firewall database name, if necessary:

```
CALL mysql.sp_migrate_firewall_user_to_group('admin@localhost', 'admins');
CALL mysql.sp_migrate_firewall_user_to_group('local_client@localhost', 'local_clients');
CALL mysql.sp_migrate_firewall_user_to_group('remote_client@localhost', 'remote_clients');
```

In each case, the account profile must exist and must not currently be in `RECORDING` mode, and the group profile must not already exist. The resulting group profile has the named account as its single enlisted member, which is also set as the group training account. The group profile operational mode is taken from the account profile operational mode.

4. (Optional) Remove `sp_migrate_firewall_user_to_group()`:

```
DROP PROCEDURE IF EXISTS mysql.sp_migrate_firewall_user_to_group;
```

If you installed MySQL Enterprise Firewall in a custom schema, make the appropriate substitution for your system.

For additional details about `sp_migrate_firewall_user_to_group()`, see [Firewall Miscellaneous Stored Procedures](#).

#### 8.4.7.4 MySQL Enterprise Firewall Reference

The following sections provide a reference to MySQL Enterprise Firewall elements:

- [MySQL Enterprise Firewall Tables](#)
- [MySQL Enterprise Firewall Stored Procedures](#)
- [MySQL Enterprise Firewall Administrative Functions](#)

- [MySQL Enterprise Firewall System Variables](#)
- [MySQL Enterprise Firewall Status Variables](#)

## MySQL Enterprise Firewall Tables

MySQL Enterprise Firewall maintains profile information on a per-group and per-account basis. It uses tables in the firewall database for persistent storage and `INFORMATION_SCHEMA` or Performance Schema tables to provide views into in-memory cached data. When enabled, the firewall bases operational decisions on the cached data. The firewall database can be the `mysql` system database or a custom schema (see [Installing MySQL Enterprise Firewall](#)).

- [Firewall Group Profile Tables](#)
- [Firewall Account Profile Tables](#)

### Firewall Group Profile Tables

MySQL Enterprise Firewall maintains group profile information using tables in the firewall database (`mysql` or custom) for persistent storage and Performance Schema tables to provide views into in-memory cached data.

Each system and Performance Schema table is accessible only by accounts that have the `SELECT` privilege for it.

The `default-database.firewall_groups` table lists names and operational modes of registered firewall group profiles. The table has the following columns (with the corresponding Performance Schema `firewall_groups` table having similar but not necessarily identical columns):

- `NAME`

The group profile name.

- `MODE`

The current operational mode for the profile. Permitted mode values are `OFF`, `DETECTING`, `PROTECTING`, and `RECORDING`. For details about their meanings, see [Firewall Concepts](#).

- `USERHOST`

The training account for the group profile, to be used when the profile is in `RECORDING` mode. The value is `NULL`, or a non-`NULL` account that has the format `user_name@host_name`:

- If the value is `NULL`, the firewall records allowlist rules for statements received from any account that is a member of the group.
- If the value is non-`NULL`, the firewall records allowlist rules only for statements received from the named account (which should be a member of the group).

The `default-database.firewall_group_allowlist` table lists allowlist rules of registered firewall group profiles. The table has the following columns (with the corresponding Performance Schema `firewall_group_allowlist` table having similar but not necessarily identical columns):

- `NAME`

The group profile name.

- `RULE`

A normalized statement indicating an acceptable statement pattern for the profile. A profile allowlist is the union of its rules.

- `ID`

An integer column that is a primary key for the table.

The `default-database.firewall_membership` table lists the members (accounts) of registered firewall group profiles. The table has the following columns (with the corresponding Performance Schema `firewall_membership` table having similar but not necessarily identical columns):

- `GROUP_ID`

The group profile name.

- `MEMBER_ID`

The name of an account that is a member of the profile.

## Firewall Account Profile Tables

MySQL Enterprise Firewall maintains account profile information using tables in the firewall database for persistent storage and `INFORMATION_SCHEMA` tables to provide views into in-memory cached data. The firewall database can be the `mysql` system database or a custom schema (see [Installing MySQL Enterprise Firewall](#)).

Each default database table is accessible only by accounts that have the `SELECT` privilege for it. The `INFORMATION_SCHEMA` tables are accessible by anyone.

These tables are deprecated, and subject to removal in a future MySQL version. See [Migrating Account Profiles to Group Profiles](#).

The `default-database.firewall_users` table lists names and operational modes of registered firewall account profiles. The table has the following columns (with the corresponding `MYSQL_FIREWALL_USERS` table having similar but not necessarily identical columns):

- `USERHOST`

The account profile name. Each account name has the format `user_name@host_name`.

- `MODE`

The current operational mode for the profile. Permitted mode values are `OFF`, `DETECTING`, `PROTECTING`, `RECORDING`, and `RESET`. For details about their meanings, see [Firewall Concepts](#).

The `firewall-database.firewall_whitelist` table lists allowlist rules of registered firewall account profiles. The table has the following columns (with the corresponding `MYSQL_FIREWALL_WHITELIST` table having similar but not necessarily identical columns):

- `USERHOST`

The account profile name. Each account name has the format `user_name@host_name`.

- `RULE`

A normalized statement indicating an acceptable statement pattern for the profile. A profile allowlist is the union of its rules.

- [ID](#)

An integer column that is a primary key for the table.

## MySQL Enterprise Firewall Stored Procedures

MySQL Enterprise Firewall stored procedures perform tasks such as registering profiles with the firewall, establishing their operational mode, and managing transfer of firewall data between the cache and persistent storage. These procedures invoke administrative functions that provide an API for lower-level tasks.

Firewall stored procedures are created in the firewall database. The firewall database can be the `mysql` system database or a custom schema (see [Installing MySQL Enterprise Firewall](#)).

To invoke a firewall stored procedure, either do so while the specified firewall database is the default database, or qualify the procedure name with the database name. For example, if `mysql` is the firewall database:

```
CALL mysql.sp_set_firewall_group_mode(group, mode);
```

In MySQL 9.1, firewall stored procedures are transactional; if an error occurs during execution of a firewall stored procedure, all changes made by it up to that point are rolled back, and an error is reported.

### Note

If you have installed MySQL Enterprise Firewall in a custom schema, then make appropriate substitution for your system. For example, if the firewall is installed in the `fwdb` schema, then execute the stored procedures like this:

```
CALL fwdb.sp_set_firewall_group_mode(group, mode);
```

- [Firewall Group Profile Stored Procedures](#)
- [Firewall Account Profile Stored Procedures](#)
- [Firewall Miscellaneous Stored Procedures](#)

## Firewall Group Profile Stored Procedures

These stored procedures perform management operations on firewall group profiles:

- `sp_firewall_group_delist(group, user)`

This stored procedure removes an account from a firewall group profile.

If the call succeeds, the change in group membership is made to both the in-memory cache and persistent storage.

Arguments:

- `group`: The name of the affected group profile.
- `user`: The account to remove, as a string in `user_name@host_name` format.

Example:

```
CALL mysql.sp_firewall_group_delist('g', 'fwuser@localhost');
```

- `sp_firewall_group_enlist(group, user)`

This stored procedure adds an account to a firewall group profile. It is not necessary to register the account itself with the firewall before adding the account to the group.

If the call succeeds, the change in group membership is made to both the in-memory cache and persistent storage.

Arguments:

- *group*: The name of the affected group profile.
- *user*: The account to add, as a string in *user\_name@host\_name* format.

Example:

```
CALL mysql.sp_firewall_group_enlist('g', 'fwuser@localhost');
```

- *sp\_reload\_firewall\_group\_rules(group)*

This stored procedure provides control over firewall operation for individual group profiles. The procedure uses firewall administrative functions to reload the in-memory rules for a group profile from the rules stored in the *firewall-database.firewall\_group\_allowlist* table.

Arguments:

- *group*: The name of the affected group profile.

Example:

```
CALL mysql.sp_reload_firewall_group_rules('myapp');
```

### Warning

This procedure clears the group profile in-memory allowlist rules before reloading them from persistent storage, and sets the profile mode to *OFF*. If the profile mode was not *OFF* prior to the *sp\_reload\_firewall\_group\_rules()* call, use *sp\_set\_firewall\_group\_mode()* to restore its previous mode after reloading the rules. For example, if the profile was in *PROTECTING* mode, that is no longer true after calling *sp\_reload\_firewall\_group\_rules()* and you must set it to *PROTECTING* again explicitly.

- *sp\_set\_firewall\_group\_mode(group, mode)*

This stored procedure establishes the operational mode for a firewall group profile, after registering the profile with the firewall if it was not already registered. The procedure also invokes firewall administrative functions as necessary to transfer firewall data between the cache and persistent storage. This procedure may be called even if the *mysql\_firewall\_mode* system variable is *OFF*, although setting the mode for a profile has no operational effect until the firewall is enabled.

If the profile previously existed, any recording limitation for it remains unchanged. To set or clear the limitation, call *sp\_set\_firewall\_group\_mode\_and\_user()* instead.

Arguments:

- *group*: The name of the affected group profile.
- *mode*: The operational mode for the profile, as a string. Permitted mode values are *OFF*, *DETECTING*, *PROTECTING*, and *RECORDING*. For details about their meanings, see [Firewall Concepts](#).

Example:

```
CALL mysql.sp_set_firewall_group_mode('myapp', 'PROTECTING');
```

- `sp_set_firewall_group_mode_and_user(group, mode, user)`

This stored procedure registers a group with the firewall and establishes its operational mode, similar to `sp_set_firewall_group_mode()`, but also specifies the training account to be used when the group is in `RECORDING` mode.

Arguments:

- `group`: The name of the affected group profile.
- `mode`: The operational mode for the profile, as a string. Permitted mode values are `OFF`, `DETECTING`, `PROTECTING`, and `RECORDING`. For details about their meanings, see [Firewall Concepts](#).
- `user`: The training account for the group profile, to be used when the profile is in `RECORDING` mode. The value is `NULL`, or a non-`NULL` account that has the format `user_name@host_name`:
  - If the value is `NULL`, the firewall records allowlist rules for statements received from any account that is a member of the group.
  - If the value is non-`NULL`, the firewall records allowlist rules only for statements received from the named account (which should be a member of the group).

Example:

```
CALL mysql.sp_set_firewall_group_mode_and_user('myapp', 'RECORDING', 'myapp_user1@localhost');
```

## Firewall Account Profile Stored Procedures

These stored procedures perform management operations on firewall account profiles:

- `sp_reload_firewall_rules(user)`

This stored procedure provides control over firewall operation for individual account profiles. The procedure uses firewall administrative functions to reload the in-memory rules for an account profile from the rules stored in the `firewall-database.firewall_whitelist` table.

Arguments:

- `user`: The name of the affected account profile, as a string in `user_name@host_name` format.

Example:

```
CALL sp_reload_firewall_rules('fwuser@localhost');
```

### Warning

This procedure clears the account profile in-memory allowlist rules before reloading them from persistent storage, and sets the profile mode to `OFF`. If the profile mode was not `OFF` prior to the `sp_reload_firewall_rules()` call, use `sp_set_firewall_mode()` to restore its previous mode after reloading the rules. For example, if the profile was in `PROTECTING` mode, that is no longer true after calling `sp_reload_firewall_rules()` and you must set it to `PROTECTING` again explicitly.

This procedure is deprecated, and subject to removal in a future MySQL version. See [Migrating Account Profiles to Group Profiles](#).

- `sp_set_firewall_mode(user, mode)`

This stored procedure establishes the operational mode for a firewall account profile, after registering the profile with the firewall if it was not already registered. The procedure also invokes firewall administrative functions as necessary to transfer firewall data between the cache and persistent storage. This procedure may be called even if the `mysql_firewall_mode` system variable is `OFF`, although setting the mode for a profile has no operational effect until the firewall is enabled.

Arguments:

- `user`: The name of the affected account profile, as a string in `user_name@host_name` format.
- `mode`: The operational mode for the profile, as a string. Permitted mode values are `OFF`, `DETECTING`, `PROTECTING`, `RECORDING`, and `RESET`. For details about their meanings, see [Firewall Concepts](#).

Switching an account profile to any mode but `RECORDING` synchronizes its firewall cache data to the firewall database tables that provide persistent underlying storage (`mysql` or `custom`). Switching the mode from `OFF` to `RECORDING` reloads the allowlist from the `firewall-database.firewall_whitelist` table into the cache.

If an account profile has an empty allowlist, its mode cannot be set to `PROTECTING` because the profile would reject every statement, effectively prohibiting the account from executing statements. In response to such a mode-setting attempt, the firewall produces a diagnostic message that is returned as a result set rather than as an SQL error:

```
mysql> CALL sp_set_firewall_mode('a@b','PROTECTING');
+-----+
| set_firewall_mode(arg_userhost, arg_mode) |
+-----+
| ERROR: PROTECTING mode requested for a@b but the allowlist is empty. |
+-----+
```

This procedure is deprecated, and subject to removal in a future MySQL version. See [Migrating Account Profiles to Group Profiles](#).

## Firewall Miscellaneous Stored Procedures

These stored procedures perform miscellaneous firewall management operations.

- `sp_migrate_firewall_user_to_group(user, group)`

The `sp_migrate_firewall_user_to_group()` stored procedure converts a firewall account profile to a group profile with the account as its single enlisted member. Run the `firewall_profile_migration.sql` script to install it. The conversion procedure is discussed in [Migrating Account Profiles to Group Profiles](#).

This routine requires the `FIREWALL_ADMIN` privilege.

Arguments:

- `user`: The name of the account profile to convert to a group profile, as a string in `user_name@host_name` format. The account profile must exist, and must not currently be in `RECORDING` mode.

- *group*: The name of the new group profile, which must not already exist. The new group profile has the named account as its single enlisted member, and that member is set as the group training account. The group profile operational mode is taken from the account profile operational mode.

Example:

```
CALL sp_migrate_firewall_user_to_group('fwuser@localhost', 'mygroup');
```

## MySQL Enterprise Firewall Administrative Functions

MySQL Enterprise Firewall administrative functions provide an API for lower-level tasks such as synchronizing the firewall cache with the underlying system tables.

*Under normal operation, these functions are invoked by the firewall stored procedures, not directly by users.* For that reason, these function descriptions do not include details such as information about their arguments and return types.

- [Firewall Group Profile Functions](#)
- [Firewall Account Profile Functions](#)
- [Firewall Miscellaneous Functions](#)

### Firewall Group Profile Functions

These functions perform management operations on firewall group profiles:

- `firewall_group_delist(group, user)`

This function removes an account from a group profile. It requires the `FIREWALL_ADMIN` privilege.

Example:

```
SELECT firewall_group_delist('g', 'fwuser@localhost');
```

- `firewall_group_enlist(group, user)`

This function adds an account to a group profile. It requires the `FIREWALL_ADMIN` privilege.

It is not necessary to register the account itself with the firewall before adding the account to the group.

Example:

```
SELECT firewall_group_enlist('g', 'fwuser@localhost');
```

- `read_firewall_group_allowlist(group, rule)`

This aggregate function updates the recorded-statement cache for the named group profile through a `SELECT` statement on the `mysql.firewall_group_allowlist` table. It requires the `FIREWALL_ADMIN` privilege.

Example:

```
SELECT read_firewall_group_allowlist('my_fw_group', fgw.rule)
FROM mysql.firewall_group_allowlist AS fgw
WHERE NAME = 'my_fw_group';
```

- `read_firewall_groups(group, mode, user)`

This aggregate function updates the firewall group profile cache through a [SELECT](#) statement on the `firewall-database.firewall_groups` table. It requires the `FIREWALL_ADMIN` privilege.

Example:

```
SELECT read_firewall_groups('g', 'RECORDING', 'fwuser@localhost')
FROM mysql.firewall_groups;
```

- `set_firewall_group_mode(group, mode[, user])`

This function manages the group profile cache, establishes the profile operational mode, and optionally specifies the profile training account. It requires the `FIREWALL_ADMIN` privilege.

If the optional `user` argument is not given, any previous `user` setting for the profile remains unchanged. To change the setting, call the function with a third argument.

If the optional `user` argument is given, it specifies the training account for the group profile, to be used when the profile is in `RECORDING` mode. The value is `NULL`, or a non-`NULL` account that has the format `user_name@host_name`:

- If the value is `NULL`, the firewall records allowlist rules for statements received from any account that is a member of the group.
- If the value is non-`NULL`, the firewall records allowlist rules only for statements received from the named account (which should be a member of the group).

Example:

```
SELECT set_firewall_group_mode('g', 'DETECTING');
```

## Firewall Account Profile Functions

These functions perform management operations on firewall account profiles:

- `read_firewall_users(user, mode)`

This aggregate function updates the firewall account profile cache through a [SELECT](#) statement on the `firewall-database.firewall_users` table. It requires the `FIREWALL_ADMIN` privilege or the deprecated `SUPER` privilege.

Example:

```
SELECT read_firewall_users('fwuser@localhost', 'RECORDING')
FROM mysql.firewall_users;
```

This function is deprecated, and subject to removal in a future MySQL version. See [Migrating Account Profiles to Group Profiles](#).

- `read_firewall_whitelist(user, rule)`

This aggregate function updates the recorded-statement cache for the named account profile through a [SELECT](#) statement on the `firewall-database.firewall_whitelist` table. It requires the `FIREWALL_ADMIN` privilege or the deprecated `SUPER` privilege.

Example:

```
SELECT read_firewall_whitelist('fwuser@localhost', fw.rule)
FROM mysql.firewall_whitelist AS fw
WHERE USERHOST = 'fwuser@localhost';
```

This function is deprecated, and subject to removal in a future MySQL version. See [Migrating Account Profiles to Group Profiles](#).

- `set_firewall_mode(user, mode)`

This function manages the account profile cache and establishes the profile operational mode. It requires the `FIREWALL_ADMIN` privilege or the deprecated `SUPER` privilege.

Example:

```
SELECT set_firewall_mode('fwuser@localhost', 'RECORDING');
```

This function is deprecated, and subject to removal in a future MySQL version. See [Migrating Account Profiles to Group Profiles](#).

## Firewall Miscellaneous Functions

These functions perform miscellaneous firewall operations:

- `mysql_firewall_flush_status()`

This function resets several firewall status variables to 0:

- `Firewall_access_denied`
- `Firewall_access_granted`
- `Firewall_access_suspicious`

This function requires the `FIREWALL_ADMIN` privilege or the deprecated `SUPER` privilege.

Example:

```
SELECT mysql_firewall_flush_status();
```

- `normalize_statement(stmt)`

This function normalizes an SQL statement into the digest form used for allowlist rules. It requires the `FIREWALL_ADMIN` privilege or the deprecated `SUPER` privilege.

Example:

```
SELECT normalize_statement('SELECT * FROM t1 WHERE c1 > 2');
```

### Note

The same digest functionality is available outside firewall context using the `STATEMENT_DIGEST_TEXT()` SQL function.

## MySQL Enterprise Firewall System Variables

MySQL Enterprise Firewall supports the following system variables. Use them to configure firewall operation. These variables are unavailable unless the firewall is installed (see [Section 8.4.7.2, “Installing or Uninstalling MySQL Enterprise Firewall”](#)).

- `mysql_firewall_database`

Command-Line Format	<code>--mysql-firewall-database[=value]</code>
---------------------	------------------------------------------------

System Variable	<code>mysql_firewall_database</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value	<code>mysql</code>

Specifies the database from which MySQL Enterprise Firewall reads data. Typically, the `MYSQL_FIREWALL` server-side plugin stores its internal data (tables, stored procedures, and functions) in the `mysql` system database, but you can create and use a custom schema instead (see [Installing MySQL Enterprise Firewall](#)). This variable permits specifying an alternative database name at startup.

- `mysql_firewall_mode`

Command-Line Format	<code>--mysql-firewall-mode[={OFF ON}]</code>
System Variable	<code>mysql_firewall_mode</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>ON</code>

Whether MySQL Enterprise Firewall is enabled (the default) or disabled.

- `mysql_firewall_reload_interval_seconds`

Command-Line Format	<code>--mysql-firewall-reload-interval-seconds[=value]</code>
System Variable	<code>mysql_firewall_reload_interval_seconds</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	<code>0</code>
Minimum Value	<code>60</code> (unless <code>0: OFF</code> )
Maximum Value	<code>INT_MAX</code>
Unit	seconds

Specifies the interval (in seconds) that the server-side plugin uses to reload its internal cache from firewall tables. When `mysql_firewall_reload_interval_seconds` has a value of zero (the default), no periodic reloading of data from tables occurs at runtime. Values between `0` and `60` (1 to 59) are not acknowledged by the plugin. Instead, these values adjust to `60` automatically.

This variable requires that the `scheduler` component be enabled (`ON`). For more information, see [Scheduling Firewall Cache Reloads](#).

- `mysql_firewall_trace`

Command-Line Format	<code>--mysql-firewall-trace[={OFF ON}]</code>
System Variable	<code>mysql_firewall_trace</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Whether the MySQL Enterprise Firewall trace is enabled or disabled (the default). When `mysql_firewall_trace` is enabled, for `PROTECTING` mode, the firewall writes rejected statements to the error log.

## MySQL Enterprise Firewall Status Variables

MySQL Enterprise Firewall supports the following status variables. Use them to obtain information about firewall operational status. These variables are unavailable unless the firewall is installed (see [Section 8.4.7.2, “Installing or Uninstalling MySQL Enterprise Firewall”](#)). Firewall status variables are set to 0 whenever the `MYSQL_FIREWALL` plugin is installed or the server is started. Many of them are reset to zero by the `mysql_firewall_flush_status()` function (see [MySQL Enterprise Firewall Administrative Functions](#)).

- `Firewall_access_denied`

The number of statements rejected by MySQL Enterprise Firewall.

- `Firewall_access_granted`

The number of statements accepted by MySQL Enterprise Firewall.

- `Firewall_access_suspicious`

The number of statements logged by MySQL Enterprise Firewall as suspicious for users who are in `DETECTING` mode.

- `Firewall_cached_entries`

The number of statements recorded by MySQL Enterprise Firewall, including duplicates.

## 8.5 MySQL Enterprise Data Masking and De-Identification

### Note

MySQL Enterprise Data Masking and De-Identification is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, <https://www.mysql.com/products/>.

MySQL Enterprise Edition provides data masking and de-identification capabilities:

- Transformation of existing data to mask it and remove identifying characteristics, such as changing all digits of a credit card number but the last four to 'X' characters.
- Generation of random data, such as email addresses and payment card numbers.

- Substitution of data by data from dictionaries stored in the database. The dictionaries are easily replicated in a standard way. Administration is restricted to authorized users who are granted special privileges so that only they can create and modify the dictionaries.

**Note**

MySQL Enterprise Data Masking and De-Identification was implemented originally in MySQL as a plugin library. As of MySQL 9.1, MySQL Enterprise Edition also provides components to access data masking and de-identification capabilities. For information about the similarities and differences, see [Table 8.46, “Comparison Between Data-Masking Components and Plugin Elements”](#).

If you are using MySQL Enterprise Data Masking and De-Identification for the first time, consider installing the components for access to the ongoing enhancements only available with component infrastructure.

The way that applications use these capabilities depends on the purpose for which the data is used and who accesses it:

- Applications that use sensitive data may protect it by performing data masking and permitting use of partially masked data for client identification. Example: A call center may ask for clients to provide their last four Social Security Number digits.
- Applications that require properly formatted data, but not necessarily the original data, can synthesize sample data. Example: An application developer who is testing data validators but has no access to original data may synthesize random data with the same format.
- Applications that must substitute a real name with a dictionary term to protect to protect sensitive information, but still provide realistic content to application users. Example: A user in training who is restricted from viewing addresses gets a random term from dictionary `city names` instead of the real city name. A variant of this scenario may be that the real city name is replaced only if it exists in `usa_city_names`.

**Example 1:**

Medical research facilities can hold patient data that comprises a mix of personal and medical data. This may include genetic sequences (long strings), test results stored in JSON format, and other data types. Although the data may be used mostly by automated analysis software, access to genome data or test results of particular patients is still possible. In such cases, data masking should be used to render this information not personally identifiable.

**Example 2:**

A credit card processor company provides a set of services using sensitive data, such as:

- Processing a large number of financial transactions per second.
- Storing a large amount of transaction-related data.
- Protecting transaction-related data with strict requirements for personal data.
- Handling client complaints about transactions using reversible or partially masked data.

A typical transaction may include many types of sensitive information, including:

- Credit card number.
- Transaction type and amount.

- Merchant type.
- Transaction cryptogram (to confirm transaction legitimacy).
- Geolocation of GPS-equipped terminal (for fraud detection).

Those types of information may then be joined within a bank or other card-issuing financial institution with client personal data, such as:

- Full client name (either person or company).
- Address.
- Date of birth.
- Social Security number.
- Email address.
- Phone number.

Various employee roles within both the card processing company and the financial institution require access to that data. Some of these roles may require access only to masked data. Other roles may require access to the original data on a case-to-case basis, which is recorded in audit logs.

Masking and de-identification are core to regulatory compliance, so MySQL Enterprise Data Masking and De-Identification can help application developers satisfy privacy requirements:

- PCI – DSS: Payment Card Data.
- HIPAA: Privacy of Health Data, Health Information Technology for Economic and Clinical Health Act (HITECH Act).
- EU General Data Protection Directive (GDPR): Protection of Personal Data.
- Data Protection Act (UK): Protection of Personal Data.
- Sarbanes Oxley, GLBA, The USA Patriot Act, Identity Theft and Assumption Deterrence Act of 1998.
- FERPA – Student Data, NASD, CA SB1386 and AB 1950, State Data Protection Laws, Basel II.

The following sections describe the elements of MySQL Enterprise Data Masking and De-Identification, discuss how to install and use it, and provide reference information for its elements.

### 8.5.1 Data-Masking Components Versus the Data-Masking Plugin

Previously, MySQL enabled masking and de-identification capabilities using a server-side plugin, but transitioned to use the component infrastructure as an alternative implementation. The following table briefly compares MySQL Enterprise Data Masking and De-Identification components and the plugin library to provide an overview of their differences. It may assist you in making the transition from the plugin to components.

#### Note

Only the data-masking components or the plugin should be enabled at a time. Enabling both components and the plugin is unsupported and results may not be as anticipated.

**Table 8.46 Comparison Between Data-Masking Components and Plugin Elements**

Category	Components	Plugin
Interface	Service functions, loadable functions	Loadable functions
Support for multibyte character sets	Yes, for general-purpose masking functions	No
General-purpose masking functions	<code>mask_inner()</code> , <code>mask_outer()</code>	<code>mask_inner()</code> , <code>mask_outer()</code>
Masking of specific types	PAN, SSN, IBAN, UUID, Canada SIN, UK NIN	PAN, SSN
Random generation, specific types	email, US phone, PAN, SSN, IBAN, UUID, Canada SIN, UK NIN	email, US phone, PAN, SSN
Random generation of integer from given range	Yes	Yes
Persisting substitution dictionaries	Database	File
Privilege to manage dictionaries	Dedicated privilege	FILE
Automated loadable-function registration/deregistration during installation/uninstallation	Yes	No
Enhancements to existing functions	More arguments added to the <code>gen_rnd_email()</code> function	N/A

## 8.5.2 MySQL Enterprise Data Masking and De-Identification Components

MySQL Enterprise Data Masking and De-Identification implements these elements:

- A table for persistent storage of dictionaries and terms.
- A component named `component_masking` that implements masking functionality and exposes it as service interface for developers.

Developers who wish to incorporate the same service functions used by `component_masking` should consult the `internal\components\masking\component_masking.h` file in a MySQL source distribution or <https://dev.mysql.com/doc/dev/mysql-server/latest>.

- A component named `component_masking_functions` that provides loadable functions.

The set of loadable functions enables an SQL-level API for performing masking and de-identification operations. Some of the functions require the `MASKING_DICTIONARIES_ADMIN` dynamic privilege.

### 8.5.2.1 MySQL Enterprise Data Masking and De-Identification Component Installation

Components provide expanded access to MySQL Enterprise Data Masking and De-Identification functionality. Previously, MySQL implemented masking and de-identification capabilities as a plugin library file containing a plugin and several loadable functions. Before you begin the component installation, remove the `data_masking` plugin and all of its loadable functions to avoid conflicts. For instructions, see [Section 8.5.3.1, “MySQL Enterprise Data Masking and De-Identification Plugin Installation”](#).

MySQL Enterprise Data Masking and De-Identification database table and components are:

- `masking_dictionaries` table

Purpose: A table that provides persistent storage for masking dictionaries and terms. While the `mysql` system schema is the traditional storage option, creating a dedicated schema for this purpose is also permitted. A dedicated schema might be preferable for these reasons:

- The `mysql` system schema is not backed up by a logical backup, such as `mysqldump` or load operations.
- A dedicated schema makes outbound replication easier.
- A user or role requires no `mysql` schema privileges when performing related data-masking tasks in the dedicated schema.

- `component_masking` component

Purpose: The component implements the core of the masking functionality and exposes it as services.

URN: `file://component_masking`

- `component_masking_functions` component

Purpose: The component exposes all functionality of the `component_masking` component as loadable functions. Some of the functions require the `MASKING_DICTIONARIES_ADMIN` dynamic privilege.

URN: `file://component_masking_functions`

If the components and functions are used on a replication source server, install them on all replica servers as well to avoid replication issues. While the components are loaded, information about them is available as described in [Section 7.5.2, “Obtaining Component Information”](#). For general information about installing or uninstalling components, see [Section 7.5.1, “Installing and Uninstalling Components”](#).

MySQL Enterprise Data Masking and De-Identification supports these setup and removal procedures:

- [Install Using the mysql System Schema](#)
- [Install Using a Dedicated Schema](#)
- [Uninstall MySQL Enterprise Data Masking and De-Identification Components](#)

## Install Using the mysql System Schema

### Note

Consider using a dedicated schema to store data-masking dictionaries (see [Install Using a Dedicated Schema](#)).

To set up MySQL Enterprise Data Masking and De-Identification:

1. Run `masking_functions_install.sql` to add the `masking_dictionaries` table to the `mysql` schema and install the components. The script is located in the `share` directory of your MySQL installation.

```
$> mysql -u root -p -D mysql < [path]/masking_functions_install.sql
Enter password: (enter root password here)
```

## Install Using a Dedicated Schema

To set up MySQL Enterprise Data Masking and De-Identification:

1. Create a database to store the `masking_dictionaries` table. For example, to use `mask_db` as the database name, execute this statement:

```
$> mysql -u root -p -e "CREATE DATABASE IF NOT EXISTS mask_db"
Enter password: (enter root password here)
```

2. Run `masking_functions_install.sql` to add the `masking_dictionaries` table to the `mask_db` schema and install the components. The script is located in the `share` directory of your MySQL installation.

```
$> mysql -u root -p -D mask_db < [path/]masking_functions_install.sql
Enter password: (enter root password here)
```

3. Set and persist the `mask_db` schema at startup by preceding the `component_masking.masking_database` read-only variable name by the `PERSIST_ONLY` keyword.

```
$> mysql -u root -p -e "SET PERSIST_ONLY component_masking.masking_database=mask_db"
Enter password: (enter root password here)
```

After modifying the variable, restart the server to cause the new setting to take effect.

## Uninstall MySQL Enterprise Data Masking and De-Identification Components

To remove MySQL Enterprise Data Masking and De-Identification when using the `mysql` system schema:

1. Run `masking_functions_uninstall.sql` to remove the `masking_dictionaries` table from the appropriate schema and uninstall the components. The script is located in the `share` directory of your MySQL installation. The example here specifies the `mysql` database.

```
$> mysql -u root -p -D mysql < [path/]masking_functions_uninstall.sql
Enter password: (enter root password here)
```

To remove MySQL Enterprise Data Masking and De-Identification when using a dedicated schema:

1. Run `masking_functions_uninstall.sql` to remove the `masking_dictionaries` table from the appropriate schema and uninstall the components. The script is located in the `share` directory of your MySQL installation. The example here specifies the `mask_db` database.

```
$> mysql -u root -p -D mask_db < [path/]masking_functions_uninstall.sql
Enter password: (enter root password here)
```

2. Stop persisting the `component_masking.masking_database` variable.

```
$> mysql -u root -p -e "RESET PERSIST component_masking.masking_database"
Enter password: (enter root password here)
```

3. [Optional] Drop the dedicated schema to ensure that it is not used for other purposes.

```
DROP DATABASE mask_db;
```

### 8.5.2.2 Using MySQL Enterprise Data Masking and De-Identification Components

Before using MySQL Enterprise Data Masking and De-Identification, install it according to the instructions provided at [Section 8.5.2.1, “MySQL Enterprise Data Masking and De-Identification Component Installation”](#).

To use MySQL Enterprise Data Masking and De-Identification in applications, invoke the functions that are appropriate for the operations you wish to perform. For detailed function descriptions, see [Section 8.5.2.4, “MySQL Enterprise Data Masking and De-Identification Component Function Descriptions”](#). This section demonstrates how to use the functions to carry out some representative tasks. It first presents an overview

of the available functions, followed by some examples of how the functions might be used in real-world context:

- [Masking Data to Remove Identifying Characteristics](#)
- [Generating Random Data with Specific Characteristics](#)
- [Generating Random Data Using Dictionaries](#)
- [Using Masked Data for Customer Identification](#)
- [Creating Views that Display Masked Data](#)

## Masking Data to Remove Identifying Characteristics

MySQL provides general-purpose masking component functions that mask arbitrary strings, and special-purpose masking functions that mask specific types of values.

### General-Purpose Masking Component Functions

`mask_inner()` and `mask_outer()` are general-purpose functions that mask parts of arbitrary strings based on position within the string. Both functions support an input string that is encoded in any character set:

- `mask_inner()` masks the interior of its string argument, leaving the ends unmasked. Other arguments specify the sizes of the unmasked ends.

```
mysql> SELECT mask_inner('This is a string', 5, 1);
+-----+
| mask_inner('This is a string', 5, 1) |
+-----+
| This XXXXXXXXXXg |
+-----+
mysql> SELECT mask_inner('This is a string', 1, 5);
+-----+
| mask_inner('This is a string', 1, 5) |
+-----+
| TXXXXXXXXXXtring |
+-----+
mysql> SELECT mask_inner("かすみがうら市", 3, 1);
+-----+
| mask_inner("かすみがうら市", 3, 1) |
+-----+
| かすみXXX市 |
+-----+
mysql> SELECT mask_inner("かすみがうら市", 1, 3);
+-----+
| mask_inner("かすみがうら市", 1, 3) |
+-----+
| かXXXうら市 |
+-----+
```

- `mask_outer()` does the reverse, masking the ends of its string argument, leaving the interior unmasked. Other arguments specify the sizes of the masked ends.

```
mysql> SELECT mask_outer('This is a string', 5, 1);
+-----+
| mask_outer('This is a string', 5, 1) |
+-----+
| XXXXXis a strinX |
+-----+
mysql> SELECT mask_outer('This is a string', 1, 5);
+-----+
```

```
| mask_outer('This is a string', 1, 5) |
+-----+
| Xhis is a sXXXXX |
+-----+
```

By default, `mask_inner()` and `mask_outer()` use 'X' as the masking character, but permit an optional masking-character argument:

```
mysql> SELECT mask_inner('This is a string', 5, 1, '*');
+-----+
| mask_inner('This is a string', 5, 1, '*') |
+-----+
| This *****g |
+-----+
mysql> SELECT mask_inner("かすみがうら市", 2, 2, "#");
+-----+
| mask_inner("かすみがうら市", 2, 2, "#") |
+-----+
| かす###ら市 |
+-----+
```

## Special-Purpose Masking Component Functions

Other masking functions expect a string argument representing a specific type of value and mask it to remove identifying characteristics.

### Note

The examples here supply function arguments using the random value generation functions that return the appropriate type of value. For more information about generation functions, see [Generating Random Data with Specific Characteristics](#).

**Payment card Primary Account Number masking.** Masking functions provide strict and relaxed masking of Primary Account numbers.

- `mask_pan()` masks all but the last four digits of the number:

```
mysql> SELECT mask_pan(gen_rnd_pan());
+-----+
| mask_pan(gen_rnd_pan()) |
+-----+
| XXXXXXXXXXXXX2461 |
+-----+
```

- `mask_pan_relaxed()` is similar but does not mask the first six digits that indicate the payment card issuer unmasked:

```
mysql> SELECT mask_pan_relaxed(gen_rnd_pan());
+-----+
| mask_pan_relaxed(gen_rnd_pan()) |
+-----+
| 770630XXXXXX0807 |
+-----+
```

**International Bank Account Number masking.** `mask_iban()` masks all but the first two letters (denoting the country) of the number:

```
mysql> SELECT mask_iban(gen_rnd_iban());
+-----+
| mask_iban(gen_rnd_iban()) |
+-----+
| ZZ** **** * |
+-----+
```

**Universally Unique Identifier masking.** `mask_uuid()` masks all meaningful characters:

```
mysql> SELECT mask_uuid(gen_rnd_uuid());
+-----+
| mask_uuid(gen_rnd_uuid()) |
+-----+
| *****_*****_*****_*****_***** |
+-----+
```

**US Social Security Number masking.** `mask_ssn()` masks all but the last four digits of the number:

```
mysql> SELECT mask_ssn(gen_rnd_ssn());
+-----+
| mask_ssn(gen_rnd_ssn()) |
+-----+
| ***-**-1723 |
+-----+
```

**Canada Social Insurance Number masking.** `mask_canada_sin()` masks meaningful digits of the number:

```
mysql> SELECT mask_canada_sin(gen_rnd_canada_sin());
+-----+
| mask_canada_sin(gen_rnd_canada_sin()) |
+-----+
| XXX-XXX-XXX |
+-----+
```

**United Kingdom National Insurance Number masking.** `mask_uk_nin()` masks all but the first two digits of the number:

```
mysql> SELECT mask_uk_nin(gen_rnd_uk_nin());
+-----+
| mask_uk_nin(gen_rnd_uk_nin()) |
+-----+
| ZH***** |
+-----+
```

## Generating Random Data with Specific Characteristics

Several component functions generate random values. These values can be used for testing, simulation, and so forth.

`gen_range()` returns a random integer selected from a given range:

```
mysql> SELECT gen_range(1, 10);
+-----+
| gen_range(1, 10) |
+-----+
| 6 |
+-----+
```

`gen_rnd_canada_sin()` returns a random number chosen from a range not used for legitimate numbers:

```
mysql> SELECT gen_rnd_canada_sin();
+-----+
| gen_rnd_canada_sin() |
+-----+
```

(The `gen_rnd_canada_sin()` function result is not shown because its return values should be used only for testing purposes, and not for publication. It cannot be guaranteed the number is not assigned to a legitimate Canada SIN.)

`gen_rnd_email()` returns a random email address with a specified number of digits for the name and surname parts in the specified domain, `mynet.com` in the following example:

```
mysql> SELECT gen_rnd_email(6, 8, 'mynet.com');
+-----+
| gen_rnd_email(6, 8, 'mynet') |
+-----+
| ayxnqu.xmkpvvyr@mynet.com |
+-----+
```

`gen_rnd_iban()` returns a number chosen from a range not used for legitimate numbers:

```
mysql> SELECT gen_rnd_iban('XO', 24);
+-----+
| gen_rnd_iban('XO', 24) |
+-----+
| X025 SL7A PGQR B9NN 6IVB RFE8 |
+-----+
```

`gen_rnd_pan()` returns a random payment card Primary Account Number:

```
mysql> SELECT gen_rnd_pan();
```

(The `gen_rnd_pan()` function result is not shown because its return values should be used only for testing purposes, and not for publication. It cannot be guaranteed the number is not assigned to a legitimate payment account.)

`gen_rnd_ssn()` returns a random US Social Security Number with the first and second parts each chosen from a range not used for legitimate numbers:

```
mysql> SELECT gen_rnd_ssn();
+-----+
| gen_rnd_ssn() |
+-----+
| 912-45-1615 |
+-----+
```

`gen_rnd_uk_nin()` returns a number chosen from a range not used for legitimate numbers:

```
mysql> SELECT gen_rnd_uk_nin();
+-----+
| gen_rnd_uk_nin() |
+-----+
```

(The `gen_rnd_uk_nin()` function result is not shown because its return values should be used only for testing purposes, and not for publication. It cannot be guaranteed the number is not assigned to a legitimate NIN.)

`gen_rnd_us_phone()` returns a random US phone number in the 555 area code not used for legitimate numbers:

```
mysql> SELECT gen_rnd_us_phone();
+-----+
| gen_rnd_us_phone() |
+-----+
| 1-555-747-5627 |
+-----+
```

`gen_rnd_uuid()` returns a number chosen from a range not used for legitimate identifiers:

```
mysql> SELECT gen_rnd_uuid();
+-----+
| gen_rnd_uuid() |
+-----+
| 68946384-6880-3150-6889-928076732539 |
+-----+
```

## Generating Random Data Using Dictionaries

MySQL Enterprise Data Masking and De-Identification enables dictionaries to be used as sources of random values called *terms*. To use a dictionary, it must first be added to the `masking_dictionaries` system table and given a name. The dictionaries are read from the table and loaded to the cache during initialization of the components (on server startup). Terms then can then be added, removed, and selected from dictionaries and used as random values or as replacements for other values.

### Note

Always edit dictionaries using dictionary administration functions rather than modifying the table directly. If you manipulate the table manually, the dictionary cache becomes inconsistent with the table.

A valid `masking_dictionaries` table has these characteristics:

- An administrator created the `masking_dictionaries` system table in the `mysql` schema as follows:

```
CREATE TABLE IF NOT EXISTS
masking_dictionaries(
 Dictionary VARCHAR(256) NOT NULL,
 Term VARCHAR(256) NOT NULL,
 UNIQUE INDEX dictionary_term_idx (Dictionary, Term),
 INDEX dictionary_idx (Dictionary)
) ENGINE = InnoDB DEFAULT CHARSET=utf8mb4;
```

- MASKING\_DICTIONARY\_ADMIN privilege is required to add and remove terms, or to remove an entire dictionary.
- The table may contain multiple dictionaries and their terms.
- Any user account can view the dictionaries. Given enough queries, all of the terms in dictionaries are retrievable. Avoid adding sensitive data to the dictionary table.

Suppose that a dictionary named `DE_cities` includes these city names in Germany:

```
Berlin
Munich
Bremen
```

Use `masking_dictionary_term_add()` to assign a dictionary name and one term:

```
mysql> SELECT masking_dictionary_term_add('DE_Cities', 'Berlin');
+-----+
| masking_dictionary_term_add('DE_Cities', 'Berlin') |
+-----+
| 1 |
+-----+
mysql> SELECT masking_dictionary_term_add('DE_Cities', 'Munich');
+-----+
| masking_dictionary_term_add('DE_Cities', 'Munich') |
+-----+
| 1 |
+-----+
mysql> SELECT masking_dictionary_term_add('DE_Cities', 'Bremen');
+-----+
| masking_dictionary_term_add('DE_Cities', 'Bremen') |
+-----+
| 1 |
+-----+
```

Also suppose that a dictionary named `US_Cities` contains these city names in the United States:

```
Houston
Phoenix
Detroit
```

```
mysql> SELECT masking_dictionary_term_add('US_Cities', 'Houston');
+-----+
| masking_dictionary_term_add('US_Cities', 'Houston') |
+-----+
| 1 |
+-----+
mysql> SELECT masking_dictionary_term_add('US_Cities', 'Phoenix');
+-----+
| masking_dictionary_term_add('US_Cities', 'Phoenix') |
+-----+
| 1 |
+-----+
mysql> SELECT masking_dictionary_term_add('US_Cities', 'Detroit');
+-----+
| masking_dictionary_term_add('US_Cities', 'Detroit') |
+-----+
| 1 |
+-----+
```

To select a random term from a dictionary, use `gen_dictionary()`:

```
mysql> SELECT gen_dictionary('DE_Cities');
+-----+
| gen_dictionary('DE_Cities') |
+-----+
| Berlin |
+-----+
mysql> SELECT gen_dictionary('US_Cities');
+-----+
| gen_dictionary('US_Cities') |
+-----+
| Phoenix |
+-----+
```

To select a random term from multiple dictionaries, randomly select one of the dictionaries, then select a term from it:

```
mysql> SELECT gen_dictionary(ELT(gen_range(1,2), 'DE_Cities', 'US_Cities'));
+-----+
| gen_dictionary(ELT(gen_range(1,2), 'DE_Cities', 'US_Cities')) |
+-----+
| Detroit |
+-----+
mysql> SELECT gen_dictionary(ELT(gen_range(1,2), 'DE_Cities', 'US_Cities'));
+-----+
| gen_dictionary(ELT(gen_range(1,2), 'DE_Cities', 'US_Cities')) |
+-----+
| Bremen |
+-----+
```

The `gen_blocklist()` function enables a term from one dictionary to be replaced by a term from another dictionary, which effects masking by substitution. Its arguments are the term to replace, the dictionary in which the term appears, and the dictionary from which to choose a replacement. For example, to substitute a US city for a German city, or vice versa, use `gen_blocklist()` like this:

```
mysql> SELECT gen_blocklist('Munich', 'DE_Cities', 'US_Cities');
+-----+
| gen_blocklist('Munich', 'DE_Cities', 'US_Cities') |
+-----+
| Houston |
+-----+
mysql> SELECT gen_blocklist('El Paso', 'US_Cities', 'DE_Cities');
```

```

+-----+
| gen_blocklist('El Paso', 'US_Cities', 'DE_Cities') |
+-----+
| Bremen |
+-----+

```

If the term to replace is not in the first dictionary, `gen_blocklist()` returns it unchanged:

```

mysql> SELECT gen_blocklist('Moscow', 'DE_Cities', 'US_Cities');
+-----+
| gen_blocklist('Moscow', 'DE_Cities', 'US_Cities') |
+-----+
| Moscow |
+-----+

```

## Using Masked Data for Customer Identification

At customer-service call centers, one common identity verification technique is to ask customers to provide their last four Social Security Number (SSN) digits. For example, a customer might say her name is Joanna Bond and that her last four SSN digits are 0007.

Suppose that a `customer` table containing customer records has these columns:

- `id`: Customer ID number.
- `first_name`: Customer first name.
- `last_name`: Customer last name.
- `ssn`: Customer Social Security Number.

For example, the table might be defined as follows:

```

CREATE TABLE customer
(
 id BIGINT NOT NULL AUTO_INCREMENT PRIMARY KEY,
 first_name VARCHAR(40),
 last_name VARCHAR(40),
 ssn VARCHAR(11)
);

```

The application used by customer-service representatives to check the customer SSN might execute a query like this:

```

mysql> SELECT id, ssn
mysql> FROM customer
mysql> WHERE first_name = 'Joanna' AND last_name = 'Bond';
+-----+
| id | ssn |
+-----+
| 786 | 906-39-0007 |
+-----+

```

However, that exposes the SSN to the customer-service representative, who has no need to see anything but the last four digits. Instead, the application can use this query to display only the masked SSN:

```

mysql> SELECT id, mask_ssn(CONVERT(ssn USING binary)) AS masked_ssn
mysql> FROM customer
mysql> WHERE first_name = 'Joanna' AND last_name = 'Bond';
+-----+
| id | masked_ssn |
+-----+
| 786 | ***-**-0007 |
+-----+

```

Now the representative sees only what is necessary, and customer privacy is preserved.

Why was the `CONVERT()` function used for the argument to `mask_ssn()`? Because `mask_ssn()` requires an argument of length 11. Thus, even though `ssn` is defined as `VARCHAR(11)`, if the `ssn` column has a multibyte character set, it may appear to be longer than 11 bytes when passed to a loadable function, and returns `NULL` while logging the error. Converting the value to a binary string ensures that the function sees an argument of length 11.

A similar technique may be needed for other data masking functions when string arguments do not have a single-byte character set.

## Creating Views that Display Masked Data

If masked data from a table is used for multiple queries, it may be convenient to define a view that produces masked data. That way, applications can select from the view without performing masking in individual queries.

For example, a masking view on the `customer` table from the previous section can be defined like this:

```
CREATE VIEW masked_customer AS
SELECT id, first_name, last_name,
mask_ssn(CONVERT(ssn USING binary)) AS masked_ssn
FROM customer;
```

Then the query to look up a customer becomes simpler but still returns masked data:

```
mysql> SELECT id, masked_ssn
mysql> FROM masked_customer
mysql> WHERE first_name = 'Joanna' AND last_name = 'Bond';
+-----+-----+
| id | masked_ssn |
+-----+-----+
| 786 | ***-**-0007 |
+-----+-----+
```

## 8.5.2.3 MySQL Enterprise Data Masking and De-Identification Component Function Reference

**Table 8.47 MySQL Enterprise Data Masking and De-Identification Component Functions**

Name	Description
<code>gen_blocklist()</code>	Perform dictionary term replacement
<code>gen_dictionary()</code>	Return random term from dictionary
<code>gen_range()</code>	Generate random number within range
<code>gen_rnd_canada_sin()</code>	Generate random Canada Social Insurance Number
<code>gen_rnd_email()</code>	Generate random email address
<code>gen_rnd_iban()</code>	Generate random International Bank Account Number
<code>gen_rnd_pan()</code>	Generate random payment card Primary Account Number
<code>gen_rnd_ssn()</code>	Generate random US Social Security Number
<code>gen_rnd_uk_nin()</code>	Generate random United Kingdom National Insurance Number
<code>gen_rnd_us_phone()</code>	Generate random US phone number
<code>gen_rnd_uuid()</code>	Generate random Universally Unique Identifier

Name	Description
<code>mask_canada_sin()</code>	Mask Canada Social Insurance Number
<code>mask_iban()</code>	Mask International Bank Account Number
<code>mask_inner()</code>	Mask interior part of string
<code>mask_outer()</code>	Mask left and right parts of string
<code>mask_pan()</code>	Mask payment card Primary Account Number part of string
<code>mask_pan_relaxed()</code>	Mask payment card Primary Account Number part of string
<code>mask_ssn()</code>	Mask US Social Security Number
<code>mask_uk_nin()</code>	Mask United Kingdom National Insurance Number
<code>mask_uuid()</code>	Mask Universally Unique Identifier part of string
<code>masking_dictionaries_flush()</code>	Cause masking_dictionaries cache to be reloaded from table
<code>masking_dictionary_remove()</code>	Remove dictionary from the database table
<code>masking_dictionary_term_add()</code>	Add new term to the dictionary
<code>masking_dictionary_term_remove()</code>	Remove existing term from the dictionary

#### 8.5.2.4 MySQL Enterprise Data Masking and De-Identification Component Function Descriptions

The MySQL Enterprise Data Masking and De-Identification components includes several functions, which may be grouped into these categories:

- [Data Masking Component Functions](#)
- [Random Data Generation Component Functions](#)
- [Dictionary Masking Administration Component Functions](#)
- [Dictionary Generating Component Functions](#)

#### Data Masking Component Functions

Each component function in this section performs a masking operation on its string argument and returns the masked result.

- `mask_canada_sin(str [, mask_char])`

Masks a Canada Social Insurance Number (SIN) and returns the number with all meaningful digits replaced by 'X' characters. An optional masking character can be specified.

Arguments:

- `str`: The string to mask. The accepted formats are:
  - Nine non-separated digits.
  - Nine digits grouped in pattern: `xxx-xxx-xxx` ('-' is any separator character).

This argument is converted to the `utf8mb4` character set.

- `mask_char`: (Optional) The single character to use for masking. The default is 'X' if `mask_char` is not given.

Return value:

The masked Canada SIN as a string encoded in the `utf8mb4` character set, an error if the argument is not the correct length, or `NULL` if `str` is in incorrect format or contains a multibyte character.

Example:

```
mysql> SELECT mask_canada_sin('046-454-286'), mask_canada_sin('abcdefijk');
+-----+-----+
| mask_canada_sin('046-454-286') | mask_canada_sin('abcdefijk') |
+-----+-----+
| XXX-XXX-XXX | XXXXXXXXX |
+-----+-----+
mysql> SELECT mask_canada_sin('909');
ERROR 1123 (HY000): Can't initialize function 'mask_canada_sin'; Argument 0 is too short.
mysql> SELECT mask_canada_sin('046-454-286-909');
ERROR 1123 (HY000): Can't initialize function 'mask_canada_sin'; Argument 0 is too long.
```

- `mask_iban(str [, mask_char])`

Masks an International Bank Account Number (IBAN) and returns the number with all but the first two letters (denoting the country) replaced by '\*' characters. An optional masking character can be specified.

Arguments:

- `str`: The string to mask. Each country can have a different national routing or account numbering system, with a minimum of 13 and a maximum of 34 alphanumeric ASCII characters. The accepted formats are:
  - Non-separated characters.
  - Character grouped by four, except the last group, and separated by space or any other separator character (for example: `xxxx-xxxx-xxxx-xx`).

This argument is converted to the `utf8mb4` character set.

- `mask_char`: (Optional) The single character to use for masking. The default is '\*' if `mask_char` is not given.

Return value:

The masked International Bank Account Number as a string encoded in the `utf8mb4` character set, an error if the argument is not the correct length, or `NULL` if `str` is in incorrect format or contains a multibyte character.

Example:

```
mysql> SELECT mask_iban('IE12 BOFI 9000 0112 3456 78'), mask_iban('abcdefghijk');
+-----+-----+
| mask_iban('IE12 BOFI 9000 0112 3456 78') | mask_iban('abcdefghijk') |
+-----+-----+
| IE** **** * | ab***** |
+-----+-----+
mysql> SELECT mask_iban('909');
ERROR 1123 (HY000): Can't initialize function 'mask_iban'; Argument 0 is too short.
```

```
mysql> SELECT mask_iban('IE12 BOFI 9000 0112 3456 78 IE12 BOFI 9000 0112 3456 78');
ERROR 1123 (HY000): Can't initialize function 'mask_iban'; Argument 0 is too long.
```

- `mask_inner(str, margin1, margin2 [, mask_char])`

Masks the interior part of a string, leaving the ends untouched, and returns the result. An optional masking character can be specified.

`mask_inner` supports all character sets.

Arguments:

- `str`: The string to mask. This argument is converted to the `utf8mb4` character set.
- `margin1`: A nonnegative integer that specifies the number of characters on the left end of the string to remain unmasked. If the value is 0, no left end characters remain unmasked.
- `margin2`: A nonnegative integer that specifies the number of characters on the right end of the string to remain unmasked. If the value is 0, no right end characters remain unmasked.
- `mask_char`: (Optional) The single character to use for masking. The default is 'X' if `mask_char` is not given.

Return value:

The masked string encoded in the same character set used for `str`, or an error if either margin is negative.

If the sum of the margin values is larger than the argument length, no masking occurs and the argument is returned unchanged.

#### Note

The function is optimized to work faster for single byte strings (having equal byte length and character length). For example, the `utf8mb4` character set uses only one byte for ASCII characters, so the function processes strings containing only ASCII characters as single-byte character strings.

Example:

```
mysql> SELECT mask_inner('abcdef', 1, 2), mask_inner('abcdef',0, 5);
+-----+-----+
| mask_inner('abcdef', 1, 2) | mask_inner('abcdef',0, 5) |
+-----+-----+
| aXXXef | Xbcdef |
+-----+-----+
mysql> SELECT mask_inner('abcdef', 1, 2, '*'), mask_inner('abcdef',0, 5, '#');
+-----+-----+
| mask_inner('abcdef', 1, 2, '*') | mask_inner('abcdef',0, 5, '#') |
+-----+-----+
| a***ef | #bcdef |
+-----+-----+
```

- `mask_outer(str, margin1, margin2 [, mask_char])`

Masks the left and right ends of a string, leaving the interior unmasked, and returns the result. An optional masking character can be specified.

`mask_outer` supports all character sets.

Arguments:

- `str`: The string to mask. This argument is converted to the `utf8mb4` character set.
- `margin1`: A nonnegative integer that specifies the number of characters on the left end of the string to mask. If the value is 0, no left end characters are masked.
- `margin2`: A nonnegative integer that specifies the number of characters on the right end of the string to mask. If the value is 0, no right end characters are masked.
- `mask_char`: (Optional) The single character to use for masking. The default is 'X' if `mask_char` is not given.

Return value:

The masked string encoded in the same character set used for `str`, or an error if either margin is negative.

If the sum of the margin values is larger than the argument length, the entire argument is masked.

#### Note

The function is optimized to work faster for single byte strings (having equal byte length and character length). For example, the `utf8mb4` character set uses only one byte for ASCII characters, so the function processes strings containing only ASCII characters as single-byte character strings.

Example:

```
mysql> SELECT mask_outer('abcdef', 1, 2), mask_outer('abcdef',0, 5);
+-----+-----+
| mask_outer('abcdef', 1, 2) | mask_outer('abcdef',0, 5) |
+-----+-----+
| XbcdXX | aXXXXX |
+-----+-----+
mysql> SELECT mask_outer('abcdef', 1, 2, '*'), mask_outer('abcdef',0, 5, '#');
+-----+-----+
| mask_outer('abcdef', 1, 2, '*') | mask_outer('abcdef',0, 5, '#') |
+-----+-----+
| *bcd** | a##### |
+-----+-----+
```

- `mask_pan(str [, mask_char])`

Masks a payment card Primary Account Number (PAN) and returns the number with all but the last four digits replaced by 'X' characters. An optional masking character can be specified.

Arguments:

- `str`: The string to mask. The string must contain a minimum of 14 and a maximum of 19 alphanumeric characters. This argument is converted to the `utf8mb4` character set.
- `mask_char`: (Optional) The single character to use for masking. The default is 'X' if `mask_char` is not given.

Return value:

The masked payment number as a string encoded in the `utf8mb4` character set, an error if the argument is not the correct length, or `NULL` if `str` is in incorrect format or contains a multibyte character.

Example:

```
mysql> SELECT mask_pan(gen_rnd_pan());
+-----+
| mask_pan(gen_rnd_pan()) |
+-----+
| XXXXXXXXXXXXX9102 |
+-----+
mysql> SELECT mask_pan(gen_rnd_pan(19));
+-----+
| mask_pan(gen_rnd_pan(19)) |
+-----+
| XXXXXXXXXXXXXXX8268 |
+-----+
mysql> SELECT mask_pan('a*Z');
ERROR 1123 (HY000): Can't initialize function 'mask_pan'; Argument 0 is too short.
```

- `mask_pan_relaxed(str)`

Masks a payment card Primary Account Number and returns the number with all but the first six and last four digits replaced by 'X' characters. The first six digits indicate the payment card issuer. An optional masking character can be specified.

Arguments:

- `str`: The string to mask. The string must be a suitable length for the Primary Account Number, but is not otherwise checked. This argument is converted to the `utf8mb4` character set.
- `mask_char`: (Optional) The single character to use for masking. The default is 'X' if `mask_char` is not given.

Return value:

The masked payment number as a string encoded in the `utf8mb4` character set, an error if the argument is not the correct length, or `NULL` if `str` is in incorrect format or contains a multibyte character.

Example:

```
mysql> SELECT mask_pan_relaxed(gen_rnd_pan());
+-----+
| mask_pan_relaxed(gen_rnd_pan()) |
+-----+
```

```

| 551279XXXXXX3108 |
+-----+
mysql> SELECT mask_pan_relaxed(gen_rnd_pan(19));
+-----+
| mask_pan_relaxed(gen_rnd_pan(19)) |
+-----+
| 462634XXXXXXXXXX6739 |
+-----+
mysql> SELECT mask_pan_relaxed('a*Z');
ERROR 1123 (HY000): Can't initialize function 'mask_pan_relaxed'; Argument 0 is too short.

```

- `mask_ssn(str [, mask_char])`

Masks a US Social Security Number (SSN) and returns the number with all but the last four digits replaced by '\*' characters. An optional masking character can be specified.

Arguments:

- `str`: The string to mask. The accepted formats are:
  - Nine non-separated digits.
  - Nine digits grouped in pattern: `xxx-xx-xxxx` ('-' is any separator character).

This argument is converted to the `utf8mb4` character set.

- `mask_char`: (Optional) The single character to use for masking. The default is '\*' if `mask_char` is not given.

Return value:

The masked Social Security Number as a string encoded in the `utf8mb4` character set, an error if the argument is not the correct length, or `NULL` if `str` is in incorrect format or contains a multibyte character.

Example:

```

mysql> SELECT mask_ssn('909-63-6922'), mask_ssn('cdefghijk');
+-----+-----+
| mask_ssn('909-63-6922') | mask_ssn('cdefghijk') |
+-----+-----+
| ***-**-6922 | *****hijk |
+-----+-----+
mysql> SELECT mask_ssn('909');
ERROR 1123 (HY000): Can't initialize function 'mask_ssn'; Argument 0 is too short.
mysql> SELECT mask_ssn('123456789123456789');
ERROR 1123 (HY000): Can't initialize function 'mask_ssn'; Argument 0 is too long.

```

- `mask_uk_nin(str [, mask_char])`

Masks a United Kingdom National Insurance Number (UK NIN) and returns the number with all but the first two digits replaced by '\*' characters. An optional masking character can be specified.

Arguments:

- `str`: The string to mask. The accepted formats are:
  - Nine non-separated digits.
  - Nine digits grouped in pattern: `xxx-xx-xxxx` ('-' is any separator character).
  - Nine digits grouped in pattern: `xx-xxxxxx-x` ('-' is any separator character).

This argument is converted to the `utf8mb4` character set.

- `mask_char`: (Optional) The single character to use for masking. The default is '\*' if `mask_char` is not given.

Return value:

The masked UK NIN as a string encoded in the `utf8mb4` character set, an error if the argument is not the correct length, or `NULL` if `str` is in incorrect format or contains a multibyte character.

Example:

```
mysql> SELECT mask_uk_nin('QQ 12 34 56 C'), mask_uk_nin('abcdefghi');
+-----+-----+
| mask_uk_nin('QQ 12 34 56 C') | mask_uk_nin('abcdefghi') |
+-----+-----+
| QQ ** ** ** * | ab***** |
+-----+-----+
mysql> SELECT mask_uk_nin('909');
ERROR 1123 (HY000): Can't initialize function 'mask_uk_nin'; Argument 0 is too short.
mysql> SELECT mask_uk_nin('abcdefghijk');
ERROR 1123 (HY000): Can't initialize function 'mask_uk_nin'; Argument 0 is too long.
```

- `mask_uuid(str [, mask_char])`

Masks a Universally Unique Identifier (UUID) and returns the number with all meaningful characters replaced by '\*' characters. An optional masking character can be specified.

Arguments:

- `str`: The string to mask. The accepted format is `xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx` in which 'x' is any digit and '-' is any separator character. This argument is converted to the `utf8mb4` character set.
- `mask_char`: (Optional) The single character to use for masking. The default is '\*' if `mask_char` is not given.

Return value:

The masked UUID as a string encoded in the `utf8mb4` character set, an error if the argument is not the correct length, or `NULL` if `str` is in incorrect format or contains a multibyte character.

Example:

```
mysql> SELECT mask_uuid(gen_rnd_uuid());
+-----+
| mask_uuid(gen_rnd_uuid()) |
+-----+
| *****_*****_*****_*****_***** |
+-----+
mysql> SELECT mask_uuid('909');
ERROR 1123 (HY000): Can't initialize function 'mask_uuid'; Argument 0 is too short.
mysql> SELECT mask_uuid('123e4567-e89b-12d3-a456-426614174000-123e4567-e89b-12d3');
ERROR 1123 (HY000): Can't initialize function 'mask_uuid'; Argument 0 is too long.
```

## Random Data Generation Component Functions

The component functions in this section generate random values for different types of data. When possible, generated values have characteristics reserved for demonstration or test values, to avoid having them mistaken for legitimate data. For example, `gen_rnd_us_phone()` returns a US phone number that uses the 555 area code, which is not assigned to phone numbers in actual use. Individual function descriptions describe any exceptions to this principle.

- `gen_range(lower, upper)`

Generates a random number chosen from a specified range.

Arguments:

- `lower`: An integer that specifies the lower boundary of the range.
- `upper`: An integer that specifies the upper boundary of the range, which must not be less than the lower boundary.

Return value:

A random integer (encoded in the `utf8mb4` character set) in the range from `lower` to `upper`, inclusive, or `NULL` if the `upper` argument is less than `lower`.

**Note**

For better quality of random values, use `RAND()` instead of this function.

Example:

```
mysql> SELECT gen_range(100, 200), gen_range(-1000, -800);
+-----+-----+
| gen_range(100, 200) | gen_range(-1000, -800) |
+-----+-----+
| 177 | -917 |
+-----+-----+
mysql> SELECT gen_range(1, 0);
+-----+
| gen_range(1, 0) |
+-----+
| NULL |
+-----+
```

- `gen_rnd_canada_sin()`

Generates a random Canada Social Insurance Number (SIN) in `AAA-BBB-CCC` format. The generated number passes the Luhn check algorithm, which ensures the consistency of this number.

**Warning**

Values returned from `gen_rnd_canada_sin()` should be used only for test purposes, and are not suitable for publication. There is no way to guarantee that a given return value is not assigned to a legitimate Canada SIN. Should it be necessary to publish a `gen_rnd_canada_sin()` result, consider masking it with `mask_canada_sin()`.

Arguments:

None.

Return value:

A random Canada SIN as a string encoded in the `utf8mb4` character set.

Example:

```
mysql> SELECT gen_rnd_canada_sin();
+-----+
| gen_rnd_canada_sin() |
+-----+
| 046-454-286 |
+-----+
```

- `gen_rnd_email(name_size, surname_size, domain)`

Generates a random email address in the form of `random_name.random_surname@domain`.

Arguments:

- `name_size`: (Optional) An integer that specifies the number of characters in the name part of an address. The default is five if `name_size` is not given.
- `surname_size`: (Optional) An integer that specifies the number of characters in the surname part of an address. The default is seven if `surname_size` is not given.
- `domain`: (Optional) A string that specifies the domain part of the address. The default is `example.com` if `domain` is not given.

Return value:

A random email address as a string encoded in the `utf8mb4` character set.

Example:

```
mysql> SELECT gen_rnd_email(name_size = 4, surname_size = 5, domain = 'mynet.com');
+-----+
| gen_rnd_email(name_size = 4, surname_size = 5, domain = 'mynet.com') |
+-----+
| lsoy.qwupp@mynet.com |
+-----+
mysql> SELECT gen_rnd_email();
+-----+
| gen_rnd_email() |
+-----+
| ijocv.mwvhhuf@example.com |
+-----+
```

- `gen_rnd_iban([country, size])`

Generates a random International Bank Account Number (IBAN) in `AAAA BBBB CCCC DDDD` format. The generated string starts with a two-character country code, two check digits computed according to the IBAN specification and random alphanumeric characters up to the required size.

### Warning

Values returned from `gen_rnd_iban()` should be used only for test purposes, and are not suitable for publication if used with a valid country code. There is no way to guarantee that a given return value is not assigned to a legitimate bank

account. Should it be necessary to publish a `gen_rnd_iban()` result, consider masking it with `mask_iban()`.

Arguments:

- `country`: (Optional) Two-character country code; default value is `ZZ`
- `size`: (Optional) Number of meaningful characters; default 16, minimum 15, maximum 34

Return value:

A random IBAN as a string encoded in the `utf8mb4` character set.

Example:

```
mysql> SELECT gen_rnd_iban();
+-----+
| gen_rnd_iban() |
+-----+
| ZZ79 3K2J WNH9 1V0DI |
+-----+
```

- `gen_rnd_pan([size])`

Generates a random payment card Primary Account Number. The number passes the Luhn check (an algorithm that performs a checksum verification against a check digit).

#### Warning

Values returned from `gen_rnd_pan()` should be used only for test purposes, and are not suitable for publication. There is no way to guarantee that a given return value is not assigned to a legitimate payment account. Should it be necessary to publish a `gen_rnd_pan()` result, consider masking it with `mask_pan()` or `mask_pan_relaxed()`.

Arguments:

- `size`: (Optional) An integer that specifies the size of the result. The default is 16 if `size` is not given. If given, `size` must be an integer in the range from 12 to 19.

Return value:

A random payment number as a string, or an error if a `size` argument outside the permitted range is given.

Example:

```
mysql> SELECT mask_pan(gen_rnd_pan());
+-----+
| mask_pan(gen_rnd_pan()) |
+-----+
| XXXXXXXXXXXXX5805 |
+-----+
mysql> SELECT mask_pan(gen_rnd_pan(19));
+-----+
| mask_pan(gen_rnd_pan(19)) |
+-----+
| XXXXXXXXXXXXXXX5067 |
+-----+
mysql> SELECT mask_pan_relaxed(gen_rnd_pan());
+-----+
```

```

| mask_pan_relaxed(gen_rnd_pan()) |
+-----+
| 398403XXXXXX9547 |
+-----+
mysql> SELECT mask_pan_relaxed(gen_rnd_pan(19));
+-----+
| mask_pan_relaxed(gen_rnd_pan(19)) |
+-----+
| 578416XXXXXXXXXX6509 |
+-----+
mysql> SELECT gen_rnd_pan(20);
ERROR 1123 (HY000): Can't initialize function 'gen_rnd_pan'; Minimal value of argument 0 is 14.

```

- `gen_rnd_ssn()`

Generates a random US Social Security Number in `AAA-BB-CCCC` format. The `AAA` part is greater than 900, which are characteristics not used for legitimate social security numbers.

Arguments:

None.

Return value:

A random Social Security Number as a string encoded in the `utf8mb4` character set.

Example:

```

mysql> SELECT gen_rnd_ssn();
+-----+
| gen_rnd_ssn() |
+-----+
| 951-26-0058 |
+-----+

```

- `gen_rnd_uk_nin()`

Generates a random United Kingdom National Insurance Number (UK NIN) in nine-character format. NIN starts with two character prefix randomly selected from the set of valid prefixes, six random numbers, and one character suffix randomly selected from the set of valid suffixes.

### Warning

Values returned from `gen_rnd_uk_nin()` should be used only for test purposes, and are not suitable for publication. There is no way to guarantee that a given return value is not assigned to a legitimate NIN. Should it be necessary to publish a `gen_rnd_uk_nin()` result, consider masking it with `mask_uk_nin()`.

Arguments:

None.

Return value:

A random UK NIN as a string encoded in the `utf8mb4` character set.

Example:

```

mysql> SELECT gen_rnd_uk_nin();
+-----+
| gen_rnd_uk_nin() |
+-----+

```

```
+-----+
| QQ123456C |
+-----+
```

- `gen_rnd_us_phone()`

Generates a random US phone number in `1-555-AAA-BBBB` format. The 555 area code is not used for legitimate phone numbers.

Arguments:

None.

Return value:

A random US phone number as a string encoded in the `utf8mb4` character set.

Example:

```
mysql> SELECT gen_rnd_us_phone();
+-----+
| gen_rnd_us_phone() |
+-----+
| 1-555-682-5423 |
+-----+
```

- `gen_rnd_uuid()`

Generates a random Universally Unique Identifier (UUID) segmented with dashes.

Arguments:

None.

Return value:

A random UUID as a string encoded in the `utf8mb4` character set.

Example:

```
mysql> SELECT gen_rnd_uuid();
+-----+
| gen_rnd_uuid() |
+-----+
| 123e4567-e89b-12d3-a456-426614174000 |
+-----+
```

## Dictionary Masking Administration Component Functions

The component functions in this section manipulate dictionaries of terms and perform administrative masking operations based on them. All of these functions require the `MASKING_DICTIONARIES_ADMIN` privilege.

When a dictionary of terms is created, it becomes part of the dictionary registry and is assigned a name to be used by other dictionary functions.

- `masking_dictionaries_flush()`

Flush the data from the masking dictionaries table to the memory cache. Requires the `MASKING_DICTIONARIES_ADMIN` privilege.

- `masking_dictionary_remove(dictionary_name)`

Removes a dictionary and all of its terms from the dictionary registry. This function requires the `MASKING_DICTIONARIES_ADMIN` privilege.

Arguments:

- `dictionary_name`: A string that names the dictionary to remove from the dictionary table. This argument is converted to the `utf8mb4` character set.

Return value:

A string that indicates whether the remove operation succeeded. `1` indicates success. `NULL` indicates the dictionary name is not found.

Example:

```
mysql> SELECT masking_dictionary_remove('mydict');
+-----+
| masking_dictionary_remove('mydict') |
+-----+
| 1 |
+-----+
mysql> SELECT masking_dictionary_remove('no-such-dict');
+-----+
| masking_dictionary_remove('no-such-dict') |
+-----+
| NULL |
+-----+
```

- `masking_dictionary_term_add(dictionary_name, term_name)`

Adds one term to the named dictionary. This function requires the `MASKING_DICTIONARIES_ADMIN` privilege.

#### Important

Dictionaries and their terms are persisted to a table in the `mysql` schema. All of the terms in a dictionary are accessible to any user account if that user

executes `gen_dictionary()` repeatedly. Avoid adding sensitive information to dictionaries.

Each term is defined by a named dictionary. `masking_dictionary_term_add()` permits you to add one dictionary term at a time.

Arguments:

- `dictionary_name`: A string that provides a name for the dictionary. This argument is converted to the `utf8mb4` character set.
- `term_name`: A string that specifies the term name in the dictionary table. This argument is converted to the `utf8mb4` character set.

Return value:

A string that indicates whether the add term operation succeeded. `1` indicates success. `NULL` indicates failure. Term add failure can occur for several reasons, including:

- A term with the given name is already added.
- The dictionary name is not found.

Example:

```
mysql> SELECT masking_dictionary_term_add('mydict','newterm');
+-----+
| masking_dictionary_term_add('mydict','newterm') |
+-----+
| 1 |
+-----+
mysql> SELECT masking_dictionary_term_add('mydict','');
+-----+
| masking_dictionary_term_add('mydict','') |
+-----+
| NULL |
+-----+
```

- `masking_dictionary_term_remove(dictionary_name, term_name)`

Removes one term from the named dictionary. This function requires the `MASKING_DICTIONARIES_ADMIN` privilege.

Arguments:

- `dictionary_name`: A string that provides a name for the dictionary. This argument is converted to the `utf8mb4` character set.
- `term_name`: A string that specifies the term name in the dictionary table. This argument is converted to the `utf8mb4` character set.

Return value:

A string that indicates whether the remove term operation succeeded. `1` indicates success. `NULL` indicates failure. Term remove failure can occur for several reasons, including:

- A term with the given name is not found.
- The dictionary name is not found.

Example:

```
mysql> SELECT masking_dictionary_term_add('mydict','newterm');
+-----+
| masking_dictionary_term_add('mydict','newterm') |
+-----+
| 1 |
+-----+
mysql> SELECT masking_dictionary_term_remove('mydict','');
+-----+
| masking_dictionary_term_remove('mydict','') |
+-----+
| NULL |
+-----+
```

## Dictionary Generating Component Functions

The component functions in this section manipulate dictionaries of terms and perform generating operations based on them.

When a dictionary of terms is created, it becomes part of the dictionary registry and is assigned a name to be used by other dictionary functions.

- `gen_blocklist(str, from_dictionary_name, to_dictionary_name)`

Replaces a term present in one dictionary with a term from a second dictionary and returns the replacement term. This masks the original term by substitution.

Arguments:

- `term`: A string that indicates the term to replace. This argument is converted to the `utf8mb4` character set.
- `from_dictionary_name`: A string that names the dictionary containing the term to replace. This argument is converted to the `utf8mb4` character set.
- `to_dictionary_name`: A string that names the dictionary from which to choose the replacement term. This argument is converted to the `utf8mb4` character set.

Return value:

A string encoded in the `utf8mb4` character set randomly chosen from `to_dictionary_name` as a replacement for `term`, or `term` if it does not appear in `from_dictionary_name`, or an error if either dictionary name is not in the dictionary registry.

#### Note

If the term to replace appears in both dictionaries, it is possible for the return value to be the same term.

Example:

```
mysql> SELECT gen_blocklist('Berlin', 'DE_Cities', 'US_Cities');
+-----+
| gen_blocklist('Berlin', 'DE_Cities', 'US_Cities') |
+-----+
| Phoenix |
+-----+
```

- `gen_dictionary(dictionary_name)`

Returns a random term from a dictionary.

Arguments:

- `dictionary_name`: A string that names the dictionary from which to choose the term. This argument is converted to the `utf8mb4` character set.

Return value:

A random term from the dictionary as a string encoded in the `utf8mb4` character set, or `NULL` if the dictionary name is not in the dictionary registry.

Example:

```
mysql> SELECT gen_dictionary('mydict');
+-----+
| gen_dictionary('mydict') |
+-----+
| My term |
+-----+
mysql> SELECT gen_dictionary('no-such-dict');
ERROR 1123 (HY000): Can't initialize function 'gen_dictionary'; Cannot access
dictionary, check if dictionary name is valid.
```

### 8.5.2.5 MySQL Enterprise Data Masking and De-Identification Component Variables

The MySQL Enterprise Data Masking and De-Identification components support the following system variables. Use these variables to configure related component operations. Variables are unavailable unless the appropriate MySQL Enterprise Data Masking and De-Identification components are installed (see [Section 8.5.2.1, “MySQL Enterprise Data Masking and De-Identification Component Installation”](#)).

- `component_masking.dictionaries_flush_interval_seconds`

Command-Line Format	<code>--component-masking.dictionaries-flush-interval-seconds=#</code>
System Variable	<code>component_masking.dictionaries_flush_interval_seconds</code>

Scope	Global
Dynamic	No
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	60
Maximum Value (Unix)	18446744073709551615
Maximum Value (Windows)	4294967295
Unit	seconds

Sets the interval, in seconds, to wait before attempting to schedule another flush of the data masking dictionaries table to the memory data masking dictionaries cache following a restart or previous execution. The value is handled as listed here:

- 0: No flushing
- 1 - 59 inclusive: Round up to 60, with a warning
- $\geq 60$ : Wait this many seconds to perform flush
- [component\\_masking.masking\\_database](#)

Command-Line Format	<code>--component_masking.masking_database[=value]</code>
System Variable	<a href="#">component_masking.masking_database</a>
Scope	Global
Dynamic	No
<a href="#">SET_VAR</a> Hint Applies	No
Type	String
Default Value	<a href="#">mysql</a>

Specifies the database to use for data masking dictionaries at server startup. This variable is read only.

Use this variable to set and persist a schema other than the default value ([mysql](#)). For additional information about setting up the data-masking components to use an alternative location for the data-masking table, see [Install Using a Dedicated Schema](#). For general guidelines about using the [PERSIST ONLY](#) keyword, see [Section 15.7.6.1, “SET Syntax for Variable Assignment”](#).

### 8.5.3 MySQL Enterprise Data Masking and De-Identification Plugin

MySQL Enterprise Data Masking and De-Identification is based on a plugin library that implements these elements:

- A server-side plugin named [data\\_masking](#).
- A set of loadable functions provides an SQL-level API for performing masking and de-identification operations. Some of these functions require the [SUPER](#) privilege.

#### 8.5.3.1 MySQL Enterprise Data Masking and De-Identification Plugin Installation

This section describes how to install or uninstall MySQL Enterprise Data Masking and De-Identification, which is implemented as a plugin library file containing a plugin and several loadable functions. For general information about installing or uninstalling plugins and loadable functions, see [Section 7.6.1, “Installing and Uninstalling Plugins”](#), and [Section 7.7.1, “Installing and Uninstalling Loadable Functions”](#).

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

The plugin library file base name is `data_masking`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

To install the MySQL Enterprise Data Masking and De-Identification plugin and functions, use the `INSTALL PLUGIN` and `CREATE FUNCTION` statements, adjusting the `.so` suffix for your platform as necessary:

```
INSTALL PLUGIN data_masking SONAME 'data_masking.so';
CREATE FUNCTION gen_blocklist RETURNS STRING
 SONAME 'data_masking.so';
CREATE FUNCTION gen_dictionary RETURNS STRING
 SONAME 'data_masking.so';
CREATE FUNCTION gen_dictionary_drop RETURNS STRING
 SONAME 'data_masking.so';
CREATE FUNCTION gen_dictionary_load RETURNS STRING
 SONAME 'data_masking.so';
CREATE FUNCTION gen_range RETURNS INTEGER
 SONAME 'data_masking.so';
CREATE FUNCTION gen_rnd_email RETURNS STRING
 SONAME 'data_masking.so';
CREATE FUNCTION gen_rnd_pan RETURNS STRING
 SONAME 'data_masking.so';
CREATE FUNCTION gen_rnd_ssn RETURNS STRING
 SONAME 'data_masking.so';
CREATE FUNCTION gen_rnd_us_phone RETURNS STRING
 SONAME 'data_masking.so';
CREATE FUNCTION mask_inner RETURNS STRING
 SONAME 'data_masking.so';
CREATE FUNCTION mask_outer RETURNS STRING
 SONAME 'data_masking.so';
CREATE FUNCTION mask_pan RETURNS STRING
 SONAME 'data_masking.so';
CREATE FUNCTION mask_pan_relaxed RETURNS STRING
 SONAME 'data_masking.so';
CREATE FUNCTION mask_ssn RETURNS STRING
 SONAME 'data_masking.so';
```

If the plugin and functions are used on a replication source server, install them on all replica servers as well to avoid replication issues.

Once installed as just described, the plugin and functions remain installed until uninstalled. To remove them, use the `UNINSTALL PLUGIN` and `DROP FUNCTION` statements:

```
UNINSTALL PLUGIN data_masking;
DROP FUNCTION gen_blocklist;
DROP FUNCTION gen_dictionary;
DROP FUNCTION gen_dictionary_drop;
DROP FUNCTION gen_dictionary_load;
DROP FUNCTION gen_range;
DROP FUNCTION gen_rnd_email;
DROP FUNCTION gen_rnd_pan;
DROP FUNCTION gen_rnd_ssn;
DROP FUNCTION gen_rnd_us_phone;
```

```
DROP FUNCTION mask_inner;
DROP FUNCTION mask_outer;
DROP FUNCTION mask_pan;
DROP FUNCTION mask_pan_relaxed;
DROP FUNCTION mask_ssn;
```

### 8.5.3.2 Using the MySQL Enterprise Data Masking and De-Identification Plugin

Before using MySQL Enterprise Data Masking and De-Identification, install it according to the instructions provided at [Section 8.5.3.1, “MySQL Enterprise Data Masking and De-Identification Plugin Installation”](#).

To use MySQL Enterprise Data Masking and De-Identification in applications, invoke the functions that are appropriate for the operations you wish to perform. For detailed function descriptions, see [Section 8.5.3.4, “MySQL Enterprise Data Masking and De-Identification Plugin Function Descriptions”](#). This section demonstrates how to use the functions to carry out some representative tasks. It first presents an overview of the available functions, followed by some examples of how the functions might be used in real-world context:

- [Masking Data to Remove Identifying Characteristics](#)
- [Generating Random Data with Specific Characteristics](#)
- [Generating Random Data Using Dictionaries](#)
- [Using Masked Data for Customer Identification](#)
- [Creating Views that Display Masked Data](#)

#### Masking Data to Remove Identifying Characteristics

MySQL provides general-purpose masking functions that mask arbitrary strings, and special-purpose masking functions that mask specific types of values.

##### General-Purpose Masking Functions

`mask_inner()` and `mask_outer()` are general-purpose functions that mask parts of arbitrary strings based on position within the string:

- `mask_inner()` masks the interior of its string argument, leaving the ends unmasked. Other arguments specify the sizes of the unmasked ends.

```
mysql> SELECT mask_inner('This is a string', 5, 1);
+-----+
| mask_inner('This is a string', 5, 1) |
+-----+
| This XXXXXXXXXXg |
+-----+
mysql> SELECT mask_inner('This is a string', 1, 5);
+-----+
| mask_inner('This is a string', 1, 5) |
+-----+
| TXXXXXXXXXXtring |
+-----+
```

- `mask_outer()` does the reverse, masking the ends of its string argument, leaving the interior unmasked. Other arguments specify the sizes of the masked ends.

```
mysql> SELECT mask_outer('This is a string', 5, 1);
+-----+
| mask_outer('This is a string', 5, 1) |
+-----+
```

```

+-----+
| XXXXXis a strinX |
+-----+
mysql> SELECT mask_outer('This is a string', 1, 5);
+-----+
| mask_outer('This is a string', 1, 5) |
+-----+
| Xhis is a sXXXXX |
+-----+

```

By default, `mask_inner()` and `mask_outer()` use 'X' as the masking character, but permit an optional masking-character argument:

```

mysql> SELECT mask_inner('This is a string', 5, 1, '*');
+-----+
| mask_inner('This is a string', 5, 1, '*') |
+-----+
| This *****g |
+-----+
mysql> SELECT mask_outer('This is a string', 5, 1, '#');
+-----+
| mask_outer('This is a string', 5, 1, '#') |
+-----+
| #####is a strin# |
+-----+

```

## Special-Purpose Masking Functions

Other masking functions expect a string argument representing a specific type of value and mask it to remove identifying characteristics.

### Note

The examples here supply function arguments using the random value generation functions that return the appropriate type of value. For more information about generation functions, see [Generating Random Data with Specific Characteristics](#).

**Payment card Primary Account Number masking.** Masking functions provide strict and relaxed masking of Primary Account Numbers.

- `mask_pan()` masks all but the last four digits of the number:

```

mysql> SELECT mask_pan(gen_rnd_pan());
+-----+
| mask_pan(gen_rnd_pan()) |
+-----+
| XXXXXXXXXXXX2461 |
+-----+

```

- `mask_pan_relaxed()` is similar but does not mask the first six digits that indicate the payment card issuer unmasked:

```

mysql> SELECT mask_pan_relaxed(gen_rnd_pan());
+-----+
| mask_pan_relaxed(gen_rnd_pan()) |
+-----+
| 770630XXXXXX0807 |
+-----+

```

**US Social Security number masking.** `mask_ssn()` masks all but the last four digits of the number:

```

mysql> SELECT mask_ssn(gen_rnd_ssn());

```

```

+-----+
| mask_ssn(gen_rnd_ssn()) |
+-----+
| XXX-XX-1723 |
+-----+

```

## Generating Random Data with Specific Characteristics

Several functions generate random values. These values can be used for testing, simulation, and so forth.

`gen_range()` returns a random integer selected from a given range:

```

mysql> SELECT gen_range(1, 10);
+-----+
| gen_range(1, 10) |
+-----+
| 6 |
+-----+

```

`gen_rnd_email()` returns a random email address in the `example.com` domain:

```

mysql> SELECT gen_rnd_email();
+-----+
| gen_rnd_email() |
+-----+
| ayxnq.xmkpvvy@example.com |
+-----+

```

`gen_rnd_pan()` returns a random payment card Primary Account Number:

```

mysql> SELECT gen_rnd_pan();

```

(The `gen_rnd_pan()` function result is not shown because its return values should be used only for testing purposes, and not for publication. It cannot be guaranteed the number is not assigned to a legitimate payment account.)

`gen_rnd_ssn()` returns a random US Social Security number with the first and second parts each chosen from a range not used for legitimate numbers:

```

mysql> SELECT gen_rnd_ssn();
+-----+
| gen_rnd_ssn() |
+-----+
| 912-45-1615 |
+-----+

```

`gen_rnd_us_phone()` returns a random US phone number in the 555 area code not used for legitimate numbers:

```

mysql> SELECT gen_rnd_us_phone();
+-----+
| gen_rnd_us_phone() |
+-----+
| 1-555-747-5627 |
+-----+

```

## Generating Random Data Using Dictionaries

MySQL Enterprise Data Masking and De-Identification enables dictionaries to be used as sources of random values. To use a dictionary, it must first be loaded from a file and given a name. Each loaded

dictionary becomes part of the dictionary registry. Items then can be selected from registered dictionaries and used as random values or as replacements for other values.

A valid dictionary file has these characteristics:

- The file contents are plain text, one term per line.
- Empty lines are ignored.
- The file must contain at least one term.

Suppose that a file named `de_cities.txt` contains these city names in Germany:

```
Berlin
Munich
Bremen
```

Also suppose that a file named `us_cities.txt` contains these city names in the United States:

```
Chicago
Houston
Phoenix
El Paso
Detroit
```

Assume that the `secure_file_priv` system variable is set to `/usr/local/mysql/mysql-files`. In that case, copy the dictionary files to that directory so that the MySQL server can access them. Then use `gen_dictionary_load()` to load the dictionaries into the dictionary registry and assign them names:

```
mysql> SELECT gen_dictionary_load('/usr/local/mysql/mysql-files/de_cities.txt', 'DE_Cities');
+-----+
| gen_dictionary_load('/usr/local/mysql/mysql-files/de_cities.txt', 'DE_Cities') |
+-----+
| Dictionary load success |
+-----+
mysql> SELECT gen_dictionary_load('/usr/local/mysql/mysql-files/us_cities.txt', 'US_Cities');
+-----+
| gen_dictionary_load('/usr/local/mysql/mysql-files/us_cities.txt', 'US_Cities') |
+-----+
| Dictionary load success |
+-----+
```

To select a random term from a dictionary, use `gen_dictionary()`:

```
mysql> SELECT gen_dictionary('DE_Cities');
+-----+
| gen_dictionary('DE_Cities') |
+-----+
| Berlin |
+-----+
mysql> SELECT gen_dictionary('US_Cities');
+-----+
| gen_dictionary('US_Cities') |
+-----+
| Phoenix |
+-----+
```

To select a random term from multiple dictionaries, randomly select one of the dictionaries, then select a term from it:

```
mysql> SELECT gen_dictionary(ELT(gen_range(1,2), 'DE_Cities', 'US_Cities'));
+-----+
```

```
| gen_dictionary(ELT(gen_range(1,2), 'DE_Cities', 'US_Cities')) |
+-----+
| Detroit |
+-----+
mysql> SELECT gen_dictionary(ELT(gen_range(1,2), 'DE_Cities', 'US_Cities'));
+-----+
| gen_dictionary(ELT(gen_range(1,2), 'DE_Cities', 'US_Cities')) |
+-----+
| Bremen |
+-----+
```

The `gen_blocklist()` function enables a term from one dictionary to be replaced by a term from another dictionary, which effects masking by substitution. Its arguments are the term to replace, the dictionary in which the term appears, and the dictionary from which to choose a replacement. For example, to substitute a US city for a German city, or vice versa, use `gen_blocklist()` like this:

```
mysql> SELECT gen_blocklist('Munich', 'DE_Cities', 'US_Cities');
+-----+
| gen_blocklist('Munich', 'DE_Cities', 'US_Cities') |
+-----+
| Houston |
+-----+
mysql> SELECT gen_blocklist('El Paso', 'US_Cities', 'DE_Cities');
+-----+
| gen_blocklist('El Paso', 'US_Cities', 'DE_Cities') |
+-----+
| Bremen |
+-----+
```

If the term to replace is not in the first dictionary, `gen_blocklist()` returns it unchanged:

```
mysql> SELECT gen_blocklist('Moscow', 'DE_Cities', 'US_Cities');
+-----+
| gen_blocklist('Moscow', 'DE_Cities', 'US_Cities') |
+-----+
| Moscow |
+-----+
```

## Using Masked Data for Customer Identification

At customer-service call centers, one common identity verification technique is to ask customers to provide their last four Social Security number (SSN) digits. For example, a customer might say her name is Joanna Bond and that her last four SSN digits are 0007.

Suppose that a `customer` table containing customer records has these columns:

- `id`: Customer ID number.
- `first_name`: Customer first name.
- `last_name`: Customer last name.
- `ssn`: Customer Social Security number.

For example, the table might be defined as follows:

```
CREATE TABLE customer
(
 id BIGINT NOT NULL AUTO_INCREMENT PRIMARY KEY,
 first_name VARCHAR(40),
 last_name VARCHAR(40),
 ssn VARCHAR(11)
```

```
);
```

The application used by customer-service representatives to check the customer SSN might execute a query like this:

```
mysql> SELECT id, ssn
mysql> FROM customer
mysql> WHERE first_name = 'Joanna' AND last_name = 'Bond';
+-----+-----+
| id | ssn |
+-----+-----+
| 786 | 906-39-0007 |
+-----+-----+
```

However, that exposes the SSN to the customer-service representative, who has no need to see anything but the last four digits. Instead, the application can use this query to display only the masked SSN:

```
mysql> SELECT id, mask_ssn(CONVERT(ssn USING binary)) AS masked_ssn
mysql> FROM customer
mysql> WHERE first_name = 'Joanna' AND last_name = 'Bond';
+-----+-----+
| id | masked_ssn |
+-----+-----+
| 786 | XXX-XX-0007 |
+-----+-----+
```

Now the representative sees only what is necessary, and customer privacy is preserved.

Why was the `CONVERT()` function used for the argument to `mask_ssn()`? Because `mask_ssn()` requires an argument of length 11. Thus, even though `ssn` is defined as `VARCHAR(11)`, if the `ssn` column has a multibyte character set, it may appear to be longer than 11 bytes when passed to a loadable function, and an error occurs. Converting the value to a binary string ensures that the function sees an argument of length 11.

A similar technique may be needed for other data masking functions when string arguments do not have a single-byte character set.

## Creating Views that Display Masked Data

If masked data from a table is used for multiple queries, it may be convenient to define a view that produces masked data. That way, applications can select from the view without performing masking in individual queries.

For example, a masking view on the `customer` table from the previous section can be defined like this:

```
CREATE VIEW masked_customer AS
SELECT id, first_name, last_name,
mask_ssn(CONVERT(ssn USING binary)) AS masked_ssn
FROM customer;
```

Then the query to look up a customer becomes simpler but still returns masked data:

```
mysql> SELECT id, masked_ssn
mysql> FROM masked_customer
mysql> WHERE first_name = 'Joanna' AND last_name = 'Bond';
+-----+-----+
| id | masked_ssn |
+-----+-----+
| 786 | XXX-XX-0007 |
+-----+-----+
```

### 8.5.3.3 MySQL Enterprise Data Masking and De-Identification Plugin Function Reference

**Table 8.48 MySQL Enterprise Data Masking and De-Identification Plugin Functions**

Name	Description	Deprecated
<code>gen_blacklist()</code>	Perform dictionary term replacement	Yes
<code>gen_blocklist()</code>	Perform dictionary term replacement	
<code>gen_dictionary_drop()</code>	Remove dictionary from registry	
<code>gen_dictionary_load()</code>	Load dictionary into registry	
<code>gen_dictionary()</code>	Return random term from dictionary	
<code>gen_range()</code>	Generate random number within range	
<code>gen_rnd_email()</code>	Generate random email address	
<code>gen_rnd_pan()</code>	Generate random payment card Primary Account Number	
<code>gen_rnd_ssn()</code>	Generate random US Social Security Number	
<code>gen_rnd_us_phone()</code>	Generate random US phone number	
<code>mask_inner()</code>	Mask interior part of string	
<code>mask_outer()</code>	Mask left and right parts of string	
<code>mask_pan()</code>	Mask payment card Primary Account Number part of string	
<code>mask_pan_relaxed()</code>	Mask payment card Primary Account Number part of string	
<code>mask_ssn()</code>	Mask US Social Security Number	

### 8.5.3.4 MySQL Enterprise Data Masking and De-Identification Plugin Function Descriptions

The MySQL Enterprise Data Masking and De-Identification plugin library includes several functions, which may be grouped into these categories:

- [Data Masking Plugin Functions](#)
- [Random Data Generation Plugin Functions](#)
- [Random Data Dictionary-Based Plugin Functions](#)

These functions support the single-byte `latin1` character set for string arguments and return values. If a string return value should be in a different character set, convert it. The following example shows how to convert the result of `gen_rnd_email()` to the `utf8mb4` character set:

```
SET @email = CONVERT(gen_rnd_email() USING utf8mb4);
```

It may also be necessary to convert string arguments, as illustrated in [Using Masked Data for Customer Identification](#).

If a MySQL Enterprise Data Masking and De-Identification function is invoked from within the `mysql` client, binary string results display using hexadecimal notation, depending on the value of the `--binary-as-hex`. For more information about that option, see [Section 6.5.1, “mysql — The MySQL Command-Line Client”](#).

## Data Masking Plugin Functions

Each plugin function in this section performs a masking operation on its string argument and returns the masked result.

- `mask_inner(str, margin1, margin2 [, mask_char])`

Masks the interior part of a string, leaving the ends untouched, and returns the result. An optional masking character can be specified.

Arguments:

- `str`: The string to mask.
- `margin1`: A nonnegative integer that specifies the number of characters on the left end of the string to remain unmasked. If the value is 0, no left end characters remain unmasked.
- `margin2`: A nonnegative integer that specifies the number of characters on the right end of the string to remain unmasked. If the value is 0, no right end characters remain unmasked.
- `mask_char`: (Optional) The single character to use for masking. The default is 'X' if `mask_char` is not given.

The masking character must be a single-byte character. Attempts to use a multibyte character produce an error.

Return value:

The masked string, or `NULL` if either margin is negative.

If the sum of the margin values is larger than the argument length, no masking occurs and the argument is returned unchanged.

Example:

```
mysql> SELECT mask_inner('abcdef', 1, 2), mask_inner('abcdef',0, 5);
+-----+-----+
| mask_inner('abcdef', 1, 2) | mask_inner('abcdef',0, 5) |
+-----+-----+
| aXXXef | Xbcdef |
+-----+-----+
mysql> SELECT mask_inner('abcdef', 1, 2, '*'), mask_inner('abcdef',0, 5, '#');
+-----+-----+
| mask_inner('abcdef', 1, 2, '*') | mask_inner('abcdef',0, 5, '#') |
+-----+-----+
| a***ef | #bcdef |
+-----+-----+
```

- `mask_outer(str, margin1, margin2 [, mask_char])`

Masks the left and right ends of a string, leaving the interior unmasked, and returns the result. An optional masking character can be specified.

Arguments:

- *str*: The string to mask.
- *margin1*: A nonnegative integer that specifies the number of characters on the left end of the string to mask. If the value is 0, no left end characters are masked.
- *margin2*: A nonnegative integer that specifies the number of characters on the right end of the string to mask. If the value is 0, no right end characters are masked.
- *mask\_char*: (Optional) The single character to use for masking. The default is 'X' if *mask\_char* is not given.

The masking character must be a single-byte character. Attempts to use a multibyte character produce an error.

Return value:

The masked string, or `NULL` if either margin is negative.

If the sum of the margin values is larger than the argument length, the entire argument is masked.

Example:

```
mysql> SELECT mask_outer('abcdef', 1, 2), mask_outer('abcdef',0, 5);
+-----+-----+
| mask_outer('abcdef', 1, 2) | mask_outer('abcdef',0, 5) |
+-----+-----+
| XbcdXX | aXXXXX |
+-----+-----+
mysql> SELECT mask_outer('abcdef', 1, 2, '*'), mask_outer('abcdef',0, 5, '#');
+-----+-----+
| mask_outer('abcdef', 1, 2, '*') | mask_outer('abcdef',0, 5, '#') |
+-----+-----+
| *bcd** | a##### |
+-----+-----+
```

- *mask\_pan(str)*

Masks a payment card Primary Account Number and returns the number with all but the last four digits replaced by 'X' characters.

Arguments:

- *str*: The string to mask. The string must be a suitable length for the Primary Account Number, but is not otherwise checked.

Return value:

The masked payment number as a string. If the argument is shorter than required, it is returned unchanged.

Example:

```
mysql> SELECT mask_pan(gen_rand_pan());
+-----+
| mask_pan(gen_rand_pan()) |
+-----+
| XXXXXXXXXXXXX9102 |
+-----+
mysql> SELECT mask_pan(gen_rand_pan(19));
+-----+
```

```

| mask_pan(gen_rnd_pan(19)) |
+-----+
| XXXXXXXXXXXXXXX8268 |
+-----+
mysql> SELECT mask_pan('a*Z');
+-----+
| mask_pan('a*Z') |
+-----+
| a*Z |
+-----+

```

- `mask_pan_relaxed(str)`

Masks a payment card Primary Account Number and returns the number with all but the first six and last four digits replaced by 'X' characters. The first six digits indicate the payment card issuer.

Arguments:

- `str`: The string to mask. The string must be a suitable length for the Primary Account Number, but is not otherwise checked.

Return value:

The masked payment number as a string. If the argument is shorter than required, it is returned unchanged.

Example:

```

mysql> SELECT mask_pan_relaxed(gen_rnd_pan());
+-----+
| mask_pan_relaxed(gen_rnd_pan()) |
+-----+
| 551279XXXXXX3108 |
+-----+
mysql> SELECT mask_pan_relaxed(gen_rnd_pan(19));
+-----+
| mask_pan_relaxed(gen_rnd_pan(19)) |
+-----+
| 462634XXXXXXX6739 |
+-----+
mysql> SELECT mask_pan_relaxed('a*Z');
+-----+
| mask_pan_relaxed('a*Z') |
+-----+
| a*Z |
+-----+

```

- `mask_ssn(str)`

Masks a US Social Security number and returns the number with all but the last four digits replaced by 'X' characters.

Arguments:

- `str`: The string to mask. The string must be 11 characters long.

Return value:

The masked Social Security number as a string, or an error if the argument is not the correct length.

Example:

```
mysql> SELECT mask_ssn('909-63-6922'), mask_ssn('abcdefghijk');
+-----+-----+
| mask_ssn('909-63-6922') | mask_ssn('abcdefghijk') |
+-----+-----+
| XXX-XX-6922 | XXX-XX-hijk |
+-----+-----+
mysql> SELECT mask_ssn('909');
ERROR 1123 (HY000): Can't initialize function 'mask_ssn'; MASK_SSN: Error:
String argument width too small
mysql> SELECT mask_ssn('123456789123456789');
ERROR 1123 (HY000): Can't initialize function 'mask_ssn'; MASK_SSN: Error:
String argument width too large
```

## Random Data Generation Plugin Functions

The plugin functions in this section generate random values for different types of data. When possible, generated values have characteristics reserved for demonstration or test values, to avoid having them mistaken for legitimate data. For example, `gen_rnd_us_phone()` returns a US phone number that uses the 555 area code, which is not assigned to phone numbers in actual use. Individual function descriptions describe any exceptions to this principle.

- `gen_range(lower, upper)`

Generates a random number chosen from a specified range.

Arguments:

- `lower`: An integer that specifies the lower boundary of the range.
- `upper`: An integer that specifies the upper boundary of the range, which must not be less than the lower boundary.

Return value:

A random integer in the range from `lower` to `upper`, inclusive, or `NULL` if the `upper` argument is less than `lower`.

Example:

```
mysql> SELECT gen_range(100, 200), gen_range(-1000, -800);
+-----+-----+
| gen_range(100, 200) | gen_range(-1000, -800) |
+-----+-----+
| 177 | -917 |
+-----+-----+
mysql> SELECT gen_range(1, 0);
```

```
+-----+
| gen_range(1, 0) |
+-----+
| |
| |
| |
+-----+
```

- `gen_rnd_email()`

Generates a random email address in the `example.com` domain.

Arguments:

None.

Return value:

A random email address as a string.

Example:

```
mysql> SELECT gen_rnd_email();
+-----+
| gen_rnd_email() |
+-----+
| ijocv.mwvhhuf@example.com |
+-----+
```

- `gen_rnd_pan([size])`

Generates a random payment card Primary Account Number. The number passes the Luhn check (an algorithm that performs a checksum verification against a check digit).

#### Warning

Values returned from `gen_rnd_pan()` should be used only for test purposes, and are not suitable for publication. There is no way to guarantee that a given return value is not assigned to a legitimate payment account. Should it be necessary to publish a `gen_rnd_pan()` result, consider masking it with `mask_pan()` or `mask_pan_relaxed()`.

Arguments:

- `size`: (Optional) An integer that specifies the size of the result. The default is 16 if `size` is not given. If given, `size` must be an integer in the range from 12 to 19.

Return value:

A random payment number as a string, or `NULL` if a `size` argument outside the permitted range is given.

Example:

```
mysql> SELECT mask_pan(gen_rnd_pan());
+-----+
| mask_pan(gen_rnd_pan()) |
+-----+
| XXXXXXXXXXXXX5805 |
+-----+
mysql> SELECT mask_pan(gen_rnd_pan(19));
+-----+
| mask_pan(gen_rnd_pan(19)) |
+-----+
```

```

| XXXXXXXXXXXXXXX5067 |
+-----+
mysql> SELECT mask_pan_relaxed(gen_rnd_pan());
+-----+
| mask_pan_relaxed(gen_rnd_pan()) |
+-----+
| 398403XXXXXX9547 |
+-----+
mysql> SELECT mask_pan_relaxed(gen_rnd_pan(19));
+-----+
| mask_pan_relaxed(gen_rnd_pan(19)) |
+-----+
| 578416XXXXXXXXX6509 |
+-----+
mysql> SELECT gen_rnd_pan(11), gen_rnd_pan(20);
+-----+
| gen_rnd_pan(11) | gen_rnd_pan(20) |
+-----+
| NULL | NULL |
+-----+

```

- `gen_rnd_ssn()`

Generates a random US Social Security number in `AAA-BB-CCCC` format. The `AAA` part is greater than 900 and the `BB` part is less than 70, which are characteristics not used for legitimate Social Security numbers.

Arguments:

None.

Return value:

A random Social Security number as a string.

Example:

```

mysql> SELECT gen_rnd_ssn();
+-----+
| gen_rnd_ssn() |
+-----+
| 951-26-0058 |
+-----+

```

- `gen_rnd_us_phone()`

Generates a random US phone number in `1-555-AAA-BBBB` format. The 555 area code is not used for legitimate phone numbers.

Arguments:

None.

Return value:

A random US phone number as a string.

Example:

```

mysql> SELECT gen_rnd_us_phone();
+-----+
| gen_rnd_us_phone() |
+-----+

```

```
| 1-555-682-5423 |
+-----+
```

## Random Data Dictionary-Based Plugin Functions

The plugin functions in this section manipulate dictionaries of terms and perform generation and masking operations based on them. Some of these functions require the [SUPER](#) privilege.

When a dictionary is loaded, it becomes part of the dictionary registry and is assigned a name to be used by other dictionary functions. Dictionaries are loaded from plain text files containing one term per line. Empty lines are ignored. To be valid, a dictionary file must contain at least one nonempty line.

- `gen_blacklist(str, dictionary_name, replacement_dictionary_name)`

Replaces a term present in one dictionary with a term from a second dictionary and returns the replacement term. This masks the original term by substitution. This function is deprecated; use `gen_blocklist()` instead.

- `gen_blocklist(str, dictionary_name, replacement_dictionary_name)`

Replaces a term present in one dictionary with a term from a second dictionary and returns the replacement term. This masks the original term by substitution. This function serves as a replacement for the deprecated `gen_blacklist()` function.

Arguments:

- `str`: A string that indicates the term to replace.
- `dictionary_name`: A string that names the dictionary containing the term to replace.
- `replacement_dictionary_name`: A string that names the dictionary from which to choose the replacement term.

Return value:

A string randomly chosen from `replacement_dictionary_name` as a replacement for `str`, or `str` if it does not appear in `dictionary_name`, or `NULL` if either dictionary name is not in the dictionary registry.

If the term to replace appears in both dictionaries, it is possible for the return value to be the same term.

Example:

```
mysql> SELECT gen_blocklist('Berlin', 'DE_Cities', 'US_Cities');
+-----+
| gen_blocklist('Berlin', 'DE_Cities', 'US_Cities') |
+-----+
| Phoenix |
+-----+
```

- `gen_dictionary(dictionary_name)`

Returns a random term from a dictionary.

Arguments:

- `dictionary_name`: A string that names the dictionary from which to choose the term.

Return value:

A random term from the dictionary as a string, or `NULL` if the dictionary name is not in the dictionary registry.

Example:

```
mysql> SELECT gen_dictionary('mydict');
+-----+
| gen_dictionary('mydict') |
+-----+
| My term |
+-----+
mysql> SELECT gen_dictionary('no-such-dict');
+-----+
| gen_dictionary('no-such-dict') |
+-----+
| NULL |
+-----+
```

- `gen_dictionary_drop(dictionary_name)`

Removes a dictionary from the dictionary registry.

This function requires the `SUPER` privilege.

Arguments:

- `dictionary_name`: A string that names the dictionary to remove from the dictionary registry.

Return value:

A string that indicates whether the drop operation succeeded. `Dictionary removed` indicates success. `Dictionary removal error` indicates failure.

Example:

```
mysql> SELECT gen_dictionary_drop('mydict');
+-----+
| gen_dictionary_drop('mydict') |
+-----+
| Dictionary removed |
+-----+
mysql> SELECT gen_dictionary_drop('no-such-dict');
+-----+
| gen_dictionary_drop('no-such-dict') |
+-----+
| Dictionary removal error |
+-----+
```

- `gen_dictionary_load(dictionary_path, dictionary_name)`

Loads a file into the dictionary registry and assigns the dictionary a name to be used with other functions that require a dictionary name argument.

This function requires the `SUPER` privilege.

#### Important

Dictionaries are not persistent. Any dictionary used by applications must be loaded for each server startup.

Once loaded into the registry, a dictionary is used as is, even if the underlying dictionary file changes. To reload a dictionary, first drop it with `gen_dictionary_drop()`, then load it again with `gen_dictionary_load()`.

Arguments:

- `dictionary_path`: A string that specifies the path name of the dictionary file.
- `dictionary_name`: A string that provides a name for the dictionary.

Return value:

A string that indicates whether the load operation succeeded. `Dictionary load success` indicates success. `Dictionary load error` indicates failure. Dictionary load failure can occur for several reasons, including:

- A dictionary with the given name is already loaded.
- The dictionary file is not found.
- The dictionary file contains no terms.
- The `secure_file_priv` system variable is set and the dictionary file is not located in the directory named by the variable.

Example:

```
mysql> SELECT gen_dictionary_load('/usr/local/mysql/mysql-files/mydict','mydict');
+-----+
| gen_dictionary_load('/usr/local/mysql/mysql-files/mydict','mydict') |
+-----+
| Dictionary load success |
+-----+
mysql> SELECT gen_dictionary_load('/dev/null','null');
+-----+
| gen_dictionary_load('/dev/null','null') |
+-----+
| Dictionary load error |
+-----+
```

## 8.6 MySQL Enterprise Encryption

#### Note

MySQL Enterprise Encryption is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, <https://www.mysql.com/products/>.

MySQL Enterprise Edition includes a set of encryption functions that expose OpenSSL capabilities at the SQL level. The functions enable Enterprise applications to perform the following operations:

- Implement added data protection using public-key asymmetric cryptography
- Create public and private keys and digital signatures
- Perform asymmetric encryption and decryption
- Use cryptographic hashing for digital signing and data verification and validation

These functions are provided by the MySQL `component_enterprise_encryption` component.

## 8.6.1 MySQL Enterprise Encryption Installation and Upgrading

The functions are provided by a MySQL component `component_enterprise_encryption`, and installing the component installs all of the functions.

MySQL Enterprise Encryption functions are provided by the MySQL `component_enterprise_encryption` component. For upgrade information, see [Upgrading MySQL Enterprise Encryption](#).

If you are upgrading from a release prior to MySQL 8.0.30: Before installing the component, unload any legacy functions using the `DROP FUNCTION` statement:

```
DROP FUNCTION asymmetric_decrypt;
DROP FUNCTION asymmetric_derive;
DROP FUNCTION asymmetric_encrypt;
DROP FUNCTION asymmetric_sign;
DROP FUNCTION asymmetric_verify;
DROP FUNCTION create_asymmetric_priv_key;
DROP FUNCTION create_asymmetric_pub_key;
DROP FUNCTION create_dh_parameters;
DROP FUNCTION create_digest;
```

The function names must be specified in lowercase. The statements require the `DROP` privilege for the `mysql` database.

To install the component, issue this `INSTALL COMPONENT` statement:

```
INSTALL COMPONENT "file://component_enterprise_encryption";
```

`INSTALL COMPONENT` requires the `INSERT` privilege for the `mysql.component` system table because it adds a row to that table to register the component. To verify that the component has been installed, issue the statement shown here:

```
SELECT * FROM mysql.component;
```

Components listed in `mysql.component` are loaded by the loader service during the startup sequence.

If you need to uninstall the component, issue an `UNINSTALL COMPONENT` statement:

```
UNINSTALL COMPONENT "file://component_enterprise_encryption";
```

Uninstalling the component uninstalls all of the functions. For more details, see [Section 7.5.1, “Installing and Uninstalling Components”](#).

### Note

Installing the component installs all of its functions, so you do not need to create them using `CREATE FUNCTION` statements as in older releases of MySQL.

When you have installed the component, if you want the component functions to support decryption and verification for content produced by legacy functions, set the `enterprise_encryption.rsa_support_legacy_padding` system variable to `ON`. Also, if you want to change the maximum length allowed for the RSA keys generated by the component functions, use the `enterprise_encryption.maximum_rsa_key_size` system variable to set an appropriate maximum. For configuration information, see [Section 8.6.2, “Configuring MySQL Enterprise Encryption”](#).

## 8.6.2 Configuring MySQL Enterprise Encryption

MySQL Enterprise Encryption lets you limit keys to a length that provides adequate security for your requirements while balancing this with resource usage. You can also configure the functions provided by the `component_enterprise_encryption` component to support decryption and verification for content produced by the old `openssl_udf` shared library functions.

### Decryption Support By Component Functions For Legacy Functions

By default, the functions provided by the `component_enterprise_encryption` component do not decrypt encrypted text, or verify signatures, that were produced by the legacy functions provided in earlier releases by the `openssl_udf` shared library. The component functions assume that encrypted text uses the RSAES-OAEP padding scheme, and signatures use the RSASSA-PSS signature scheme. However, encrypted text produced by the legacy functions uses the RSAES-PKCS1-v1\_5 padding scheme, and signatures produced by the legacy functions use the RSASSA-PKCS1-v1\_5 signature scheme.

If you want the component functions to support content produced by the legacy functions, set the `enterprise_encryption.rsa_support_legacy_padding` system variable to `ON`. This variable is available when the component is installed. When you set it to `ON`, the component functions first attempt to decrypt or verify content assuming it has their normal schemes. If that does not work, they also attempt to decrypt or verify the content assuming it has the schemes used by the old functions. This behavior is not the default because it increases the time taken to process content that cannot be decrypted or verified at all. If you are not handling content produced by the old functions, let the system variable default to `OFF`.

### Key Length Limits

The amount of CPU resources required by MySQL Enterprise Encryption's key generation functions increases as the key length increases. For some installations, this might result in unacceptable CPU usage if applications frequently generate excessively long keys.

The functions provided by the `component_enterprise_encryption` component have a minimum key length of 2048 bits for RSA keys, which is in line with current best practice for minimum key lengths. The `enterprise_encryption.maximum_rsa_key_size` system variable specifies the maximum key size.

## 8.6.3 MySQL Enterprise Encryption Usage and Examples

To use MySQL Enterprise Encryption in applications, invoke the functions that are appropriate for the operations you wish to perform. This section demonstrates how to carry out some representative tasks.

MySQL Enterprise Encryption functions are provided by a MySQL component `component_enterprise_encryption`. For information about these functions, see [Section 8.6.4, “MySQL Enterprise Encryption Function Reference”](#).

The following general considerations apply when choosing key lengths and encryption algorithms:

- The strength of encryption for private and public keys increases with the key size, but the time for key generation increases as well.
- Component functions support RSA keys only.

- Asymmetric encryption functions consume more resources compared to symmetric functions. They are good for encrypting small amounts of data and creating and verifying signatures. For encrypting large amounts of data, symmetric encryption functions are faster. MySQL Server provides the `AES_ENCRYPT()` and `AES_DECRYPT()` functions for symmetric encryption.

Key string values can be created at runtime and stored into a variable or table using `SET`, `SELECT`, or `INSERT`, as shown here:

```
SET @priv1 = create_asymmetric_priv_key('RSA', 2048);
SELECT create_asymmetric_priv_key('RSA', 2048) INTO @priv2;
INSERT INTO t (key_col) VALUES(create_asymmetric_priv_key('RSA', 1024));
```

Key string values stored in files can be read using the `LOAD_FILE()` function by users who have the `FILE` privilege. Digest and signature strings can be handled similarly.

- [Create a private/public key pair](#)
- [Use the public key to encrypt data and the private key to decrypt it](#)
- [Generate a digest from a string](#)
- [Use the digest with a key pair](#)

## Create a private/public key pair

This example works with both the component functions and the legacy functions:

```
-- Encryption algorithm
SET @algo = 'RSA';
-- Key length in bits; make larger for stronger keys
SET @key_len = 2048;

-- Create private key
SET @priv = create_asymmetric_priv_key(@algo, @key_len);
-- Derive corresponding public key from private key, using same algorithm
SET @pub = create_asymmetric_pub_key(@algo, @priv);
```

You can use the key pair to encrypt and decrypt data or to sign and verify data.

## Use the public key to encrypt data and the private key to decrypt it

This example works with both the component functions and the legacy functions. In both cases, the members of the key pair must be RSA keys:

```
SET @ciphertext = asymmetric_encrypt(@algo, 'My secret text', @pub);
SET @plaintext = asymmetric_decrypt(@algo, @ciphertext, @priv);
```

## Generate a digest from a string

This example works with both the component functions and the legacy functions:

```
-- Digest type
SET @dig_type = 'SHA512';

-- Generate digest string
SET @dig = create_digest(@dig_type, 'My text to digest');
```

## Use the digest with a key pair

The key pair can be used to sign data, then verify that the signature matches the digest. This example works with both the component functions and the legacy functions:

```
-- Encryption algorithm; keys must
-- have been created using same algorithm
SET @algo = 'RSA';
-- Digest algorithm to sign the data
SET @dig_type = 'SHA512';

-- Generate signature for digest and verify signature against digest
SET @sig = asymmetric_sign(@algo, @dig, @priv, @dig_type);
-- Verify signature against digest
SET @verf = asymmetric_verify(@algo, @dig, @sig, @pub, @dig_type);
```

For the legacy functions, signatures require a digest. For the component functions, signatures do not require a digest, and can use any data string. The digest type in these functions refers to the algorithm that is used to sign the data, not the algorithm that was used to create the original input for the signature. This example is for the component functions:

```
-- Encryption algorithm; keys must
-- have been created using same algorithm
SET @algo = 'RSA';
-- Arbitrary text string for signature
SET @text = repeat('j', 256);
-- Digest algorithm to sign the data
SET @dig_type = 'SHA512';

-- Generate signature for digest and verify signature against digest
SET @sig = asymmetric_sign(@algo, @text, @priv, @dig_type);
-- Verify signature against digest
SET @verf = asymmetric_verify(@algo, @text, @sig, @pub, @dig_type);
```

## 8.6.4 MySQL Enterprise Encryption Function Reference

MySQL Enterprise Encryption functions are provided by the MySQL [component\\_enterprise\\_encryption](#) component. See [Section 8.6.5, “MySQL Enterprise Encryption Component Function Descriptions”](#).

**Table 8.49 MySQL Enterprise Encryption Functions**

Name	Description
<a href="#">asymmetric_decrypt()</a>	Decrypt ciphertext using private or public key
<a href="#">asymmetric_derive()</a>	Derive symmetric key from asymmetric keys
<a href="#">asymmetric_encrypt()</a>	Encrypt cleartext using private or public key
<a href="#">asymmetric_sign()</a>	Generate signature from digest
<a href="#">asymmetric_verify()</a>	Verify that signature matches digest
<a href="#">create_asymmetric_priv_key()</a>	Create private key
<a href="#">create_asymmetric_pub_key()</a>	Create public key
<a href="#">create_dh_parameters()</a>	Generate shared DH secret
<a href="#">create_digest()</a>	Generate digest from string

## 8.6.5 MySQL Enterprise Encryption Component Function Descriptions

MySQL Enterprise Encryption functions have these general characteristics:

- For arguments of the wrong type or an incorrect number of arguments, each function returns an error.
- If the arguments are not suitable to permit a function to perform the requested operation, it returns [NULL](#) or 0 as appropriate. This occurs, for example, if a function does not support a specified algorithm, a key length is too short or long, or a string expected to be a key string in PEM format is not a valid key.

- The underlying SSL library takes care of randomness initialization.

The component functions only support the RSA encryption algorithm.

For additional examples and discussion, see [Section 8.6.3, “MySQL Enterprise Encryption Usage and Examples”](#).

- `asymmetric_decrypt(algorithm, data_str, priv_key_str)`

Decrypts an encrypted string using the given algorithm and key string, and returns the resulting plaintext as a binary string. If decryption fails, the result is `NULL`.

For the legacy version of this function in use before MySQL 8.0.29, see [MySQL Enterprise Encryption Legacy Function Descriptions](#).

By default, the `component_enterprise_encryption` function assumes that encrypted text uses the RSAES-OAEP padding scheme. The function supports decryption for content encrypted by the old `openssl_udf` shared library functions if the system variable `enterprise_encryption.rsa_support_legacy_padding` is set to `ON` (the default is `OFF`). When this is `ON`, the function also supports the RSAES-PKCS1-v1\_5 padding scheme, as used by the old `openssl_udf` shared library functions. When the variable is set to `OFF`, content encrypted by the legacy functions cannot be decrypted, and the function returns null output for such content.

*algorithm* is the encryption algorithm used to create the key. The supported algorithm value is `'RSA'`.

*data\_str* is the encrypted string to decrypt, which was encrypted with `asymmetric_encrypt()`.

*priv\_key\_str* is a valid PEM encoded RSA private key. For successful decryption, the key string must correspond to the public key string used with `asymmetric_encrypt()` to produce the encrypted string. The `asymmetric_encrypt()` component function only supports encryption using a public key, so decryption takes place with the corresponding private key.

For a usage example, see the description of `asymmetric_encrypt()`.

- `asymmetric_encrypt(algorithm, data_str, pub_key_str)`

Encrypts a string using the given algorithm and key string, and returns the resulting ciphertext as a binary string. If encryption fails, the result is `NULL`.

For the legacy version of this function in use before MySQL 8.0.29, see [MySQL Enterprise Encryption Legacy Function Descriptions](#).

*algorithm* is the encryption algorithm used to create the key. The supported algorithm value is `'RSA'`.

*data\_str* is the string to encrypt. The length of this string cannot be greater than the key string length in bytes, minus 42 (to account for the padding).

*pub\_key\_str* is a valid PEM encoded RSA public key. The `asymmetric_encrypt()` component function only supports encryption using a public key.

To recover the original unencrypted string, pass the encrypted string to `asymmetric_decrypt()`, along with the other part of the key pair used for encryption, as in the following example:

```
-- Generate private/public key pair
SET @priv = create_asymmetric_priv_key('RSA', 2048);
SET @pub = create_asymmetric_pub_key('RSA', @priv);

-- Encrypt using public key, decrypt using private key
```

```
SET @ciphertext = asymmetric_encrypt('RSA', 'The quick brown fox', @pub);
SET @plaintext = asymmetric_decrypt('RSA', @ciphertext, @priv);
```

Suppose that:

```
SET @s = a string to be encrypted
SET @priv = a valid private RSA key string in PEM format
SET @pub = the corresponding public RSA key string in PEM format
```

Then these identity relationships hold:

```
asymmetric_decrypt('RSA', asymmetric_encrypt('RSA', @s, @pub), @priv) = @s
```

- `asymmetric_sign(algorithm, text, priv_key_str, digest_type)`

Signs a digest string or data string using a private key, and returns the signature as a binary string. If signing fails, the result is `NULL`.

For the legacy version of this function in use before MySQL 8.0.29, see [MySQL Enterprise Encryption Legacy Function Descriptions](#).

*algorithm* is the encryption algorithm used to create the key. The supported algorithm value is `'RSA'`.

*text* is a data string or digest string. The function accepts digests but does not require them, as it is also capable of handling data strings of an arbitrary length. A digest string can be generated by calling `create_digest()`.

*priv\_key\_str* is the private key string to use for signing the digest string. It must be a valid PEM encoded RSA private key.

*digest\_type* is the algorithm to be used to sign the data. The supported *digest\_type* values are `'SHA224'`, `'SHA256'`, `'SHA384'`, and `'SHA512'` when OpenSSL 1.0.1 is in use. If OpenSSL 1.1.1 is in use, the additional *digest\_type* values `'SHA3-224'`, `'SHA3-256'`, `'SHA3-384'`, and `'SHA3-512'` are available.

For a usage example, see the description of `asymmetric_verify()`.

- `asymmetric_verify(algorithm, text, sig_str, pub_key_str, digest_type)`

Verifies whether the signature string matches the digest string, and returns 1 or 0 to indicate whether verification succeeded or failed. If verification fails, the result is `NULL`.

By default, the `component_enterprise_encryption` function assumes that signatures use the RSASSA-PSS signature scheme. The function supports verification for signatures produced by the old `openssl_udf` shared library functions if the system variable `enterprise_encryption.rsa_support_legacy_padding` is set to `ON` (the default is `OFF`). When this is `ON`, the function also supports the RSASSA-PKCS1-v1\_5 signature scheme, as used by the old

`openssl_udf` shared library functions; when it is `OFF`, signatures produced by the legacy functions cannot be verified, and the function returns null output for such content.

`algorithm` is the encryption algorithm used to create the key. The supported algorithm value is `'RSA'`.

`text` is a data string or digest string. The component function accepts digests but does not require them, as it is also capable of handling data strings of an arbitrary length. A digest string can be generated by calling `create_digest()`.

`sig_str` is the signature string to be verified. A signature string can be generated by calling `asymmetric_sign()`.

`pub_key_str` is the public key string of the signer. It corresponds to the private key passed to `asymmetric_sign()` to generate the signature string. It must be a valid PEM encoded RSA public key.

`digest_type` is the algorithm that was used to sign the data. The supported `digest_type` values are `'SHA224'`, `'SHA256'`, `'SHA384'`, and `'SHA512'` when OpenSSL 1.0.1 is in use. If OpenSSL 1.1.1 is in use, the additional `digest_type` values `'SHA3-224'`, `'SHA3-256'`, `'SHA3-384'`, and `'SHA3-512'` are available.

```
-- Set the encryption algorithm and digest type
SET @algo = 'RSA';
SET @dig_type = 'SHA512';

-- Create private/public key pair
SET @priv = create_asymmetric_priv_key(@algo, 2048);
SET @pub = create_asymmetric_pub_key(@algo, @priv);

-- Generate digest from string
SET @dig = create_digest(@dig_type, 'The quick brown fox');

-- Generate signature for digest and verify signature against digest
SET @sig = asymmetric_sign(@algo, @dig, @priv, @dig_type);
SET @verf = asymmetric_verify(@algo, @dig, @sig, @pub, @dig_type);
```

- `create_asymmetric_priv_key(algorithm, key_length)`

Creates a private key using the given algorithm and key length, and returns the key as a binary string in PEM format. The key is in PKCS #8 format. If key generation fails, the result is `NULL`.

For the legacy version of this function in use before MySQL 8.0.29, see [MySQL Enterprise Encryption Legacy Function Descriptions](#).

`algorithm` is the encryption algorithm used to create the key. The supported algorithm value is `'RSA'`.

`key_length` is the key length in bits. If you exceed the maximum allowed key length or specify less than the minimum, key generation fails and the result is null output. The minimum allowed key length in bits is 2048. The maximum allowed key length is the value of the `enterprise_encryption.maximum_rsa_key_size` system variable, which defaults to 4096. It has a maximum setting of 16384, which is the maximum key length allowed for the RSA algorithm. See [Section 8.6.2, “Configuring MySQL Enterprise Encryption”](#).

#### Note

Generating longer keys can consume significant CPU resources. Limiting the key length using the `enterprise_encryption.maximum_rsa_key_size` system

variable lets you provide adequate security for your requirements while balancing this with resource usage.

This example creates a 2048-bit RSA private key, then derives a public key from the private key:

```
SET @priv = create_asymmetric_priv_key('RSA', 2048);
SET @pub = create_asymmetric_pub_key('RSA', @priv);
```

- `create_asymmetric_pub_key(algorithm, priv_key_str)`

Derives a public key from the given private key using the given algorithm, and returns the key as a binary string in PEM format. The key is in PKCS #8 format. If key derivation fails, the result is `NULL`.

For the legacy version of this function in use before MySQL 8.0.29, see [MySQL Enterprise Encryption Legacy Function Descriptions](#).

*algorithm* is the encryption algorithm used to create the key. The supported algorithm value is `'RSA'`.

*priv\_key\_str* is a valid PEM encoded RSA private key.

For a usage example, see the description of `create_asymmetric_priv_key()`.

- `create_digest(digest_type, str)`

Creates a digest from the given string using the given digest type, and returns the digest as a binary string. If digest generation fails, the result is `NULL`.

For the legacy version of this function in use before MySQL 8.0.29, see [MySQL Enterprise Encryption Legacy Function Descriptions](#).

The resulting digest string is suitable for use with `asymmetric_sign()` and `asymmetric_verify()`. The component versions of these functions accept digests but do not require them, as they are capable of handling data of an arbitrary length.

*digest\_type* is the digest algorithm to be used to generate the digest string. The supported *digest\_type* values are `'SHA224'`, `'SHA256'`, `'SHA384'`, and `'SHA512'` when OpenSSL 1.0.1 is in use. If OpenSSL 1.1.1 is in use, the additional *digest\_type* values `'SHA3-224'`, `'SHA3-256'`, `'SHA3-384'`, and `'SHA3-512'` are available.

*str* is the non-null data string for which the digest is to be generated.

```
SET @dig = create_digest('SHA512', 'The quick brown fox');
```

## 8.7 SELinux

Security-Enhanced Linux (SELinux) is a mandatory access control (MAC) system that implements access rights by applying a security label referred to as an *SELinux context* to each system object. SELinux policy modules use SELinux contexts to define rules for how processes, files, ports, and other system objects interact with each other. Interaction between system objects is only permitted if a policy rule allows it.

An SELinux context (the label applied to a system object) has the following fields: `user`, `role`, `type`, and `security level`. Type information rather than the entire SELinux context is used most commonly to define rules for how processes interact with other system objects. MySQL SELinux policy modules, for example, define policy rules using `type` information.

You can view SELinux contexts using operating system commands such as `ls` and `ps` with the `-Z` option. Assuming that SELinux is enabled and a MySQL Server is running, the following commands show the SELinux context for the `mysqld` process and MySQL data directory:

`mysqld` process:

```
$> ps -eZ | grep mysqld
system_u:system_r:mysqld_t:s0 5924 ? 00:00:03 mysqld
```

MySQL data directory:

```
$> cd /var/lib
$> ls -lZ | grep mysql
system_u:object_r:mysqld_db_t:s0 mysql
```

where:

- `system_u` is an SELinux user identity for system processes and objects.
- `system_r` is an SELinux role used for system processes.
- `objects_r` is an SELinux role used for system objects.
- `mysqld_t` is the type associated with the `mysqld` process.
- `mysqld_db_t` is the type associated with the MySQL data directory and its files.
- `s0` is the security level.

For more information about interpreting SELinux contexts, refer to your distribution's SELinux documentation.

## 8.7.1 Check if SELinux is Enabled

SELinux is enabled by default on some Linux distributions including Oracle Linux, RHEL, CentOS, and Fedora. Use the `sestatus` command to determine if SELinux is enabled on your distribution:

```
$> sestatus
SELinux status: enabled
SELinuxfs mount: /sys/fs/selinux
SELinux root directory: /etc/selinux
Loaded policy name: targeted
Current mode: enforcing
Mode from config file: enforcing
Policy MLS status: enabled
Policy deny_unknown status: allowed
Memory protection checking: actual (secure)
Max kernel policy version: 31
```

If SELinux is disabled or the `sestatus` command is not found, refer to your distribution's SELinux documentation for guidance before enabling SELinux.

## 8.7.2 Changing the SELinux Mode

SELinux supports enforcing, permissive, and disabled modes. Enforcing mode is the default. Permissive mode allows operations that are not permitted in enforcing mode and logs those operations to the SELinux audit log. Permissive mode is typically used when developing policies or troubleshooting. In disabled mode, policies are not enforced, and contexts are not applied to system objects, which makes it difficult to enable SELinux later.

To view the current SELinux mode, use the `sestatus` command mentioned previously or the `getenforce` utility.

```
$> getenforce
```

```
Enforcing
```

To change the SELinux mode, use the `setenforce` utility:

```
$> setenforce 0
$> getenforce
Permissive
```

```
$> setenforce 1
$> getenforce
Enforcing
```

Changes made with `setenforce` are lost when you restart the system. To permanently change the SELinux mode, edit the `/etc/selinux/config` file and restart the system.

### 8.7.3 MySQL Server SELinux Policies

MySQL Server SELinux policy modules are typically installed by default. You can view installed modules using the `semodule -l` command. MySQL Server SELinux policy modules include:

- `mysqld_selinux`
- `mysqld_safe_selinux`

For information about MySQL Server SELinux policy modules, refer to the SELinux manual pages. The manual pages provide information about types and Booleans associated with the MySQL service. Manual pages are named in the `service-name_selinux` format.

```
man mysqld_selinux
```

If SELinux manual pages are not available, refer to your distribution's SELinux documentation for information about how to generate manual pages using the `sepolicy manpage` utility.

### 8.7.4 SELinux File Context

The MySQL Server reads from and writes to many files. If the SELinux context is not set correctly for these files, access to the files could be denied.

The instructions that follow use the `semanage` binary to manage file context; on RHEL, it's part of the `policycoreutils-python-utils` package:

```
yum install -y policycoreutils-python-utils
```

After installing the `semanage` binary, you can list MySQL file contexts using `semanage` with the `fcontext` option.

```
semanage fcontext -l | grep -i mysql
```

### Setting the MySQL Data Directory Context

The default data directory location is `/var/lib/mysql/`; and the SELinux context used is `mysqld_db_t`.

If you edit the configuration file to use a different location for the data directory, or for any of the files normally in the data directory (such as the binary logs), you may need to set the context for the new location. For example:

```
semanage fcontext -a -t mysqld_db_t "/path/to/my/custom/datadir(/.*)?"
restorecon -Rv /path/to/my/custom/datadir

semanage fcontext -a -t mysqld_db_t "/path/to/my/custom/logdir(/.*)?"
```

```
restorecon -Rv /path/to/my/custom/logdir
```

## Setting the MySQL Error Log File Context

The default location for RedHat RPMs is `/var/log/mysqld.log`; and the SELinux context type used is `mysqld_log_t`.

If you edit the configuration file to use a different location, you may need to set the context for the new location. For example:

```
semanage fcontext -a -t mysqld_log_t "/path/to/my/custom/error.log"
restorecon -Rv /path/to/my/custom/error.log
```

## Setting the PID File Context

The default location for the PID file is `/var/run/mysqld/mysqld.pid`; and the SELinux context type used is `mysqld_var_run_t`.

If you edit the configuration file to use a different location, you may need to set the context for the new location. For example:

```
semanage fcontext -a -t mysqld_var_run_t "/path/to/my/custom/pidfile/directory/*.?"
restorecon -Rv /path/to/my/custom/pidfile/directory
```

## Setting the Unix Domain Socket Context

The default location for the Unix domain socket is `/var/lib/mysql/mysql.sock`; and the SELinux context type used is `mysqld_var_run_t`.

If you edit the configuration file to use a different location, you may need to set the context for the new location. For example:

```
semanage fcontext -a -t mysqld_var_run_t "/path/to/my/custom/mysql*.sock"
restorecon -Rv /path/to/my/custom/mysql.sock
```

## Setting the `secure_file_priv` Directory Context

For MySQL versions since 5.6.34, 5.7.16, and 8.0.11.

Installing the MySQL Server RPM creates a `/var/lib/mysql-files/` directory but does not set the SELinux context for it. The `/var/lib/mysql-files/` directory is intended to be used for operations such as `SELECT ... INTO OUTFILE`.

If you enabled the use of this directory by setting `secure_file_priv`, you may need to set the context like so:

```
semanage fcontext -a -t mysqld_db_t "/var/lib/mysql-files/(.*)?"
restorecon -Rv /var/lib/mysql-files
```

Edit this path if you used a different location. For security purposes, this directory should never be within the data directory.

For more information about this variable, see the `secure_file_priv` documentation.

## 8.7.5 SELinux TCP Port Context

The instructions that follow use the `semanage` binary to manage port context; on RHEL, it's part of the `policycoreutils-python-utils` package:

```
yum install -y policycoreutils-python-utils
```

After installing the `semanage` binary, you can list ports defined with the `mysqld_port_t` context using `semanage` with the `port` option.

```
$> semanage port -l | grep mysqld
mysqld_port_t tcp 1186, 3306, 63132-63164
```

### 8.7.5.1 Setting the TCP Port Context for mysqld

The default TCP port for `mysqld` is `3306`; and the SELinux context type used is `mysqld_port_t`.

If you configure `mysqld` to use a different TCP `port`, you may need to set the context for the new port. For example to define the SELinux context for a non-default port such as port `3307`:

```
semanage port -a -t mysqld_port_t -p tcp 3307
```

To confirm that the port is added:

```
$> semanage port -l | grep mysqld
mysqld_port_t tcp 3307, 1186, 3306, 63132-63164
```

### 8.7.5.2 Setting the TCP Port Context for MySQL Features

If you enable certain MySQL features, you might need to set the SELinux TCP port context for additional ports used by those features. If ports used by MySQL features do not have the correct SELinux context, the features might not function correctly.

The following sections describe how to set port contexts for MySQL features. Generally, the same method can be used to set the port context for any MySQL features. For information about ports used by MySQL features, refer to the [MySQL Port Reference](#).

For MySQL 9.1, enabling `mysql_connect_any` is not required or recommended.

```
setsebool -P mysql_connect_any=ON
```

### Setting the TCP Port Context for Group Replication

If SELinux is enabled, you must set the port context for the Group Replication communication port, which is defined by the `group_replication_local_address` variable. `mysqld` must be able to bind to the Group Replication communication port and listen there. InnoDB Cluster relies on Group Replication so this applies equally to instances used in a cluster. To view ports currently used by MySQL, issue:

```
semanage port -l | grep mysqld
```

Assuming the Group Replication communication port is `33061`, set the port context by issuing:

```
semanage port -a -t mysqld_port_t -p tcp 33061
```

### Setting the TCP Port Context for Document Store

If SELinux is enabled, you must set the port context for the communication port used by X Plugin, which is defined by the `mysqlx_port` variable. `mysqld` must be able to bind to the X Plugin communication port and listen there.

Assuming the X Plugin communication port is `33060`, set the port context by issuing:

```
semanage port -a -t mysqld_port_t -p tcp 33060
```

### Setting the TCP Port Context for MySQL Router

If SELinux is enabled, you must set the port context for the communication ports used by MySQL Router. Assuming the additional communication ports used by MySQL Router are the default 6446, 6447, 64460 and 64470, on each instance set the port context by issuing:

```
semanage port -a -t mysqld_port_t -p tcp 6446
semanage port -a -t mysqld_port_t -p tcp 6447
semanage port -a -t mysqld_port_t -p tcp 64460
semanage port -a -t mysqld_port_t -p tcp 64470
```

## 8.7.6 Troubleshooting SELinux

Troubleshooting SELinux typically involves placing SELinux into permissive mode, rerunning problematic operations, checking for access denial messages in the SELinux audit log, and placing SELinux back into enforcing mode after problems are resolved.

To avoid placing the entire system into permissive mode using `setenforce`, you can permit only the MySQL service to run permissively by placing its SELinux domain (`mysqld_t`) into permissive mode using the `semanage` command:

```
semanage permissive -a mysqld_t
```

When you are finished troubleshooting, use this command to place the `mysqld_t` domain back into enforcing mode:

```
semanage permissive -d mysqld_t
```

SELinux writes logs for denied operations to `/var/log/audit/audit.log`. You can check for denials by searching for “denied” messages.

```
grep "denied" /var/log/audit/audit.log
```

The following sections describes a few common areas where SELinux-related issues may be encountered.

### File Contexts

If a MySQL directory or file has an incorrect SELinux context, access may be denied. This issue can occur if MySQL is configured to read from or write to a non-default directory or file. For example, if you configure MySQL to use a non-default data directory, the directory may not have the expected SELinux context.

Attempting to start the MySQL service on a non-default data directory with an invalid SELinux context causes the following startup failure.

```
$> systemctl start mysql.service
Job for mysqld.service failed because the control process exited with error code.
See "systemctl status mysqld.service" and "journalctl -xe" for details.
```

In this case, a “denial” message is logged to `/var/log/audit/audit.log`:

```
$> grep "denied" /var/log/audit/audit.log
type=AVC msg=audit(1587133719.786:194): avc: denied { write } for pid=7133 comm="mysqld"
name="mysql" dev="dm-0" ino=51347078 scontext=system_u:system_r:mysqld_t:s0
tcontext=unconfined_u:object_r:default_t:s0 tclass=dir permissive=0
```

For information about setting the proper SELinux context for MySQL directories and files, see [Section 8.7.4, “SELinux File Context”](#).

### Port Access

SELinux expects services such as MySQL Server to use specific ports. Changing ports without updating the SELinux policies may cause a service failure.

The `mysqld_port_t` port type defines the ports that the MySQL listens on. If you configure the MySQL Server to use a non-default port, such as port 3307, and do not update the policy to reflect the change, the MySQL service fails to start:

```
$> systemctl start mysqld.service
Job for mysqld.service failed because the control process exited with error code.
See "systemctl status mysqld.service" and "journalctl -xe" for details.
```

In this case, a denial message is logged to `/var/log/audit/audit.log`:

```
$> grep "denied" /var/log/audit/audit.log
type=AVC msg=audit(1587134375.845:198): avc: denied { name_bind } for pid=7340
comm="mysqld" src=3307 scontext=system_u:system_r:mysqld_t:s0
tcontext=system_u:object_r:unreserved_port_t:s0 tclass=tcp_socket permissive=0
```

For information about setting the proper SELinux port context for MySQL, see [Section 8.7.5, “SELinux TCP Port Context”](#). Similar port access issues can occur when enabling MySQL features that use ports that are not defined with the required context. For more information, see [Section 8.7.5.2, “Setting the TCP Port Context for MySQL Features”](#).

## Application Changes

SELinux may not be aware of application changes. For example, a new release, an application extension, or a new feature may access system resources in a way that is not permitted by SELinux, resulting in access denials. In such cases, you can use the `audit2allow` utility to create custom policies to permit access where it is required. The typical method for creating custom policies is to change the SELinux mode to permissive, identify access denial messages in the SELinux audit log, and use the `audit2allow` utility to create custom policies to permit access.

For information about using the `audit2allow` utility, refer to your distribution's SELinux documentation.

If you encounter access issues for MySQL that you believe should be handled by standard MySQL SELinux policy modules, please open a bug report in your distribution's bug tracking system.

## 8.8 FIPS Support

MySQL supports FIPS mode when a supported OpenSSL library and FIPS Object Module are available on the host system.

FIPS mode on the server side applies to cryptographic operations performed by the server. This includes replication (source/replica and Group Replication) and X Plugin, which run within the server. FIPS mode also applies to attempts by clients to connect to the server.

The following sections describe FIPS mode and how to take advantage of it within MySQL:

- [FIPS Overview](#)
- [System Requirements for FIPS Mode in MySQL](#)
- [Enabling FIPS Mode in MySQL](#)

## FIPS Overview

Federal Information Processing Standards 140-2 (FIPS 140-2) describes a security standard that can be required by Federal (US Government) agencies for cryptographic modules used to protect sensitive or valuable information. To be considered acceptable for such Federal use, a cryptographic module must

be certified for FIPS 140-2. If a system intended to protect sensitive data lacks the proper FIPS 140-2 certificate, Federal agencies cannot purchase it.

Products such as OpenSSL can be used in FIPS mode, although the OpenSSL library itself is not validated for FIPS. Instead, the OpenSSL library is used with the OpenSSL FIPS Object Module to enable OpenSSL-based applications to operate in FIPS mode.

For general information about FIPS and its implementation in OpenSSL, these references may be helpful:

- [National Institute of Standards and Technology FIPS PUB 140-2](#)
- [OpenSSL FIPS 140-2 Security Policy](#)
- [fips\\_module manual page](#)

#### Important

FIPS mode imposes conditions on cryptographic operations such as restrictions on acceptable encryption algorithms or requirements for longer key lengths. For OpenSSL, the exact FIPS behavior depends on the OpenSSL version.

## System Requirements for FIPS Mode in MySQL

For MySQL to support FIPS mode, these system requirements must be satisfied:

1. MySQL must be compiled with an OpenSSL version that is certified for use with FIPS. OpenSSL 1.0.2 and OpenSSL 3.0 are certified, but OpenSSL 1.1.1 is not. Binary distributions for recent versions of MySQL are compiled using OpenSSL 3.0 on some platforms, which means they are not certified for FIPS. This means you have the following options, depending on system and MySQL configuration:
  - Use a system that has OpenSSL 3.0 and the required FIPS object module. In this case, you can enable FIPS mode for MySQL if you use a binary distribution compiled using OpenSSL 3.0, or compile MySQL from source using OpenSSL 3.0.

For general information about upgrading to OpenSSL 3.0, see [OpenSSL 3.0 Migration Guide](#).

- Use a system that has OpenSSL 1.1.1 or higher. In this case, you can install MySQL using binary packages, and you can use the TLS v1.3 protocol and ciphersuites, in addition to other already supported TLS protocols. However, you cannot enable FIPS mode for MySQL.
  - Use a system that has OpenSSL 1.0.2 and the required FIPS Object Module. In this case, you can enable FIPS mode for MySQL if you use a binary distribution compiled using OpenSSL 1.0.2, or compile MySQL from source using OpenSSL 1.0.2. In this case, you cannot use the TLS v1.3 protocol or ciphersuites, which require OpenSSL 1.1.1 or 3.0. In addition, you should be aware that OpenSSL 1.0.2 reached end of life status in 2019, and that all operating platforms embedding OpenSSL 1.1.1 reach their end of life in 2024.
2. At runtime, the OpenSSL library and OpenSSL FIPS Object Module must be available as shared (dynamically linked) objects.

## Enabling FIPS Mode in MySQL

To determine whether MySQL is running on a system with FIPS mode enabled, check the value of the `ssl_fips_mode` server system variable using an SQL statement such as `SHOW VARIABLES LIKE '%fips%'` or `SELECT @@ssl_fips_mode`. If the value of this variable is 1 (**ON**) or 2 (**STRICT**), FIPS mode is enabled for OpenSSL; if it is 0 (**OFF**), FIPS mode is not available.

**Important**

In general, `STRICT` imposes more restrictions than `ON`, but MySQL itself has no FIPS-specific code other than to specify the FIPS mode value to OpenSSL. The exact behavior of FIPS mode for `ON` or `STRICT` depends on the OpenSSL version. For details, refer to the [fips\\_module](#) manpage (see [FIPS Overview](#)).

FIPS mode on the server side applies to cryptographic operations performed by the server, including those performed by MySQL Replication (including Group Replication) and X Plugin, which run within the server.

FIPS mode also applies to attempts by clients to connect to the server. When enabled, on either the client or server side, it restricts which of the supported encryption ciphers can be chosen. However, enabling FIPS mode does not require that an encrypted connection must be used, or that user credentials must be encrypted. For example, if FIPS mode is enabled, stronger cryptographic algorithms are required. In particular, MD5 is restricted, so trying to establish an encrypted connection using an encryption cipher such as `RC4-MD5` does not work. But there is nothing about FIPS mode that prevents establishing an unencrypted connection. (To do that, you can use the `REQUIRE` clause for `CREATE USER` or `ALTER USER` for specific user accounts, or set the `require_secure_transport` system variable to affect all accounts.)

If FIPS mode is required, it is recommended to use an operating platforms that includes it; if it does, you can (and should) use it. If your platform does not include FIPS, you have two options:

- Migrate to a platform which has FIPS OpenSSL support.
- Build the OpenSSL library and FIPS object module from source, using the instructions from the [fips\\_module](#) manpage (see [FIPS Overview](#)).

**Note**

If the OpenSSL FIPS Object Module is not available, the only permitted value for `ssl_fips_mode` and `--ssl-fips-mode` is `OFF`. An error occurs for attempts to set the FIPS mode to a different value.

If FIPS mode is required, it is recommended to use an operating platform that includes it; if it does, you can (and should) use it. If your platform does not include FIPS, you have two options:

- Migrate to a platform which has FIPS OpenSSL support.
- Build the OpenSSL library and FIPS object module from source, using the instructions from the [fips\\_module](#) manpage (see [FIPS Overview](#)).

9.6.4 MyISAM Table Optimization .....	1736
9.6.5 Setting Up a MyISAM Table Maintenance Schedule .....	1737

It is important to back up your databases so that you can recover your data and be up and running again in case problems occur, such as system crashes, hardware failures, or users deleting data by mistake. Backups are also essential as a safeguard before upgrading a MySQL installation, and they can be used to transfer a MySQL installation to another system or to set up replica servers.

MySQL offers a variety of backup strategies from which you can choose the methods that best suit the requirements for your installation. This chapter discusses several backup and recovery topics with which you should be familiar:

- Types of backups: Logical versus physical, full versus incremental, and so forth.
- Methods for creating backups.
- Recovery methods, including point-in-time recovery.
- Backup scheduling, compression, and encryption.
- Table maintenance, to enable recovery of corrupt tables.

### Additional Resources

Resources related to backup or to maintaining data availability include the following:

- Customers of MySQL Enterprise Edition can use the MySQL Enterprise Backup product for backups. For an overview of the MySQL Enterprise Backup product, see [Section 32.1, “MySQL Enterprise Backup Overview”](#).

- A forum dedicated to backup issues is available at <https://forums.mysql.com/list.php?28>.
- Details for `mysqldump` can be found in [Chapter 6, MySQL Programs](#).
- The syntax of the SQL statements described here is given in [Chapter 15, SQL Statements](#).
- For additional information about `InnoDB` backup procedures, see [Section 17.18.1, “InnoDB Backup”](#).
- Replication enables you to maintain identical data on multiple servers. This has several benefits, such as enabling client query load to be distributed over servers, availability of data even if a given server is taken offline or fails, and the ability to make backups with no impact on the source by using a replica. See [Chapter 19, Replication](#).
- MySQL InnoDB Cluster is a collection of products that work together to provide a high availability solution. A group of MySQL servers can be configured to create a cluster using MySQL Shell. The cluster of servers has a single source, called the primary, which acts as the read-write source. Multiple secondary servers are replicas of the source. A minimum of three servers are required to create a high availability cluster. A client application is connected to the primary via MySQL Router. If the primary fails, a secondary is automatically promoted to the role of primary, and MySQL Router routes requests to the new primary.
- NDB Cluster provides a high-availability, high-redundancy version of MySQL adapted for the distributed computing environment. See [Chapter 25, MySQL NDB Cluster 9.1](#), which provides information about MySQL NDB Cluster 9.2.0.

## 9.1 Backup and Recovery Types

This section describes the characteristics of different types of backups.

### Physical (Raw) Versus Logical Backups

Physical backups consist of raw copies of the directories and files that store database contents. This type of backup is suitable for large, important databases that need to be recovered quickly when problems occur.

Logical backups save information represented as logical database structure (`CREATE DATABASE`, `CREATE TABLE` statements) and content (`INSERT` statements or delimited-text files). This type of backup is suitable for smaller amounts of data where you might edit the data values or table structure, or recreate the data on a different machine architecture.

Physical backup methods have these characteristics:

- The backup consists of exact copies of database directories and files. Typically this is a copy of all or part of the MySQL data directory.
- Physical backup methods are faster than logical because they involve only file copying without conversion.
- Output is more compact than for logical backup.
- Because backup speed and compactness are important for busy, important databases, the MySQL Enterprise Backup product performs physical backups. For an overview of the MySQL Enterprise Backup product, see [Section 32.1, “MySQL Enterprise Backup Overview”](#).
- Backup and restore granularity ranges from the level of the entire data directory down to the level of individual files. This may or may not provide for table-level granularity, depending on storage engine. For

example, [InnoDB](#) tables can each be in a separate file, or share file storage with other [InnoDB](#) tables; each [MyISAM](#) table corresponds uniquely to a set of files.

- In addition to databases, the backup can include any related files such as log or configuration files.
- Data from [MEMORY](#) tables is tricky to back up this way because their contents are not stored on disk. (The MySQL Enterprise Backup product has a feature where you can retrieve data from [MEMORY](#) tables during a backup.)
- Backups are portable only to other machines that have identical or similar hardware characteristics.
- Backups can be performed while the MySQL server is not running. If the server is running, it is necessary to perform appropriate locking so that the server does not change database contents during the backup. MySQL Enterprise Backup does this locking automatically for tables that require it.
- Physical backup tools include the [mysqlbackup](#) of MySQL Enterprise Backup for [InnoDB](#) or any other tables, or file system-level commands (such as [cp](#), [scp](#), [tar](#), [rsync](#)) for [MyISAM](#) tables.
- For restore:
  - MySQL Enterprise Backup restores [InnoDB](#) and other tables that it backed up.
  - [ndb\\_restore](#) restores [NDB](#) tables.
  - Files copied at the file system level can be copied back to their original locations with file system commands.

Logical backup methods have these characteristics:

- The backup is done by querying the MySQL server to obtain database structure and content information.
- Backup is slower than physical methods because the server must access database information and convert it to logical format. If the output is written on the client side, the server must also send it to the backup program.
- Output is larger than for physical backup, particularly when saved in text format.
- Backup and restore granularity is available at the server level (all databases), database level (all tables in a particular database), or table level. This is true regardless of storage engine.
- The backup does not include log or configuration files, or other database-related files that are not part of databases.
- Backups stored in logical format are machine independent and highly portable.
- Logical backups are performed with the MySQL server running. The server is not taken offline.
- Logical backup tools include the [mysqldump](#) program and the [SELECT ... INTO OUTFILE](#) statement. These work for any storage engine, even [MEMORY](#).
- To restore logical backups, SQL-format dump files can be processed using the [mysql](#) client. To load delimited-text files, use the [LOAD DATA](#) statement or the [mysqlimport](#) client.

## Online Versus Offline Backups

Online backups take place while the MySQL server is running so that the database information can be obtained from the server. Offline backups take place while the server is stopped. This distinction can also

be described as “hot” versus “cold” backups; a “warm” backup is one where the server remains running but locked against modifying data while you access database files externally.

Online backup methods have these characteristics:

- The backup is less intrusive to other clients, which can connect to the MySQL server during the backup and may be able to access data depending on what operations they need to perform.
- Care must be taken to impose appropriate locking so that data modifications do not take place that would compromise backup integrity. The MySQL Enterprise Backup product does such locking automatically.

Offline backup methods have these characteristics:

- Clients can be affected adversely because the server is unavailable during backup. For that reason, such backups are often taken from a replica that can be taken offline without harming availability.
- The backup procedure is simpler because there is no possibility of interference from client activity.

A similar distinction between online and offline applies for recovery operations, and similar characteristics apply. However, it is more likely for clients to be affected by online recovery than by online backup because recovery requires stronger locking. During backup, clients might be able to read data while it is being backed up. Recovery modifies data and does not just read it, so clients must be prevented from accessing data while it is being restored.

## Local Versus Remote Backups

A local backup is performed on the same host where the MySQL server runs, whereas a remote backup is done from a different host. For some types of backups, the backup can be initiated from a remote host even if the output is written locally on the server host.

- `mysqldump` can connect to local or remote servers. For SQL output (`CREATE` and `INSERT` statements), local or remote dumps can be done and generate output on the client. For delimited-text output (with the `--tab` option), data files are created on the server host.
- `SELECT ... INTO OUTFILE` can be initiated from a local or remote client host, but the output file is created on the server host.
- Physical backup methods typically are initiated locally on the MySQL server host so that the server can be taken offline, although the destination for copied files might be remote.

## Snapshot Backups

Some file system implementations enable “snapshots” to be taken. These provide logical copies of the file system at a given point in time, without requiring a physical copy of the entire file system. (For example, the implementation may use copy-on-write techniques so that only parts of the file system modified after the snapshot time need be copied.) MySQL itself does not provide the capability for taking file system snapshots. It is available through third-party solutions such as Veritas, LVM, or ZFS.

## Full Versus Incremental Backups

A full backup includes all data managed by a MySQL server at a given point in time. An incremental backup consists of the changes made to the data during a given time span (from one point in time to another). MySQL has different ways to perform full backups, such as those described earlier in this section. Incremental backups are made possible by enabling the server's binary log, which the server uses to record data changes.

## Full Versus Point-in-Time (Incremental) Recovery

A full recovery restores all data from a full backup. This restores the server instance to the state that it had when the backup was made. If that state is not sufficiently current, a full recovery can be followed by recovery of incremental backups made since the full backup, to bring the server to a more up-to-date state.

Incremental recovery is recovery of changes made during a given time span. This is also called point-in-time recovery because it makes a server's state current up to a given time. Point-in-time recovery is based on the binary log and typically follows a full recovery from the backup files that restores the server to its state when the backup was made. Then the data changes written in the binary log files are applied as incremental recovery to redo data modifications and bring the server up to the desired point in time.

## Table Maintenance

Data integrity can be compromised if tables become corrupt. For [InnoDB](#) tables, this is not a typical issue. For programs to check [MyISAM](#) tables and repair them if problems are found, see [Section 9.6, “MyISAM Table Maintenance and Crash Recovery”](#).

## Backup Scheduling, Compression, and Encryption

Backup scheduling is valuable for automating backup procedures. Compression of backup output reduces space requirements, and encryption of the output provides better security against unauthorized access of backed-up data. MySQL itself does not provide these capabilities. The MySQL Enterprise Backup product can compress [InnoDB](#) backups, and compression or encryption of backup output can be achieved using file system utilities. Other third-party solutions may be available.

## 9.2 Database Backup Methods

This section summarizes some general methods for making backups.

### Making a Hot Backup with MySQL Enterprise Backup

Customers of MySQL Enterprise Edition can use the [MySQL Enterprise Backup](#) product to do [physical](#) backups of entire instances or selected databases, tables, or both. This product includes features for [incremental](#) and [compressed](#) backups. Backing up the physical database files makes restore much faster than logical techniques such as the [mysqldump](#) command. [InnoDB](#) tables are copied using a [hot backup](#) mechanism. (Ideally, the [InnoDB](#) tables should represent a substantial majority of the data.) Tables from other storage engines are copied using a [warm backup](#) mechanism. For an overview of the MySQL Enterprise Backup product, see [Section 32.1, “MySQL Enterprise Backup Overview”](#).

### Making Backups with mysqldump

The [mysqldump](#) program can make backups. It can back up all kinds of tables. (See [Section 9.4, “Using mysqldump for Backups”](#).)

For [InnoDB](#) tables, it is possible to perform an online backup that takes no locks on tables using the [--single-transaction](#) option to [mysqldump](#). See [Section 9.3.1, “Establishing a Backup Policy”](#).

### Making Backups by Copying Table Files

MyISAM tables can be backed up by copying table files ([\\*.MYD](#), [\\*.MYI](#) files, and associated [\\*.sdi](#) files). To get a consistent backup, stop the server or lock and flush the relevant tables:

```
FLUSH TABLES tbl_list WITH READ LOCK;
```

You need only a read lock; this enables other clients to continue to query the tables while you are making a copy of the files in the database directory. The flush is needed to ensure that the all active index pages are written to disk before you start the backup. See [Section 15.3.6, “LOCK TABLES and UNLOCK TABLES Statements”](#), and [Section 15.7.8.3, “FLUSH Statement”](#).

You can also create a binary backup simply by copying the table files, as long as the server is not updating anything. (But note that table file copying methods do not work if your database contains [InnoDB](#) tables. Also, even if the server is not actively updating data, [InnoDB](#) may still have modified data cached in memory and not flushed to disk.)

For an example of this backup method, refer to the export and import example in [Section 15.2.6, “IMPORT TABLE Statement”](#).

## Making Delimited-Text File Backups

To create a text file containing a table's data, you can use `SELECT * INTO OUTFILE 'file_name' FROM tbl_name`. The file is created on the MySQL server host, not the client host. For this statement, the output file cannot already exist because permitting files to be overwritten constitutes a security risk. See [Section 15.2.13, “SELECT Statement”](#). This method works for any kind of data file, but saves only table data, not the table structure.

Another way to create text data files (along with files containing `CREATE TABLE` statements for the backed up tables) is to use `mysqldump` with the `--tab` option. See [Section 9.4.3, “Dumping Data in Delimited-Text Format with mysqldump”](#).

To reload a delimited-text data file, use `LOAD DATA` or `mysqlimport`.

## Making Incremental Backups by Enabling the Binary Log

MySQL supports incremental backups using the binary log. The binary log files provide you with the information you need to replicate changes to the database that are made subsequent to the point at which you performed a backup. Therefore, to allow a server to be restored to a point-in-time, binary logging must be enabled on it, which is the default setting for MySQL 9.1 ; see [Section 7.4.4, “The Binary Log”](#).

At the moment you want to make an incremental backup (containing all changes that happened since the last full or incremental backup), you should rotate the binary log by using `FLUSH LOGS`. This done, you need to copy to the backup location all binary logs which range from the one of the moment of the last full or incremental backup to the last but one. These binary logs are the incremental backup; at restore time, you apply them as explained in [Section 9.5, “Point-in-Time \(Incremental\) Recovery”](#). The next time you do a full backup, you should also rotate the binary log using `FLUSH LOGS` or `mysqldump --flush-logs`. See [Section 6.5.4, “mysqldump — A Database Backup Program”](#).

## Making Backups Using Replicas

If you have performance problems with a server while making backups, one strategy that can help is to set up replication and perform backups on the replica rather than on the source. See [Section 19.4.1, “Using Replication for Backups”](#).

If you are backing up a replica, you should back up its connection metadata repository and applier metadata repository (see [Section 19.2.4, “Relay Log and Replication Metadata Repositories”](#)) when you back up the replica's databases, regardless of the backup method you choose. This information is always needed to resume replication after you restore the replica's data. If your replica is replicating `LOAD DATA` statements, you should also back up any `SQL_LOAD-*` files that exist in the directory that the replica uses for this purpose. The replica needs these files to resume replication of any interrupted `LOAD DATA`

operations. The location of this directory is the value of the system variable `replica_load_tmpdir`. If the server was not started with that variable set, the directory location is the value of the `tmpdir` system variable.

## Recovering Corrupt Tables

If you have to restore `MyISAM` tables that have become corrupt, try to recover them using `REPAIR TABLE` or `myisamchk -r` first. That should work in 99.9% of all cases. If `myisamchk` fails, see [Section 9.6](#), “`MyISAM` Table Maintenance and Crash Recovery”.

## Making Backups Using a File System Snapshot

If you are using a Veritas file system, you can make a backup like this:

1. From a client program, execute `FLUSH TABLES WITH READ LOCK`.
2. From another shell, execute `mount vxfs snapshot`.
3. From the first client, execute `UNLOCK TABLES`.
4. Copy files from the snapshot.
5. Unmount the snapshot.

Similar snapshot capabilities may be available in other file systems, such as LVM or ZFS.

## 9.3 Example Backup and Recovery Strategy

This section discusses a procedure for performing backups that enables you to recover data after several types of crashes:

- Operating system crash
- Power failure
- File system crash
- Hardware problem (hard drive, motherboard, and so forth)

The example commands do not include options such as `--user` and `--password` for the `mysqldump` and `mysql` client programs. You should include such options as necessary to enable client programs to connect to the MySQL server.

Assume that data is stored in the `InnoDB` storage engine, which has support for transactions and automatic crash recovery. Assume also that the MySQL server is under load at the time of the crash. If it were not, no recovery would ever be needed.

For cases of operating system crashes or power failures, we can assume that MySQL's disk data is available after a restart. The `InnoDB` data files might not contain consistent data due to the crash, but `InnoDB` reads its logs and finds in them the list of pending committed and noncommitted transactions that have not been flushed to the data files. `InnoDB` automatically rolls back those transactions that were not committed, and flushes to its data files those that were committed. Information about this recovery process is conveyed to the user through the MySQL error log. The following is an example log excerpt:

```
InnoDB: Database was not shut down normally.
InnoDB: Starting recovery from log files...
```

```

InnoDB: Starting log scan based on checkpoint at
InnoDB: log sequence number 0 13674004
InnoDB: Doing recovery: scanned up to log sequence number 0 13739520
InnoDB: Doing recovery: scanned up to log sequence number 0 13805056
InnoDB: Doing recovery: scanned up to log sequence number 0 13870592
InnoDB: Doing recovery: scanned up to log sequence number 0 13936128
...
InnoDB: Doing recovery: scanned up to log sequence number 0 20555264
InnoDB: Doing recovery: scanned up to log sequence number 0 20620800
InnoDB: Doing recovery: scanned up to log sequence number 0 20664692
InnoDB: 1 uncommitted transaction(s) which must be rolled back
InnoDB: Starting rollback of uncommitted transactions
InnoDB: Rolling back trx no 16745
InnoDB: Rolling back of trx no 16745 completed
InnoDB: Rollback of uncommitted transactions completed
InnoDB: Starting an apply batch of log records to the database...
InnoDB: Apply batch completed
InnoDB: Started
mysqld: ready for connections

```

For the cases of file system crashes or hardware problems, we can assume that the MySQL disk data is *not* available after a restart. This means that MySQL fails to start successfully because some blocks of disk data are no longer readable. In this case, it is necessary to reformat the disk, install a new one, or otherwise correct the underlying problem. Then it is necessary to recover our MySQL data from backups, which means that backups must already have been made. To make sure that is the case, design and implement a backup policy.

### 9.3.1 Establishing a Backup Policy

To be useful, backups must be scheduled regularly. A full backup (a snapshot of the data at a point in time) can be done in MySQL with several tools. For example, [MySQL Enterprise Backup](#) can perform a [physical backup](#) of an entire instance, with optimizations to minimize overhead and avoid disruption when backing up [InnoDB](#) data files; [mysqldump](#) provides online [logical backup](#). This discussion uses [mysqldump](#).

Assume that we make a full backup of all our [InnoDB](#) tables in all databases using the following command on Sunday at 1 p.m., when load is low:

```
$> mysqldump --all-databases --source-data --single-transaction > backup_sunday_1_PM.sql
```

The resulting `.sql` file produced by [mysqldump](#) contains a set of SQL `INSERT` statements that can be used to reload the dumped tables at a later time.

This backup operation acquires a global read lock on all tables at the beginning of the dump (using `FLUSH TABLES WITH READ LOCK`). As soon as this lock has been acquired, the binary log coordinates are read and the lock is released. If long updating statements are running when the `FLUSH` statement is issued, the backup operation may stall until those statements finish. After that, the dump becomes lock-free and does not disturb reads and writes on the tables.

It was assumed earlier that the tables to back up are [InnoDB](#) tables, so `--single-transaction` uses a consistent read and guarantees that data seen by [mysqldump](#) does not change. (Changes made by other clients to [InnoDB](#) tables are not seen by the [mysqldump](#) process.) If the backup operation includes nontransactional tables, consistency requires that they do not change during the backup. For example, for the [MyISAM](#) tables in the `mysql` database, there must be no administrative changes to MySQL accounts during the backup.

Full backups are necessary, but it is not always convenient to create them. They produce large backup files and take time to generate. They are not optimal in the sense that each successive full backup includes all data, even that part that has not changed since the previous full backup. It is more efficient to make an initial full backup, and then to make incremental backups. The incremental backups are smaller and take

less time to produce. The tradeoff is that, at recovery time, you cannot restore your data just by reloading the full backup. You must also process the incremental backups to recover the incremental changes.

To make incremental backups, we need to save the incremental changes. In MySQL, these changes are represented in the binary log, so the MySQL server should always be started with the `--log-bin` option to enable that log. With binary logging enabled, the server writes each data change into a file while it updates data. Looking at the data directory of a MySQL server that has been running for some days, we find these MySQL binary log files:

```
-rw-rw---- 1 guilhem guilhem 1277324 Nov 10 23:59 gbichot2-bin.000001
-rw-rw---- 1 guilhem guilhem 4 Nov 10 23:59 gbichot2-bin.000002
-rw-rw---- 1 guilhem guilhem 79 Nov 11 11:06 gbichot2-bin.000003
-rw-rw---- 1 guilhem guilhem 508 Nov 11 11:08 gbichot2-bin.000004
-rw-rw---- 1 guilhem guilhem 220047446 Nov 12 16:47 gbichot2-bin.000005
-rw-rw---- 1 guilhem guilhem 998412 Nov 14 10:08 gbichot2-bin.000006
-rw-rw---- 1 guilhem guilhem 361 Nov 14 10:07 gbichot2-bin.index
```

Each time it restarts, the MySQL server creates a new binary log file using the next number in the sequence. While the server is running, you can also tell it to close the current binary log file and begin a new one manually by issuing a `FLUSH LOGS` SQL statement or with a `mysqladmin flush-logs` command. `mysqldump` also has an option to flush the logs. The `.index` file in the data directory contains the list of all MySQL binary logs in the directory.

The MySQL binary logs are important for recovery because they form the set of incremental backups. If you make sure to flush the logs when you make your full backup, the binary log files created afterward contain all the data changes made since the backup. Let's modify the previous `mysqldump` command a bit so that it flushes the MySQL binary logs at the moment of the full backup, and so that the dump file contains the name of the new current binary log:

```
$> mysqldump --single-transaction --flush-logs --source-data=2 \
 --all-databases > backup_sunday_1_PM.sql
```

After executing this command, the data directory contains a new binary log file, `gbichot2-bin.000007`, because the `--flush-logs` option causes the server to flush its logs. The `--source-data` option causes `mysqldump` to write binary log information to its output, so the resulting `.sql` dump file includes these lines:

```
-- Position to start replication or point-in-time recovery from
-- CHANGE REPLICATION SOURCE TO SOURCE_LOG_FILE='gbichot2-bin.000007',SOURCE_LOG_POS=4;
```

Because the `mysqldump` command made a full backup, those lines mean two things:

- The dump file contains all changes made before any changes written to the `gbichot2-bin.000007` binary log file or higher.
- All data changes logged after the backup are not present in the dump file, but are present in the `gbichot2-bin.000007` binary log file or higher.

On Monday at 1 p.m., we can create an incremental backup by flushing the logs to begin a new binary log file. For example, executing a `mysqladmin flush-logs` command creates `gbichot2-bin.000008`. All changes between the Sunday 1 p.m. full backup and Monday 1 p.m. are written in `gbichot2-bin.000007`. This incremental backup is important, so it is a good idea to copy it to a safe place. (For example, back it up on tape or DVD, or copy it to another machine.) On Tuesday at 1 p.m., execute another `mysqladmin flush-logs` command. All changes between Monday 1 p.m. and Tuesday 1 p.m. are written in `gbichot2-bin.000008` (which also should be copied somewhere safe).

The MySQL binary logs take up disk space. To free up space, purge them from time to time. One way to do this is by deleting the binary logs that are no longer needed, such as when we make a full backup:

```
$> mysqldump --single-transaction --flush-logs --source-data=2 \
--all-databases --delete-source-logs > backup_sunday_1_PM.sql
```

#### Note

Deleting the MySQL binary logs with `mysqldump --delete-source-logs` can be dangerous if your server is a replication source server, because replicas might not yet fully have processed the contents of the binary log. The description for the `PURGE BINARY LOGS` statement explains what should be verified before deleting the MySQL binary logs. See [Section 15.4.1.1, “PURGE BINARY LOGS Statement”](#).

## 9.3.2 Using Backups for Recovery

Now, suppose that we have a catastrophic unexpected exit on Wednesday at 8 a.m. that requires recovery from backups. To recover, first we restore the last full backup we have (the one from Sunday 1 p.m.). The full backup file is just a set of SQL statements, so restoring it is very easy:

```
$> mysql < backup_sunday_1_PM.sql
```

At this point, the data is restored to its state as of Sunday 1 p.m.. To restore the changes made since then, we must use the incremental backups; that is, the `gbichot2-bin.000007` and `gbichot2-bin.000008` binary log files. Fetch the files if necessary from where they were backed up, and then process their contents like this:

```
$> mysqlbinlog gbichot2-bin.000007 gbichot2-bin.000008 | mysql
```

We now have recovered the data to its state as of Tuesday 1 p.m., but still are missing the changes from that date to the date of the crash. To not lose them, we would have needed to have the MySQL server store its MySQL binary logs into a safe location (RAID disks, SAN, ...) different from the place where it stores its data files, so that these logs were not on the destroyed disk. (That is, we can start the server with a `--log-bin` option that specifies a location on a different physical device from the one on which the data directory resides. That way, the logs are safe even if the device containing the directory is lost.) If we had done this, we would have the `gbichot2-bin.000009` file (and any subsequent files) at hand, and we could apply them using `mysqlbinlog` and `mysql` to restore the most recent data changes with no loss up to the moment of the crash:

```
$> mysqlbinlog gbichot2-bin.000009 ... | mysql
```

For more information about using `mysqlbinlog` to process binary log files, see [Section 9.5, “Point-in-Time \(Incremental\) Recovery”](#).

## 9.3.3 Backup Strategy Summary

In case of an operating system crash or power failure, `InnoDB` itself does all the job of recovering data. But to make sure that you can sleep well, observe the following guidelines:

- Always tun the MySQL server with binary logging enabled (that is the default setting for MySQL 9.1). If you have such safe media, this technique can also be good for disk load balancing (which results in a performance improvement).
- Make periodic full backups, using the `mysqldump` command shown earlier in [Section 9.3.1, “Establishing a Backup Policy”](#), that makes an online, nonblocking backup.
- Make periodic incremental backups by flushing the logs with `FLUSH LOGS` or `mysqladmin flush-logs`.

## 9.4 Using mysqldump for Backups

**Tip**

Consider using the [MySQL Shell dump utilities](#), which provide parallel dumping with multiple threads, file compression, and progress information display, as well as cloud features such as Oracle Cloud Infrastructure Object Storage streaming, and MySQL HeatWave Service compatibility checks and modifications. Dumps can be easily imported into a MySQL Server instance or a MySQL HeatWave Service DB System using the [MySQL Shell load dump utilities](#). Installation instructions for MySQL Shell can be found [here](#).

This section describes how to use `mysqldump` to produce dump files, and how to reload dump files. A dump file can be used in several ways:

- As a backup to enable data recovery in case of data loss.
- As a source of data for setting up replicas.
- As a source of data for experimentation:
  - To make a copy of a database that you can use without changing the original data.
  - To test potential upgrade incompatibilities.

`mysqldump` produces two types of output, depending on whether the `--tab` option is given:

- Without `--tab`, `mysqldump` writes SQL statements to the standard output. This output consists of `CREATE` statements to create dumped objects (databases, tables, stored routines, and so forth), and `INSERT` statements to load data into tables. The output can be saved in a file and reloaded later using `mysql` to recreate the dumped objects. Options are available to modify the format of the SQL statements, and to control which objects are dumped.
- With `--tab`, `mysqldump` produces two output files for each dumped table. The server writes one file as tab-delimited text, one line per table row. This file is named `tbl_name.txt` in the output directory. The server also sends a `CREATE TABLE` statement for the table to `mysqldump`, which writes it as a file named `tbl_name.sql` in the output directory.

## 9.4.1 Dumping Data in SQL Format with mysqldump

This section describes how to use `mysqldump` to create SQL-format dump files. For information about reloading such dump files, see [Section 9.4.2, “Reloading SQL-Format Backups”](#).

By default, `mysqldump` writes information as SQL statements to the standard output. You can save the output in a file:

```
$> mysqldump [arguments] > file_name
```

To dump all databases, invoke `mysqldump` with the `--all-databases` option:

```
$> mysqldump --all-databases > dump.sql
```

To dump only specific databases, name them on the command line and use the `--databases` option:

```
$> mysqldump --databases db1 db2 db3 > dump.sql
```

The `--databases` option causes all names on the command line to be treated as database names. Without this option, `mysqldump` treats the first name as a database name and those following as table names.

With `--all-databases` or `--databases`, `mysqldump` writes `CREATE DATABASE` and `USE` statements prior to the dump output for each database. This ensures that when the dump file is reloaded, it creates each database if it does not exist and makes it the default database so database contents are loaded into the same database from which they came. If you want to cause the dump file to force a drop of each database before recreating it, use the `--add-drop-database` option as well. In this case, `mysqldump` writes a `DROP DATABASE` statement preceding each `CREATE DATABASE` statement.

To dump a single database, name it on the command line:

```
$> mysqldump --databases test > dump.sql
```

In the single-database case, it is permissible to omit the `--databases` option:

```
$> mysqldump test > dump.sql
```

The difference between the two preceding commands is that without `--databases`, the dump output contains no `CREATE DATABASE` or `USE` statements. This has several implications:

- When you reload the dump file, you must specify a default database name so that the server knows which database to reload.
- For reloading, you can specify a database name different from the original name, which enables you to reload the data into a different database.
- If the database to be reloaded does not exist, you must create it first.
- Because the output contains no `CREATE DATABASE` statement, the `--add-drop-database` option has no effect. If you use it, it produces no `DROP DATABASE` statement.

To dump only specific tables from a database, name them on the command line following the database name:

```
$> mysqldump test t1 t3 t7 > dump.sql
```

By default, if GTIDs are in use on the server where you create the dump file (`gtid_mode=ON`), `mysqldump` includes a `SET @@GLOBAL.gtid_purged` statement in the output to add the GTIDs from the `gtid_executed` set on the source server to the `gtid_purged` set on the target server. If you are dumping only specific databases or tables, it is important to note that the value that is included by `mysqldump` includes the GTIDs of all transactions in the `gtid_executed` set on the source server, even those that changed suppressed parts of the database, or other databases on the server that were not included in the partial dump. If you only replay one partial dump file on the target server, the extra GTIDs do not cause any problems with the future operation of that server. However, if you replay a second dump file on the target server that contains the same GTIDs (for example, another partial dump from the same source server), any `SET @@GLOBAL.gtid_purged` statement in the second dump file fails. To avoid this issue, either set the `mysqldump` option `--set-gtid-purged` to `OFF` or `COMMENTED` to output the second dump file without an active `SET @@GLOBAL.gtid_purged` statement, or remove the statement manually before replaying the dump file.

## 9.4.2 Reloading SQL-Format Backups

To reload a dump file written by `mysqldump` that consists of SQL statements, use it as input to the `mysql` client. If the dump file was created by `mysqldump` with the `--all-databases` or `--databases` option, it contains `CREATE DATABASE` and `USE` statements and it is not necessary to specify a default database into which to load the data:

```
$> mysql < dump.sql
```

Alternatively, from within `mysql`, use a `source` command:

```
mysql> source dump.sql
```

If the file is a single-database dump not containing `CREATE DATABASE` and `USE` statements, create the database first (if necessary):

```
$> mysqladmin create db1
```

Then specify the database name when you load the dump file:

```
$> mysql db1 < dump.sql
```

Alternatively, from within `mysql`, create the database, select it as the default database, and load the dump file:

```
mysql> CREATE DATABASE IF NOT EXISTS db1;
mysql> USE db1;
mysql> source dump.sql
```

**Note**

For Windows PowerShell users: Because the "<" character is reserved for future use in PowerShell, an alternative approach is required, such as using quotes `cmd.exe /c "mysql < dump.sql"`.

### 9.4.3 Dumping Data in Delimited-Text Format with mysqldump

This section describes how to use `mysqldump` to create delimited-text dump files. For information about reloading such dump files, see [Section 9.4.4, “Reloading Delimited-Text Format Backups”](#).

If you invoke `mysqldump` with the `--tab=dir_name` option, it uses `dir_name` as the output directory and dumps tables individually in that directory using two files for each table. The table name is the base name for these files. For a table named `t1`, the files are named `t1.sql` and `t1.txt`. The `.sql` file contains a `CREATE TABLE` statement for the table. The `.txt` file contains the table data, one line per table row.

The following command dumps the contents of the `db1` database to files in the `/tmp` database:

```
$> mysqldump --tab=/tmp db1
```

The `.txt` files containing table data are written by the server, so they are owned by the system account used for running the server. The server uses `SELECT ... INTO OUTFILE` to write the files, so you must have the `FILE` privilege to perform this operation, and an error occurs if a given `.txt` file already exists.

The server sends the `CREATE` definitions for dumped tables to `mysqldump`, which writes them to `.sql` files. These files therefore are owned by the user who executes `mysqldump`.

It is best that `--tab` be used only for dumping a local server. If you use it with a remote server, the `--tab` directory must exist on both the local and remote hosts, and the `.txt` files are written by the server in the remote directory (on the server host), whereas the `.sql` files are written by `mysqldump` in the local directory (on the client host).

For `mysqldump --tab`, the server by default writes table data to `.txt` files one line per row with tabs between column values, no quotation marks around column values, and newline as the line terminator. (These are the same defaults as for `SELECT ... INTO OUTFILE`.)

To enable data files to be written using a different format, `mysqldump` supports these options:

- `--fields-terminated-by=str`

The string for separating column values (default: tab).

- `--fields-enclosed-by=char`

The character within which to enclose column values (default: no character).

- `--fields-optionally-enclosed-by=char`

The character within which to enclose non-numeric column values (default: no character).

- `--fields-escaped-by=char`

The character for escaping special characters (default: no escaping).

- `--lines-terminated-by=str`

The line-termination string (default: newline).

Depending on the value you specify for any of these options, it might be necessary on the command line to quote or escape the value appropriately for your command interpreter. Alternatively, specify the value using hex notation. Suppose that you want `mysqldump` to quote column values within double quotation marks. To do so, specify double quote as the value for the `--fields-enclosed-by` option. But this character is often special to command interpreters and must be treated specially. For example, on Unix, you can quote the double quote like this:

```
--fields-enclosed-by='\"'
```

On any platform, you can specify the value in hex:

```
--fields-enclosed-by=0x22
```

It is common to use several of the data-formatting options together. For example, to dump tables in comma-separated values format with lines terminated by carriage-return/newline pairs (`\r\n`), use this command (enter it on a single line):

```
$> mysqldump --tab=/tmp --fields-terminated-by=,
 --fields-enclosed-by='\"' --lines-terminated-by=0x0d0a db1
```

Should you use any of the data-formatting options to dump table data, you need to specify the same format when you reload data files later, to ensure proper interpretation of the file contents.

## 9.4.4 Reloading Delimited-Text Format Backups

For backups produced with `mysqldump --tab`, each table is represented in the output directory by an `.sql` file containing the `CREATE TABLE` statement for the table, and a `.txt` file containing the table data. To reload a table, first change location into the output directory. Then process the `.sql` file with `mysql` to create an empty table and process the `.txt` file to load the data into the table:

```
$> mysql db1 < t1.sql
$> mysqlimport db1 t1.txt
```

An alternative to using `mysqlimport` to load the data file is to use the `LOAD DATA` statement from within the `mysql` client:

```
mysql> USE db1;
mysql> LOAD DATA INFILE 't1.txt' INTO TABLE t1;
```

If you used any data-formatting options with `mysqldump` when you initially dumped the table, you must use the same options with `mysqlimport` or `LOAD DATA` to ensure proper interpretation of the data file contents:

```
$> mysqlimport --fields-terminated-by=,
 --fields-enclosed-by='"' --lines-terminated-by=0x0d0a db1 t1.txt
```

Or:

```
mysql> USE db1;
mysql> LOAD DATA INFILE 't1.txt' INTO TABLE t1
 FIELDS TERMINATED BY ',' FIELDS ENCLOSED BY '"'
 LINES TERMINATED BY '\r\n';
```

## 9.4.5 mysqldump Tips

This section surveys techniques that enable you to use `mysqldump` to solve specific problems:

- How to make a copy a database
- How to copy a database from one server to another
- How to dump stored programs (stored procedures and functions, triggers, and events)
- How to dump definitions and data separately

### 9.4.5.1 Making a Copy of a Database

```
$> mysqldump db1 > dump.sql
$> mysqladmin create db2
$> mysql db2 < dump.sql
```

Do not use `--databases` on the `mysqldump` command line because that causes `USE db1` to be included in the dump file, which overrides the effect of naming `db2` on the `mysql` command line.

### 9.4.5.2 Copy a Database from one Server to Another

On Server 1:

```
$> mysqldump --databases db1 > dump.sql
```

Copy the dump file from Server 1 to Server 2.

On Server 2:

```
$> mysql < dump.sql
```

Use of `--databases` with the `mysqldump` command line causes the dump file to include `CREATE DATABASE` and `USE` statements that create the database if it does exist and make it the default database for the reloaded data.

Alternatively, you can omit `--databases` from the `mysqldump` command. Then you need to create the database on Server 2 (if necessary) and specify it as the default database when you reload the dump file.

On Server 1:

```
$> mysqldump db1 > dump.sql
```

On Server 2:

```
$> mysqladmin create db1
$> mysql db1 < dump.sql
```

You can specify a different database name in this case, so omitting `--databases` from the `mysqldump` command enables you to dump data from one database and load it into another.

### 9.4.5.3 Dumping Stored Programs

Several options control how `mysqldump` handles stored programs (stored procedures and functions, triggers, and events):

- `--events`: Dump Event Scheduler events
- `--routines`: Dump stored procedures and functions
- `--triggers`: Dump triggers for tables

The `--triggers` option is enabled by default so that when tables are dumped, they are accompanied by any triggers they have. The other options are disabled by default and must be specified explicitly to dump the corresponding objects. To disable any of these options explicitly, use its skip form: `--skip-events`, `--skip-routines`, or `--skip-triggers`.

### 9.4.5.4 Dumping Table Definitions and Content Separately

The `--no-data` option tells `mysqldump` not to dump table data, resulting in the dump file containing only statements to create the tables. Conversely, the `--no-create-info` option tells `mysqldump` to suppress `CREATE` statements from the output, so that the dump file contains only table data.

For example, to dump table definitions and data separately for the `test` database, use these commands:

```
$> mysqldump --no-data test > dump-defs.sql
$> mysqldump --no-create-info test > dump-data.sql
```

For a definition-only dump, add the `--routines` and `--events` options to also include stored routine and event definitions:

```
$> mysqldump --no-data --routines --events test > dump-defs.sql
```

### 9.4.5.5 Using `mysqldump` to Test for Upgrade Incompatibilities

When contemplating a MySQL upgrade, it is prudent to install the newer version separately from your current production version. Then you can dump the database and database object definitions from the production server and load them into the new server to verify that they are handled properly. (This is also useful for testing downgrades.)

On the production server:

```
$> mysqldump --all-databases --no-data --routines --events > dump-defs.sql
```

On the upgraded server:

```
$> mysql < dump-defs.sql
```

Because the dump file does not contain table data, it can be processed quickly. This enables you to spot potential incompatibilities without waiting for lengthy data-loading operations. Look for warnings or errors while the dump file is being processed.

After you have verified that the definitions are handled properly, dump the data and try to load it into the upgraded server.

On the production server:

```
$> mysqldump --all-databases --no-create-info > dump-data.sql
```

On the upgraded server:

```
$> mysql < dump-data.sql
```

Now check the table contents and run some test queries.

## 9.5 Point-in-Time (Incremental) Recovery

Point-in-time recovery refers to recovery of data changes up to a given point in time. Typically, this type of recovery is performed after restoring a full backup that brings the server to its state as of the time the backup was made. (The full backup can be made in several ways, such as those listed in [Section 9.2, “Database Backup Methods”](#).) Point-in-time recovery then brings the server up to date incrementally from the time of the full backup to a more recent time.

### 9.5.1 Point-in-Time Recovery Using Binary Log

This section explains the general idea of using the binary log to perform a point-in-time-recovery. The next section, [Section 9.5.2, “Point-in-Time Recovery Using Event Positions”](#), explains the operation in details with an example.

#### Note

Many of the examples in this and the next section use the `mysql` client to process binary log output produced by `mysqlbinlog`. If your binary log contains `\0` (null) characters, that output cannot be parsed by `mysql` unless you invoke it with the `--binary-mode` option.

The source of information for point-in-time recovery is the set of binary log files generated subsequent to the full backup operation. Therefore, to allow a server to be restored to a point-in-time, binary logging must be enabled on it, which is the default setting for MySQL 9.1 (see [Section 7.4.4, “The Binary Log”](#)).

To restore data from the binary log, you must know the name and location of the current binary log files. By default, the server creates binary log files in the data directory, but a path name can be specified with the `--log-bin` option to place the files in a different location. To see a listing of all binary log files, use this statement:

```
mysql> SHOW BINARY LOGS;
```

To determine the name of the current binary log file, issue the following statement:

```
mysql> SHOW BINARY LOG STATUS;
```

The `mysqlbinlog` utility converts the events in the binary log files from binary format to text so that they can be viewed or applied. `mysqlbinlog` has options for selecting sections of the binary log based on event times or position of events within the log. See [Section 6.6.9, “mysqlbinlog — Utility for Processing Binary Log Files”](#).

Applying events from the binary log causes the data modifications they represent to be reexecuted. This enables recovery of data changes for a given span of time. To apply events from the binary log, process `mysqlbinlog` output using the `mysql` client:

```
$> mysqlbinlog binlog_files | mysql -u root -p
```

If binary log files have been encrypted, `mysqlbinlog` cannot read them directly as in the previous example, but can read them from the server using the `--read-from-remote-server` (`-R`) option. For example:

```
$> mysqlbinlog --read-from-remote-server --host=host_name --port=3306 --user=root --password --ssl-mode=r
```

Here, the option `--ssl-mode=required` has been used to ensure that the data from the binary log files is protected in transit, because it is sent to `mysqlbinlog` in an unencrypted format.

### Important

`VERIFY_CA` and `VERIFY_IDENTITY` are better choices than `REQUIRED` for the SSL mode, because they help prevent man-in-the-middle attacks. To implement one of these settings, you must first ensure that the CA certificate for the server is reliably available to all the clients that use it in your environment, otherwise availability issues will result. See [Command Options for Encrypted Connections](#).

Viewing log contents can be useful when you need to determine event times or positions to select partial log contents prior to executing events. To view events from the log, send `mysqlbinlog` output into a paging program:

```
$> mysqlbinlog binlog_files | more
```

Alternatively, save the output in a file and view the file in a text editor:

```
$> mysqlbinlog binlog_files > tmpfile
$> ... edit tmpfile ...
```

After editing the file, apply the contents as follows:

```
$> mysql -u root -p < tmpfile
```

If you have more than one binary log to apply on the MySQL server, use a single connection to apply the contents of all binary log files that you want to process. Here is one way to do so:

```
$> mysqlbinlog binlog.000001 binlog.000002 | mysql -u root -p
```

Another approach is to write the whole log to a single file and then process the file:

```
$> mysqlbinlog binlog.000001 > /tmp/statements.sql
$> mysqlbinlog binlog.000002 >> /tmp/statements.sql
$> mysql -u root -p -e "source /tmp/statements.sql"
```

## 9.5.2 Point-in-Time Recovery Using Event Positions

The last section, [Section 9.5.1, “Point-in-Time Recovery Using Binary Log”](#), explains the general idea of using the binary log to perform a point-in-time-recovery. The section explains the operation in details with an example.

As an example, suppose that around 20:06:00 on March 11, 2020, an SQL statement was executed that deleted a table. You can perform a point-in-time recovery to restore the server up to its state right before the table deletion. These are some sample steps to achieve that:

1. Restore the last full backup created before the point-in-time of interest (call it  $t_p$ , which is 20:06:00 on March 11, 2020 in our example). When finished, note the binary log position up to which you have restored the server for later use, and restart the server.

### Note

While the last binary log position recovered is also displayed by InnoDB after the restore and server restart, that is *not* a reliable means for obtaining the ending log position of your restore, as there could be DDL events and non-InnoDB changes that have taken place after the time reflected by the displayed position. Your backup and restore tool should provide you with the last binary

log position for your recovery: for example, if you are using `mysqlbinlog` for the task, check the stop position of the binary log replay; if you are using MySQL Enterprise Backup, the last binary log position has been saved in your backup. See [Point-in-Time Recovery](#).

- Find the precise binary log event position corresponding to the point in time up to which you want to restore your database. In our example, given that we know the rough time where the table deletion took place ( $t_p$ ), we can find the log position by checking the log contents around that time using the `mysqlbinlog` utility. Use the `--start-datetime` and `--stop-datetime` options to specify a short time period around  $t_p$ , and then look for the event in the output. For example:

```
$> mysqlbinlog --start-datetime="2020-03-11 20:05:00" \
 --stop-datetime="2020-03-11 20:08:00" --verbose \
 /var/lib/mysql/bin.123456 | grep -C 15 "DROP TABLE"

use `pets`/*!*/;;
SET TIMESTAMP=1583971668/*!*/;;
/*!80013 SET @@session.sql_require_primary_key=0/*!*/;;
CREATE TABLE dogs
```

From the output of `mysqlbinlog`, the `DROP TABLE `pets`.`cats`` statement can be found in the segment of the binary log between the line `# at 232` and `# at 355`, which means the statement takes place *after* the log position 232, and the log is at position 355 after the `DROP TABLE` statement.

#### Note

Only use the `--start-datetime` and `--stop-datetime` options to help you find the actual event positions of interest. Using the two options to specify the range of binary log segment to apply is not recommended: there is a higher risk of missing binary log events when using the options. Use `--start-position` and `--stop-position` instead.

- Apply the events in binary log file to the server, starting with the log position your found in step 1 (assume it is 155) and ending at the position you have found in step 2 that is *before* your point-in-time of interest (which is 232):

```
$> mysqlbinlog --start-position=155 --stop-position=232 /var/lib/mysql/bin.123456 \
| mysql -u root -p
```

The command recovers all the transactions from the starting position until just before the stop position. Because the output of `mysqlbinlog` includes `SET TIMESTAMP` statements before each SQL statement recorded, the recovered data and related MySQL logs reflect the original times at which the transactions were executed.

Your database has now been restored to the point-in-time of interest,  $t_p$ , right before the table `pets.cats` was dropped.

4. Beyond the point-in-time recovery that has been finished, if you also want to reexecute all the statements *after* your point-in-time of interest, use `mysqlbinlog` again to apply all the events after  $t_p$  to the server. We noted in step 2 that after the statement we wanted to skip, the log is at position 355; we can use it for the `--start-position` option, so that any statements after the position are included:

```
$> mysqlbinlog --start-position=355 /var/lib/mysql/bin.123456 \
| mysql -u root -p
```

Your database has been restored the latest statement recorded in the binary log file, but with the selected event skipped.

## 9.6 MyISAM Table Maintenance and Crash Recovery

This section discusses how to use `myisamchk` to check or repair MyISAM tables (tables that have `.MYD` and `.MYI` files for storing data and indexes). For general `myisamchk` background, see [Section 6.6.4, “myisamchk — MyISAM Table-Maintenance Utility”](#). Other table-repair information can be found at [Section 3.14, “Rebuilding or Repairing Tables or Indexes”](#).

You can use `myisamchk` to check, repair, or optimize database tables. The following sections describe how to perform these operations and how to set up a table maintenance schedule. For information about using `myisamchk` to get information about your tables, see [Section 6.6.4.5, “Obtaining Table Information with myisamchk”](#).

Even though table repair with `myisamchk` is quite secure, it is always a good idea to make a backup *before* doing a repair or any maintenance operation that could make a lot of changes to a table.

`myisamchk` operations that affect indexes can cause MyISAM FULLTEXT indexes to be rebuilt with full-text parameters that are incompatible with the values used by the MySQL server. To avoid this problem, follow the guidelines in [Section 6.6.4.1, “myisamchk General Options”](#).

MyISAM table maintenance can also be done using the SQL statements that perform operations similar to what `myisamchk` can do:

- To check MyISAM tables, use `CHECK TABLE`.
- To repair MyISAM tables, use `REPAIR TABLE`.
- To optimize MyISAM tables, use `OPTIMIZE TABLE`.
- To analyze MyISAM tables, use `ANALYZE TABLE`.

For additional information about these statements, see [Section 15.7.3, “Table Maintenance Statements”](#).

These statements can be used directly or by means of the `mysqlcheck` client program. One advantage of these statements over `myisamchk` is that the server does all the work. With `myisamchk`, you must

make sure that the server does not use the tables at the same time so that there is no unwanted interaction between `myisamchk` and the server.

## 9.6.1 Using myisamchk for Crash Recovery

This section describes how to check for and deal with data corruption in MySQL databases. If your tables become corrupted frequently, you should try to find the reason why. See [Section B.3.3.3, “What to Do If MySQL Keeps Crashing”](#).

For an explanation of how `MyISAM` tables can become corrupted, see [Section 18.2.4, “MyISAM Table Problems”](#).

If you run `mysqld` with external locking disabled (which is the default), you cannot reliably use `myisamchk` to check a table when `mysqld` is using the same table. If you can be certain that no one can access the tables using `mysqld` while you run `myisamchk`, you only have to execute `mysqladmin flush-tables` before you start checking the tables. If you cannot guarantee this, you must stop `mysqld` while you check the tables. If you run `myisamchk` to check tables that `mysqld` is updating at the same time, you may get a warning that a table is corrupt even when it is not.

If the server is run with external locking enabled, you can use `myisamchk` to check tables at any time. In this case, if the server tries to update a table that `myisamchk` is using, the server waits for `myisamchk` to finish before it continues.

If you use `myisamchk` to repair or optimize tables, you *must* always ensure that the `mysqld` server is not using the table (this also applies if external locking is disabled). If you do not stop `mysqld`, you should at least do a `mysqladmin flush-tables` before you run `myisamchk`. Your tables *may become corrupted* if the server and `myisamchk` access the tables simultaneously.

When performing crash recovery, it is important to understand that each `MyISAM` table `tbl_name` in a database corresponds to the three files in the database directory shown in the following table.

File	Purpose
<code>tbl_name.MYD</code>	Data file
<code>tbl_name.MYI</code>	Index file

Each of these three file types is subject to corruption in various ways, but problems occur most often in data files and index files.

`myisamchk` works by creating a copy of the `.MYD` data file row by row. It ends the repair stage by removing the old `.MYD` file and renaming the new file to the original file name. If you use `--quick`, `myisamchk` does not create a temporary `.MYD` file, but instead assumes that the `.MYD` file is correct and generates only a new index file without touching the `.MYD` file. This is safe, because `myisamchk` automatically detects whether the `.MYD` file is corrupt and aborts the repair if it is. You can also specify the `--quick` option twice to `myisamchk`. In this case, `myisamchk` does not abort on some errors (such as duplicate-key errors) but instead tries to resolve them by modifying the `.MYD` file. Normally the use of two `--quick` options is useful only if you have too little free disk space to perform a normal repair. In this case, you should at least make a backup of the table before running `myisamchk`.

## 9.6.2 How to Check MyISAM Tables for Errors

To check a `MyISAM` table, use the following commands:

- `myisamchk tbl_name`

This finds 99.99% of all errors. What it cannot find is corruption that involves *only* the data file (which is very unusual). If you want to check a table, you should normally run `myisamchk` without options or with the `-s` (silent) option.

- `myisamchk -m tbl_name`

This finds 99.999% of all errors. It first checks all index entries for errors and then reads through all rows. It calculates a checksum for all key values in the rows and verifies that the checksum matches the checksum for the keys in the index tree.

- `myisamchk -e tbl_name`

This does a complete and thorough check of all data (`-e` means “extended check”). It does a check-read of every key for each row to verify that they indeed point to the correct row. This may take a long time for a large table that has many indexes. Normally, `myisamchk` stops after the first error it finds. If you want to obtain more information, you can add the `-v` (verbose) option. This causes `myisamchk` to keep going, up through a maximum of 20 errors.

- `myisamchk -e -i tbl_name`

This is like the previous command, but the `-i` option tells `myisamchk` to print additional statistical information.

In most cases, a simple `myisamchk` command with no arguments other than the table name is sufficient to check a table.

### 9.6.3 How to Repair MyISAM Tables

The discussion in this section describes how to use `myisamchk` on `MyISAM` tables (extensions `.MYI` and `.MYD`).

You can also use the `CHECK TABLE` and `REPAIR TABLE` statements to check and repair `MyISAM` tables. See [Section 15.7.3.2, “CHECK TABLE Statement”](#), and [Section 15.7.3.5, “REPAIR TABLE Statement”](#).

Symptoms of corrupted tables include queries that abort unexpectedly and observable errors such as these:

- Can't find file `tbl_name.MYI` (Errcode: `nnn`)
- Unexpected end of file
- Record file is crashed
- Got error `nnn` from table handler

To get more information about the error, run `perror nnn`, where `nnn` is the error number. The following example shows how to use `perror` to find the meanings for the most common error numbers that indicate a problem with a table:

```
$> perror 126 127 132 134 135 136 141 144 145
MySQL error code 126 = Index file is crashed
MySQL error code 127 = Record-file is crashed
MySQL error code 132 = Old database file
MySQL error code 134 = Record was already deleted (or record file crashed)
MySQL error code 135 = No more room in record file
MySQL error code 136 = No more room in index file
MySQL error code 141 = Duplicate unique key or constraint on write or update
MySQL error code 144 = Table is crashed and last repair failed
```

MySQL error code 145 = Table was marked as crashed and should be repaired

Note that error 135 (no more room in record file) and error 136 (no more room in index file) are not errors that can be fixed by a simple repair. In this case, you must use `ALTER TABLE` to increase the `MAX_ROWS` and `AVG_ROW_LENGTH` table option values:

```
ALTER TABLE tbl_name MAX_ROWS=xxx AVG_ROW_LENGTH=yyy;
```

If you do not know the current table option values, use `SHOW CREATE TABLE`.

For the other errors, you must repair your tables. `myisamchk` can usually detect and fix most problems that occur.

The repair process involves up to three stages, described here. Before you begin, you should change location to the database directory and check the permissions of the table files. On Unix, make sure that they are readable by the user that `mysqld` runs as (and to you, because you need to access the files you are checking). If it turns out you need to modify files, they must also be writable by you.

This section is for the cases where a table check fails (such as those described in [Section 9.6.2, “How to Check MyISAM Tables for Errors”](#)), or you want to use the extended features that `myisamchk` provides.

The `myisamchk` options used for table maintenance with are described in [Section 6.6.4, “myisamchk — MyISAM Table-Maintenance Utility”](#). `myisamchk` also has variables that you can set to control memory allocation that may improve performance. See [Section 6.6.4.6, “myisamchk Memory Usage”](#).

If you are going to repair a table from the command line, you must first stop the `mysqld` server. Note that when you do `mysqladmin shutdown` on a remote server, the `mysqld` server is still available for a while after `mysqladmin` returns, until all statement-processing has stopped and all index changes have been flushed to disk.

### Stage 1: Checking your tables

Run `myisamchk *.MYI` or `myisamchk -e *.MYI` if you have more time. Use the `-s` (silent) option to suppress unnecessary information.

If the `mysqld` server is stopped, you should use the `--update-state` option to tell `myisamchk` to mark the table as “checked.”

You have to repair only those tables for which `myisamchk` announces an error. For such tables, proceed to Stage 2.

If you get unexpected errors when checking (such as `out of memory` errors), or if `myisamchk` crashes, go to Stage 3.

### Stage 2: Easy safe repair

First, try `myisamchk -r -q tbl_name` (`-r -q` means “quick recovery mode”). This attempts to repair the index file without touching the data file. If the data file contains everything that it should and the delete links point at the correct locations within the data file, this should work, and the table is fixed. Start repairing the next table. Otherwise, use the following procedure:

1. Make a backup of the data file before continuing.
2. Use `myisamchk -r tbl_name` (`-r` means “recovery mode”). This removes incorrect rows and deleted rows from the data file and reconstructs the index file.
3. If the preceding step fails, use `myisamchk --safe-recover tbl_name`. Safe recovery mode uses an old recovery method that handles a few cases that regular recovery mode does not (but is slower).

**Note**

If you want a repair operation to go much faster, you should set the values of the `sort_buffer_size` and `key_buffer_size` variables each to about 25% of your available memory when running `myisamchk`.

If you get unexpected errors when repairing (such as `out of memory` errors), or if `myisamchk` crashes, go to Stage 3.

**Stage 3: Difficult repair**

You should reach this stage only if the first 16KB block in the index file is destroyed or contains incorrect information, or if the index file is missing. In this case, it is necessary to create a new index file. Do so as follows:

1. Move the data file to a safe place.
2. Use the table description file to create new (empty) data and index files:

```
$> mysql db_name
```

```
mysql> SET autocommit=1;
mysql> TRUNCATE TABLE tbl_name;
mysql> quit
```

3. Copy the old data file back onto the newly created data file. (Do not just move the old file back onto the new file. You want to retain a copy in case something goes wrong.)

**Important**

If you are using replication, you should stop it prior to performing the above procedure, since it involves file system operations, and these are not logged by MySQL.

Go back to Stage 2. `myisamchk -r -q` should work. (This should not be an endless loop.)

You can also use the `REPAIR TABLE tbl_name USE_FRM` SQL statement, which performs the whole procedure automatically. There is also no possibility of unwanted interaction between a utility and the server, because the server does all the work when you use `REPAIR TABLE`. See [Section 15.7.3.5, “REPAIR TABLE Statement”](#).

## 9.6.4 MyISAM Table Optimization

To coalesce fragmented rows and eliminate wasted space that results from deleting or updating rows, run `myisamchk` in recovery mode:

```
$> myisamchk -r tbl_name
```

You can optimize a table in the same way by using the `OPTIMIZE TABLE` SQL statement. `OPTIMIZE TABLE` does a table repair and a key analysis, and also sorts the index tree so that key lookups are faster. There is also no possibility of unwanted interaction between a utility and the server, because the server does all the work when you use `OPTIMIZE TABLE`. See [Section 15.7.3.4, “OPTIMIZE TABLE Statement”](#).

`myisamchk` has a number of other options that you can use to improve the performance of a table:

- `--analyze` or `-a`: Perform key distribution analysis. This improves join performance by enabling the join optimizer to better choose the order in which to join the tables and which indexes it should use.

- `--sort-index` or `-S`: Sort the index blocks. This optimizes seeks and makes table scans that use indexes faster.
- `--sort-records=index_num` or `-R index_num`: Sort data rows according to a given index. This makes your data much more localized and may speed up range-based `SELECT` and `ORDER BY` operations that use this index.

For a full description of all available options, see [Section 6.6.4, “myisamchk — MyISAM Table-Maintenance Utility”](#).

## 9.6.5 Setting Up a MyISAM Table Maintenance Schedule

It is a good idea to perform table checks on a regular basis rather than waiting for problems to occur. One way to check and repair MyISAM tables is with the `CHECK TABLE` and `REPAIR TABLE` statements. See [Section 15.7.3, “Table Maintenance Statements”](#).

Another way to check tables is to use `myisamchk`. For maintenance purposes, you can use `myisamchk -s`. The `-s` option (short for `--silent`) causes `myisamchk` to run in silent mode, printing messages only when errors occur.

It is also a good idea to enable automatic MyISAM table checking. For example, whenever the machine has done a restart in the middle of an update, you usually need to check each table that could have been affected before it is used further. (These are “expected crashed tables.”) To cause the server to check MyISAM tables automatically, start it with the `myisam_recover_options` system variable set. See [Section 7.1.8, “Server System Variables”](#).

You should also check your tables regularly during normal system operation. For example, you can run a `cron` job to check important tables once a week, using a line like this in a `crontab` file:

```
35 0 * * 0 /path/to/myisamchk --fast --silent /path/to/datadir/*/*.MYI
```

This prints out information about crashed tables so that you can examine and repair them as necessary.

To start with, execute `myisamchk -s` each night on all tables that have been updated during the last 24 hours. As you see that problems occur infrequently, you can back off the checking frequency to once a week or so.

Normally, MySQL tables need little maintenance. If you are performing many updates to MyISAM tables with dynamic-sized rows (tables with `VARCHAR`, `BLOB`, or `TEXT` columns) or have tables with many deleted rows you may want to defragment/reclaim space from the tables from time to time. You can do this by using `OPTIMIZE TABLE` on the tables in question. Alternatively, if you can stop the `mysqld` server for a while, change location into the data directory and use this command while the server is stopped:

```
$> myisamchk -r -s --sort-index --myisam_sort_buffer_size=16M /*.MYI
```

---

This chapter explains how to optimize MySQL performance and provides examples. Optimization involves configuring, tuning, and measuring performance, at several levels. Depending on your job role (developer, DBA, or a combination of both), you might optimize at the level of individual SQL statements, entire applications, a single database server, or multiple networked database servers. Sometimes you can be proactive and plan in advance for performance, while other times you might troubleshoot a configuration or code issue after a problem occurs. Optimizing CPU and memory usage can also improve scalability, allowing the database to handle more load without slowing down.

## 10.1 Optimization Overview

Database performance depends on several factors at the database level, such as tables, queries, and configuration settings. These software constructs result in CPU and I/O operations at the hardware level, which you must minimize and make as efficient as possible. As you work on database performance, you start by learning the high-level rules and guidelines for the software side, and measuring performance using wall-clock time. As you become an expert, you learn more about what happens internally, and start measuring things such as CPU cycles and I/O operations.

Typical users aim to get the best database performance out of their existing software and hardware configurations. Advanced users look for opportunities to improve the MySQL software itself, or develop their own storage engines and hardware appliances to expand the MySQL ecosystem.

- [Optimizing at the Database Level](#)
- [Optimizing at the Hardware Level](#)
- [Balancing Portability and Performance](#)

### Optimizing at the Database Level

The most important factor in making a database application fast is its basic design:

- Are the tables structured properly? In particular, do the columns have the right data types, and does each table have the appropriate columns for the type of work? For example, applications that perform frequent updates often have many tables with few columns, while applications that analyze large amounts of data often have few tables with many columns.
- Are the right [indexes](#) in place to make queries efficient?
- Are you using the appropriate storage engine for each table, and taking advantage of the strengths and features of each storage engine you use? In particular, the choice of a transactional storage engine such as [InnoDB](#) or a nontransactional one such as [MyISAM](#) can be very important for performance and scalability.

#### Note

[InnoDB](#) is the default storage engine for new tables. In practice, the advanced [InnoDB](#) performance features mean that [InnoDB](#) tables often outperform the simpler [MyISAM](#) tables, especially for a busy database.

- Does each table use an appropriate row format? This choice also depends on the storage engine used for the table. In particular, compressed tables use less disk space and so require less disk I/O to read and write the data. Compression is available for all kinds of workloads with [InnoDB](#) tables, and for read-only [MyISAM](#) tables.
- Does the application use an appropriate [locking strategy](#)? For example, by allowing shared access when possible so that database operations can run concurrently, and requesting exclusive access when appropriate so that critical operations get top priority. Again, the choice of storage engine is significant. The [InnoDB](#) storage engine handles most locking issues without involvement from you, allowing for better concurrency in the database and reducing the amount of experimentation and tuning for your code.
- Are all [memory areas used for caching](#) sized correctly? That is, large enough to hold frequently accessed data, but not so large that they overload physical memory and cause paging. The main memory areas to configure are the [InnoDB](#) buffer pool and the [MyISAM](#) key cache.

## Optimizing at the Hardware Level

Any database application eventually hits hardware limits as the database becomes more and more busy. A DBA must evaluate whether it is possible to tune the application or reconfigure the server to avoid these [bottlenecks](#), or whether more hardware resources are required. System bottlenecks typically arise from these sources:

- Disk seeks. It takes time for the disk to find a piece of data. With modern disks, the mean time for this is usually lower than 10ms, so we can in theory do about 100 seeks a second. This time improves slowly with new disks and is very hard to optimize for a single table. The way to optimize seek time is to distribute the data onto more than one disk.
- Disk reading and writing. When the disk is at the correct position, we need to read or write the data. With modern disks, one disk delivers at least 10–20MB/s throughput. This is easier to optimize than seeks because you can read in parallel from multiple disks.
- CPU cycles. When the data is in main memory, we must process it to get our result. Having large tables compared to the amount of memory is the most common limiting factor. But with small tables, speed is usually not the problem.
- Memory bandwidth. When the CPU needs more data than can fit in the CPU cache, main memory bandwidth becomes a bottleneck. This is an uncommon bottleneck for most systems, but one to be aware of.

## Balancing Portability and Performance

To use performance-oriented SQL extensions in a portable MySQL program, you can wrap MySQL-specific keywords in a statement within `/*! */` comment delimiters. Other SQL servers ignore the commented keywords. For information about writing comments, see [Section 11.7, “Comments”](#).

## 10.2 Optimizing SQL Statements

The core logic of a database application is performed through SQL statements, whether issued directly through an interpreter or submitted behind the scenes through an API. The tuning guidelines in this section help to speed up all kinds of MySQL applications. The guidelines cover SQL operations that read and write data, the behind-the-scenes overhead for SQL operations in general, and operations used in specific scenarios such as database monitoring.

### 10.2.1 Optimizing SELECT Statements

Queries, in the form of `SELECT` statements, perform all the lookup operations in the database. Tuning these statements is a top priority, whether to achieve sub-second response times for dynamic web pages, or to chop hours off the time to generate huge overnight reports.

Besides `SELECT` statements, the tuning techniques for queries also apply to constructs such as `CREATE TABLE...AS SELECT`, `INSERT INTO...SELECT`, and `WHERE` clauses in `DELETE` statements. Those statements have additional performance considerations because they combine write operations with the read-oriented query operations.

NDB Cluster supports a join pushdown optimization whereby a qualifying join is sent in its entirety to NDB Cluster data nodes, where it can be distributed among them and executed in parallel. For more information about this optimization, see [Conditions for NDB pushdown joins](#).

The main considerations for optimizing queries are:

- To make a slow `SELECT ... WHERE` query faster, the first thing to check is whether you can add an [index](#). Set up indexes on columns used in the `WHERE` clause, to speed up evaluation, filtering, and the final retrieval of results. To avoid wasted disk space, construct a small set of indexes that speed up many related queries used in your application.

Indexes are especially important for queries that reference different tables, using features such as [joins](#) and [foreign keys](#). You can use the `EXPLAIN` statement to determine which indexes are used for a `SELECT`. See [Section 10.3.1, “How MySQL Uses Indexes”](#) and [Section 10.8.1, “Optimizing Queries with EXPLAIN”](#).

- Isolate and tune any part of the query, such as a function call, that takes excessive time. Depending on how the query is structured, a function could be called once for every row in the result set, or even once for every row in the table, greatly magnifying any inefficiency.
- Minimize the number of [full table scans](#) in your queries, particularly for big tables.
- Keep table statistics up to date by using the `ANALYZE TABLE` statement periodically, so the optimizer has the information needed to construct an efficient execution plan.
- Learn the tuning techniques, indexing techniques, and configuration parameters that are specific to the storage engine for each table. Both [InnoDB](#) and [MyISAM](#) have sets of guidelines for enabling and sustaining high performance in queries. For details, see [Section 10.5.6, “Optimizing InnoDB Queries”](#) and [Section 10.6.1, “Optimizing MyISAM Queries”](#).
- You can optimize single-query transactions for [InnoDB](#) tables, using the technique in [Section 10.5.3, “Optimizing InnoDB Read-Only Transactions”](#).
- Avoid transforming the query in ways that make it hard to understand, especially if the optimizer does some of the same transformations automatically.
- If a performance issue is not easily solved by one of the basic guidelines, investigate the internal details of the specific query by reading the `EXPLAIN` plan and adjusting your indexes, `WHERE` clauses, join clauses, and so on. (When you reach a certain level of expertise, reading the `EXPLAIN` plan might be your first step for every query.)
- Adjust the size and properties of the memory areas that MySQL uses for caching. With efficient use of the [InnoDB buffer pool](#), [MyISAM](#) key cache, and the MySQL query cache, repeated queries run faster because the results are retrieved from memory the second and subsequent times.
- Even for a query that runs fast using the cache memory areas, you might still optimize further so that they require less cache memory, making your application more scalable. Scalability means that your

application can handle more simultaneous users, larger requests, and so on without experiencing a big drop in performance.

- Deal with locking issues, where the speed of your query might be affected by other sessions accessing the tables at the same time.

### 10.2.1.1 WHERE Clause Optimization

This section discusses optimizations that can be made for processing [WHERE](#) clauses. The examples use [SELECT](#) statements, but the same optimizations apply for [WHERE](#) clauses in [DELETE](#) and [UPDATE](#) statements.

#### Note

Because work on the MySQL optimizer is ongoing, not all of the optimizations that MySQL performs are documented here.

You might be tempted to rewrite your queries to make arithmetic operations faster, while sacrificing readability. Because MySQL does similar optimizations automatically, you can often avoid this work, and leave the query in a more understandable and maintainable form. Some of the optimizations performed by MySQL follow:

- Removal of unnecessary parentheses:

```
((a AND b) AND c OR ((a AND b) AND (c AND d)))
-> (a AND b AND c) OR (a AND b AND c AND d)
```

- Constant folding:

```
(a<b AND b=c) AND a=5
-> b>5 AND b=c AND a=5
```

- Constant condition removal:

```
(b>=5 AND b=5) OR (b=6 AND 5=5) OR (b=7 AND 5=6)
-> b=5 OR b=6
```

This takes place during preparation rather than during the optimization phase, which helps in simplification of joins. See [Section 10.2.1.9, “Outer Join Optimization”](#), for further information and examples.

- Constant expressions used by indexes are evaluated only once.
- Comparisons of columns of numeric types with constant values are checked and folded or removed for invalid or out-of-range values:

```
CREATE TABLE t (c TINYINT UNSIGNED NOT NULL);
SELECT * FROM t WHERE c <= 256;
-> SELECT * FROM t WHERE 1;
```

See [Section 10.2.1.14, “Constant-Folding Optimization”](#), for more information.

- [COUNT\( \\*\)](#) on a single table without a [WHERE](#) is retrieved directly from the table information for [MyISAM](#) and [MEMORY](#) tables. This is also done for any [NOT NULL](#) expression when used with only one table.
- Early detection of invalid constant expressions. MySQL quickly detects that some [SELECT](#) statements are impossible and returns no rows.
- [HAVING](#) is merged with [WHERE](#) if you do not use [GROUP BY](#) or aggregate functions ([COUNT\( \)](#), [MIN\( \)](#), and so on).

- For each table in a join, a simpler `WHERE` is constructed to get a fast `WHERE` evaluation for the table and also to skip rows as soon as possible.
- All constant tables are read first before any other tables in the query. A constant table is any of the following:
  - An empty table or a table with one row.
  - A table that is used with a `WHERE` clause on a `PRIMARY KEY` or a `UNIQUE` index, where all index parts are compared to constant expressions and are defined as `NOT NULL`.

All of the following tables are used as constant tables:

```
SELECT * FROM t WHERE primary_key=1;
SELECT * FROM t1,t2
 WHERE t1.primary_key=1 AND t2.primary_key=t1.id;
```

- The best join combination for joining the tables is found by trying all possibilities. If all columns in `ORDER BY` and `GROUP BY` clauses come from the same table, that table is preferred first when joining.
- If there is an `ORDER BY` clause and a different `GROUP BY` clause, or if the `ORDER BY` or `GROUP BY` contains columns from tables other than the first table in the join queue, a temporary table is created.
- If you use the `SQL_SMALL_RESULT` modifier, MySQL uses an in-memory temporary table.
- Each table index is queried, and the best index is used unless the optimizer believes that it is more efficient to use a table scan. At one time, a scan was used based on whether the best index spanned more than 30% of the table, but a fixed percentage no longer determines the choice between using an index or a scan. The optimizer now is more complex and bases its estimate on additional factors such as table size, number of rows, and I/O block size.
- In some cases, MySQL can read rows from the index without even consulting the data file. If all columns used from the index are numeric, only the index tree is used to resolve the query.
- Before each row is output, those that do not match the `HAVING` clause are skipped.

Some examples of queries that are very fast:

```
SELECT COUNT(*) FROM tbl_name;

SELECT MIN(key_part1),MAX(key_part1) FROM tbl_name;

SELECT MAX(key_part2) FROM tbl_name
 WHERE key_part1=constant;

SELECT ... FROM tbl_name
 ORDER BY key_part1,key_part2,... LIMIT 10;

SELECT ... FROM tbl_name
 ORDER BY key_part1 DESC, key_part2 DESC, ... LIMIT 10;
```

MySQL resolves the following queries using only the index tree, assuming that the indexed columns are numeric:

```
SELECT key_part1,key_part2 FROM tbl_name WHERE key_part1=val;

SELECT COUNT(*) FROM tbl_name
 WHERE key_part1=val1 AND key_part2=val2;

SELECT MAX(key_part2) FROM tbl_name GROUP BY key_part1;
```

The following queries use indexing to retrieve the rows in sorted order without a separate sorting pass:

```
SELECT ... FROM tbl_name
ORDER BY key_part1, key_part2, ... ;

SELECT ... FROM tbl_name
ORDER BY key_part1 DESC, key_part2 DESC, ... ;
```

### 10.2.1.2 Range Optimization

The [range](#) access method uses a single index to retrieve a subset of table rows that are contained within one or several index value intervals. It can be used for a single-part or multiple-part index. The following sections describe conditions under which the optimizer uses range access.

- [Range Access Method for Single-Part Indexes](#)
- [Range Access Method for Multiple-Part Indexes](#)
- [Equality Range Optimization of Many-Valued Comparisons](#)
- [Skip Scan Range Access Method](#)
- [Range Optimization of Row Constructor Expressions](#)
- [Limiting Memory Use for Range Optimization](#)

#### Range Access Method for Single-Part Indexes

For a single-part index, index value intervals can be conveniently represented by corresponding conditions in the [WHERE](#) clause, denoted as *range conditions* rather than “intervals.”

The definition of a range condition for a single-part index is as follows:

- For both [BTREE](#) and [HASH](#) indexes, comparison of a key part with a constant value is a range condition when using the `=`, `<=>`, `IN()`, `IS NULL`, or `IS NOT NULL` operators.
- Additionally, for [BTREE](#) indexes, comparison of a key part with a constant value is a range condition when using the `>`, `<`, `>=`, `<=`, `BETWEEN`, `!=`, or `<>` operators, or [LIKE](#) comparisons if the argument to [LIKE](#) is a constant string that does not start with a wildcard character.
- For all index types, multiple range conditions combined with [OR](#) or [AND](#) form a range condition.

“Constant value” in the preceding descriptions means one of the following:

- A constant from the query string
- A column of a [const](#) or [system](#) table from the same join
- The result of an uncorrelated subquery
- Any expression composed entirely from subexpressions of the preceding types

Here are some examples of queries with range conditions in the [WHERE](#) clause:

```
SELECT * FROM t1
WHERE key_col > 1
AND key_col < 10;

SELECT * FROM t1
WHERE key_col = 1
OR key_col IN (15, 18, 20);

SELECT * FROM t1
```

```
WHERE key_col LIKE 'ab%'
OR key_col BETWEEN 'bar' AND 'foo';
```

Some nonconstant values may be converted to constants during the optimizer constant propagation phase.

MySQL tries to extract range conditions from the `WHERE` clause for each of the possible indexes. During the extraction process, conditions that cannot be used for constructing the range condition are dropped, conditions that produce overlapping ranges are combined, and conditions that produce empty ranges are removed.

Consider the following statement, where `key1` is an indexed column and `nonkey` is not indexed:

```
SELECT * FROM t1 WHERE
(key1 < 'abc' AND (key1 LIKE 'abcde%' OR key1 LIKE '%b')) OR
(key1 < 'bar' AND nonkey = 4) OR
(key1 < 'uux' AND key1 > 'z');
```

The extraction process for key `key1` is as follows:

1. Start with original `WHERE` clause:

```
(key1 < 'abc' AND (key1 LIKE 'abcde%' OR key1 LIKE '%b')) OR
(key1 < 'bar' AND nonkey = 4) OR
(key1 < 'uux' AND key1 > 'z')
```

2. Remove `nonkey = 4` and `key1 LIKE '%b'` because they cannot be used for a range scan. The correct way to remove them is to replace them with `TRUE`, so that we do not miss any matching rows when doing the range scan. Replacing them with `TRUE` yields:

```
(key1 < 'abc' AND (key1 LIKE 'abcde%' OR TRUE)) OR
(key1 < 'bar' AND TRUE) OR
(key1 < 'uux' AND key1 > 'z')
```

3. Collapse conditions that are always true or false:

- `(key1 LIKE 'abcde%' OR TRUE)` is always true
- `(key1 < 'uux' AND key1 > 'z')` is always false

Replacing these conditions with constants yields:

```
(key1 < 'abc' AND TRUE) OR (key1 < 'bar' AND TRUE) OR (FALSE)
```

Removing unnecessary `TRUE` and `FALSE` constants yields:

```
(key1 < 'abc') OR (key1 < 'bar')
```

4. Combining overlapping intervals into one yields the final condition to be used for the range scan:

```
(key1 < 'bar')
```

In general (and as demonstrated by the preceding example), the condition used for a range scan is less restrictive than the `WHERE` clause. MySQL performs an additional check to filter out rows that satisfy the range condition but not the full `WHERE` clause.

The range condition extraction algorithm can handle nested `AND/OR` constructs of arbitrary depth, and its output does not depend on the order in which conditions appear in `WHERE` clause.

MySQL does not support merging multiple ranges for the `range` access method for spatial indexes. To work around this limitation, you can use a `UNION` with identical `SELECT` statements, except that you put each spatial predicate in a different `SELECT`.

## Range Access Method for Multiple-Part Indexes

Range conditions on a multiple-part index are an extension of range conditions for a single-part index. A range condition on a multiple-part index restricts index rows to lie within one or several key tuple intervals. Key tuple intervals are defined over a set of key tuples, using ordering from the index.

For example, consider a multiple-part index defined as `key1(key_part1, key_part2, key_part3)`, and the following set of key tuples listed in key order:

<code>key_part1</code>	<code>key_part2</code>	<code>key_part3</code>
NULL	1	'abc'
NULL	1	'xyz'
NULL	2	'foo'
1	1	'abc'
1	1	'xyz'
1	2	'abc'
2	1	'aaa'

The condition `key_part1 = 1` defines this interval:

```
(1,-inf,-inf) <= (key_part1,key_part2,key_part3) < (1,+inf,+inf)
```

The interval covers the 4th, 5th, and 6th tuples in the preceding data set and can be used by the range access method.

By contrast, the condition `key_part3 = 'abc'` does not define a single interval and cannot be used by the range access method.

The following descriptions indicate how range conditions work for multiple-part indexes in greater detail.

- For [HASH](#) indexes, each interval containing identical values can be used. This means that the interval can be produced only for conditions in the following form:

```
key_part1 cmp const1
AND key_part2 cmp const2
AND ...
AND key_partN cmp constN;
```

Here, `const1`, `const2`, ... are constants, `cmp` is one of the `=`, `<=>`, or `IS NULL` comparison operators, and the conditions cover all index parts. (That is, there are `N` conditions, one for each part of an `N`-part index.) For example, the following is a range condition for a three-part [HASH](#) index:

```
key_part1 = 1 AND key_part2 IS NULL AND key_part3 = 'foo'
```

For the definition of what is considered to be a constant, see [Range Access Method for Single-Part Indexes](#).

- For a [BTREE](#) index, an interval might be usable for conditions combined with `AND`, where each condition compares a key part with a constant value using `=`, `<=>`, `IS NULL`, `>`, `<`, `>=`, `<=`, `!=`, `<>`, `BETWEEN`, or `LIKE 'pattern'` (where `'pattern'` does not start with a wildcard). An interval can be used as long as it is possible to determine a single key tuple containing all rows that match the condition (or two intervals if `<>` or `!=` is used).

The optimizer attempts to use additional key parts to determine the interval as long as the comparison operator is `=`, `<=>`, or `IS NULL`. If the operator is `>`, `<`, `>=`, `<=`, `!=`, `<>`, `BETWEEN`, or `LIKE`, the optimizer uses it but considers no more key parts. For the following expression, the optimizer uses `=` from the first comparison. It also uses `>=` from the second comparison but considers no further key parts and does not use the third comparison for interval construction:

```
key_part1 = 'foo' AND key_part2 >= 10 AND key_part3 > 10
```

The single interval is:

```
('foo',10,-inf) < (key_part1,key_part2,key_part3) < ('foo',+inf,+inf)
```

It is possible that the created interval contains more rows than the initial condition. For example, the preceding interval includes the value ('foo', 11, 0), which does not satisfy the original condition.

- If conditions that cover sets of rows contained within intervals are combined with [OR](#), they form a condition that covers a set of rows contained within the union of their intervals. If the conditions are combined with [AND](#), they form a condition that covers a set of rows contained within the intersection of their intervals. For example, for this condition on a two-part index:

```
(key_part1 = 1 AND key_part2 < 2) OR (key_part1 > 5)
```

The intervals are:

```
(1,-inf) < (key_part1,key_part2) < (1,2)
(5,-inf) < (key_part1,key_part2)
```

In this example, the interval on the first line uses one key part for the left bound and two key parts for the right bound. The interval on the second line uses only one key part. The [key\\_len](#) column in the [EXPLAIN](#) output indicates the maximum length of the key prefix used.

In some cases, [key\\_len](#) may indicate that a key part was used, but that might be not what you would expect. Suppose that [key\\_part1](#) and [key\\_part2](#) can be [NULL](#). Then the [key\\_len](#) column displays two key part lengths for the following condition:

```
key_part1 >= 1 AND key_part2 < 2
```

But, in fact, the condition is converted to this:

```
key_part1 >= 1 AND key_part2 IS NOT NULL
```

For a description of how optimizations are performed to combine or eliminate intervals for range conditions on a single-part index, see [Range Access Method for Single-Part Indexes](#). Analogous steps are performed for range conditions on multiple-part indexes.

## Equality Range Optimization of Many-Valued Comparisons

Consider these expressions, where [col\\_name](#) is an indexed column:

```
col_name IN(val1, ..., valN)
col_name = val1 OR ... OR col_name = valN
```

Each expression is true if [col\\_name](#) is equal to any of several values. These comparisons are equality range comparisons (where the “range” is a single value). The optimizer estimates the cost of reading qualifying rows for equality range comparisons as follows:

- If there is a unique index on [col\\_name](#), the row estimate for each range is 1 because at most one row can have the given value.
- Otherwise, any index on [col\\_name](#) is nonunique and the optimizer can estimate the row count for each range using dives into the index or index statistics.

With index dives, the optimizer makes a dive at each end of a range and uses the number of rows in the range as the estimate. For example, the expression [col\\_name IN \(10, 20, 30\)](#) has three equality

ranges and the optimizer makes two dives per range to generate a row estimate. Each pair of dives yields an estimate of the number of rows that have the given value.

Index dives provide accurate row estimates, but as the number of comparison values in the expression increases, the optimizer takes longer to generate a row estimate. Use of index statistics is less accurate than index dives but permits faster row estimation for large value lists.

The `eq_range_index_dive_limit` system variable enables you to configure the number of values at which the optimizer switches from one row estimation strategy to the other. To permit use of index dives for comparisons of up to  $N$  equality ranges, set `eq_range_index_dive_limit` to  $N + 1$ . To disable use of statistics and always use index dives regardless of  $N$ , set `eq_range_index_dive_limit` to 0.

To update table index statistics for best estimates, use `ANALYZE TABLE`.

Prior to MySQL 9.1, there is no way of skipping the use of index dives to estimate index usefulness, except by using the `eq_range_index_dive_limit` system variable. In MySQL 9.1, index dive skipping is possible for queries that satisfy all these conditions:

- The query is for a single table, not a join on multiple tables.
- A single-index `FORCE INDEX` index hint is present. The idea is that if index use is forced, there is nothing to be gained from the additional overhead of performing dives into the index.
- The index is nonunique and not a `FULLTEXT` index.
- No subquery is present.
- No `DISTINCT`, `GROUP BY`, or `ORDER BY` clause is present.

For `EXPLAIN FOR CONNECTION`, the output changes as follows if index dives are skipped:

- For traditional output, the `rows` and `filtered` values are `NULL`.
- For JSON output, `rows_examined_per_scan` and `rows_produced_per_join` do not appear, `skip_index_dive_due_to_force` is `true`, and cost calculations are not accurate.

Without `FOR CONNECTION`, `EXPLAIN` output does not change when index dives are skipped.

After execution of a query for which index dives are skipped, the corresponding row in the Information Schema `OPTIMIZER_TRACE` table contains an `index_dives_for_range_access` value of `skipped_due_to_force_index`.

## Skip Scan Range Access Method

Consider the following scenario:

```
CREATE TABLE t1 (f1 INT NOT NULL, f2 INT NOT NULL, PRIMARY KEY(f1, f2));
INSERT INTO t1 VALUES
 (1,1), (1,2), (1,3), (1,4), (1,5),
 (2,1), (2,2), (2,3), (2,4), (2,5);
INSERT INTO t1 SELECT f1, f2 + 5 FROM t1;
INSERT INTO t1 SELECT f1, f2 + 10 FROM t1;
INSERT INTO t1 SELECT f1, f2 + 20 FROM t1;
INSERT INTO t1 SELECT f1, f2 + 40 FROM t1;
ANALYZE TABLE t1;

EXPLAIN SELECT f1, f2 FROM t1 WHERE f2 > 40;
```

To execute this query, MySQL can choose an index scan to fetch all rows (the index includes all columns to be selected), then apply the `f2 > 40` condition from the `WHERE` clause to produce the final result set.

A range scan is more efficient than a full index scan, but cannot be used in this case because there is no condition on `f1`, the first index column. The optimizer can perform multiple range scans, one for each value of `f1`, using a method called Skip Scan that is similar to Loose Index Scan (see [Section 10.2.1.17, "GROUP BY Optimization"](#)):

1. Skip between distinct values of the first index part, `f1` (the index prefix).
2. Perform a subrange scan on each distinct prefix value for the `f2 > 40` condition on the remaining index part.

For the data set shown earlier, the algorithm operates like this:

1. Get the first distinct value of the first key part (`f1 = 1`).
2. Construct the range based on the first and second key parts (`f1 = 1 AND f2 > 40`).
3. Perform a range scan.
4. Get the next distinct value of the first key part (`f1 = 2`).
5. Construct the range based on the first and second key parts (`f1 = 2 AND f2 > 40`).
6. Perform a range scan.

Using this strategy decreases the number of accessed rows because MySQL skips the rows that do not qualify for each constructed range. This Skip Scan access method is applicable under the following conditions:

- Table T has at least one compound index with key parts of the form `([A_1, ..., A_k], B_1, ..., B_m, C [, D_1, ..., D_n])`. Key parts A and D may be empty, but B and C must be nonempty.
- The query references only one table.
- The query does not use `GROUP BY` or `DISTINCT`.
- The query references only columns in the index.
- The predicates on `A_1, ..., A_k` must be equality predicates and they must be constants. This includes the `IN()` operator.
- The query must be a conjunctive query; that is, an `AND` of `OR` conditions: `(cond1(key_part1) OR cond2(key_part1)) AND (cond1(key_part2) OR ...) AND ...`
- There must be a range condition on C.
- Conditions on D columns are permitted. Conditions on D must be in conjunction with the range condition on C.

Use of Skip Scan is indicated in `EXPLAIN` output as follows:

- `Using index for skip scan` in the `Extra` column indicates that the loose index Skip Scan access method is used.
- If the index can be used for Skip Scan, the index should be visible in the `possible_keys` column.

Use of Skip Scan is indicated in optimizer trace output by a `"skip scan"` element of this form:

```
"skip_scan_range": {
```

```

"type": "skip_scan",
"index": index_used_for_skip_scan,
"key_parts_used_for_access": [key_parts_used_for_access],
"range": [range]
}

```

You may also see a `"best_skip_scan_summary"` element. If Skip Scan is chosen as the best range access variant, a `"chosen_range_access_summary"` is written. If Skip Scan is chosen as the overall best access method, a `"best_access_path"` element is present.

Use of Skip Scan is subject to the value of the `skip_scan` flag of the `optimizer_switch` system variable. See [Section 10.9.2, “Switchable Optimizations”](#). By default, this flag is `on`. To disable it, set `skip_scan` to `off`.

In addition to using the `optimizer_switch` system variable to control optimizer use of Skip Scan session-wide, MySQL supports optimizer hints to influence the optimizer on a per-statement basis. See [Section 10.9.3, “Optimizer Hints”](#).

## Range Optimization of Row Constructor Expressions

The optimizer is able to apply the range scan access method to queries of this form:

```
SELECT ... FROM t1 WHERE (col_1, col_2) IN (('a', 'b'), ('c', 'd'));
```

Previously, for range scans to be used, it was necessary to write the query as:

```
SELECT ... FROM t1 WHERE (col_1 = 'a' AND col_2 = 'b')
OR (col_1 = 'c' AND col_2 = 'd');
```

For the optimizer to use a range scan, queries must satisfy these conditions:

- Only `IN()` predicates are used, not `NOT IN()`.
- On the left side of the `IN()` predicate, the row constructor contains only column references.
- On the right side of the `IN()` predicate, row constructors contain only runtime constants, which are either literals or local column references that are bound to constants during execution.
- On the right side of the `IN()` predicate, there is more than one row constructor.

For more information about the optimizer and row constructors, see [Section 10.2.1.22, “Row Constructor Expression Optimization”](#)

## Limiting Memory Use for Range Optimization

To control the memory available to the range optimizer, use the `range_optimizer_max_mem_size` system variable:

- A value of 0 means “no limit.”
- With a value greater than 0, the optimizer tracks the memory consumed when considering the range access method. If the specified limit is about to be exceeded, the range access method is abandoned and other methods, including a full table scan, are considered instead. This could be less optimal. If this happens, the following warning occurs (where *N* is the current `range_optimizer_max_mem_size` value):

```
Warning 3170 Memory capacity of N bytes for
```

'range\_optimizer\_max\_mem\_size' exceeded. Range optimization was not done for this query.

- For `UPDATE` and `DELETE` statements, if the optimizer falls back to a full table scan and the `sql_safe_updates` system variable is enabled, an error occurs rather than a warning because, in effect, no key is used to determine which rows to modify. For more information, see [Using Safe-Updates Mode \(--safe-updates\)](#).

For individual queries that exceed the available range optimization memory and for which the optimizer falls back to less optimal plans, increasing the `range_optimizer_max_mem_size` value may improve performance.

To estimate the amount of memory needed to process a range expression, use these guidelines:

- For a simple query such as the following, where there is one candidate key for the range access method, each predicate combined with `OR` uses approximately 230 bytes:

```
SELECT COUNT(*) FROM t
WHERE a=1 OR a=2 OR a=3 OR ... a=N;
```

- Similarly for a query such as the following, each predicate combined with `AND` uses approximately 125 bytes:

```
SELECT COUNT(*) FROM t
WHERE a=1 AND b=1 AND c=1 ... N;
```

- For a query with `IN( )` predicates:

```
SELECT COUNT(*) FROM t
WHERE a IN (1,2, ..., M) AND b IN (1,2, ..., N);
```

Each literal value in an `IN( )` list counts as a predicate combined with `OR`. If there are two `IN( )` lists, the number of predicates combined with `OR` is the product of the number of literal values in each list. Thus, the number of predicates combined with `OR` in the preceding case is  $M \times N$ .

### 10.2.1.3 Index Merge Optimization

The *Index Merge* access method retrieves rows with multiple `range` scans and merges their results into one. This access method merges index scans from a single table only, not scans across multiple tables. The merge can produce unions, intersections, or unions-of-intersections of its underlying scans.

Example queries for which Index Merge may be used:

```
SELECT * FROM tbl_name WHERE key1 = 10 OR key2 = 20;

SELECT * FROM tbl_name
WHERE (key1 = 10 OR key2 = 20) AND non_key = 30;

SELECT * FROM t1, t2
WHERE (t1.key1 IN (1,2) OR t1.key2 LIKE 'value%')
AND t2.key1 = t1.some_col1;

SELECT * FROM t1, t2
WHERE t1.key1 = 1
AND (t2.key1 = t1.some_col1 OR t2.key2 = t1.some_col2);
```

#### Note

The Index Merge optimization algorithm has the following known limitations:

- If your query has a complex `WHERE` clause with deep `AND/OR` nesting and MySQL does not choose the optimal plan, try distributing terms using the following identity transformations:

```
(x AND y) OR z => (x OR z) AND (y OR z)
(x OR y) AND z => (x AND z) OR (y AND z)
```

- Index Merge is not applicable to full-text indexes.

In `EXPLAIN` output, the Index Merge method appears as `index_merge` in the `type` column. In this case, the `key` column contains a list of indexes used, and `key_len` contains a list of the longest key parts for those indexes.

The Index Merge access method has several algorithms, which are displayed in the `Extra` field of `EXPLAIN` output:

- `Using intersect(...)`
- `Using union(...)`
- `Using sort_union(...)`

The following sections describe these algorithms in greater detail. The optimizer chooses between different possible Index Merge algorithms and other access methods based on cost estimates of the various available options.

- [Index Merge Intersection Access Algorithm](#)
- [Index Merge Union Access Algorithm](#)
- [Index Merge Sort-Union Access Algorithm](#)
- [Influencing Index Merge Optimization](#)

## Index Merge Intersection Access Algorithm

This access algorithm is applicable when a `WHERE` clause is converted to several range conditions on different keys combined with `AND`, and each condition is one of the following:

- An `N`-part expression of this form, where the index has exactly `N` parts (that is, all index parts are covered):

```
key_part1 = const1 AND key_part2 = const2 ... AND key_partN = constN
```

- Any range condition over the primary key of an `InnoDB` table.

Examples:

```
SELECT * FROM innodb_table
WHERE primary_key < 10 AND key_coll = 20;

SELECT * FROM tbl_name
WHERE key1_part1 = 1 AND key1_part2 = 2 AND key2 = 2;
```

The Index Merge intersection algorithm performs simultaneous scans on all used indexes and produces the intersection of row sequences that it receives from the merged index scans.

If all columns used in the query are covered by the used indexes, full table rows are not retrieved (`EXPLAIN` output contains `Using index` in `Extra` field in this case). Here is an example of such a query:

```
SELECT COUNT(*) FROM t1 WHERE key1 = 1 AND key2 = 1;
```

If the used indexes do not cover all columns used in the query, full rows are retrieved only when the range conditions for all used keys are satisfied.

If one of the merged conditions is a condition over the primary key of an [InnoDB](#) table, it is not used for row retrieval, but is used to filter out rows retrieved using other conditions.

## Index Merge Union Access Algorithm

The criteria for this algorithm are similar to those for the Index Merge intersection algorithm. The algorithm is applicable when the table's [WHERE](#) clause is converted to several range conditions on different keys combined with [OR](#), and each condition is one of the following:

- An *N*-part expression of this form, where the index has exactly *N* parts (that is, all index parts are covered):

```
key_part1 = const1 OR key_part2 = const2 ... OR key_partN = constN
```

- Any range condition over a primary key of an [InnoDB](#) table.
- A condition for which the Index Merge intersection algorithm is applicable.

Examples:

```
SELECT * FROM t1
 WHERE key1 = 1 OR key2 = 2 OR key3 = 3;

SELECT * FROM innodb_table
 WHERE (key1 = 1 AND key2 = 2)
 OR (key3 = 'foo' AND key4 = 'bar') AND key5 = 5;
```

## Index Merge Sort-Union Access Algorithm

This access algorithm is applicable when the [WHERE](#) clause is converted to several range conditions combined by [OR](#), but the Index Merge union algorithm is not applicable.

Examples:

```
SELECT * FROM tbl_name
 WHERE key_col1 < 10 OR key_col2 < 20;

SELECT * FROM tbl_name
 WHERE (key_col1 > 10 OR key_col2 = 20) AND nonkey_col = 30;
```

The difference between the sort-union algorithm and the union algorithm is that the sort-union algorithm must first fetch row IDs for all rows and sort them before returning any rows.

## Influencing Index Merge Optimization

Use of Index Merge is subject to the value of the [index\\_merge](#), [index\\_merge\\_intersection](#), [index\\_merge\\_union](#), and [index\\_merge\\_sort\\_union](#) flags of the [optimizer\\_switch](#) system variable. See [Section 10.9.2, “Switchable Optimizations”](#). By default, all those flags are [on](#). To enable only certain algorithms, set [index\\_merge](#) to [off](#), and enable only such of the others as should be permitted.

In addition to using the [optimizer\\_switch](#) system variable to control optimizer use of the Index Merge algorithms session-wide, MySQL supports optimizer hints to influence the optimizer on a per-statement basis. See [Section 10.9.3, “Optimizer Hints”](#).

### 10.2.1.4 Hash Join Optimization

By default, MySQL employs hash joins whenever possible. It is possible to control whether hash joins are employed using one of the [BNL](#) and [NO\\_BNL](#) optimizer hints, or by setting [block\\_nested\\_loop=on](#) or [block\\_nested\\_loop=off](#) as part of the setting for the `optimizer_switch` server system variable.

MySQL employs a hash join for any query for which each join has an equi-join condition, and in which there are no indexes that can be applied to any join conditions, such as this one:

```
SELECT *
 FROM t1
 JOIN t2
 ON t1.c1=t2.c1;
```

A hash join can also be used when there are one or more indexes that can be used for single-table predicates.

In the example just shown and the remaining examples in this section, we assume that the three tables [t1](#), [t2](#), and [t3](#) have been created using the following statements:

```
CREATE TABLE t1 (c1 INT, c2 INT);
CREATE TABLE t2 (c1 INT, c2 INT);
CREATE TABLE t3 (c1 INT, c2 INT);
```

You can see that a hash join is being employed by using [EXPLAIN](#), like this:

```
mysql> EXPLAIN
-> SELECT * FROM t1
-> JOIN t2 ON t1.c1=t2.c1\G
***** 1. row *****
 id: 1
 select_type: SIMPLE
 table: t1
 partitions: NULL
 type: ALL
possible_keys: NULL
 key: NULL
 key_len: NULL
 ref: NULL
 rows: 1
 filtered: 100.00
 Extra: NULL
***** 2. row *****
 id: 1
 select_type: SIMPLE
 table: t2
 partitions: NULL
 type: ALL
possible_keys: NULL
 key: NULL
 key_len: NULL
 ref: NULL
 rows: 1
 filtered: 100.00
 Extra: Using where; Using join buffer (hash join)
```

[EXPLAIN ANALYZE](#) also displays information about hash joins used.

The hash join is used for queries involving multiple joins as well, as long as at least one join condition for each pair of tables is an equi-join, like the query shown here:

```
SELECT * FROM t1
 JOIN t2 ON (t1.c1 = t2.c1 AND t1.c2 < t2.c2)
```

```
JOIN t3 ON (t2.c1 = t3.c1);
```

In cases like the one just shown, which makes use of an inner join, any extra conditions which are not equi-joins are applied as filters after the join is executed. (For outer joins, such as left joins, semijoins, and antijoins, they are printed as part of the join.) This can be seen here in the output of [EXPLAIN](#):

```
mysql> EXPLAIN FORMAT=TREE
-> SELECT *
-> FROM t1
-> JOIN t2
-> ON (t1.c1 = t2.c1 AND t1.c2 < t2.c2)
-> JOIN t3
-> ON (t2.c1 = t3.c1)\G
***** 1. row *****
EXPLAIN: -> Inner hash join (t3.c1 = t1.c1) (cost=1.05 rows=1)
-> Table scan on t3 (cost=0.35 rows=1)
-> Hash
-> Filter: (t1.c2 < t2.c2) (cost=0.70 rows=1)
-> Inner hash join (t2.c1 = t1.c1) (cost=0.70 rows=1)
-> Table scan on t2 (cost=0.35 rows=1)
-> Hash
-> Table scan on t1 (cost=0.35 rows=1)
```

As also can be seen from the output just shown, multiple hash joins can be (and are) used for joins having multiple equi-join conditions.

A hash join is used even if any pair of joined tables does not have at least one equi-join condition, as shown here:

```
mysql> EXPLAIN FORMAT=TREE
-> SELECT * FROM t1
-> JOIN t2 ON (t1.c1 = t2.c1)
-> JOIN t3 ON (t2.c1 < t3.c1)\G
***** 1. row *****
EXPLAIN: -> Filter: (t1.c1 < t3.c1) (cost=1.05 rows=1)
-> Inner hash join (no condition) (cost=1.05 rows=1)
-> Table scan on t3 (cost=0.35 rows=1)
-> Hash
-> Inner hash join (t2.c1 = t1.c1) (cost=0.70 rows=1)
-> Table scan on t2 (cost=0.35 rows=1)
-> Hash
-> Table scan on t1 (cost=0.35 rows=1)
```

(Additional examples are provided later in this section.)

A hash join is also applied for a Cartesian product—that is, when no join condition is specified, as shown here:

```
mysql> EXPLAIN FORMAT=TREE
-> SELECT *
-> FROM t1
-> JOIN t2
-> WHERE t1.c2 > 50\G
***** 1. row *****
EXPLAIN: -> Inner hash join (cost=0.70 rows=1)
-> Table scan on t2 (cost=0.35 rows=1)
-> Hash
-> Filter: (t1.c2 > 50) (cost=0.35 rows=1)
-> Table scan on t1 (cost=0.35 rows=1)
```

It is not necessary for the join to contain at least one equi-join condition in order for a hash join to be used. This means that the types of queries which can be optimized using hash joins include those in the following list (with examples):

- *Inner non-equi-join:*

```
mysql> EXPLAIN FORMAT=TREE SELECT * FROM t1 JOIN t2 ON t1.c1 < t2.c1\G
***** 1. row *****
EXPLAIN: -> Filter: (t1.c1 < t2.c1) (cost=4.70 rows=12)
 -> Inner hash join (no condition) (cost=4.70 rows=12)
 -> Table scan on t2 (cost=0.08 rows=6)
 -> Hash
 -> Table scan on t1 (cost=0.85 rows=6)
```

- *Semijoin:*

```
mysql> EXPLAIN FORMAT=TREE SELECT * FROM t1
-> WHERE t1.c1 IN (SELECT t2.c2 FROM t2)\G
***** 1. row *****
EXPLAIN: -> Hash semijoin (t2.c2 = t1.c1) (cost=0.70 rows=1)
 -> Table scan on t1 (cost=0.35 rows=1)
 -> Hash
 -> Table scan on t2 (cost=0.35 rows=1)
```

- *Antijoin:*

```
mysql> EXPLAIN FORMAT=TREE SELECT * FROM t2
-> WHERE NOT EXISTS (SELECT * FROM t1 WHERE t1.c1 = t2.c1)\G
***** 1. row *****
EXPLAIN: -> Hash antijoin (t1.c1 = t2.c1) (cost=0.70 rows=1)
 -> Table scan on t2 (cost=0.35 rows=1)
 -> Hash
 -> Table scan on t1 (cost=0.35 rows=1)

1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Note
Code: 1276
Message: Field or reference 't3.t2.c1' of SELECT #2 was resolved in SELECT #1
```

- *Left outer join:*

```
mysql> EXPLAIN FORMAT=TREE SELECT * FROM t1 LEFT JOIN t2 ON t1.c1 = t2.c1\G
***** 1. row *****
EXPLAIN: -> Left hash join (t2.c1 = t1.c1) (cost=0.70 rows=1)
 -> Table scan on t1 (cost=0.35 rows=1)
 -> Hash
 -> Table scan on t2 (cost=0.35 rows=1)
```

- *Right outer join* (observe that MySQL rewrites all right outer joins as left outer joins):

```
mysql> EXPLAIN FORMAT=TREE SELECT * FROM t1 RIGHT JOIN t2 ON t1.c1 = t2.c1\G
***** 1. row *****
EXPLAIN: -> Left hash join (t1.c1 = t2.c1) (cost=0.70 rows=1)
 -> Table scan on t2 (cost=0.35 rows=1)
 -> Hash
 -> Table scan on t1 (cost=0.35 rows=1)
```

By default, MySQL employs hash joins whenever possible. It is possible to control whether hash joins are employed using one of the [BNL](#) and [NO\\_BNL](#) optimizer hints.

Memory usage by hash joins can be controlled using the [join\\_buffer\\_size](#) system variable; a hash join cannot use more memory than this amount. When the memory required for a hash join exceeds the amount available, MySQL handles this by using files on disk. If this happens, you should be aware that the join may not succeed if a hash join cannot fit into memory and it creates more files than set for [open\\_files\\_limit](#). To avoid such problems, make either of the following changes:

- Increase `join_buffer_size` so that the hash join does not spill over to disk.
- Increase `open_files_limit`.

Join buffers for hash joins are allocated incrementally; thus, you can set `join_buffer_size` higher without small queries allocating very large amounts of RAM, but outer joins allocate the entire buffer. Hash joins are used for outer joins (including antijoins and semijoins) as well, so this is no longer an issue.

### 10.2.1.5 Engine Condition Pushdown Optimization

This optimization improves the efficiency of direct comparisons between a nonindexed column and a constant. In such cases, the condition is “pushed down” to the storage engine for evaluation. This optimization can be used only by the `NDB` storage engine.

For NDB Cluster, this optimization can eliminate the need to send nonmatching rows over the network between the cluster's data nodes and the MySQL server that issued the query, and can speed up queries where it is used by a factor of 5 to 10 times over cases where condition pushdown could be but is not used.

Suppose that an NDB Cluster table is defined as follows:

```
CREATE TABLE t1 (
 a INT,
 b INT,
 KEY(a)
) ENGINE=NDB;
```

Engine condition pushdown can be used with queries such as the one shown here, which includes a comparison between a nonindexed column and a constant:

```
SELECT a, b FROM t1 WHERE b = 10;
```

The use of engine condition pushdown can be seen in the output of `EXPLAIN`:

```
mysql> EXPLAIN SELECT a, b FROM t1 WHERE b = 10\G
***** 1. row *****
 id: 1
 select_type: SIMPLE
 table: t1
 type: ALL
possible_keys: NULL
 key: NULL
 key_len: NULL
 ref: NULL
 rows: 10
 Extra: Using where with pushed condition
```

However, engine condition pushdown *cannot* be used with the following query:

```
SELECT a,b FROM t1 WHERE a = 10;
```

Engine condition pushdown is not applicable here because an index exists on column `a`. (An index access method would be more efficient and so would be chosen in preference to condition pushdown.)

Engine condition pushdown may also be employed when an indexed column is compared with a constant using a `>` or `<` operator:

```
mysql> EXPLAIN SELECT a, b FROM t1 WHERE a < 2\G
***** 1. row *****
 id: 1
 select_type: SIMPLE
 table: t1
```

```

 type: range
possible_keys: a
 key: a
 key_len: 5
 ref: NULL
 rows: 2
Extra: Using where with pushed condition

```

Other supported comparisons for engine condition pushdown include the following:

- `column [NOT] LIKE pattern`

`pattern` must be a string literal containing the pattern to be matched; for syntax, see [Section 14.8.1, “String Comparison Functions and Operators”](#).

- `column IS [NOT] NULL`
- `column IN (value_list)`

Each item in the `value_list` must be a constant, literal value.

- `column BETWEEN constant1 AND constant2`

`constant1` and `constant2` must each be a constant, literal value.

In all of the cases in the preceding list, it is possible for the condition to be converted into the form of one or more direct comparisons between a column and a constant.

Engine condition pushdown is enabled by default. To disable it at server startup, set the `optimizer_switch` system variable's `engine_condition_pushdown` flag to `off`. For example, in a `my.cnf` file, use these lines:

```

[mysqld]
optimizer_switch=engine_condition_pushdown=off

```

At runtime, disable condition pushdown like this:

```

SET optimizer_switch='engine_condition_pushdown=off';

```

**Limitations.** Engine condition pushdown is subject to the following limitations:

- Engine condition pushdown is supported only by the [NDB](#) storage engine.
- In NDB 9.1, columns can be compared with one another as long as they are of exactly the same type, including the same signedness, length, character set, precision, and scale, where these are applicable.
- Columns used in comparisons cannot be of any of the [BLOB](#) or [TEXT](#) types. This exclusion extends to [JSON](#), [BIT](#), and [ENUM](#) columns as well.
- A string value to be compared with a column must use the same collation as the column.
- Joins are not directly supported; conditions involving multiple tables are pushed separately where possible. Use extended [EXPLAIN](#) output to determine which conditions are actually pushed down. See [Section 10.8.3, “Extended EXPLAIN Output Format”](#).

Previously, engine condition pushdown was limited to terms referring to column values from the same table to which the condition was being pushed. In NDB 9.1, column values from tables earlier in the query plan can also be referred to from pushed conditions. This reduces the number of rows which must be handled by the SQL node during join processing. Filtering can be also performed in parallel in the LDM threads,

rather than in a single `mysqld` process. This has the potential to improve performance of queries by a significant margin.

`NDB` can push an outer join using a scan if there are no unpushable conditions on any table used in the same join nest, or on any table in join nests above it on which it depends. This is also true for a semijoin, provided the optimization strategy employed is `firstMatch` (see [Optimizing IN and EXISTS Subquery Predicates with Semijoin Transformations](#)).

Join algorithms cannot be combined with referring columns from previous tables in the following two situations:

1. When any of the referred previous tables are in a join buffer. In this case, each row retrieved from the scan-filtered table is matched against every row in the buffer. This means that there is no single specific row from which column values can be fetched from when generating the scan filter.
2. When the column originates from a child operation in a pushed join. This is because rows referenced from ancestor operations in the join have not yet been retrieved when the scan filter is generated.

Columns from ancestor tables in a join can be pushed down, provided that they meet the requirements listed previously. An example of such a query, using the table `t1` created previously, is shown here:

```
mysql> EXPLAIN
-> SELECT * FROM t1 AS x
-> LEFT JOIN t1 AS y
-> ON x.a=0 AND y.b>=3\G
***** 1. row *****
 id: 1
 select_type: SIMPLE
 table: x
 partitions: p0,p1
 type: ALL
possible_keys: NULL
 key: NULL
 key_len: NULL
 ref: NULL
 rows: 4
 filtered: 100.00
 Extra: NULL
***** 2. row *****
 id: 1
 select_type: SIMPLE
 table: y
 partitions: p0,p1
 type: ALL
possible_keys: NULL
 key: NULL
 key_len: NULL
 ref: NULL
 rows: 4
 filtered: 100.00
 Extra: Using where; Using pushed condition (`test`.`y`.`b` >= 3); Using join buffer (hash join)
2 rows in set, 2 warnings (0.00 sec)
```

### 10.2.1.6 Index Condition Pushdown Optimization

Index Condition Pushdown (ICP) is an optimization for the case where MySQL retrieves rows from a table using an index. Without ICP, the storage engine traverses the index to locate rows in the base table and returns them to the MySQL server which evaluates the `WHERE` condition for the rows. With ICP enabled, and if parts of the `WHERE` condition can be evaluated by using only columns from the index, the MySQL server pushes this part of the `WHERE` condition down to the storage engine. The storage engine then evaluates the pushed index condition by using the index entry and only if this is satisfied is the row read

from the table. ICP can reduce the number of times the storage engine must access the base table and the number of times the MySQL server must access the storage engine.

Applicability of the Index Condition Pushdown optimization is subject to these conditions:

- ICP is used for the `range`, `ref`, `eq_ref`, and `ref_or_null` access methods when there is a need to access full table rows.
- ICP can be used for `InnoDB` and `MyISAM` tables, including partitioned `InnoDB` and `MyISAM` tables.
- For `InnoDB` tables, ICP is used only for secondary indexes. The goal of ICP is to reduce the number of full-row reads and thereby reduce I/O operations. For `InnoDB` clustered indexes, the complete record is already read into the `InnoDB` buffer. Using ICP in this case does not reduce I/O.
- ICP is not supported with secondary indexes created on virtual generated columns. `InnoDB` supports secondary indexes on virtual generated columns.
- Conditions that refer to subqueries cannot be pushed down.
- Conditions that refer to stored functions cannot be pushed down. Storage engines cannot invoke stored functions.
- Triggered conditions cannot be pushed down. (For information about triggered conditions, see [Section 10.2.2.3, “Optimizing Subqueries with the EXISTS Strategy”](#).)
- Conditions cannot be pushed down to derived tables containing references to system variables.

To understand how this optimization works, first consider how an index scan proceeds when Index Condition Pushdown is not used:

1. Get the next row, first by reading the index tuple, and then by using the index tuple to locate and read the full table row.
2. Test the part of the `WHERE` condition that applies to this table. Accept or reject the row based on the test result.

Using Index Condition Pushdown, the scan proceeds like this instead:

1. Get the next row's index tuple (but not the full table row).
2. Test the part of the `WHERE` condition that applies to this table and can be checked using only index columns. If the condition is not satisfied, proceed to the index tuple for the next row.
3. If the condition is satisfied, use the index tuple to locate and read the full table row.
4. Test the remaining part of the `WHERE` condition that applies to this table. Accept or reject the row based on the test result.

`EXPLAIN` output shows `Using index condition` in the `Extra` column when Index Condition Pushdown is used. It does not show `Using index` because that does not apply when full table rows must be read.

Suppose that a table contains information about people and their addresses and that the table has an index defined as `INDEX (zipcode, lastname, firstname)`. If we know a person's `zipcode` value but are not sure about the last name, we can search like this:

```
SELECT * FROM people
 WHERE zipcode='95054'
 AND lastname LIKE '%etrunia%'
```

```
AND address LIKE '%Main Street%';
```

MySQL can use the index to scan through people with `zipcode='95054'`. The second part (`lastname LIKE '%etrunia%'`) cannot be used to limit the number of rows that must be scanned, so without Index Condition Pushdown, this query must retrieve full table rows for all people who have `zipcode='95054'`.

With Index Condition Pushdown, MySQL checks the `lastname LIKE '%etrunia%'` part before reading the full table row. This avoids reading full rows corresponding to index tuples that match the `zipcode` condition but not the `lastname` condition.

Index Condition Pushdown is enabled by default. It can be controlled with the `optimizer_switch` system variable by setting the `index_condition_pushdown` flag:

```
SET optimizer_switch = 'index_condition_pushdown=off';
SET optimizer_switch = 'index_condition_pushdown=on';
```

See [Section 10.9.2, “Switchable Optimizations”](#).

### 10.2.1.7 Nested-Loop Join Algorithms

MySQL executes joins between tables using a nested-loop algorithm or variations on it.

- [Nested-Loop Join Algorithm](#)

#### Nested-Loop Join Algorithm

A simple nested-loop join (NLJ) algorithm reads rows from the first table in a loop one at a time, passing each row to a nested loop that processes the next table in the join. This process is repeated as many times as there remain tables to be joined.

Assume that a join between three tables `t1`, `t2`, and `t3` is to be executed using the following join types:

Table	Join Type
<code>t1</code>	range
<code>t2</code>	ref
<code>t3</code>	ALL

If a simple NLJ algorithm is used, the join is processed like this:

```
for each row in t1 matching range {
 for each row in t2 matching reference key {
 for each row in t3 {
 if row satisfies join conditions, send to client
 }
 }
}
```

Because the NLJ algorithm passes rows one at a time from outer loops to inner loops, it typically reads tables processed in the inner loops many times.

### 10.2.1.8 Nested Join Optimization

The syntax for expressing joins permits nested joins. The following discussion refers to the join syntax described in [Section 15.2.13.2, “JOIN Clause”](#).

The syntax of `table_factor` is extended in comparison with the SQL Standard. The latter accepts only `table_reference`, not a list of them inside a pair of parentheses. This is a conservative extension if we consider each comma in a list of `table_reference` items as equivalent to an inner join. For example:

```
SELECT * FROM t1 LEFT JOIN (t2, t3, t4)
 ON (t2.a=t1.a AND t3.b=t1.b AND t4.c=t1.c)
```

Is equivalent to:

```
SELECT * FROM t1 LEFT JOIN (t2 CROSS JOIN t3 CROSS JOIN t4)
ON (t2.a=t1.a AND t3.b=t1.b AND t4.c=t1.c)
```

In MySQL, `CROSS JOIN` is syntactically equivalent to `INNER JOIN`; they can replace each other. In standard SQL, they are not equivalent. `INNER JOIN` is used with an `ON` clause; `CROSS JOIN` is used otherwise.

In general, parentheses can be ignored in join expressions containing only inner join operations. Consider this join expression:

```
t1 LEFT JOIN (t2 LEFT JOIN t3 ON t2.b=t3.b OR t2.b IS NULL)
ON t1.a=t2.a
```

After removing parentheses and grouping operations to the left, that join expression transforms into this expression:

```
(t1 LEFT JOIN t2 ON t1.a=t2.a) LEFT JOIN t3
ON t2.b=t3.b OR t2.b IS NULL
```

Yet, the two expressions are not equivalent. To see this, suppose that the tables `t1`, `t2`, and `t3` have the following state:

- Table `t1` contains rows (1), (2)
- Table `t2` contains row (1,101)
- Table `t3` contains row (101)

In this case, the first expression returns a result set including the rows (1,1,101,101), (2,NULL,NULL,NULL), whereas the second expression returns the rows (1,1,101,101), (2,NULL,NULL,101):

```
mysql> SELECT *
FROM t1
LEFT JOIN
(t2 LEFT JOIN t3 ON t2.b=t3.b OR t2.b IS NULL)
ON t1.a=t2.a;
```

a	a	b	b
1	1	101	101
2	NULL	NULL	NULL

```
mysql> SELECT *
FROM (t1 LEFT JOIN t2 ON t1.a=t2.a)
LEFT JOIN t3
ON t2.b=t3.b OR t2.b IS NULL;
```

a	a	b	b
1	1	101	101
2	NULL	NULL	101

In the following example, an outer join operation is used together with an inner join operation:

```
t1 LEFT JOIN (t2, t3) ON t1.a=t2.a
```

That expression cannot be transformed into the following expression:

```
t1 LEFT JOIN t2 ON t1.a=t2.a, t3
```

For the given table states, the two expressions return different sets of rows:

```
mysql> SELECT *
 FROM t1 LEFT JOIN (t2, t3) ON t1.a=t2.a;
```

a	a	b	b
1	1	101	101
2	NULL	NULL	NULL

```
mysql> SELECT *
 FROM t1 LEFT JOIN t2 ON t1.a=t2.a, t3;
```

a	a	b	b
1	1	101	101
2	NULL	NULL	101

Therefore, if we omit parentheses in a join expression with outer join operators, we might change the result set for the original expression.

More exactly, we cannot ignore parentheses in the right operand of the left outer join operation and in the left operand of a right join operation. In other words, we cannot ignore parentheses for the inner table expressions of outer join operations. Parentheses for the other operand (operand for the outer table) can be ignored.

The following expression:

```
(t1,t2) LEFT JOIN t3 ON P(t2.b,t3.b)
```

Is equivalent to this expression for any tables `t1,t2,t3` and any condition `P` over attributes `t2.b` and `t3.b`:

```
t1, t2 LEFT JOIN t3 ON P(t2.b,t3.b)
```

Whenever the order of execution of join operations in a join expression (*joined\_table*) is not from left to right, we talk about nested joins. Consider the following queries:

```
SELECT * FROM t1 LEFT JOIN (t2 LEFT JOIN t3 ON t2.b=t3.b) ON t1.a=t2.a
 WHERE t1.a > 1
```

```
SELECT * FROM t1 LEFT JOIN (t2, t3) ON t1.a=t2.a
 WHERE (t2.b=t3.b OR t2.b IS NULL) AND t1.a > 1
```

Those queries are considered to contain these nested joins:

```
t2 LEFT JOIN t3 ON t2.b=t3.b
t2, t3
```

In the first query, the nested join is formed with a left join operation. In the second query, it is formed with an inner join operation.

In the first query, the parentheses can be omitted: The grammatical structure of the join expression dictates the same order of execution for join operations. For the second query, the parentheses cannot be omitted, although the join expression here can be interpreted unambiguously without them. In our extended syntax, the parentheses in `(t2, t3)` of the second query are required, although theoretically the query could be parsed without them: We still would have unambiguous syntactical structure for the query because `LEFT JOIN` and `ON` play the role of the left and right delimiters for the expression `(t2,t3)`.

The preceding examples demonstrate these points:

- For join expressions involving only inner joins (and not outer joins), parentheses can be removed and joins evaluated left to right. In fact, tables can be evaluated in any order.
- The same is not true, in general, for outer joins or for outer joins mixed with inner joins. Removal of parentheses may change the result.

Queries with nested outer joins are executed in the same pipeline manner as queries with inner joins. More exactly, a variation of the nested-loop join algorithm is exploited. Recall the algorithm by which the nested-loop join executes a query (see [Section 10.2.1.7, “Nested-Loop Join Algorithms”](#)). Suppose that a join query over 3 tables *T1*, *T2*, *T3* has this form:

```
SELECT * FROM T1 INNER JOIN T2 ON P1(T1,T2)
 INNER JOIN T3 ON P2(T2,T3)
WHERE P(T1,T2,T3)
```

Here, *P1(T1,T2)* and *P2(T2,T3)* are some join conditions (on expressions), whereas *P(T1,T2,T3)* is a condition over columns of tables *T1*, *T2*, *T3*.

The nested-loop join algorithm would execute this query in the following manner:

```
FOR each row t1 in T1 {
 FOR each row t2 in T2 such that P1(t1,t2) {
 FOR each row t3 in T3 such that P2(t2,t3) {
 IF P(t1,t2,t3) {
 t:=t1||t2||t3; OUTPUT t;
 }
 }
 }
}
```

The notation *t1||t2||t3* indicates a row constructed by concatenating the columns of rows *t1*, *t2*, and *t3*. In some of the following examples, *NULL* where a table name appears means a row in which *NULL* is used for each column of that table. For example, *t1||t2||NULL* indicates a row constructed by concatenating the columns of rows *t1* and *t2*, and *NULL* for each column of *t3*. Such a row is said to be *NULL-complemented*.

Now consider a query with nested outer joins:

```
SELECT * FROM T1 LEFT JOIN
 (T2 LEFT JOIN T3 ON P2(T2,T3))
 ON P1(T1,T2)
WHERE P(T1,T2,T3)
```

For this query, modify the nested-loop pattern to obtain:

```
FOR each row t1 in T1 {
 BOOL f1:=FALSE;
 FOR each row t2 in T2 such that P1(t1,t2) {
 BOOL f2:=FALSE;
 FOR each row t3 in T3 such that P2(t2,t3) {
 IF P(t1,t2,t3) {
 t:=t1||t2||t3; OUTPUT t;
 }
 f2=TRUE;
 }
 f1=TRUE;
 }
 IF (!f2) {
 IF P(t1,t2,NULL) {
 t:=t1||t2||NULL; OUTPUT t;
 }
 }
}
```

```

 }
 f1=TRUE;
 }
}
IF (!f1) {
 IF P(t1,NULL,NULL) {
 t:=t1||NULL||NULL; OUTPUT t;
 }
}
}

```

In general, for any nested loop for the first inner table in an outer join operation, a flag is introduced that is turned off before the loop and is checked after the loop. The flag is turned on when for the current row from the outer table a match from the table representing the inner operand is found. If at the end of the loop cycle the flag is still off, no match has been found for the current row of the outer table. In this case, the row is complemented by `NULL` values for the columns of the inner tables. The result row is passed to the final check for the output or into the next nested loop, but only if the row satisfies the join condition of all embedded outer joins.

In the example, the outer join table expressed by the following expression is embedded:

```
(T2 LEFT JOIN T3 ON P2(T2,T3))
```

For the query with inner joins, the optimizer could choose a different order of nested loops, such as this one:

```

FOR each row t3 in T3 {
 FOR each row t2 in T2 such that P2(t2,t3) {
 FOR each row t1 in T1 such that P1(t1,t2) {
 IF P(t1,t2,t3) {
 t:=t1||t2||t3; OUTPUT t;
 }
 }
 }
}

```

For queries with outer joins, the optimizer can choose only such an order where loops for outer tables precede loops for inner tables. Thus, for our query with outer joins, only one nesting order is possible. For the following query, the optimizer evaluates two different nestings. In both nestings, `T1` must be processed in the outer loop because it is used in an outer join. `T2` and `T3` are used in an inner join, so that join must be processed in the inner loop. However, because the join is an inner join, `T2` and `T3` can be processed in either order.

```

SELECT * T1 LEFT JOIN (T2,T3) ON P1(T1,T2) AND P2(T1,T3)
WHERE P(T1,T2,T3)

```

One nesting evaluates `T2`, then `T3`:

```

FOR each row t1 in T1 {
 BOOL f1:=FALSE;
 FOR each row t2 in T2 such that P1(t1,t2) {
 FOR each row t3 in T3 such that P2(t1,t3) {
 IF P(t1,t2,t3) {
 t:=t1||t2||t3; OUTPUT t;
 }
 }
 f1:=TRUE
 }
}
IF (!f1) {
 IF P(t1,NULL,NULL) {
 t:=t1||NULL||NULL; OUTPUT t;
 }
}
}

```

```
}
```

The other nesting evaluates **T3**, then **T2**:

```
FOR each row t1 in T1 {
 BOOL f1:=FALSE;
 FOR each row t3 in T3 such that P2(t1,t3) {
 FOR each row t2 in T2 such that P1(t1,t2) {
 IF P(t1,t2,t3) {
 t:=t1||t2||t3; OUTPUT t;
 }
 f1:=TRUE
 }
 }
 IF (!f1) {
 IF P(t1,NULL,NULL) {
 t:=t1||NULL||NULL; OUTPUT t;
 }
 }
}
```

When discussing the nested-loop algorithm for inner joins, we omitted some details whose impact on the performance of query execution may be huge. We did not mention so-called “pushed-down” conditions. Suppose that our **WHERE** condition **P(T1,T2,T3)** can be represented by a conjunctive formula:

```
P(T1,T2,T2) = C1(T1) AND C2(T2) AND C3(T3).
```

In this case, MySQL actually uses the following nested-loop algorithm for the execution of the query with inner joins:

```
FOR each row t1 in T1 such that C1(t1) {
 FOR each row t2 in T2 such that P1(t1,t2) AND C2(t2) {
 FOR each row t3 in T3 such that P2(t2,t3) AND C3(t3) {
 IF P(t1,t2,t3) {
 t:=t1||t2||t3; OUTPUT t;
 }
 }
 }
}
```

You see that each of the conjuncts **C1(T1)**, **C2(T2)**, **C3(T3)** are pushed out of the most inner loop to the most outer loop where it can be evaluated. If **C1(T1)** is a very restrictive condition, this condition pushdown may greatly reduce the number of rows from table **T1** passed to the inner loops. As a result, the execution time for the query may improve immensely.

For a query with outer joins, the **WHERE** condition is to be checked only after it has been found that the current row from the outer table has a match in the inner tables. Thus, the optimization of pushing conditions out of the inner nested loops cannot be applied directly to queries with outer joins. Here we must introduce conditional pushed-down predicates guarded by the flags that are turned on when a match has been encountered.

Recall this example with outer joins:

```
P(T1,T2,T3)=C1(T1) AND C(T2) AND C3(T3)
```

For that example, the nested-loop algorithm using guarded pushed-down conditions looks like this:

```
FOR each row t1 in T1 such that C1(t1) {
 BOOL f1:=FALSE;
 FOR each row t2 in T2
 such that P1(t1,t2) AND (f1?C2(t2):TRUE) {
 BOOL f2:=FALSE;
 FOR each row t3 in T3
```

```

such that P2(t2,t3) AND (f1&&f2?C3(t3):TRUE) {
 IF (f1&&f2?TRUE:(C2(t2) AND C3(t3))) {
 t:=t1||t2||t3; OUTPUT t;
 }
 f2=TRUE;
 f1=TRUE;
}
IF (!f2) {
 IF (f1?TRUE:C2(t2) && P(t1,t2,NULL)) {
 t:=t1||t2||NULL; OUTPUT t;
 }
 f1=TRUE;
}
}
IF (!f1 && P(t1,NULL,NULL)) {
 t:=t1||NULL||NULL; OUTPUT t;
}
}

```

In general, pushed-down predicates can be extracted from join conditions such as `P1(T1,T2)` and `P(T2,T3)`. In this case, a pushed-down predicate is guarded also by a flag that prevents checking the predicate for the `NULL`-complemented row generated by the corresponding outer join operation.

Access by key from one inner table to another in the same nested join is prohibited if it is induced by a predicate from the `WHERE` condition.

### 10.2.1.9 Outer Join Optimization

Outer joins include `LEFT JOIN` and `RIGHT JOIN`.

MySQL implements an `A LEFT JOIN B join_specification` as follows:

- Table `B` is set to depend on table `A` and all tables on which `A` depends.
- Table `A` is set to depend on all tables (except `B`) that are used in the `LEFT JOIN` condition.
- The `LEFT JOIN` condition is used to decide how to retrieve rows from table `B`. (In other words, any condition in the `WHERE` clause is not used.)
- All standard join optimizations are performed, with the exception that a table is always read after all tables on which it depends. If there is a circular dependency, an error occurs.
- All standard `WHERE` optimizations are performed.
- If there is a row in `A` that matches the `WHERE` clause, but there is no row in `B` that matches the `ON` condition, an extra `B` row is generated with all columns set to `NULL`.
- If you use `LEFT JOIN` to find rows that do not exist in some table and you have the following test: `col_name IS NULL` in the `WHERE` part, where `col_name` is a column that is declared as `NOT NULL`, MySQL stops searching for more rows (for a particular key combination) after it has found one row that matches the `LEFT JOIN` condition.

The `RIGHT JOIN` implementation is analogous to that of `LEFT JOIN` with the table roles reversed. Right joins are converted to equivalent left joins, as described in [Section 10.2.1.10, “Outer Join Simplification”](#).

For a `LEFT JOIN`, if the `WHERE` condition is always false for the generated `NULL` row, the `LEFT JOIN` is changed to an inner join. For example, the `WHERE` clause would be false in the following query if `t2.column1` were `NULL`:

```
SELECT * FROM t1 LEFT JOIN t2 ON (column1) WHERE t2.column2=5;
```

Therefore, it is safe to convert the query to an inner join:

```
SELECT * FROM t1, t2 WHERE t2.column2=5 AND t1.column1=t2.column1;
```

Trivial `WHERE` conditions arising from constant literal expressions are removed during preparation, rather than at a later stage in optimization, by which time joins have already been simplified. Earlier removal of trivial conditions allows the optimizer to convert outer joins to inner joins; this can result in improved plans for queries with outer joins containing trivial conditions in the `WHERE` clause, such as this one:

```
SELECT * FROM t1 LEFT JOIN t2 ON condition_1 WHERE condition_2 OR 0 = 1
```

The optimizer now sees during preparation that `0 = 1` is always false, making `OR 0 = 1` redundant, and removes it, leaving this:

```
SELECT * FROM t1 LEFT JOIN t2 ON condition_1 where condition_2
```

Now the optimizer can rewrite the query as an inner join, like this:

```
SELECT * FROM t1 JOIN t2 WHERE condition_1 AND condition_2
```

Now the optimizer can use table `t2` before table `t1` if doing so would result in a better query plan. To provide a hint about the table join order, use optimizer hints; see [Section 10.9.3, “Optimizer Hints”](#). Alternatively, use `STRAIGHT_JOIN`; see [Section 15.2.13, “SELECT Statement”](#). However, `STRAIGHT_JOIN` may prevent indexes from being used because it disables semijoin transformations; see [Optimizing IN and EXISTS Subquery Predicates with Semijoin Transformations](#).

### 10.2.1.10 Outer Join Simplification

Table expressions in the `FROM` clause of a query are simplified in many cases.

At the parser stage, queries with right outer join operations are converted to equivalent queries containing only left join operations. In the general case, the conversion is performed such that this right join:

```
(T1, ...) RIGHT JOIN (T2, ...) ON P(T1, ..., T2, ...)
```

Becomes this equivalent left join:

```
(T2, ...) LEFT JOIN (T1, ...) ON P(T1, ..., T2, ...)
```

All inner join expressions of the form `T1 INNER JOIN T2 ON P(T1,T2)` are replaced by the list `T1,T2`, `P(T1,T2)` being joined as a conjunct to the `WHERE` condition (or to the join condition of the embedding join, if there is any).

When the optimizer evaluates plans for outer join operations, it takes into consideration only plans where, for each such operation, the outer tables are accessed before the inner tables. The optimizer choices are limited because only such plans enable outer joins to be executed using the nested-loop algorithm.

Consider a query of this form, where `R(T2)` greatly narrows the number of matching rows from table `T2`:

```
SELECT * T1 FROM T1
 LEFT JOIN T2 ON P1(T1,T2)
 WHERE P(T1,T2) AND R(T2)
```

If the query is executed as written, the optimizer has no choice but to access the less-restricted table `T1` before the more-restricted table `T2`, which may produce a very inefficient execution plan.

Instead, MySQL converts the query to a query with no outer join operation if the `WHERE` condition is null-rejected. (That is, it converts the outer join to an inner join.) A condition is said to be null-rejected for an

outer join operation if it evaluates to **FALSE** or **UNKNOWN** for any **NULL**-complemented row generated for the operation.

Thus, for this outer join:

```
T1 LEFT JOIN T2 ON T1.A=T2.A
```

Conditions such as these are null-rejected because they cannot be true for any **NULL**-complemented row (with **T2** columns set to **NULL**):

```
T2.B IS NOT NULL
T2.B > 3
T2.C <= T1.C
T2.B < 2 OR T2.C > 1
```

Conditions such as these are not null-rejected because they might be true for a **NULL**-complemented row:

```
T2.B IS NULL
T1.B < 3 OR T2.B IS NOT NULL
T1.B < 3 OR T2.B > 3
```

The general rules for checking whether a condition is null-rejected for an outer join operation are simple:

- It is of the form **A IS NOT NULL**, where **A** is an attribute of any of the inner tables
- It is a predicate containing a reference to an inner table that evaluates to **UNKNOWN** when one of its arguments is **NULL**
- It is a conjunction containing a null-rejected condition as a conjunct
- It is a disjunction of null-rejected conditions

A condition can be null-rejected for one outer join operation in a query and not null-rejected for another. In this query, the **WHERE** condition is null-rejected for the second outer join operation but is not null-rejected for the first one:

```
SELECT * FROM T1 LEFT JOIN T2 ON T2.A=T1.A
 LEFT JOIN T3 ON T3.B=T1.B
WHERE T3.C > 0
```

If the **WHERE** condition is null-rejected for an outer join operation in a query, the outer join operation is replaced by an inner join operation.

For example, in the preceding query, the second outer join is null-rejected and can be replaced by an inner join:

```
SELECT * FROM T1 LEFT JOIN T2 ON T2.A=T1.A
 INNER JOIN T3 ON T3.B=T1.B
WHERE T3.C > 0
```

For the original query, the optimizer evaluates only plans compatible with the single table-access order **T1, T2, T3**. For the rewritten query, it additionally considers the access order **T3, T1, T2**.

A conversion of one outer join operation may trigger a conversion of another. Thus, the query:

```
SELECT * FROM T1 LEFT JOIN T2 ON T2.A=T1.A
 LEFT JOIN T3 ON T3.B=T2.B
WHERE T3.C > 0
```

Is first converted to the query:

```
SELECT * FROM T1 LEFT JOIN T2 ON T2.A=T1.A
```

```
INNER JOIN T3 ON T3.B=T2.B
WHERE T3.C > 0
```

Which is equivalent to the query:

```
SELECT * FROM (T1 LEFT JOIN T2 ON T2.A=T1.A), T3
WHERE T3.C > 0 AND T3.B=T2.B
```

The remaining outer join operation can also be replaced by an inner join because the condition `T3.B=T2.B` is null-rejected. This results in a query with no outer joins at all:

```
SELECT * FROM (T1 INNER JOIN T2 ON T2.A=T1.A), T3
WHERE T3.C > 0 AND T3.B=T2.B
```

Sometimes the optimizer succeeds in replacing an embedded outer join operation, but cannot convert the embedding outer join. The following query:

```
SELECT * FROM T1 LEFT JOIN
 (T2 LEFT JOIN T3 ON T3.B=T2.B)
 ON T2.A=T1.A
WHERE T3.C > 0
```

Is converted to:

```
SELECT * FROM T1 LEFT JOIN
 (T2 INNER JOIN T3 ON T3.B=T2.B)
 ON T2.A=T1.A
WHERE T3.C > 0
```

That can be rewritten only to the form still containing the embedding outer join operation:

```
SELECT * FROM T1 LEFT JOIN
 (T2,T3)
 ON (T2.A=T1.A AND T3.B=T2.B)
WHERE T3.C > 0
```

Any attempt to convert an embedded outer join operation in a query must take into account the join condition for the embedding outer join together with the `WHERE` condition. In this query, the `WHERE` condition is not null-rejected for the embedded outer join, but the join condition of the embedding outer join `T2.A=T1.A AND T3.C=T1.C` is null-rejected:

```
SELECT * FROM T1 LEFT JOIN
 (T2 LEFT JOIN T3 ON T3.B=T2.B)
 ON T2.A=T1.A AND T3.C=T1.C
WHERE T3.D > 0 OR T1.D > 0
```

Consequently, the query can be converted to:

```
SELECT * FROM T1 LEFT JOIN
 (T2, T3)
 ON T2.A=T1.A AND T3.C=T1.C AND T3.B=T2.B
WHERE T3.D > 0 OR T1.D > 0
```

## 10.2.1.11 Multi-Range Read Optimization

Reading rows using a range scan on a secondary index can result in many random disk accesses to the base table when the table is large and not stored in the storage engine's cache. With the Disk-Sweep Multi-Range Read (MRR) optimization, MySQL tries to reduce the number of random disk access for range scans by first scanning the index only and collecting the keys for the relevant rows. Then the keys are sorted and finally the rows are retrieved from the base table using the order of the primary key. The motivation for Disk-sweep MRR is to reduce the number of random disk accesses and instead achieve a more sequential scan of the base table data.

The Multi-Range Read optimization provides these benefits:

- MRR enables data rows to be accessed sequentially rather than in random order, based on index tuples. The server obtains a set of index tuples that satisfy the query conditions, sorts them according to data row ID order, and uses the sorted tuples to retrieve data rows in order. This makes data access more efficient and less expensive.
- MRR enables batch processing of requests for key access for operations that require access to data rows through index tuples, such as range index scans and equi-joins that use an index for the join attribute. MRR iterates over a sequence of index ranges to obtain qualifying index tuples. As these results accumulate, they are used to access the corresponding data rows. It is not necessary to acquire all index tuples before starting to read data rows.

The MRR optimization is not supported with secondary indexes created on virtual generated columns. [InnoDB](#) supports secondary indexes on virtual generated columns.

The following scenarios illustrate when MRR optimization can be advantageous:

Scenario A: MRR can be used for [InnoDB](#) and [MyISAM](#) tables for index range scans and equi-join operations.

1. A portion of the index tuples are accumulated in a buffer.
2. The tuples in the buffer are sorted by their data row ID.
3. Data rows are accessed according to the sorted index tuple sequence.

Scenario B: MRR can be used for [NDB](#) tables for multiple-range index scans or when performing an equi-join by an attribute.

1. A portion of ranges, possibly single-key ranges, is accumulated in a buffer on the central node where the query is submitted.
2. The ranges are sent to the execution nodes that access data rows.
3. The accessed rows are packed into packages and sent back to the central node.
4. The received packages with data rows are placed in a buffer.
5. Data rows are read from the buffer.

When MRR is used, the [Extra](#) column in [EXPLAIN](#) output shows [Using MRR](#).

[InnoDB](#) and [MyISAM](#) do not use MRR if full table rows need not be accessed to produce the query result. This is the case if results can be produced entirely on the basis on information in the index tuples (through a [covering index](#)); MRR provides no benefit.

Two [optimizer\\_switch](#) system variable flags provide an interface to the use of MRR optimization. The [mrr](#) flag controls whether MRR is enabled. If [mrr](#) is enabled ([on](#)), the [mrr\\_cost\\_based](#) flag controls whether the optimizer attempts to make a cost-based choice between using and not using MRR ([on](#)) or uses MRR whenever possible ([off](#)). By default, [mrr](#) is [on](#) and [mrr\\_cost\\_based](#) is [on](#). See [Section 10.9.2, “Switchable Optimizations”](#).

For MRR, a storage engine uses the value of the [read\\_rnd\\_buffer\\_size](#) system variable as a guideline for how much memory it can allocate for its buffer. The engine uses up to [read\\_rnd\\_buffer\\_size](#) bytes and determines the number of ranges to process in a single pass.

### 10.2.1.12 Block Nested-Loop and Batched Key Access Joins

In MySQL, a Batched Key Access (BKA) Join algorithm is available that uses both index access to the joined table and a join buffer. The BKA algorithm supports inner join, outer join, and semijoin operations, including nested outer joins. Benefits of BKA include improved join performance due to more efficient table scanning. Also, the Block Nested-Loop (BNL) Join algorithm previously used only for inner joins is extended and can be employed for outer join and semijoin operations, including nested outer joins.

The following sections discuss the join buffer management that underlies the extension of the original BNL algorithm, the extended BNL algorithm, and the BKA algorithm. For information about semijoin strategies, see [Optimizing IN and EXISTS Subquery Predicates with Semijoin Transformations](#)

- [Join Buffer Management for Block Nested-Loop and Batched Key Access Algorithms](#)
- [Block Nested-Loop Algorithm for Outer Joins and Semijoins](#)
- [Batched Key Access Joins](#)
- [Optimizer Hints for Block Nested-Loop and Batched Key Access Algorithms](#)

## Join Buffer Management for Block Nested-Loop and Batched Key Access Algorithms

MySQL can employ join buffers to execute not only inner joins without index access to the inner table, but also outer joins and semijoins that appear after subquery flattening. Moreover, a join buffer can be effectively used when there is an index access to the inner table.

The join buffer management code slightly more efficiently utilizes join buffer space when storing the values of the interesting row columns: No additional bytes are allocated in buffers for a row column if its value is `NULL`, and the minimum number of bytes is allocated for any value of the `VARCHAR` type.

The code supports two types of buffers, regular and incremental. Suppose that join buffer `B1` is employed to join tables `t1` and `t2` and the result of this operation is joined with table `t3` using join buffer `B2`:

- A regular join buffer contains columns from each join operand. If `B2` is a regular join buffer, each row `r` put into `B2` is composed of the columns of a row `r1` from `B1` and the interesting columns of a matching row `r2` from table `t3`.
- An incremental join buffer contains only columns from rows of the table produced by the second join operand. That is, it is incremental to a row from the first operand buffer. If `B2` is an incremental join buffer, it contains the interesting columns of the row `r2` together with a link to the row `r1` from `B1`.

Incremental join buffers are always incremental relative to a join buffer from an earlier join operation, so the buffer from the first join operation is always a regular buffer. In the example just given, the buffer `B1` used to join tables `t1` and `t2` must be a regular buffer.

Each row of the incremental buffer used for a join operation contains only the interesting columns of a row from the table to be joined. These columns are augmented with a reference to the interesting columns of the matched row from the table produced by the first join operand. Several rows in the incremental buffer can refer to the same row `r` whose columns are stored in the previous join buffers insofar as all these rows match row `r`.

Incremental buffers enable less frequent copying of columns from buffers used for previous join operations. This provides a savings in buffer space because in the general case a row produced by the first join operand can be matched by several rows produced by the second join operand. It is unnecessary to make several copies of a row from the first operand. Incremental buffers also provide a savings in processing time due to the reduction in copying time.

The `block_nested_loop` flag of the `optimizer_switch` system variable controls hash joins.

The `batched_key_access` flag controls how the optimizer uses the Batched Key Access join algorithms.

By default, `block_nested_loop` is `on` and `batched_key_access` is `off`. See [Section 10.9.2, “Switchable Optimizations”](#). Optimizer hints may also be applied; see [Optimizer Hints for Block Nested-Loop and Batched Key Access Algorithms](#).

For information about semijoin strategies, see [Optimizing IN and EXISTS Subquery Predicates with Semijoin Transformations](#)

## Block Nested-Loop Algorithm for Outer Joins and Semijoins

The original implementation of the MySQL BNL algorithm was extended to support outer join and semijoin operations (and was later superseded by the hash join algorithm; see [Section 10.2.1.4, “Hash Join Optimization”](#)).

When these operations are executed with a join buffer, each row put into the buffer is supplied with a match flag.

If an outer join operation is executed using a join buffer, each row of the table produced by the second operand is checked for a match against each row in the join buffer. When a match is found, a new extended row is formed (the original row plus columns from the second operand) and sent for further extensions by the remaining join operations. In addition, the match flag of the matched row in the buffer is enabled. After all rows of the table to be joined have been examined, the join buffer is scanned. Each row from the buffer that does not have its match flag enabled is extended by `NULL` complements (`NULL` values for each column in the second operand) and sent for further extensions by the remaining join operations.

The `block_nested_loop` flag of the `optimizer_switch` system variable controls hash joins.

See [Section 10.9.2, “Switchable Optimizations”](#), for more information. Optimizer hints may also be applied; see [Optimizer Hints for Block Nested-Loop and Batched Key Access Algorithms](#).

In `EXPLAIN` output, use of BNL for a table is signified when the `Extra` value contains `Using join buffer (Block Nested Loop)` and the `type` value is `ALL`, `index`, or `range`.

For information about semijoin strategies, see [Optimizing IN and EXISTS Subquery Predicates with Semijoin Transformations](#)

## Batched Key Access Joins

MySQL implements a method of joining tables called the Batched Key Access (BKA) join algorithm. BKA can be applied when there is an index access to the table produced by the second join operand. Like the BNL join algorithm, the BKA join algorithm employs a join buffer to accumulate the interesting columns of the rows produced by the first operand of the join operation. Then the BKA algorithm builds keys to access the table to be joined for all rows in the buffer and submits these keys in a batch to the database engine for index lookups. The keys are submitted to the engine through the Multi-Range Read (MRR) interface (see [Section 10.2.1.11, “Multi-Range Read Optimization”](#)). After submission of the keys, the MRR engine functions perform lookups in the index in an optimal way, fetching the rows of the joined table found by these keys, and starts feeding the BKA join algorithm with matching rows. Each matching row is coupled with a reference to a row in the join buffer.

When BKA is used, the value of `join_buffer_size` defines how large the batch of keys is in each request to the storage engine. The larger the buffer, the more sequential access is made to the right hand table of a join operation, which can significantly improve performance.

For BKA to be used, the `batched_key_access` flag of the `optimizer_switch` system variable must be set to `on`. BKA uses MRR, so the `mrr` flag must also be `on`. Currently, the cost estimation for MRR is too

pessimistic. Hence, it is also necessary for `mrr_cost_based` to be `off` for BKA to be used. The following setting enables BKA:

```
mysql> SET optimizer_switch='mrr=on,mrr_cost_based=off,batched_key_access=on';
```

There are two scenarios by which MRR functions execute:

- The first scenario is used for conventional disk-based storage engines such as [InnoDB](#) and [MyISAM](#). For these engines, usually the keys for all rows from the join buffer are submitted to the MRR interface at once. Engine-specific MRR functions perform index lookups for the submitted keys, get row IDs (or primary keys) from them, and then fetch rows for all these selected row IDs one by one by request from BKA algorithm. Every row is returned with an association reference that enables access to the matched row in the join buffer. The rows are fetched by the MRR functions in an optimal way: They are fetched in the row ID (primary key) order. This improves performance because reads are in disk order rather than random order.
- The second scenario is used for remote storage engines such as [NDB](#). A package of keys for a portion of rows from the join buffer, together with their associations, is sent by a MySQL Server (SQL node) to MySQL Cluster data nodes. In return, the SQL node receives a package (or several packages) of matching rows coupled with corresponding associations. The BKA join algorithm takes these rows and builds new joined rows. Then a new set of keys is sent to the data nodes and the rows from the returned packages are used to build new joined rows. The process continues until the last keys from the join buffer are sent to the data nodes, and the SQL node has received and joined all rows matching these keys. This improves performance because fewer key-bearing packages sent by the SQL node to the data nodes means fewer round trips between it and the data nodes to perform the join operation.

With the first scenario, a portion of the join buffer is reserved to store row IDs (primary keys) selected by index lookups and passed as a parameter to the MRR functions.

There is no special buffer to store keys built for rows from the join buffer. Instead, a function that builds the key for the next row in the buffer is passed as a parameter to the MRR functions.

In [EXPLAIN](#) output, use of BKA for a table is signified when the `Extra` value contains `Using join buffer (Batched Key Access)` and the `type` value is `ref` or `eq_ref`.

### Optimizer Hints for Block Nested-Loop and Batched Key Access Algorithms

In addition to using the `optimizer_switch` system variable to control optimizer use of the BNL and BKA algorithms session-wide, MySQL supports optimizer hints to influence the optimizer on a per-statement basis. See [Section 10.9.3, “Optimizer Hints”](#).

To use a BNL or BKA hint to enable join buffering for any inner table of an outer join, join buffering must be enabled for all inner tables of the outer join.

#### 10.2.1.13 Condition Filtering

In join processing, prefix rows are those rows passed from one table in a join to the next. In general, the optimizer attempts to put tables with low prefix counts early in the join order to keep the number of row combinations from increasing rapidly. To the extent that the optimizer can use information about conditions on rows selected from one table and passed to the next, the more accurately it can compute row estimates and choose the best execution plan.

Without condition filtering, the prefix row count for a table is based on the estimated number of rows selected by the `WHERE` clause according to whichever access method the optimizer chooses. Condition filtering enables the optimizer to use other relevant conditions in the `WHERE` clause not taken into account

by the access method, and thus improve its prefix row count estimates. For example, even though there might be an index-based access method that can be used to select rows from the current table in a join, there might also be additional conditions for the table in the `WHERE` clause that can filter (further restrict) the estimate for qualifying rows passed to the next table.

A condition contributes to the filtering estimate only if:

- It refers to the current table.
- It depends on a constant value or values from earlier tables in the join sequence.
- It was not already taken into account by the access method.

In `EXPLAIN` output, the `rows` column indicates the row estimate for the chosen access method, and the `filtered` column reflects the effect of condition filtering. `filtered` values are expressed as percentages. The maximum value is 100, which means no filtering of rows occurred. Values decreasing from 100 indicate increasing amounts of filtering.

The prefix row count (the number of rows estimated to be passed from the current table in a join to the next) is the product of the `rows` and `filtered` values. That is, the prefix row count is the estimated row count, reduced by the estimated filtering effect. For example, if `rows` is 1000 and `filtered` is 20%, condition filtering reduces the estimated row count of 1000 to a prefix row count of  $1000 \times 20\% = 1000 \times .2 = 200$ .

Consider the following query:

```
SELECT *
FROM employee JOIN department ON employee.dept_no = department.dept_no
WHERE employee.first_name = 'John'
AND employee.hire_date BETWEEN '2018-01-01' AND '2018-06-01';
```

Suppose that the data set has these characteristics:

- The `employee` table has 1024 rows.
- The `department` table has 12 rows.
- Both tables have an index on `dept_no`.
- The `employee` table has an index on `first_name`.
- 8 rows satisfy this condition on `employee.first_name`:

```
employee.first_name = 'John'
```

- 150 rows satisfy this condition on `employee.hire_date`:

```
employee.hire_date BETWEEN '2018-01-01' AND '2018-06-01'
```

- 1 row satisfies both conditions:

```
employee.first_name = 'John'
AND employee.hire_date BETWEEN '2018-01-01' AND '2018-06-01'
```

Without condition filtering, `EXPLAIN` produces output like this:

id	table	type	possible_keys	key	ref	rows	filtered
1	employee	ref	name,h_date,dept	name	const	8	100.00

1	department	eq_ref	PRIMARY	PRIMARY	dept_no	1	100.00
---	------------	--------	---------	---------	---------	---	--------

For `employee`, the access method on the `name` index picks up the 8 rows that match a name of 'John'. No filtering is done (`filtered` is 100%), so all rows are prefix rows for the next table: The prefix row count is `rows × filtered = 8 × 100% = 8`.

With condition filtering, the optimizer additionally takes into account conditions from the `WHERE` clause not taken into account by the access method. In this case, the optimizer uses heuristics to estimate a filtering effect of 16.31% for the `BETWEEN` condition on `employee.hire_date`. As a result, `EXPLAIN` produces output like this:

id	table	type	possible_keys	key	ref	rows	filtered
1	employee	ref	name,h_date,dept	name	const	8	16.31
1	department	eq_ref	PRIMARY	PRIMARY	dept_no	1	100.00

Now the prefix row count is `rows × filtered = 8 × 16.31% = 1.3`, which more closely reflects actual data set.

Normally, the optimizer does not calculate the condition filtering effect (prefix row count reduction) for the last joined table because there is no next table to pass rows to. An exception occurs for `EXPLAIN`: To provide more information, the filtering effect is calculated for all joined tables, including the last one.

To control whether the optimizer considers additional filtering conditions, use the `condition_fanout_filter` flag of the `optimizer_switch` system variable (see [Section 10.9.2, “Switchable Optimizations”](#)). This flag is enabled by default but can be disabled to suppress condition filtering (for example, if a particular query is found to yield better performance without it).

If the optimizer overestimates the effect of condition filtering, performance may be worse than if condition filtering is not used. In such cases, these techniques may help:

- If a column is not indexed, index it so that the optimizer has some information about the distribution of column values and can improve its row estimates.
- Similarly, if no column histogram information is available, generate a histogram (see [Section 10.9.6, “Optimizer Statistics”](#)).
- Change the join order. Ways to accomplish this include join-order optimizer hints (see [Section 10.9.3, “Optimizer Hints”](#)), `STRAIGHT_JOIN` immediately following the `SELECT`, and the `STRAIGHT_JOIN` join operator.
- Disable condition filtering for the session:

```
SET optimizer_switch = 'condition_fanout_filter=off';
```

Or, for a given query, using an optimizer hint:

```
SELECT /*+ SET_VAR(optimizer_switch = 'condition_fanout_filter=off') */ ...
```

## 10.2.1.14 Constant-Folding Optimization

Comparisons between constants and column values in which the constant value is out of range or of the wrong type with respect to the column type are now handled once during query optimization rather row-by-row than during execution. The comparisons that can be treated in this manner are `>`, `>=`, `<`, `<=`, `<>`/`!=`, `=`, and `<=>`.

Consider the table created by the following statement:

```
CREATE TABLE t (c TINYINT UNSIGNED NOT NULL);
```

The `WHERE` condition in the query `SELECT * FROM t WHERE c < 256` contains the integral constant 256 which is out of range for a `TINYINT UNSIGNED` column. Previously, this was handled by treating both operands as the larger type, but now, since any allowed value for `c` is less than the constant, the `WHERE` expression can instead be folded as `WHERE 1`, so that the query is rewritten as `SELECT * FROM t WHERE 1`.

This makes it possible for the optimizer to remove the `WHERE` expression altogether. If the column `c` were nullable (that is, defined only as `TINYINT UNSIGNED`) the query would be rewritten like this:

```
SELECT * FROM t WHERE ti IS NOT NULL
```

Folding is performed for constants compared to supported MySQL column types as follows:

- **Integer column type.** Integer types are compared with constants of the following types as described here:
- **Integer value.** If the constant is out of range for the column type, the comparison is folded to `1` or `IS NOT NULL`, as already shown.

If the constant is a range boundary, the comparison is folded to `=`. For example (using the same table as already defined):

```
mysql> EXPLAIN SELECT * FROM t WHERE c >= 255;
***** 1. row *****
 id: 1
 select_type: SIMPLE
 table: t
 partitions: NULL
 type: ALL
possible_keys: NULL
 key: NULL
 key_len: NULL
 ref: NULL
 rows: 5
 filtered: 20.00
 Extra: Using where
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS;
***** 1. row *****
 Level: Note
 Code: 1003
 Message: /* select#1 */ select `test`.`t`.`ti` AS `ti` from `test`.`t` where (`test`.`t`.`ti` = 255)
1 row in set (0.00 sec)
```

- **Floating- or fixed-point value.** If the constant is one of the decimal types (such as `DECIMAL`, `REAL`, `DOUBLE`, or `FLOAT`) and has a nonzero decimal portion, it cannot be equal; fold accordingly. For other comparisons, round up or down to an integer value according to the sign, then perform a range check and handle as already described for integer-integer comparisons.

A `REAL` value that is too small to be represented as `DECIMAL` is rounded to .01 or -.01 depending on the sign, then handled as a `DECIMAL`.

- **String types.** Try to interpret the string value as an integer type, then handle the comparison as between integer values. If this fails, attempt to handle the value as a `REAL`.
- **DECIMAL or REAL column.** Decimal types are compared with constants of the following types as described here:

- **Integer value.** Perform a range check against the column value's integer part. If no folding results, convert the constant to `DECIMAL` with the same number of decimal places as the column value, then check it as a `DECIMAL` (see next).

- **DECIMAL or REAL value.** Check for overflow (that is, whether the constant has more digits in its integer part than allowed for the column's decimal type). If so, fold.

If the constant has more significant fractional digits than column's type, truncate the constant. If the comparison operator is `=` or `<>`, fold. If the operator is `>=` or `<=`, adjust the operator due to truncation. For example, if column's type is `DECIMAL(3,1)`, `SELECT * FROM t WHERE f >= 10.13` becomes `SELECT * FROM t WHERE f > 10.1`.

If the constant has fewer decimal digits than the column's type, convert it to a constant with same number of digits. For underflow of a `REAL` value (that is, too few fractional digits to represent it), convert the constant to decimal 0.

- **String value.** If the value can be interpreted as an integer type, handle it as such. Otherwise, try to handle it as `REAL`.
- **FLOAT or DOUBLE column.** `FLOAT(m,n)` or `DOUBLE(m,n)` values compared with constants are handled as follows:

If the value overflows the range of the column, fold.

If the value has more than `n` decimals, truncate, compensating during folding. For `=` and `<>` comparisons, fold to `TRUE`, `FALSE`, or `IS [NOT] NULL` as described previously; for other operators, adjust the operator.

If the value has more than `m` integer digits, fold.

**Limitations.** This optimization cannot be used in the following cases:

1. With comparisons using `BETWEEN` or `IN`.
2. With `BIT` columns or columns using date or time types.
3. During the preparation phase for a prepared statement, although it can be applied during the optimization phase when the prepared statement is actually executed. This due to the fact that, during statement preparation, the value of the constant is not yet known.

### 10.2.1.15 IS NULL Optimization

MySQL can perform the same optimization on `col_name IS NULL` that it can use for `col_name = constant_value`. For example, MySQL can use indexes and ranges to search for `NULL` with `IS NULL`.

Examples:

```
SELECT * FROM tbl_name WHERE key_col IS NULL;

SELECT * FROM tbl_name WHERE key_col <=> NULL;

SELECT * FROM tbl_name
WHERE key_col=const1 OR key_col=const2 OR key_col IS NULL;
```

If a `WHERE` clause includes a `col_name IS NULL` condition for a column that is declared as `NOT NULL`, that expression is optimized away. This optimization does not occur in cases when the column might produce `NULL` anyway (for example, if it comes from a table on the right side of a `LEFT JOIN`).

MySQL can also optimize the combination `col_name = expr OR col_name IS NULL`, a form that is common in resolved subqueries. `EXPLAIN` shows `ref_or_null` when this optimization is used.

This optimization can handle one `IS NULL` for any key part.

Some examples of queries that are optimized, assuming that there is an index on columns `a` and `b` of table `t2`:

```
SELECT * FROM t1 WHERE t1.a=expr OR t1.a IS NULL;

SELECT * FROM t1, t2 WHERE t1.a=t2.a OR t2.a IS NULL;

SELECT * FROM t1, t2
 WHERE (t1.a=t2.a OR t2.a IS NULL) AND t2.b=t1.b;

SELECT * FROM t1, t2
 WHERE t1.a=t2.a AND (t2.b=t1.b OR t2.b IS NULL);

SELECT * FROM t1, t2
 WHERE (t1.a=t2.a AND t2.a IS NULL AND ...)
 OR (t1.a=t2.a AND t2.a IS NULL AND ...);
```

`ref_or_null` works by first doing a read on the reference key, and then a separate search for rows with a `NULL` key value.

The optimization can handle only one `IS NULL` level. In the following query, MySQL uses key lookups only on the expression `(t1.a=t2.a AND t2.a IS NULL)` and is not able to use the key part on `b`:

```
SELECT * FROM t1, t2
 WHERE (t1.a=t2.a AND t2.a IS NULL)
 OR (t1.b=t2.b AND t2.b IS NULL);
```

### 10.2.1.16 ORDER BY Optimization

This section describes when MySQL can use an index to satisfy an `ORDER BY` clause, the `filesort` operation used when an index cannot be used, and execution plan information available from the optimizer about `ORDER BY`.

An `ORDER BY` with and without `LIMIT` may return rows in different orders, as discussed in [Section 10.2.1.19, “LIMIT Query Optimization”](#).

- [Use of Indexes to Satisfy ORDER BY](#)
- [Use of filesort to Satisfy ORDER BY](#)
- [Influencing ORDER BY Optimization](#)
- [ORDER BY Execution Plan Information Available](#)

#### Use of Indexes to Satisfy ORDER BY

In some cases, MySQL may use an index to satisfy an `ORDER BY` clause and avoid the extra sorting involved in performing a `filesort` operation.

The index may also be used even if the `ORDER BY` does not match the index exactly, as long as all unused portions of the index and all extra `ORDER BY` columns are constants in the `WHERE` clause. If the index does not contain all columns accessed by the query, the index is used only if index access is cheaper than other access methods.

Assuming that there is an index on `(key_part1, key_part2)`, the following queries may use the index to resolve the `ORDER BY` part. Whether the optimizer actually does so depends on whether reading the index is more efficient than a table scan if columns not in the index must also be read.

- In this query, the index on `(key_part1, key_part2)` enables the optimizer to avoid sorting:

```
SELECT * FROM t1
ORDER BY key_part1, key_part2;
```

However, the query uses `SELECT *`, which may select more columns than `key_part1` and `key_part2`. In that case, scanning an entire index and looking up table rows to find columns not in the index may be more expensive than scanning the table and sorting the results. If so, the optimizer probably does not use the index. If `SELECT *` selects only the index columns, the index is used and sorting avoided.

If `t1` is an InnoDB table, the table primary key is implicitly part of the index, and the index can be used to resolve the `ORDER BY` for this query:

```
SELECT pk, key_part1, key_part2 FROM t1
ORDER BY key_part1, key_part2;
```

- In this query, `key_part1` is constant, so all rows accessed through the index are in `key_part2` order, and an index on `(key_part1, key_part2)` avoids sorting if the `WHERE` clause is selective enough to make an index range scan cheaper than a table scan:

```
SELECT * FROM t1
WHERE key_part1 = constant
ORDER BY key_part2;
```

- In the next two queries, whether the index is used is similar to the same queries without `DESC` shown previously:

```
SELECT * FROM t1
ORDER BY key_part1 DESC, key_part2 DESC;

SELECT * FROM t1
WHERE key_part1 = constant
ORDER BY key_part2 DESC;
```

- Two columns in an `ORDER BY` can sort in the same direction (both `ASC`, or both `DESC`) or in opposite directions (one `ASC`, one `DESC`). A condition for index use is that the index must have the same homogeneity, but need not have the same actual direction.

If a query mixes `ASC` and `DESC`, the optimizer can use an index on the columns if the index also uses corresponding mixed ascending and descending columns:

```
SELECT * FROM t1
ORDER BY key_part1 DESC, key_part2 ASC;
```

The optimizer can use an index on `(key_part1, key_part2)` if `key_part1` is descending and `key_part2` is ascending. It can also use an index on those columns (with a backward scan) if `key_part1` is ascending and `key_part2` is descending. See [Section 10.3.13, “Descending Indexes”](#).

- In the next two queries, `key_part1` is compared to a constant. The index is used if the `WHERE` clause is selective enough to make an index range scan cheaper than a table scan:

```
SELECT * FROM t1
WHERE key_part1 > constant
ORDER BY key_part1 ASC;

SELECT * FROM t1
```

```
WHERE key_part1 < constant
ORDER BY key_part1 DESC;
```

- In the next query, the `ORDER BY` does not name *key\_part1*, but all rows selected have a constant *key\_part1* value, so the index can still be used:

```
SELECT * FROM t1
WHERE key_part1 = constant1 AND key_part2 > constant2
ORDER BY key_part2;
```

In some cases, MySQL *cannot* use indexes to resolve the `ORDER BY`, although it may still use indexes to find the rows that match the `WHERE` clause. Examples:

- The query uses `ORDER BY` on different indexes:

```
SELECT * FROM t1 ORDER BY key1, key2;
```

- The query uses `ORDER BY` on nonconsecutive parts of an index:

```
SELECT * FROM t1 WHERE key2=constant ORDER BY key1_part1, key1_part3;
```

- The index used to fetch the rows differs from the one used in the `ORDER BY`:

```
SELECT * FROM t1 WHERE key2=constant ORDER BY key1;
```

- The query uses `ORDER BY` with an expression that includes terms other than the index column name:

```
SELECT * FROM t1 ORDER BY ABS(key);
SELECT * FROM t1 ORDER BY -key;
```

- The query joins many tables, and the columns in the `ORDER BY` are not all from the first nonconstant table that is used to retrieve rows. (This is the first table in the `EXPLAIN` output that does not have a `const` join type.)
- The query has different `ORDER BY` and `GROUP BY` expressions.
- There is an index on only a prefix of a column named in the `ORDER BY` clause. In this case, the index cannot be used to fully resolve the sort order. For example, if only the first 10 bytes of a `CHAR(20)` column are indexed, the index cannot distinguish values past the 10th byte and a `filesort` is needed.
- The index does not store rows in order. For example, this is true for a `HASH` index in a `MEMORY` table.

Availability of an index for sorting may be affected by the use of column aliases. Suppose that the column `t1.a` is indexed. In this statement, the name of the column in the select list is `a`. It refers to `t1.a`, as does the reference to `a` in the `ORDER BY`, so the index on `t1.a` can be used:

```
SELECT a FROM t1 ORDER BY a;
```

In this statement, the name of the column in the select list is also `a`, but it is the alias name. It refers to `ABS(a)`, as does the reference to `a` in the `ORDER BY`, so the index on `t1.a` cannot be used:

```
SELECT ABS(a) AS a FROM t1 ORDER BY a;
```

In the following statement, the `ORDER BY` refers to a name that is not the name of a column in the select list. But there is a column in `t1` named `a`, so the `ORDER BY` refers to `t1.a` and the index on `t1.a` can be used. (The resulting sort order may be completely different from the order for `ABS(a)`, of course.)

```
SELECT ABS(a) AS b FROM t1 ORDER BY a;
```

Previously (MySQL 9.0 and lower), `GROUP BY` sorted implicitly under certain conditions. In MySQL 9.1, that no longer occurs, so specifying `ORDER BY NULL` at the end to suppress implicit sorting (as was done

previously) is no longer necessary. However, query results may differ from previous MySQL versions. To produce a given sort order, provide an `ORDER BY` clause.

## Use of filesort to Satisfy ORDER BY

If an index cannot be used to satisfy an `ORDER BY` clause, MySQL performs a `filesort` operation that reads table rows and sorts them. A `filesort` constitutes an extra sorting phase in query execution.

To obtain memory for `filesort` operations, the optimizer allocates memory buffers incrementally as needed, up to the size indicated by the `sort_buffer_size` system variable. This enables users to set `sort_buffer_size` to larger values to speed up larger sorts, without concern for excessive memory use for small sorts. (This benefit may not occur for multiple concurrent sorts on Windows, which has a weak multithreaded `malloc`.)

A `filesort` operation uses temporary disk files as necessary if the result set is too large to fit in memory. Some types of queries are particularly suited to completely in-memory `filesort` operations. For example, the optimizer can use `filesort` to efficiently handle in memory, without temporary files, the `ORDER BY` operation for queries (and subqueries) of the following form:

```
SELECT ... FROM single_table ... ORDER BY non_index_column [DESC] LIMIT [M],[N];
```

Such queries are common in web applications that display only a few rows from a larger result set. Examples:

```
SELECT col1, ... FROM t1 ... ORDER BY name LIMIT 10;
SELECT col1, ... FROM t1 ... ORDER BY RAND() LIMIT 15;
```

## Influencing ORDER BY Optimization

To increase `ORDER BY` speed, check whether you can get MySQL to use indexes rather than an extra sorting phase. If this is not possible, try the following strategies:

- Increase the `sort_buffer_size` variable value. Ideally, the value should be large enough for the entire result set to fit in the sort buffer (to avoid writes to disk and merge passes).

Take into account that the size of column values stored in the sort buffer is affected by the `max_sort_length` system variable value. For example, if tuples store values of long string columns and you increase the value of `max_sort_length`, the size of sort buffer tuples increases as well and may require you to increase `sort_buffer_size`.

To monitor the number of merge passes (to merge temporary files), check the `Sort_merge_passes` status variable.

- Increase the `read_rnd_buffer_size` variable value so that more rows are read at a time.
- Change the `tmpdir` system variable to point to a dedicated file system with large amounts of free space. The variable value can list several paths that are used in round-robin fashion; you can use this feature to spread the load across several directories. Separate the paths by colon characters (:) on Unix and semicolon characters (;) on Windows. The paths should name directories in file systems located on different *physical* disks, not different partitions on the same disk.

## ORDER BY Execution Plan Information Available

With `EXPLAIN` (see [Section 10.8.1, “Optimizing Queries with EXPLAIN”](#)), you can check whether MySQL can use indexes to resolve an `ORDER BY` clause:

- If the `Extra` column of `EXPLAIN` output does not contain `Using filesort`, the index is used and a `filesort` is not performed.

- If the `Extra` column of `EXPLAIN` output contains `Using filesort`, the index is not used and a `filesort` is performed.

In addition, if a `filesort` is performed, optimizer trace output includes a `filesort_summary` block. For example:

```
"filesort_summary": {
 "rows": 100,
 "examined_rows": 100,
 "number_of_tmp_files": 0,
 "peak_memory_used": 25192,
 "sort_mode": "<sort_key, packed_additional_fields>"
}
```

`peak_memory_used` indicates the maximum memory used at any one time during the sort. This is a value up to but not necessarily as large as the value of the `sort_buffer_size` system variable. The optimizer allocates sort-buffer memory incrementally, beginning with a small amount and adding more as necessary, up to `sort_buffer_size` bytes.)

The `sort_mode` value provides information about the contents of tuples in the sort buffer:

- `<sort_key, rowid>`: This indicates that sort buffer tuples are pairs that contain the sort key value and row ID of the original table row. Tuples are sorted by sort key value and the row ID is used to read the row from the table.
- `<sort_key, additional_fields>`: This indicates that sort buffer tuples contain the sort key value and columns referenced by the query. Tuples are sorted by sort key value and column values are read directly from the tuple.
- `<sort_key, packed_additional_fields>`: Like the previous variant, but the additional columns are packed tightly together instead of using a fixed-length encoding.

`EXPLAIN` does not distinguish whether the optimizer does or does not perform a `filesort` in memory. Use of an in-memory `filesort` can be seen in optimizer trace output. Look for `filesort_priority_queue_optimization`. For information about the optimizer trace, see [Section 10.15, “Tracing the Optimizer”](#).

### 10.2.1.17 GROUP BY Optimization

The most general way to satisfy a `GROUP BY` clause is to scan the whole table and create a new temporary table where all rows from each group are consecutive, and then use this temporary table to discover groups and apply aggregate functions (if any). In some cases, MySQL is able to do much better than that and avoid creation of temporary tables by using index access.

The most important preconditions for using indexes for `GROUP BY` are that all `GROUP BY` columns reference attributes from the same index, and that the index stores its keys in order (as is true, for example, for a `BTREE` index, but not for a `HASH` index). Whether use of temporary tables can be replaced by index access also depends on which parts of an index are used in a query, the conditions specified for these parts, and the selected aggregate functions.

There are two ways to execute a `GROUP BY` query through index access, as detailed in the following sections. The first method applies the grouping operation together with all range predicates (if any). The second method first performs a range scan, and then groups the resulting tuples.

- [Loose Index Scan](#)
- [Tight Index Scan](#)

Loose Index Scan can also be used in the absence of `GROUP BY` under some conditions. See [Skip Scan Range Access Method](#).

## Loose Index Scan

The most efficient way to process `GROUP BY` is when an index is used to directly retrieve the grouping columns. With this access method, MySQL uses the property of some index types that the keys are ordered (for example, `BTREE`). This property enables use of lookup groups in an index without having to consider all keys in the index that satisfy all `WHERE` conditions. This access method considers only a fraction of the keys in an index, so it is called a *Loose Index Scan*. When there is no `WHERE` clause, a Loose Index Scan reads as many keys as the number of groups, which may be a much smaller number than that of all keys. If the `WHERE` clause contains range predicates (see the discussion of the `range` join type in [Section 10.8.1, “Optimizing Queries with EXPLAIN”](#)), a Loose Index Scan looks up the first key of each group that satisfies the range conditions, and again reads the smallest possible number of keys. This is possible under the following conditions:

- The query is over a single table.
- The `GROUP BY` names only columns that form a leftmost prefix of the index and no other columns. (If, instead of `GROUP BY`, the query has a `DISTINCT` clause, all distinct attributes refer to columns that form a leftmost prefix of the index.) For example, if a table `t1` has an index on `(c1,c2,c3)`, Loose Index Scan is applicable if the query has `GROUP BY c1, c2`. It is not applicable if the query has `GROUP BY c2, c3` (the columns are not a leftmost prefix) or `GROUP BY c1, c2, c4` (`c4` is not in the index).
- The only aggregate functions used in the select list (if any) are `MIN()` and `MAX()`, and all of them refer to the same column. The column must be in the index and must immediately follow the columns in the `GROUP BY`.
- Any other parts of the index than those from the `GROUP BY` referenced in the query must be constants (that is, they must be referenced in equalities with constants), except for the argument of `MIN()` or `MAX()` functions.
- For columns in the index, full column values must be indexed, not just a prefix. For example, with `c1 VARCHAR(20)`, `INDEX (c1(10))`, the index uses only a prefix of `c1` values and cannot be used for Loose Index Scan.

If Loose Index Scan is applicable to a query, the `EXPLAIN` output shows `Using index for group-by` in the `Extra` column.

Assume that there is an index `idx(c1,c2,c3)` on table `t1(c1,c2,c3,c4)`. The Loose Index Scan access method can be used for the following queries:

```
SELECT c1, c2 FROM t1 GROUP BY c1, c2;
SELECT DISTINCT c1, c2 FROM t1;
SELECT c1, MIN(c2) FROM t1 GROUP BY c1;
SELECT c1, c2 FROM t1 WHERE c1 < const GROUP BY c1, c2;
SELECT MAX(c3), MIN(c3), c1, c2 FROM t1 WHERE c2 > const GROUP BY c1, c2;
SELECT c2 FROM t1 WHERE c1 < const GROUP BY c1, c2;
SELECT c1, c2 FROM t1 WHERE c3 = const GROUP BY c1, c2;
```

The following queries cannot be executed with this quick select method, for the reasons given:

- There are aggregate functions other than `MIN()` or `MAX()`:

```
SELECT c1, SUM(c2) FROM t1 GROUP BY c1;
```

- The columns in the `GROUP BY` clause do not form a leftmost prefix of the index:

```
SELECT c1, c2 FROM t1 GROUP BY c2, c3;
```

- The query refers to a part of a key that comes after the `GROUP BY` part, and for which there is no equality with a constant:

```
SELECT c1, c3 FROM t1 GROUP BY c1, c2;
```

Were the query to include `WHERE c3 = const`, Loose Index Scan could be used.

The Loose Index Scan access method can be applied to other forms of aggregate function references in the select list, in addition to the `MIN()` and `MAX()` references already supported:

- `AVG(DISTINCT)`, `SUM(DISTINCT)`, and `COUNT(DISTINCT)` are supported. `AVG(DISTINCT)` and `SUM(DISTINCT)` take a single argument. `COUNT(DISTINCT)` can have more than one column argument.
- There must be no `GROUP BY` or `DISTINCT` clause in the query.
- The Loose Index Scan limitations described previously still apply.

Assume that there is an index `idx(c1,c2,c3)` on table `t1(c1,c2,c3,c4)`. The Loose Index Scan access method can be used for the following queries:

```
SELECT COUNT(DISTINCT c1), SUM(DISTINCT c1) FROM t1;
SELECT COUNT(DISTINCT c1, c2), COUNT(DISTINCT c2, c1) FROM t1;
```

## Tight Index Scan

A Tight Index Scan may be either a full index scan or a range index scan, depending on the query conditions.

When the conditions for a Loose Index Scan are not met, it still may be possible to avoid creation of temporary tables for `GROUP BY` queries. If there are range conditions in the `WHERE` clause, this method reads only the keys that satisfy these conditions. Otherwise, it performs an index scan. Because this method reads all keys in each range defined by the `WHERE` clause, or scans the whole index if there are no range conditions, it is called a *Tight Index Scan*. With a Tight Index Scan, the grouping operation is performed only after all keys that satisfy the range conditions have been found.

For this method to work, it is sufficient that there be a constant equality condition for all columns in a query referring to parts of the key coming before or in between parts of the `GROUP BY` key. The constants from the equality conditions fill in any “gaps” in the search keys so that it is possible to form complete prefixes of the index. These index prefixes then can be used for index lookups. If the `GROUP BY` result requires sorting, and it is possible to form search keys that are prefixes of the index, MySQL also avoids extra sorting operations because searching with prefixes in an ordered index already retrieves all the keys in order.

Assume that there is an index `idx(c1,c2,c3)` on table `t1(c1,c2,c3,c4)`. The following queries do not work with the Loose Index Scan access method described previously, but still work with the Tight Index Scan access method.

- There is a gap in the `GROUP BY`, but it is covered by the condition `c2 = 'a'`:

```
SELECT c1, c2, c3 FROM t1 WHERE c2 = 'a' GROUP BY c1, c3;
```

- The `GROUP BY` does not begin with the first part of the key, but there is a condition that provides a constant for that part:

```
SELECT c1, c2, c3 FROM t1 WHERE c1 = 'a' GROUP BY c2, c3;
```

### 10.2.1.18 DISTINCT Optimization

`DISTINCT` combined with `ORDER BY` needs a temporary table in many cases.

Because `DISTINCT` may use `GROUP BY`, learn how MySQL works with columns in `ORDER BY` or `HAVING` clauses that are not part of the selected columns. See [Section 14.19.3, “MySQL Handling of GROUP BY”](#).

In most cases, a `DISTINCT` clause can be considered as a special case of `GROUP BY`. For example, the following two queries are equivalent:

```
SELECT DISTINCT c1, c2, c3 FROM t1
WHERE c1 > const;

SELECT c1, c2, c3 FROM t1
WHERE c1 > const GROUP BY c1, c2, c3;
```

Due to this equivalence, the optimizations applicable to `GROUP BY` queries can be also applied to queries with a `DISTINCT` clause. Thus, for more details on the optimization possibilities for `DISTINCT` queries, see [Section 10.2.1.17, “GROUP BY Optimization”](#).

When combining `LIMIT row_count` with `DISTINCT`, MySQL stops as soon as it finds `row_count` unique rows.

If you do not use columns from all tables named in a query, MySQL stops scanning any unused tables as soon as it finds the first match. In the following case, assuming that `t1` is used before `t2` (which you can check with `EXPLAIN`), MySQL stops reading from `t2` (for any particular row in `t1`) when it finds the first row in `t2`:

```
SELECT DISTINCT t1.a FROM t1, t2 where t1.a=t2.a;
```

## 10.2.1.19 LIMIT Query Optimization

If you need only a specified number of rows from a result set, use a `LIMIT` clause in the query, rather than fetching the whole result set and throwing away the extra data.

MySQL sometimes optimizes a query that has a `LIMIT row_count` clause and no `HAVING` clause:

- If you select only a few rows with `LIMIT`, MySQL uses indexes in some cases when normally it would prefer to do a full table scan.
- If you combine `LIMIT row_count` with `ORDER BY`, MySQL stops sorting as soon as it has found the first `row_count` rows of the sorted result, rather than sorting the entire result. If ordering is done by using an index, this is very fast. If a filesort must be done, all rows that match the query without the `LIMIT` clause are selected, and most or all of them are sorted, before the first `row_count` are found. After the initial rows have been found, MySQL does not sort any remainder of the result set.

One manifestation of this behavior is that an `ORDER BY` query with and without `LIMIT` may return rows in different order, as described later in this section.

- If you combine `LIMIT row_count` with `DISTINCT`, MySQL stops as soon as it finds `row_count` unique rows.
- In some cases, a `GROUP BY` can be resolved by reading the index in order (or doing a sort on the index), then calculating summaries until the index value changes. In this case, `LIMIT row_count` does not calculate any unnecessary `GROUP BY` values.
- As soon as MySQL has sent the required number of rows to the client, it aborts the query unless you are using `SQL_CALC_FOUND_ROWS`. In that case, the number of rows can be retrieved with `SELECT FOUND_ROWS()`. See [Section 14.15, “Information Functions”](#).

- `LIMIT 0` quickly returns an empty set. This can be useful for checking the validity of a query. It can also be employed to obtain the types of the result columns within applications that use a MySQL API that makes result set metadata available. With the `mysql` client program, you can use the `--column-type-info` option to display result column types.
- If the server uses temporary tables to resolve a query, it uses the `LIMIT row_count` clause to calculate how much space is required.
- If an index is not used for `ORDER BY` but a `LIMIT` clause is also present, the optimizer may be able to avoid using a merge file and sort the rows in memory using an in-memory `filesort` operation.

If multiple rows have identical values in the `ORDER BY` columns, the server is free to return those rows in any order, and may do so differently depending on the overall execution plan. In other words, the sort order of those rows is nondeterministic with respect to the nonordered columns.

One factor that affects the execution plan is `LIMIT`, so an `ORDER BY` query with and without `LIMIT` may return rows in different orders. Consider this query, which is sorted by the `category` column but nondeterministic with respect to the `id` and `rating` columns:

```
mysql> SELECT * FROM ratings ORDER BY category;
```

id	category	rating
1	1	4.5
5	1	3.2
3	2	3.7
4	2	3.5
6	2	3.5
2	3	5.0
7	3	2.7

Including `LIMIT` may affect order of rows within each `category` value. For example, this is a valid query result:

```
mysql> SELECT * FROM ratings ORDER BY category LIMIT 5;
```

id	category	rating
1	1	4.5
5	1	3.2
4	2	3.5
3	2	3.7
6	2	3.5

In each case, the rows are sorted by the `ORDER BY` column, which is all that is required by the SQL standard.

If it is important to ensure the same row order with and without `LIMIT`, include additional columns in the `ORDER BY` clause to make the order deterministic. For example, if `id` values are unique, you can make rows for a given `category` value appear in `id` order by sorting like this:

```
mysql> SELECT * FROM ratings ORDER BY category, id;
```

id	category	rating
1	1	4.5
5	1	3.2
3	2	3.7
4	2	3.5
6	2	3.5
2	3	5.0

```
| 7 | 3 | 2.7 |
+-----+
mysql> SELECT * FROM ratings ORDER BY category, id LIMIT 5;
+-----+
| id | category | rating |
+-----+
| 1 | 1 | 4.5 |
| 5 | 1 | 3.2 |
| 3 | 2 | 3.7 |
| 4 | 2 | 3.5 |
| 6 | 2 | 3.5 |
+-----+
```

For a query with an `ORDER BY` or `GROUP BY` and a `LIMIT` clause, the optimizer tries to choose an ordered index by default when it appears doing so would speed up query execution. In cases where using some other optimization might be faster, it is possible to turn off this optimization by setting the `optimizer_switch` system variable's `prefer_ordering_index` flag to `off`.

*Example:* First we create and populate a table `t` as shown here:

```
Create and populate a table t:

mysql> CREATE TABLE t (
-> id1 BIGINT NOT NULL,
-> id2 BIGINT NOT NULL,
-> c1 VARCHAR(50) NOT NULL,
-> c2 VARCHAR(50) NOT NULL,
-> PRIMARY KEY (id1),
-> INDEX i (id2, c1)
->);

[Insert some rows into table t - not shown]
```

Verify that the `prefer_ordering_index` flag is enabled:

```
mysql> SELECT @@optimizer_switch LIKE '%prefer_ordering_index=on%';
+-----+
| @@optimizer_switch LIKE '%prefer_ordering_index=on%' |
+-----+
| 1 |
+-----+
```

Since the following query has a `LIMIT` clause, we expect it to use an ordered index, if possible. In this case, as we can see from the `EXPLAIN` output, it uses the table's primary key.

```
mysql> EXPLAIN SELECT c2 FROM t
-> WHERE id2 > 3
-> ORDER BY id1 ASC LIMIT 2\G
***** 1. row *****
id: 1
select_type: SIMPLE
table: t
partitions: NULL
type: index
possible_keys: i
key: PRIMARY
key_len: 8
ref: NULL
rows: 2
filtered: 70.00
Extra: Using where
```

Now we disable the `prefer_ordering_index` flag, and re-run the same query; this time it uses the index `i` (which includes the `id2` column used in the `WHERE` clause), and a filesort:

```
mysql> SET optimizer_switch = "prefer_ordering_index=off";

mysql> EXPLAIN SELECT c2 FROM t
-> WHERE id2 > 3
-> ORDER BY id1 ASC LIMIT 2\G
***** 1. row *****
 id: 1
 select_type: SIMPLE
 table: t
 partitions: NULL
 type: range
possible_keys: i
 key: i
 key_len: 8
 ref: NULL
 rows: 14
 filtered: 100.00
 Extra: Using index condition; Using filesort
```

See also [Section 10.9.2, “Switchable Optimizations”](#).

### 10.2.1.20 Function Call Optimization

MySQL functions are tagged internally as deterministic or nondeterministic. A function is nondeterministic if, given fixed values for its arguments, it can return different results for different invocations. Examples of nondeterministic functions: [RAND\( \)](#), [UUID\( \)](#).

If a function is tagged nondeterministic, a reference to it in a [WHERE](#) clause is evaluated for every row (when selecting from one table) or combination of rows (when selecting from a multiple-table join).

MySQL also determines when to evaluate functions based on types of arguments, whether the arguments are table columns or constant values. A deterministic function that takes a table column as argument must be evaluated whenever that column changes value.

Nondeterministic functions may affect query performance. For example, some optimizations may not be available, or more locking might be required. The following discussion uses [RAND\( \)](#) but applies to other nondeterministic functions as well.

Suppose that a table `t` has this definition:

```
CREATE TABLE t (id INT NOT NULL PRIMARY KEY, col_a VARCHAR(100));
```

Consider these two queries:

```
SELECT * FROM t WHERE id = POW(1,2);
SELECT * FROM t WHERE id = FLOOR(1 + RAND() * 49);
```

Both queries appear to use a primary key lookup because of the equality comparison against the primary key, but that is true only for the first of them:

- The first query always produces a maximum of one row because [POW\( \)](#) with constant arguments is a constant value and is used for index lookup.
- The second query contains an expression that uses the nondeterministic function [RAND\( \)](#), which is not constant in the query but in fact has a new value for every row of table `t`. Consequently, the query reads every row of the table, evaluates the predicate for each row, and outputs all rows for which the primary key matches the random value. This might be zero, one, or multiple rows, depending on the `id` column values and the values in the [RAND\( \)](#) sequence.

The effects of nondeterminism are not limited to [SELECT](#) statements. This [UPDATE](#) statement uses a nondeterministic function to select rows to be modified:

```
UPDATE t SET col_a = some_expr WHERE id = FLOOR(1 + RAND() * 49);
```

Presumably the intent is to update at most a single row for which the primary key matches the expression. However, it might update zero, one, or multiple rows, depending on the `id` column values and the values in the `RAND()` sequence.

The behavior just described has implications for performance and replication:

- Because a nondeterministic function does not produce a constant value, the optimizer cannot use strategies that might otherwise be applicable, such as index lookups. The result may be a table scan.
- **InnoDB** might escalate to a range-key lock rather than taking a single row lock for one matching row.
- Updates that do not execute deterministically are unsafe for replication.

The difficulties stem from the fact that the `RAND()` function is evaluated once for every row of the table. To avoid multiple function evaluations, use one of these techniques:

- Move the expression containing the nondeterministic function to a separate statement, saving the value in a variable. In the original statement, replace the expression with a reference to the variable, which the optimizer can treat as a constant value:

```
SET @keyval = FLOOR(1 + RAND() * 49);
UPDATE t SET col_a = some_expr WHERE id = @keyval;
```

- Assign the random value to a variable in a derived table. This technique causes the variable to be assigned a value, once, prior to its use in the comparison in the `WHERE` clause:

```
UPDATE /*+ NO_MERGE(dt) */ t, (SELECT FLOOR(1 + RAND() * 49) AS r) AS dt
SET col_a = some_expr WHERE id = dt.r;
```

As mentioned previously, a nondeterministic expression in the `WHERE` clause might prevent optimizations and result in a table scan. However, it may be possible to partially optimize the `WHERE` clause if other expressions are deterministic. For example:

```
SELECT * FROM t WHERE partial_key=5 AND some_column=RAND();
```

If the optimizer can use `partial_key` to reduce the set of rows selected, `RAND()` is executed fewer times, which diminishes the effect of nondeterminism on optimization.

## 10.2.1.21 Window Function Optimization

Window functions affect the strategies the optimizer considers:

- Derived table merging for a subquery is disabled if the subquery has window functions. The subquery is always materialized.
- Semijoins are not applicable to window function optimization because semijoins apply to subqueries in `WHERE` and `JOIN ... ON`, which cannot contain window functions.
- The optimizer processes multiple windows that have the same ordering requirements in sequence, so sorting can be skipped for windows following the first one.
- The optimizer makes no attempt to merge windows that could be evaluated in a single step (for example, when multiple `OVER` clauses contain identical window definitions). The workaround is to define the window in a `WINDOW` clause and refer to the window name in the `OVER` clauses.

An aggregate function not used as a window function is aggregated in the outermost possible query. For example, in this query, MySQL sees that `COUNT(t1.b)` is something that cannot exist in the outer query because of its placement in the `WHERE` clause:

```
SELECT * FROM t1 WHERE t1.a = (SELECT COUNT(t1.b) FROM t2);
```

Consequently, MySQL aggregates inside the subquery, treating `t1.b` as a constant and returning the count of rows of `t2`.

Replacing `WHERE` with `HAVING` results in an error:

```
mysql> SELECT * FROM t1 HAVING t1.a = (SELECT COUNT(t1.b) FROM t2);
ERROR 1140 (42000): In aggregated query without GROUP BY, expression #1
of SELECT list contains nonaggregated column 'test.t1.a'; this is
incompatible with sql_mode=only_full_group_by
```

The error occurs because `COUNT(t1.b)` can exist in the `HAVING`, and so makes the outer query aggregated.

Window functions (including aggregate functions used as window functions) do not have the preceding complexity. They always aggregate in the subquery where they are written, never in the outer query.

Window function evaluation may be affected by the value of the `windowing_use_high_precision` system variable, which determines whether to compute window operations without loss of precision. By default, `windowing_use_high_precision` is enabled.

For some moving frame aggregates, the inverse aggregate function can be applied to remove values from the aggregate. This can improve performance but possibly with a loss of precision. For example, adding a very small floating-point value to a very large value causes the very small value to be “hidden” by the large value. When inverting the large value later, the effect of the small value is lost.

Loss of precision due to inverse aggregation is a factor only for operations on floating-point (approximate-value) data types. For other types, inverse aggregation is safe; this includes `DECIMAL`, which permits a fractional part but is an exact-value type.

For faster execution, MySQL always uses inverse aggregation when it is safe:

- For floating-point values, inverse aggregation is not always safe and might result in loss of precision. The default is to avoid inverse aggregation, which is slower but preserves precision. If it is permissible to sacrifice safety for speed, `windowing_use_high_precision` can be disabled to permit inverse aggregation.
- For nonfloating-point data types, inverse aggregation is always safe and is used regardless of the `windowing_use_high_precision` value.
- `windowing_use_high_precision` has no effect on `MIN()` and `MAX()`, which do not use inverse aggregation in any case.

For evaluation of the variance functions `STDDEV_POP()`, `STDDEV_SAMP()`, `VAR_POP()`, `VAR_SAMP()`, and their synonyms, evaluation can occur in optimized mode or default mode. Optimized mode may produce slightly different results in the last significant digits. If such differences are permissible, `windowing_use_high_precision` can be disabled to permit optimized mode.

For `EXPLAIN`, windowing execution plan information is too extensive to display in traditional output format. To see windowing information, use `EXPLAIN FORMAT=JSON` and look for the `windowing` element.

### 10.2.1.22 Row Constructor Expression Optimization

Row constructors permit simultaneous comparisons of multiple values. For example, these two statements are semantically equivalent:

```
SELECT * FROM t1 WHERE (column1,column2) = (1,1);
SELECT * FROM t1 WHERE column1 = 1 AND column2 = 1;
```

In addition, the optimizer handles both expressions the same way.

The optimizer is less likely to use available indexes if the row constructor columns do not cover the prefix of an index. Consider the following table, which has a primary key on (c1, c2, c3):

```
CREATE TABLE t1 (
 c1 INT, c2 INT, c3 INT, c4 CHAR(100),
 PRIMARY KEY(c1,c2,c3)
);
```

In this query, the `WHERE` clause uses all columns in the index. However, the row constructor itself does not cover an index prefix, with the result that the optimizer uses only `c1` (`key_len=4`, the size of `c1`):

```
mysql> EXPLAIN SELECT * FROM t1
 WHERE c1=1 AND (c2,c3) > (1,1)\G
***** 1. row *****
 id: 1
 select_type: SIMPLE
 table: t1
 partitions: NULL
 type: ref
possible_keys: PRIMARY
 key: PRIMARY
 key_len: 4
 ref: const
 rows: 3
 filtered: 100.00
 Extra: Using where
```

In such cases, rewriting the row constructor expression using an equivalent nonconstructor expression may result in more complete index use. For the given query, the row constructor and equivalent nonconstructor expressions are:

```
(c2,c3) > (1,1)
c2 > 1 OR ((c2 = 1) AND (c3 > 1))
```

Rewriting the query to use the nonconstructor expression results in the optimizer using all three columns in the index (`key_len=12`):

```
mysql> EXPLAIN SELECT * FROM t1
 WHERE c1 = 1 AND (c2 > 1 OR ((c2 = 1) AND (c3 > 1)))\G
***** 1. row *****
 id: 1
 select_type: SIMPLE
 table: t1
 partitions: NULL
 type: range
possible_keys: PRIMARY
 key: PRIMARY
 key_len: 12
 ref: NULL
 rows: 3
 filtered: 100.00
 Extra: Using where
```

Thus, for better results, avoid mixing row constructors with `AND/OR` expressions. Use one or the other.

Under certain conditions, the optimizer can apply the range access method to `IN()` expressions that have row constructor arguments. See [Range Optimization of Row Constructor Expressions](#).

## 10.2.1.23 Avoiding Full Table Scans

The output from `EXPLAIN` shows `ALL` in the `type` column when MySQL uses a `full table scan` to resolve a query. This usually happens under the following conditions:

- The table is so small that it is faster to perform a table scan than to bother with a key lookup. This is common for tables with fewer than 10 rows and a short row length.
- There are no usable restrictions in the `ON` or `WHERE` clause for indexed columns.
- You are comparing indexed columns with constant values and MySQL has calculated (based on the index tree) that the constants cover too large a part of the table and that a table scan would be faster. See [Section 10.2.1.1, “WHERE Clause Optimization”](#).
- You are using a key with low cardinality (many rows match the key value) through another column. In this case, MySQL assumes that by using the key probably requires many key lookups and that a table scan would be faster.

For small tables, a table scan often is appropriate and the performance impact is negligible. For large tables, try the following techniques to avoid having the optimizer incorrectly choose a table scan:

- Use `ANALYZE TABLE tbl_name` to update the key distributions for the scanned table. See [Section 15.7.3.1, “ANALYZE TABLE Statement”](#).
- Use `FORCE INDEX` for the scanned table to tell MySQL that table scans are very expensive compared to using the given index:

```
SELECT * FROM t1, t2 FORCE INDEX (index_for_column)
WHERE t1.col_name=t2.col_name;
```

See [Section 10.9.4, “Index Hints”](#).

- Start `mysqld` with the `--max-seeks-for-key=1000` option or use `SET max_seeks_for_key=1000` to tell the optimizer to assume that no key scan causes more than 1,000 key seeks. See [Section 7.1.8, “Server System Variables”](#).

## 10.2.2 Optimizing Subqueries, Derived Tables, View References, and Common Table Expressions

The MySQL query optimizer has different strategies available to evaluate subqueries:

- For a subquery used with an `IN`, `= ANY`, or `EXISTS` predicate, the optimizer has these choices:
  - Semijoin
  - Materialization
  - `EXISTS` strategy
- For a subquery used with a `NOT IN`, `<> ALL` or `NOT EXISTS` predicate, the optimizer has these choices:
  - Materialization
  - `EXISTS` strategy

For a derived table, the optimizer has these choices (which also apply to view references and common table expressions):

- Merge the derived table into the outer query block
- Materialize the derived table to an internal temporary table

The following discussion provides more information about the preceding optimization strategies.

**Note**

A limitation on **UPDATE** and **DELETE** statements that use a subquery to modify a single table is that the optimizer does not use semijoin or materialization subquery optimizations. As a workaround, try rewriting them as multiple-table **UPDATE** and **DELETE** statements that use a join rather than a subquery.

### 10.2.2.1 Optimizing IN and EXISTS Subquery Predicates with Semijoin and Antijoin Transformations

A semijoin is a preparation-time transformation that enables multiple execution strategies such as table pullout, duplicate weedout, first match, loose scan, and materialization. The optimizer uses semijoin strategies to improve subquery execution, as described in this section.

For an inner join between two tables, the join returns a row from one table as many times as there are matches in the other table. But for some questions, the only information that matters is whether there is a match, not the number of matches. Suppose that there are tables named **class** and **roster** that list classes in a course curriculum and class rosters (students enrolled in each class), respectively. To list the classes that actually have students enrolled, you could use this join:

```
SELECT class.class_num, class.class_name
FROM class
INNER JOIN roster
WHERE class.class_num = roster.class_num;
```

However, the result lists each class once for each enrolled student. For the question being asked, this is unnecessary duplication of information.

Assuming that **class\_num** is a primary key in the **class** table, duplicate suppression is possible by using **SELECT DISTINCT**, but it is inefficient to generate all matching rows first only to eliminate duplicates later.

The same duplicate-free result can be obtained by using a subquery:

```
SELECT class_num, class_name
FROM class
WHERE class_num IN
 (SELECT class_num FROM roster);
```

Here, the optimizer can recognize that the **IN** clause requires the subquery to return only one instance of each class number from the **roster** table. In this case, the query can use a *semijoin*; that is, an operation that returns only one instance of each row in **class** that is matched by rows in **roster**.

The following statement, which contains an **EXISTS** subquery predicate, is equivalent to the previous statement containing an **IN** subquery predicate:

```
SELECT class_num, class_name
FROM class
WHERE EXISTS
 (SELECT * FROM roster WHERE class.class_num = roster.class_num);
```

Any statement with an **EXISTS** subquery predicate is subject to the same semijoin transforms as a statement with an equivalent **IN** subquery predicate.

The following subqueries are transformed into antijoins:

- **NOT IN** (**SELECT** ... **FROM** ...)
- **NOT EXISTS** (**SELECT** ... **FROM** ...).
- **IN** (**SELECT** ... **FROM** ...) **IS NOT TRUE**

- `EXISTS (SELECT ... FROM ...) IS NOT TRUE.`
- `IN (SELECT ... FROM ...) IS FALSE`
- `EXISTS (SELECT ... FROM ...) IS FALSE.`

In short, any negation of a subquery of the form `IN (SELECT ... FROM ...)` or `EXISTS (SELECT ... FROM ...)` is transformed into an antijoin.

An antijoin is an operation that returns only rows for which there is no match. Consider the query shown here:

```
SELECT class_num, class_name
FROM class
WHERE class_num NOT IN
 (SELECT class_num FROM roster);
```

This query is rewritten internally as the antijoin `SELECT class_num, class_name FROM class ANTIJOIN roster ON class_num`, which returns one instance of each row in `class` that is *not* matched by any rows in `roster`. This means that, for each row in `class`, as soon as a match is found in `roster`, the row in `class` can be discarded.

Antijoin transformations cannot in most cases be applied if the expressions being compared are nullable. An exception to this rule is that `(... NOT IN (SELECT ...)) IS NOT FALSE` and its equivalent `(... IN (SELECT ...)) IS NOT TRUE` can be transformed into antijoins.

Outer join and inner join syntax is permitted in the outer query specification, and table references may be base tables, derived tables, view references, or common table expressions.

In MySQL, a subquery must satisfy these criteria to be handled as a semijoin (or an antijoin, if `NOT` modifies the subquery):

- It must be part of an `IN`, `= ANY`, or `EXISTS` predicate that appears at the top level of the `WHERE` or `ON` clause, possibly as a term in an `AND` expression. For example:

```
SELECT ...
FROM ot1, ...
WHERE (oe1, ...) IN
 (SELECT ie1, ... FROM it1, ... WHERE ...);
```

Here, `oti` and `iti` represent tables in the outer and inner parts of the query, and `oei` and `iei` represent expressions that refer to columns in the outer and inner tables.

The subquery can also be the argument to an expression modified by `NOT`, `IS [NOT] TRUE`, or `IS [NOT] FALSE`.

- It must be a single `SELECT` without `UNION` constructs.
- It must not contain a `HAVING` clause.
- It must not contain any aggregate functions (whether it is explicitly or implicitly grouped).
- It must not have a `LIMIT` clause.
- The statement must not use the `STRAIGHT_JOIN` join type in the outer query.
- The `STRAIGHT_JOIN` modifier must not be present.
- The number of outer and inner tables together must be less than the maximum number of tables permitted in a join.

- The subquery may be correlated or uncorrelated. Decorrelation looks at trivially correlated predicates in the `WHERE` clause of a subquery used as the argument to `EXISTS`, and makes it possible to optimize it as if it was used within `IN (SELECT b FROM ...)`. The term *trivially correlated* means that the predicate is an equality predicate, that it is the sole predicate in the `WHERE` clause (or is combined with `AND`), and that one operand is from a table referenced in the subquery and the other operand is from the outer query block.
- The `DISTINCT` keyword is permitted but ignored. Semijoin strategies automatically handle duplicate removal.
- A `GROUP BY` clause is permitted but ignored, unless the subquery also contains one or more aggregate functions.
- An `ORDER BY` clause is permitted but ignored, since ordering is irrelevant to the evaluation of semijoin strategies.

If a subquery meets the preceding criteria, MySQL converts it to a semijoin (or to an antijoin if applicable) and makes a cost-based choice from these strategies:

- Convert the subquery to a join, or use table pullout and run the query as an inner join between subquery tables and outer tables. Table pullout pulls a table out from the subquery to the outer query.
- *Duplicate Weedout*: Run the semijoin as if it was a join and remove duplicate records using a temporary table.
- *FirstMatch*: When scanning the inner tables for row combinations and there are multiple instances of a given value group, choose one rather than returning them all. This "shortcuts" scanning and eliminates production of unnecessary rows.
- *LooseScan*: Scan a subquery table using an index that enables a single value to be chosen from each subquery's value group.
- Materialize the subquery into an indexed temporary table that is used to perform a join, where the index is used to remove duplicates. The index might also be used later for lookups when joining the temporary table with the outer tables; if not, the table is scanned. For more information about materialization, see [Section 10.2.2.2, "Optimizing Subqueries with Materialization"](#).

Each of these strategies can be enabled or disabled using the following `optimizer_switch` system variable flags:

- The `semi_join` flag controls whether semijoins and antijoins are used.
- If `semi_join` is enabled, the `firstmatch`, `loosescan`, `duplicateweedout`, and `materialization` flags enable finer control over the permitted semijoin strategies.
- If the `duplicateweedout` semijoin strategy is disabled, it is not used unless all other applicable strategies are also disabled.
- If `duplicateweedout` is disabled, on occasion the optimizer may generate a query plan that is far from optimal. This occurs due to heuristic pruning during greedy search, which can be avoided by setting `optimizer_prune_level=0`.

These flags are enabled by default. See [Section 10.9.2, "Switchable Optimizations"](#).

The optimizer minimizes differences in handling of views and derived tables. This affects queries that use the `STRAIGHT_JOIN` modifier and a view with an `IN` subquery that can be converted to a semijoin. The following query illustrates this because the change in processing causes a change in transformation, and thus a different execution strategy:

```
CREATE VIEW v AS
SELECT *
FROM t1
WHERE a IN (SELECT b
 FROM t2);

SELECT STRAIGHT_JOIN *
FROM t3 JOIN v ON t3.x = v.a;
```

The optimizer first looks at the view and converts the `IN` subquery to a semijoin, then checks whether it is possible to merge the view into the outer query. Because the `STRAIGHT_JOIN` modifier in the outer query prevents semijoin, the optimizer refuses the merge, causing derived table evaluation using a materialized table.

`EXPLAIN` output indicates the use of semijoin strategies as follows:

- For extended `EXPLAIN` output, the text displayed by a following `SHOW WARNINGS` shows the rewritten query, which displays the semijoin structure. (See [Section 10.8.3, “Extended EXPLAIN Output Format”](#).) From this you can get an idea about which tables were pulled out of the semijoin. If a subquery was converted to a semijoin, you should see that the subquery predicate is gone and its tables and `WHERE` clause were merged into the outer query join list and `WHERE` clause.
- Temporary table use for Duplicate Weedout is indicated by `Start temporary` and `End temporary` in the `Extra` column. Tables that were not pulled out and are in the range of `EXPLAIN` output rows covered by `Start temporary` and `End temporary` have their `rowid` in the temporary table.
- `FirstMatch(tbl_name)` in the `Extra` column indicates join shortcutting.
- `LooseScan(m..n)` in the `Extra` column indicates use of the LooseScan strategy. `m` and `n` are key part numbers.
- Temporary table use for materialization is indicated by rows with a `select_type` value of `MATERIALIZED` and rows with a `table` value of `<subqueryN>`.

A semijoin transformation can also be applied to a single-table `UPDATE` or `DELETE` statement that uses a `[NOT] IN` or `[NOT] EXISTS` subquery predicate, provided that the statement does not use `ORDER BY` or `LIMIT`, and that semijoin transformations are allowed by an optimizer hint or by the `optimizer_switch` setting.

### 10.2.2.2 Optimizing Subqueries with Materialization

The optimizer uses materialization to enable more efficient subquery processing. Materialization speeds up query execution by generating a subquery result as a temporary table, normally in memory. The first time MySQL needs the subquery result, it materializes that result into a temporary table. Any subsequent time the result is needed, MySQL refers again to the temporary table. The optimizer may index the table with a hash index to make lookups fast and inexpensive. The index contains unique values to eliminate duplicates and make the table smaller.

Subquery materialization uses an in-memory temporary table when possible, falling back to on-disk storage if the table becomes too large. See [Section 10.4.4, “Internal Temporary Table Use in MySQL”](#).

If materialization is not used, the optimizer sometimes rewrites a noncorrelated subquery as a correlated subquery. For example, the following `IN` subquery is noncorrelated (`where_condition` involves only columns from `t2` and not `t1`):

```
SELECT * FROM t1
WHERE t1.a IN (SELECT t2.b FROM t2 WHERE where_condition);
```

The optimizer might rewrite this as an `EXISTS` correlated subquery:

```
SELECT * FROM t1
WHERE EXISTS (SELECT t2.b FROM t2 WHERE where_condition AND t1.a=t2.b);
```

Subquery materialization using a temporary table avoids such rewrites and makes it possible to execute the subquery only once rather than once per row of the outer query.

For subquery materialization to be used in MySQL, the `optimizer_switch` system variable `materialization` flag must be enabled. (See [Section 10.9.2, “Switchable Optimizations”](#).) With the `materialization` flag enabled, materialization applies to subquery predicates that appear anywhere (in the select list, `WHERE`, `ON`, `GROUP BY`, `HAVING`, or `ORDER BY`), for predicates that fall into any of these use cases:

- The predicate has this form, when no outer expression `oe_i` or inner expression `ie_i` is nullable. *N* is 1 or larger.

```
(oe_1, oe_2, ..., oe_N) [NOT] IN (SELECT ie_1, ie_2, ..., ie_N ...)
```

- The predicate has this form, when there is a single outer expression `oe` and inner expression `ie`. The expressions can be nullable.

```
oe [NOT] IN (SELECT ie ...)
```

- The predicate is `IN` or `NOT IN` and a result of `UNKNOWN` (`NULL`) has the same meaning as a result of `FALSE`.

The following examples illustrate how the requirement for equivalence of `UNKNOWN` and `FALSE` predicate evaluation affects whether subquery materialization can be used. Assume that `where_condition` involves columns only from `t2` and not `t1` so that the subquery is noncorrelated.

This query is subject to materialization:

```
SELECT * FROM t1
WHERE t1.a IN (SELECT t2.b FROM t2 WHERE where_condition);
```

Here, it does not matter whether the `IN` predicate returns `UNKNOWN` or `FALSE`. Either way, the row from `t1` is not included in the query result.

An example where subquery materialization is not used is the following query, where `t2.b` is a nullable column:

```
SELECT * FROM t1
WHERE (t1.a,t1.b) NOT IN (SELECT t2.a,t2.b FROM t2
 WHERE where_condition);
```

The following restrictions apply to the use of subquery materialization:

- The types of the inner and outer expressions must match. For example, the optimizer might be able to use materialization if both expressions are integer or both are decimal, but cannot if one expression is integer and the other is decimal.
- The inner expression cannot be a `BLOB`.

Use of `EXPLAIN` with a query provides some indication of whether the optimizer uses subquery materialization:

- Compared to query execution that does not use materialization, `select_type` may change from `DEPENDENT SUBQUERY` to `SUBQUERY`. This indicates that, for a subquery that would be executed once per outer row, materialization enables the subquery to be executed just once.

- For extended `EXPLAIN` output, the text displayed by a following `SHOW WARNINGS` includes `materialize` and `materialized-subquery`.

MySQL can also apply subquery materialization to a single-table `UPDATE` or `DELETE` statement that uses a `[NOT] IN` or `[NOT] EXISTS` subquery predicate, provided that the statement does not use `ORDER BY` or `LIMIT`, and that subquery materialization is allowed by an optimizer hint or by the `optimizer_switch` setting.

### 10.2.2.3 Optimizing Subqueries with the EXISTS Strategy

Certain optimizations are applicable to comparisons that use the `IN` (or `=ANY`) operator to test subquery results. This section discusses these optimizations, particularly with regard to the challenges that `NULL` values present. The last part of the discussion suggests how you can help the optimizer.

Consider the following subquery comparison:

```
outer_expr IN (SELECT inner_expr FROM ... WHERE subquery_where)
```

MySQL evaluates queries “from outside to inside.” That is, it first obtains the value of the outer expression `outer_expr`, and then runs the subquery and captures the rows that it produces.

A very useful optimization is to “inform” the subquery that the only rows of interest are those where the inner expression `inner_expr` is equal to `outer_expr`. This is done by pushing down an appropriate equality into the subquery's `WHERE` clause to make it more restrictive. The converted comparison looks like this:

```
EXISTS (SELECT 1 FROM ... WHERE subquery_where AND outer_expr=inner_expr)
```

After the conversion, MySQL can use the pushed-down equality to limit the number of rows it must examine to evaluate the subquery.

More generally, a comparison of `N` values to a subquery that returns `N`-value rows is subject to the same conversion. If `oe_i` and `ie_i` represent corresponding outer and inner expression values, this subquery comparison:

```
(oe_1, ..., oe_N) IN
 (SELECT ie_1, ..., ie_N FROM ... WHERE subquery_where)
```

Becomes:

```
EXISTS (SELECT 1 FROM ... WHERE subquery_where
 AND oe_1 = ie_1
 AND ...
 AND oe_N = ie_N)
```

For simplicity, the following discussion assumes a single pair of outer and inner expression values.

The “pushdown” strategy just described works if either of these conditions is true:

- `outer_expr` and `inner_expr` cannot be `NULL`.
- You need not distinguish `NULL` from `FALSE` subquery results. If the subquery is a part of an `OR` or `AND` expression in the `WHERE` clause, MySQL assumes that you do not care. Another instance where the optimizer notices that `NULL` and `FALSE` subquery results need not be distinguished is this construct:

```
... WHERE outer_expr IN (subquery)
```

In this case, the `WHERE` clause rejects the row whether `IN (subquery)` returns `NULL` or `FALSE`.

Suppose that `outer_expr` is known to be a non-NULL value but the subquery does not produce a row such that `outer_expr = inner_expr`. Then `outer_expr IN (SELECT ...)` evaluates as follows:

- **NULL**, if the `SELECT` produces any row where `inner_expr` is **NULL**
- **FALSE**, if the `SELECT` produces only non-NULL values or produces nothing

In this situation, the approach of looking for rows with `outer_expr = inner_expr` is no longer valid. It is necessary to look for such rows, but if none are found, also look for rows where `inner_expr` is **NULL**. Roughly speaking, the subquery can be converted to something like this:

```
EXISTS (SELECT 1 FROM ... WHERE subquery_where AND
 (outer_expr=inner_expr OR inner_expr IS NULL))
```

The need to evaluate the extra `IS NULL` condition is why MySQL has the `ref_or_null` access method:

```
mysql> EXPLAIN
 SELECT outer_expr IN (SELECT t2.maybe_null_key
 FROM t2, t3 WHERE ...)
 FROM t1;
***** 1. row *****
 id: 1
 select_type: PRIMARY
 table: t1
 ...
***** 2. row *****
 id: 2
 select_type: DEPENDENT SUBQUERY
 table: t2
 type: ref_or_null
possible_keys: maybe_null_key
 key: maybe_null_key
 key_len: 5
 ref: func
 rows: 2
 Extra: Using where; Using index
 ...
```

The `unique_subquery` and `index_subquery` subquery-specific access methods also have “or **NULL**” variants.

The additional `OR ... IS NULL` condition makes query execution slightly more complicated (and some optimizations within the subquery become inapplicable), but generally this is tolerable.

The situation is much worse when `outer_expr` can be **NULL**. According to the SQL interpretation of **NULL** as “unknown value,” `NULL IN (SELECT inner_expr ...)` should evaluate to:

- **NULL**, if the `SELECT` produces any rows
- **FALSE**, if the `SELECT` produces no rows

For proper evaluation, it is necessary to be able to check whether the `SELECT` has produced any rows at all, so `outer_expr = inner_expr` cannot be pushed down into the subquery. This is a problem because many real world subqueries become very slow unless the equality can be pushed down.

Essentially, there must be different ways to execute the subquery depending on the value of `outer_expr`.

The optimizer chooses SQL compliance over speed, so it accounts for the possibility that `outer_expr` might be **NULL**:

- If `outer_expr` is **NULL**, to evaluate the following expression, it is necessary to execute the `SELECT` to determine whether it produces any rows:

```
NULL IN (SELECT inner_expr FROM ... WHERE subquery_where)
```

It is necessary to execute the original `SELECT` here, without any pushed-down equalities of the kind mentioned previously.

- On the other hand, when *outer\_expr* is not `NULL`, it is absolutely essential that this comparison:

```
outer_expr IN (SELECT inner_expr FROM ... WHERE subquery_where)
```

Be converted to this expression that uses a pushed-down condition:

```
EXISTS (SELECT 1 FROM ... WHERE subquery_where AND outer_expr=inner_expr)
```

Without this conversion, subqueries are slow.

To solve the dilemma of whether or not to push down conditions into the subquery, the conditions are wrapped within “trigger” functions. Thus, an expression of the following form:

```
outer_expr IN (SELECT inner_expr FROM ... WHERE subquery_where)
```

Is converted into:

```
EXISTS (SELECT 1 FROM ... WHERE subquery_where
 AND trigcond(outer_expr=inner_expr))
```

More generally, if the subquery comparison is based on several pairs of outer and inner expressions, the conversion takes this comparison:

```
(oe_1, ..., oe_N) IN (SELECT ie_1, ..., ie_N FROM ... WHERE subquery_where)
```

And converts it to this expression:

```
EXISTS (SELECT 1 FROM ... WHERE subquery_where
 AND trigcond(oe_1=ie_1)
 AND ...
 AND trigcond(oe_N=ie_N)
)
```

Each `trigcond(X)` is a special function that evaluates to the following values:

- `X` when the “linked” outer expression *oe\_i* is not `NULL`
- `TRUE` when the “linked” outer expression *oe\_i* is `NULL`

#### Note

Trigger functions are *not* triggers of the kind that you create with `CREATE TRIGGER`.

Equalities that are wrapped within `trigcond()` functions are not first class predicates for the query optimizer. Most optimizations cannot deal with predicates that may be turned on and off at query execution time, so they assume any `trigcond(X)` to be an unknown function and ignore it. Triggered equalities can be used by those optimizations:

- Reference optimizations: `trigcond(X=Y [OR Y IS NULL])` can be used to construct `ref`, `eq_ref`, or `ref_or_null` table accesses.
- Index lookup-based subquery execution engines: `trigcond(X=Y)` can be used to construct `unique_subquery` or `index_subquery` accesses.

- Table-condition generator: If the subquery is a join of several tables, the triggered condition is checked as soon as possible.

When the optimizer uses a triggered condition to create some kind of index lookup-based access (as for the first two items of the preceding list), it must have a fallback strategy for the case when the condition is turned off. This fallback strategy is always the same: Do a full table scan. In `EXPLAIN` output, the fallback shows up as `Full scan on NULL key` in the `Extra` column:

```
mysql> EXPLAIN SELECT t1.col1,
 t1.col1 IN (SELECT t2.key1 FROM t2 WHERE t2.col2=t1.col2) FROM t1\G
***** 1. row *****
 id: 1
 select_type: PRIMARY
 table: t1
 ...
***** 2. row *****
 id: 2
 select_type: DEPENDENT SUBQUERY
 table: t2
 type: index_subquery
possible_keys: key1
 key: key1
 key_len: 5
 ref: func
 rows: 2
 Extra: Using where; Full scan on NULL key
```

If you run `EXPLAIN` followed by `SHOW WARNINGS`, you can see the triggered condition:

```
***** 1. row *****
Level: Note
Code: 1003
Message: select `test`.`t1`.`col1` AS `col1`,
 <in_optimizer>(`test`.`t1`.`col1`,
 <exists>(<index_lookup>(<cache>(`test`.`t1`.`col1`) in t2
 on key1 checking NULL
 where (`test`.`t2`.`col2` = `test`.`t1`.`col2`) having
 trigcond(<is_not_null_test>(`test`.`t2`.`key1`)))) AS
 `t1.col1 IN (select t2.key1 from t2 where t2.col2=t1.col2)`
 from `test`.`t1`
```

The use of triggered conditions has some performance implications. A `NULL IN (SELECT ...)` expression now may cause a full table scan (which is slow) when it previously did not. This is the price paid for correct results (the goal of the trigger-condition strategy is to improve compliance, not speed).

For multiple-table subqueries, execution of `NULL IN (SELECT ...)` is particularly slow because the join optimizer does not optimize for the case where the outer expression is `NULL`. It assumes that subquery evaluations with `NULL` on the left side are very rare, even if there are statistics that indicate otherwise. On the other hand, if the outer expression might be `NULL` but never actually is, there is no performance penalty.

To help the query optimizer better execute your queries, use these suggestions:

- Declare a column as `NOT NULL` if it really is. This also helps other aspects of the optimizer by simplifying condition testing for the column.
- If you need not distinguish a `NULL` from `FALSE` subquery result, you can easily avoid the slow execution path. Replace a comparison that looks like this:

```
outer_expr [NOT] IN (SELECT inner_expr FROM ...)
```

with this expression:

```
(outer_expr IS NOT NULL) AND (outer_expr [NOT] IN (SELECT inner_expr FROM ...))
```

Then `NULL IN (SELECT ...)` is never evaluated because MySQL stops evaluating `AND` parts as soon as the expression result is clear.

Another possible rewrite:

```
[NOT] EXISTS (SELECT inner_expr FROM ...
 WHERE inner_expr=outer_expr)
```

The `subquery_materialization_cost_based` flag of the `optimizer_switch` system variable enables control over the choice between subquery materialization and `IN-to-EXISTS` subquery transformation. See [Section 10.9.2, “Switchable Optimizations”](#).

### 10.2.2.4 Optimizing Derived Tables, View References, and Common Table Expressions with Merging or Materialization

The optimizer can handle derived table references using two strategies (which also apply to view references and common table expressions):

- Merge the derived table into the outer query block
- Materialize the derived table to an internal temporary table

Example 1:

```
SELECT * FROM (SELECT * FROM t1) AS derived_t1;
```

With merging of the derived table `derived_t1`, that query is executed similar to:

```
SELECT * FROM t1;
```

Example 2:

```
SELECT *
FROM t1 JOIN (SELECT t2.f1 FROM t2) AS derived_t2 ON t1.f2=derived_t2.f1
WHERE t1.f1 > 0;
```

With merging of the derived table `derived_t2`, that query is executed similar to:

```
SELECT t1.*, t2.f1
FROM t1 JOIN t2 ON t1.f2=t2.f1
WHERE t1.f1 > 0;
```

With materialization, `derived_t1` and `derived_t2` are each treated as a separate table within their respective queries.

The optimizer handles derived tables, view references, and common table expressions the same way: It avoids unnecessary materialization whenever possible, which enables pushing down conditions from the outer query to derived tables and produces more efficient execution plans. (For an example, see [Section 10.2.2.2, “Optimizing Subqueries with Materialization”](#).)

If merging would result in an outer query block that references more than 61 base tables, the optimizer chooses materialization instead.

The optimizer propagates an `ORDER BY` clause in a derived table or view reference to the outer query block if these conditions are all true:

- The outer query is not grouped or aggregated.

- The outer query does not specify `DISTINCT`, `HAVING`, or `ORDER BY`.
- The outer query has this derived table or view reference as the only source in the `FROM` clause.

Otherwise, the optimizer ignores the `ORDER BY` clause.

The following means are available to influence whether the optimizer attempts to merge derived tables, view references, and common table expressions into the outer query block:

- The `MERGE` and `NO_MERGE` optimizer hints can be used. They apply assuming that no other rule prevents merging. See [Section 10.9.3, “Optimizer Hints”](#).
- Similarly, you can use the `derived_merge` flag of the `optimizer_switch` system variable. See [Section 10.9.2, “Switchable Optimizations”](#). By default, the flag is enabled to permit merging. Disabling the flag prevents merging and avoids `ER_UPDATE_TABLE_USED` errors.

The `derived_merge` flag also applies to views that contain no `ALGORITHM` clause. Thus, if an `ER_UPDATE_TABLE_USED` error occurs for a view reference that uses an expression equivalent to the subquery, adding `ALGORITHM=TEMPTABLE` to the view definition prevents merging and takes precedence over the `derived_merge` value.

- It is possible to disable merging by using in the subquery any constructs that prevent merging, although these are not as explicit in their effect on materialization. Constructs that prevent merging are the same for derived tables, common table expressions, and view references:
  - Aggregate functions or window functions (`SUM()`, `MIN()`, `MAX()`, `COUNT()`, and so forth)
  - `DISTINCT`
  - `GROUP BY`
  - `HAVING`
  - `LIMIT`
  - `UNION` or `UNION ALL`
  - Subqueries in the select list
  - Assignments to user variables
  - References only to literal values (in this case, there is no underlying table)

If the optimizer chooses the materialization strategy rather than merging for a derived table, it handles the query as follows:

- The optimizer postpones derived table materialization until its contents are needed during query execution. This improves performance because delaying materialization may result in not having to do it at all. Consider a query that joins the result of a derived table to another table: If the optimizer processes that other table first and finds that it returns no rows, the join need not be carried out further and the optimizer can completely skip materializing the derived table.
- During query execution, the optimizer may add an index to a derived table to speed up row retrieval from it.

Consider the following `EXPLAIN` statement, for a `SELECT` query that contains a derived table:

```
EXPLAIN SELECT * FROM (SELECT * FROM t1) AS derived_t1;
```

The optimizer avoids materializing the derived table by delaying it until the result is needed during `SELECT` execution. In this case, the query is not executed (because it occurs in an `EXPLAIN` statement), so the result is never needed.

Even for queries that are executed, delay of derived table materialization may enable the optimizer to avoid materialization entirely. When this happens, query execution is quicker by the time needed to perform materialization. Consider the following query, which joins the result of a derived table to another table:

```
SELECT *
FROM t1 JOIN (SELECT t2.f1 FROM t2) AS derived_t2
 ON t1.f2=derived_t2.f1
WHERE t1.f1 > 0;
```

If the optimization processes `t1` first and the `WHERE` clause produces an empty result, the join must necessarily be empty and the derived table need not be materialized.

For cases when a derived table requires materialization, the optimizer may add an index to the materialized table to speed up access to it. If such an index enables `ref` access to the table, it can greatly reduce amount of data read during query execution. Consider the following query:

```
SELECT *
FROM t1 JOIN (SELECT DISTINCT f1 FROM t2) AS derived_t2
 ON t1.f1=derived_t2.f1;
```

The optimizer constructs an index over column `f1` from `derived_t2` if doing so would enable use of `ref` access for the lowest cost execution plan. After adding the index, the optimizer can treat the materialized derived table the same as a regular table with an index, and it benefits similarly from the generated index. The overhead of index creation is negligible compared to the cost of query execution without the index. If `ref` access would result in higher cost than some other access method, the optimizer creates no index and loses nothing.

For optimizer trace output, a merged derived table or view reference is not shown as a node. Only its underlying tables appear in the top query's plan.

What is true for materialization of derived tables is also true for common table expressions (CTEs). In addition, the following considerations pertain specifically to CTEs.

If a CTE is materialized by a query, it is materialized once for the query, even if the query references it several times.

A recursive CTE is always materialized.

If a CTE is materialized, the optimizer automatically adds relevant indexes if it estimates that indexing can speed up access by the top-level statement to the CTE. This is similar to automatic indexing of derived tables, except that if the CTE is referenced multiple times, the optimizer may create multiple indexes, to speed up access by each reference in the most appropriate way.

The `MERGE` and `NO_MERGE` optimizer hints can be applied to CTEs. Each CTE reference in the top-level statement can have its own hint, permitting CTE references to be selectively merged or materialized. The following statement uses hints to indicate that `cte1` should be merged and `cte2` should be materialized:

```
WITH
 cte1 AS (SELECT a, b FROM table1),
 cte2 AS (SELECT c, d FROM table2)
SELECT /*+ MERGE(cte1) NO_MERGE(cte2) */ cte1.b, cte2.d
FROM cte1 JOIN cte2
WHERE cte1.a = cte2.c;
```

The `ALGORITHM` clause for `CREATE VIEW` does not affect materialization for any `WITH` clause preceding the `SELECT` statement in the view definition. Consider this statement:

```
CREATE ALGORITHM={TEMPTABLE|MERGE} VIEW v1 AS WITH ... SELECT ...
```

The `ALGORITHM` value affects materialization only of the `SELECT`, not the `WITH` clause.

As mentioned previously, a CTE, if materialized, is materialized once, even if referenced multiple times. To indicate one-time materialization, optimizer trace output contains an occurrence of `creating_tmp_table` plus one or more occurrences of `reusing_tmp_table`.

CTEs are similar to derived tables, for which the `materialized_from_subquery` node follows the reference. This is true for a CTE that is referenced multiple times, so there is no duplication of `materialized_from_subquery` nodes (which would give the impression that the subquery is executed multiple times, and produce unnecessarily verbose output). Only one reference to the CTE has a complete `materialized_from_subquery` node with the description of its subquery plan. Other references have a reduced `materialized_from_subquery` node. The same idea applies to `EXPLAIN` output in `TRADITIONAL` format: Subqueries for other references are not shown.

### 10.2.2.5 Derived Condition Pushdown Optimization

MySQL supports derived condition pushdown for eligible subqueries. For a query such as `SELECT * FROM (SELECT i, j FROM t1) AS dt WHERE i > constant`, it is possible in many cases to push the outer `WHERE` condition down to the derived table, in this case resulting in `SELECT * FROM (SELECT i, j FROM t1 WHERE i > constant) AS dt`. When a derived table cannot be merged into the outer query (for example, if the derived table uses aggregation), pushing the outer `WHERE` condition down to the derived table should decrease the number of rows that need to be processed and thus speed up execution of the query.

Outer `WHERE` conditions can be pushed down to derived materialized tables under the following circumstances:

- When the derived table uses no aggregate or window functions, the outer `WHERE` condition can be pushed down to it directly. This includes `WHERE` conditions having multiple predicates joined with `AND`, `OR`, or both.

For example, the query `SELECT * FROM (SELECT f1, f2 FROM t1) AS dt WHERE f1 < 3 AND f2 > 11` is rewritten as `SELECT f1, f2 FROM (SELECT f1, f2 FROM t1 WHERE f1 < 3 AND f2 > 11) AS dt`.

- When the derived table has a `GROUP BY` and uses no window functions, an outer `WHERE` condition referencing one or more columns which are not part of the `GROUP BY` can be pushed down to the derived table as a `HAVING` condition.

For example, `SELECT * FROM (SELECT i, j, SUM(k) AS sum FROM t1 GROUP BY i, j) AS dt WHERE sum > 100` is rewritten following derived condition pushdown as `SELECT * FROM (SELECT i, j, SUM(k) AS sum FROM t1 GROUP BY i, j HAVING sum > 100) AS dt`.

- When the derived table uses a `GROUP BY` and the columns in the outer `WHERE` condition are `GROUP BY` columns, the `WHERE` conditions referencing those columns can be pushed down directly to the derived table.

For example, the query `SELECT * FROM (SELECT i, j, SUM(k) AS sum FROM t1 GROUP BY i, j) AS dt WHERE i > 10` is rewritten as `SELECT * FROM (SELECT i, j, SUM(k) AS sum FROM t1 WHERE i > 10 GROUP BY i, j) AS dt`.

In the event that the outer `WHERE` condition has predicates referencing columns which are part of the `GROUP BY` as well as predicates referencing columns which are not, predicates of the former sort are pushed down as `WHERE` conditions, while those of the latter type are pushed down as `HAVING`

conditions. For example, in the query `SELECT * FROM (SELECT i, j, SUM(k) AS sum FROM t1 GROUP BY i, j) AS dt WHERE i > 10 AND sum > 100`, the predicate `i > 10` in the outer `WHERE` clause references a `GROUP BY` column, whereas the predicate `sum > 100` does not reference any `GROUP BY` column. Thus the derived table pushdown optimization causes the query to be rewritten in a manner similar to what is shown here:

```
SELECT * FROM (
 SELECT i, j, SUM(k) AS sum FROM t1
 WHERE i > 10
 GROUP BY i, j
 HAVING sum > 100
) AS dt;
```

To enable derived condition pushdown, the `optimizer_switch` system variable's `derived_condition_pushdown` flag (added in this release) must be set to `on`, which is the default setting. If this optimization is disabled by `optimizer_switch`, you can enable it for a specific query using the `DERIVED_CONDITION_PUSHDOWN` optimizer hint. To disable the optimization for a given query, use the `NO_DERIVED_CONDITION_PUSHDOWN` optimizer hint.

The following restrictions and limitations apply to the derived table condition pushdown optimization:

- The derived table condition pushdown optimization can be employed with `UNION` queries, with the following exceptions:
  - Condition pushdown cannot be used with a `UNION` query if any materialized derived table that is part of the `UNION` is a recursive common table expression (see [Recursive Common Table Expressions](#)).
  - Conditions containing nondeterministic expressions cannot be pushed down to a derived table.
- The derived table cannot use a `LIMIT` clause.
- Conditions containing subqueries cannot be pushed down.
- The optimization cannot be used if the derived table is an inner table of an outer join.
- If a materialized derived table is a common table expression, conditions are not pushed down to it if it is referenced multiple times.
- Conditions using parameters can be pushed down if the condition is of the form `derived_column > ?`. If a derived column in an outer `WHERE` condition is an expression having a `?` in the underlying derived table, this condition cannot be pushed down.
- For a query in which the condition is on the tables of a view created using `ALGORITHM=TEMPTABLE` instead of on the view itself, the multiple equality is not recognized at resolution, and thus the condition cannot be pushed down. This is because, when optimizing a query, condition pushdown takes place during resolution phase while multiple equality propagation occurs during optimization.

This is not an issue in such cases for a view using `ALGORITHM=MERGE`, where the equality can be propagated and the condition pushed down.

- A condition cannot be pushed down if the derived table's `SELECT` list contain any assignments to user variables.

### 10.2.3 Optimizing INFORMATION\_SCHEMA Queries

Applications that monitor databases may make frequent use of `INFORMATION_SCHEMA` tables. To write queries for these tables most efficiently, use the following general guidelines:

- Try to query only [INFORMATION\\_SCHEMA](#) tables that are views on data dictionary tables.
- Try to query only for static metadata. Selecting columns or using retrieval conditions for dynamic metadata along with static metadata adds overhead to process the dynamic metadata.

**Note**

Comparison behavior for database and table names in [INFORMATION\\_SCHEMA](#) queries might differ from what you expect. For details, see [Section 12.8.7, “Using Collation in INFORMATION\\_SCHEMA Searches”](#).

These [INFORMATION\\_SCHEMA](#) tables are implemented as views on data dictionary tables, so queries on them retrieve information from the data dictionary:

```
CHARACTER_SETS
CHECK_CONSTRAINTS
COLLATIONS
COLLATION_CHARACTER_SET_APPLICABILITY
COLUMNS
EVENTS
FILES
INNODB_COLUMNS
INNODB_DATAFILES
INNODB_FIELDS
INNODB_FOREIGN
INNODB_FOREIGN_COLS
INNODB_INDEXES
INNODB_TABLES
INNODB_TABLESPACES
INNODB_TABLESPACES_BRIEF
INNODB_TABLESTATS
KEY_COLUMN_USAGE
PARAMETERS
PARTITIONS
REFERENTIAL_CONSTRAINTS
RESOURCE_GROUPS
ROUTINES
SCHEMATA
STATISTICS
TABLES
TABLE_CONSTRAINTS
TRIGGERS
VIEWS
VIEW_ROUTINE_USAGE
VIEW_TABLE_USAGE
```

Some types of values, even for a non-view [INFORMATION\\_SCHEMA](#) table, are retrieved by lookups from the data dictionary. This includes values such as database and table names, table types, and storage engines.

Some [INFORMATION\\_SCHEMA](#) tables contain columns that provide table statistics:

```
STATISTICS.CARDINALITY
TABLES.AUTO_INCREMENT
TABLES.AVG_ROW_LENGTH
TABLES.CHECKSUM
TABLES.CHECK_TIME
TABLES.CREATE_TIME
TABLES.DATA_FREE
TABLES.DATA_LENGTH
TABLES.INDEX_LENGTH
TABLES.MAX_DATA_LENGTH
TABLES.TABLE_ROWS
TABLES.UPDATE_TIME
```

Those columns represent dynamic table metadata; that is, information that changes as table contents change.

By default, MySQL retrieves cached values for those columns from the `mysql.index_stats` and `mysql.innodb_table_stats` dictionary tables when the columns are queried, which is more efficient than retrieving statistics directly from the storage engine. If cached statistics are not available or have expired, MySQL retrieves the latest statistics from the storage engine and caches them in the `mysql.index_stats` and `mysql.innodb_table_stats` dictionary tables. Subsequent queries retrieve the cached statistics until the cached statistics expire. A server restart or the first opening of the `mysql.index_stats` and `mysql.innodb_table_stats` tables do not update cached statistics automatically.

The `information_schema_stats_expiry` session variable defines the period of time before cached statistics expire. The default is 86400 seconds (24 hours), but the time period can be extended to as much as one year.

To update cached values at any time for a given table, use `ANALYZE TABLE`.

Querying statistics columns does not store or update statistics in the `mysql.index_stats` and `mysql.innodb_table_stats` dictionary tables under these circumstances:

- When cached statistics have not expired.
- When `information_schema_stats_expiry` is set to 0.
- When the server is in `read_only`, `super_read_only`, `transaction_read_only`, or `innodb_read_only` mode.
- When the query also fetches Performance Schema data.

`information_schema_stats_expiry` is a session variable, and each client session can define its own expiration value. Statistics that are retrieved from the storage engine and cached by one session are available to other sessions.

#### Note

If the `innodb_read_only` system variable is enabled, `ANALYZE TABLE` may fail because it cannot update statistics tables in the data dictionary, which use InnoDB. For `ANALYZE TABLE` operations that update the key distribution, failure may occur even if the operation updates the table itself (for example, if it is a `MyISAM` table). To obtain the updated distribution statistics, set `information_schema_stats_expiry=0`.

For `INFORMATION_SCHEMA` tables implemented as views on data dictionary tables, indexes on the underlying data dictionary tables permit the optimizer to construct efficient query execution plans. To see the choices made by the optimizer, use `EXPLAIN`. To also see the query used by the server to execute an `INFORMATION_SCHEMA` query, use `SHOW WARNINGS` immediately following `EXPLAIN`.

Consider this statement, which identifies collations for the `utf8mb4` character set:

```
mysql> SELECT COLLATION_NAME
 FROM INFORMATION_SCHEMA.COLLATION_CHARACTER_SET_APPLICABILITY
 WHERE CHARACTER_SET_NAME = 'utf8mb4';
```

COLLATION_NAME
utf8mb4_general_ci
utf8mb4_bin

```
| utf8mb4_unicode_ci |
| utf8mb4_icelandic_ci |
| utf8mb4_latvian_ci |
| utf8mb4_romanian_ci |
| utf8mb4_slovenian_ci |
...
```

How does the server process that statement? To find out, use [EXPLAIN](#):

```
mysql> EXPLAIN SELECT COLLATION_NAME
FROM INFORMATION_SCHEMA.COLLATION_CHARACTER_SET_APPLICABILITY
WHERE CHARACTER_SET_NAME = 'utf8mb4'\G
***** 1. row *****
 id: 1
 select_type: SIMPLE
 table: cs
 partitions: NULL
 type: const
possible_keys: PRIMARY,name
 key: name
 key_len: 194
 ref: const
 rows: 1
 filtered: 100.00
 Extra: Using index
***** 2. row *****
 id: 1
 select_type: SIMPLE
 table: col
 partitions: NULL
 type: ref
possible_keys: character_set_id
 key: character_set_id
 key_len: 8
 ref: const
 rows: 68
 filtered: 100.00
 Extra: NULL
2 rows in set, 1 warning (0.01 sec)
```

To see the query used to satisfy that statement, use [SHOW WARNINGS](#):

```
mysql> SHOW WARNINGS\G
***** 1. row *****
 Level: Note
 Code: 1003
Message: /* select#1 */ select `mysql`.`col`.`name` AS `COLLATION_NAME`
 from `mysql`.`character_sets` `cs`
 join `mysql`.`collations` `col`
 where ((`mysql`.`col`.`character_set_id` = '45')
 and ('utf8mb4' = 'utf8mb4'))
```

As indicated by [SHOW WARNINGS](#), the server handles the query on [COLLATION\\_CHARACTER\\_SET\\_APPLICABILITY](#) as a query on the [character\\_sets](#) and [collations](#) data dictionary tables in the [mysql](#) system database.

## 10.2.4 Optimizing Performance Schema Queries

Applications that monitor databases may make frequent use of Performance Schema tables. To write queries for these tables most efficiently, take advantage of their indexes. For example, include a [WHERE](#) clause that restricts retrieved rows based on comparison to specific values in an indexed column.

Most Performance Schema tables have indexes. Tables that do not are those that normally contain few rows or are unlikely to be queried frequently. Performance Schema indexes give the optimizer access to

execution plans other than full table scans. These indexes also improve performance for related objects, such as `sys` schema views that use those tables.

To see whether a given Performance Schema table has indexes and what they are, use `SHOW INDEX` or `SHOW CREATE TABLE`:

```
mysql> SHOW INDEX FROM performance_schema.accounts\G
***** 1. row *****
 Table: accounts
 Non_unique: 0
 Key_name: ACCOUNT
 Seq_in_index: 1
 Column_name: USER
 Collation: NULL
 Cardinality: NULL
 Sub_part: NULL
 Packed: NULL
 Null: YES
 Index_type: HASH
 Comment:
 Index_comment:
 Visible: YES
***** 2. row *****
 Table: accounts
 Non_unique: 0
 Key_name: ACCOUNT
 Seq_in_index: 2
 Column_name: HOST
 Collation: NULL
 Cardinality: NULL
 Sub_part: NULL
 Packed: NULL
 Null: YES
 Index_type: HASH
 Comment:
 Index_comment:
 Visible: YES

mysql> SHOW CREATE TABLE performance_schema.rwlock_instances\G
***** 1. row *****
 Table: rwlock_instances
 Create Table: CREATE TABLE `rwlock_instances` (
 `NAME` varchar(128) NOT NULL,
 `OBJECT_INSTANCE_BEGIN` bigint(20) unsigned NOT NULL,
 `WRITE_LOCKED_BY_THREAD_ID` bigint(20) unsigned DEFAULT NULL,
 `READ_LOCKED_BY_COUNT` int(10) unsigned NOT NULL,
 PRIMARY KEY (`OBJECT_INSTANCE_BEGIN`),
 KEY `NAME` (`NAME`),
 KEY `WRITE_LOCKED_BY_THREAD_ID` (`WRITE_LOCKED_BY_THREAD_ID`)
) ENGINE=PERFORMANCE_SCHEMA DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci
```

To see the execution plan for a Performance Schema query and whether it uses any indexes, use `EXPLAIN`:

```
mysql> EXPLAIN SELECT * FROM performance_schema.accounts
 WHERE (USER,HOST) = ('root','localhost')\G
***** 1. row *****
 id: 1
 select_type: SIMPLE
 table: accounts
 partitions: NULL
 type: const
 possible_keys: ACCOUNT
 key: ACCOUNT
 key_len: 278
 ref: const,const
```

```
rows: 1
filtered: 100.00
Extra: NULL
```

The `EXPLAIN` output indicates that the optimizer uses the `accounts` table `ACCOUNT` index that comprises the `USER` and `HOST` columns.

Performance Schema indexes are virtual: They are a construct of the Performance Schema storage engine and use no memory or disk storage. The Performance Schema reports index information to the optimizer so that it can construct efficient execution plans. The Performance Schema in turn uses optimizer information about what to look for (for example, a particular key value), so that it can perform efficient lookups without building actual index structures. This implementation provides two important benefits:

- It entirely avoids the maintenance cost normally incurred for tables that undergo frequent updates.
- It reduces at an early stage of query execution the amount of data retrieved. For conditions on the indexed columns, the Performance Schema efficiently returns only table rows that satisfy the query conditions. Without an index, the Performance Schema would return all rows in the table, requiring that the optimizer later evaluate the conditions against each row to produce the final result.

Performance Schema indexes are predefined and cannot be dropped, added, or altered.

Performance Schema indexes are similar to hash indexes. For example:

- They are used only for equality comparisons that use the `=` or `<=>` operators.
- They are unordered. If a query result must have specific row ordering characteristics, include an `ORDER BY` clause.

For additional information about hash indexes, see [Section 10.3.9, “Comparison of B-Tree and Hash Indexes”](#).

## 10.2.5 Optimizing Data Change Statements

This section explains how to speed up data change statements: `INSERT`, `UPDATE`, and `DELETE`. Traditional OLTP applications and modern web applications typically do many small data change operations, where concurrency is vital. Data analysis and reporting applications typically run data change operations that affect many rows at once, where the main considerations is the I/O to write large amounts of data and keep indexes up-to-date. For inserting and updating large volumes of data (known in the industry as ETL, for “extract-transform-load”), sometimes you use other SQL statements or external commands, that mimic the effects of `INSERT`, `UPDATE`, and `DELETE` statements.

### 10.2.5.1 Optimizing INSERT Statements

To optimize insert speed, combine many small operations into a single large operation. Ideally, you make a single connection, send the data for many new rows at once, and delay all index updates and consistency checking until the very end.

The time required for inserting a row is determined by the following factors, where the numbers indicate approximate proportions:

- Connecting: (3)
- Sending query to server: (2)
- Parsing query: (2)
- Inserting row: (1 × size of row)

- Inserting indexes: (1 × number of indexes)
- Closing: (1)

This does not take into consideration the initial overhead to open tables, which is done once for each concurrently running query.

The size of the table slows down the insertion of indexes by  $\log N$ , assuming B-tree indexes.

You can use the following methods to speed up inserts:

- If you are inserting many rows from the same client at the same time, use `INSERT` statements with multiple `VALUES` lists to insert several rows at a time. This is considerably faster (many times faster in some cases) than using separate single-row `INSERT` statements. If you are adding data to a nonempty table, you can tune the `bulk_insert_buffer_size` variable to make data insertion even faster. See [Section 7.1.8, “Server System Variables”](#).
- When loading a table from a text file, use `LOAD DATA`. This is usually 20 times faster than using `INSERT` statements. See [Section 15.2.9, “LOAD DATA Statement”](#).
- Take advantage of the fact that columns have default values. Insert values explicitly only when the value to be inserted differs from the default. This reduces the parsing that MySQL must do and improves the insert speed.
- See [Section 10.5.5, “Bulk Data Loading for InnoDB Tables”](#) for tips specific to `InnoDB` tables.
- See [Section 10.6.2, “Bulk Data Loading for MyISAM Tables”](#) for tips specific to `MyISAM` tables.

### 10.2.5.2 Optimizing UPDATE Statements

An update statement is optimized like a `SELECT` query with the additional overhead of a write. The speed of the write depends on the amount of data being updated and the number of indexes that are updated. Indexes that are not changed do not get updated.

Another way to get fast updates is to delay updates and then do many updates in a row later. Performing multiple updates together is much quicker than doing one at a time if you lock the table.

For a `MyISAM` table that uses dynamic row format, updating a row to a longer total length may split the row. If you do this often, it is very important to use `OPTIMIZE TABLE` occasionally. See [Section 15.7.3.4, “OPTIMIZE TABLE Statement”](#).

### 10.2.5.3 Optimizing DELETE Statements

The time required to delete individual rows in a `MyISAM` table is exactly proportional to the number of indexes. To delete rows more quickly, you can increase the size of the key cache by increasing the `key_buffer_size` system variable. See [Section 7.1.1, “Configuring the Server”](#).

To delete all rows from a `MyISAM` table, `TRUNCATE TABLE tbl_name` is faster than `DELETE FROM tbl_name`. Truncate operations are not transaction-safe; an error occurs when attempting one in the course of an active transaction or active table lock. See [Section 15.1.37, “TRUNCATE TABLE Statement”](#).

## 10.2.6 Optimizing Database Privileges

The more complex your privilege setup, the more overhead applies to all SQL statements. Simplifying the privileges established by `GRANT` statements enables MySQL to reduce permission-checking overhead when clients execute statements. For example, if you do not grant any table-level or column-level

privileges, the server need not ever check the contents of the `tables_priv` and `columns_priv` tables. Similarly, if you place no resource limits on any accounts, the server does not have to perform resource counting. If you have a very high statement-processing load, consider using a simplified grant structure to reduce permission-checking overhead.

## 10.2.7 Other Optimization Tips

This section lists a number of miscellaneous tips for improving query processing speed:

- If your application makes several database requests to perform related updates, combining the statements into a stored routine can help performance. Similarly, if your application computes a single result based on several column values or large volumes of data, combining the computation into a loadable function can help performance. The resulting fast database operations are then available to be reused by other queries, applications, and even code written in different programming languages. See [Section 27.2, “Using Stored Routines”](#) and [Adding Functions to MySQL](#) for more information.
- To fix any compression issues that occur with `ARCHIVE` tables, use `OPTIMIZE TABLE`. See [Section 18.5, “The ARCHIVE Storage Engine”](#).
- If possible, classify reports as “live” or as “statistical”, where data needed for statistical reports is created only from summary tables that are generated periodically from the live data.
- If you have data that does not conform well to a rows-and-columns table structure, you can pack and store data into a `BLOB` column. In this case, you must provide code in your application to pack and unpack information, but this might save I/O operations to read and write the sets of related values.
- With Web servers, store images and other binary assets as files, with the path name stored in the database rather than the file itself. Most Web servers are better at caching files than database contents, so using files is generally faster. (Although you must handle backups and storage issues yourself in this case.)
- If you need really high speed, look at the low-level MySQL interfaces. For example, by accessing the MySQL `InnoDB` or `MyISAM` storage engine directly, you could get a substantial speed increase compared to using the SQL interface.

Similarly, for databases using the `NDBCLUSTER` storage engine, you may wish to investigate possible use of the NDB API (see [MySQL NDB Cluster API Developer Guide](#)).

- Replication can provide a performance benefit for some operations. You can distribute client retrievals among replicas to split up the load. To avoid slowing down the source while making backups, you can make backups using a replica. See [Chapter 19, Replication](#).

## 10.3 Optimization and Indexes

The best way to improve the performance of `SELECT` operations is to create indexes on one or more of the columns that are tested in the query. The index entries act like pointers to the table rows, allowing the query to quickly determine which rows match a condition in the `WHERE` clause, and retrieve the other column values for those rows. All MySQL data types can be indexed.

Although it can be tempting to create an indexes for every possible column used in a query, unnecessary indexes waste space and waste time for MySQL to determine which indexes to use. Indexes also add to the cost of inserts, updates, and deletes because each index must be updated. You must find the right balance to achieve fast queries using the optimal set of indexes.

### 10.3.1 How MySQL Uses Indexes

Indexes are used to find rows with specific column values quickly. Without an index, MySQL must begin with the first row and then read through the entire table to find the relevant rows. The larger the table, the more this costs. If the table has an index for the columns in question, MySQL can quickly determine the position to seek to in the middle of the data file without having to look at all the data. This is much faster than reading every row sequentially.

Most MySQL indexes ([PRIMARY KEY](#), [UNIQUE](#), [INDEX](#), and [FULLTEXT](#)) are stored in [B-trees](#). Exceptions: Indexes on spatial data types use R-trees; [MEMORY](#) tables also support [hash indexes](#); [InnoDB](#) uses inverted lists for [FULLTEXT](#) indexes.

In general, indexes are used as described in the following discussion. Characteristics specific to hash indexes (as used in [MEMORY](#) tables) are described in [Section 10.3.9, “Comparison of B-Tree and Hash Indexes”](#).

MySQL uses indexes for these operations:

- To find the rows matching a [WHERE](#) clause quickly.
- To eliminate rows from consideration. If there is a choice between multiple indexes, MySQL normally uses the index that finds the smallest number of rows (the most [selective](#) index).
- If the table has a multiple-column index, any leftmost prefix of the index can be used by the optimizer to look up rows. For example, if you have a three-column index on [\(col1, col2, col3\)](#), you have indexed search capabilities on [\(col1\)](#), [\(col1, col2\)](#), and [\(col1, col2, col3\)](#). For more information, see [Section 10.3.6, “Multiple-Column Indexes”](#).
- To retrieve rows from other tables when performing joins. MySQL can use indexes on columns more efficiently if they are declared as the same type and size. In this context, [VARCHAR](#) and [CHAR](#) are considered the same if they are declared as the same size. For example, [VARCHAR\(10\)](#) and [CHAR\(10\)](#) are the same size, but [VARCHAR\(10\)](#) and [CHAR\(15\)](#) are not.

For comparisons between nonbinary string columns, both columns should use the same character set. For example, comparing a [utf8mb4](#) column with a [latin1](#) column precludes use of an index.

Comparison of dissimilar columns (comparing a string column to a temporal or numeric column, for example) may prevent use of indexes if values cannot be compared directly without conversion. For a given value such as [1](#) in the numeric column, it might compare equal to any number of values in the string column such as ['1'](#), [' 1'](#), ['00001'](#), or ['01.e1'](#). This rules out use of any indexes for the string column.

- To find the [MIN\(\)](#) or [MAX\(\)](#) value for a specific indexed column [key\\_col](#). This is optimized by a preprocessor that checks whether you are using [WHERE key\\_part\\_N = constant](#) on all key parts that occur before [key\\_col](#) in the index. In this case, MySQL does a single key lookup for each [MIN\(\)](#) or [MAX\(\)](#) expression and replaces it with a constant. If all expressions are replaced with constants, the query returns at once. For example:

```
SELECT MIN(key_part2),MAX(key_part2)
FROM tbl_name WHERE key_part1=10;
```

- To sort or group a table if the sorting or grouping is done on a leftmost prefix of a usable index (for example, [ORDER BY key\\_part1, key\\_part2](#)). If all key parts are followed by [DESC](#), the key is read in reverse order. (Or, if the index is a descending index, the key is read in forward order.) See [Section 10.2.1.16, “ORDER BY Optimization”](#), [Section 10.2.1.17, “GROUP BY Optimization”](#), and [Section 10.3.13, “Descending Indexes”](#).
- In some cases, a query can be optimized to retrieve values without consulting the data rows. (An index that provides all the necessary results for a query is called a [covering index](#).) If a query uses from a table

only columns that are included in some index, the selected values can be retrieved from the index tree for greater speed:

```
SELECT key_part3 FROM tbl_name
WHERE key_part1=1
```

Indexes are less important for queries on small tables, or big tables where report queries process most or all of the rows. When a query needs to access most of the rows, reading sequentially is faster than working through an index. Sequential reads minimize disk seeks, even if not all the rows are needed for the query. See [Section 10.2.1.23, “Avoiding Full Table Scans”](#) for details.

## 10.3.2 Primary Key Optimization

The primary key for a table represents the column or set of columns that you use in your most vital queries. It has an associated index, for fast query performance. Query performance benefits from the `NOT NULL` optimization, because it cannot include any `NULL` values. With the `InnoDB` storage engine, the table data is physically organized to do ultra-fast lookups and sorts based on the primary key column or columns.

If your table is big and important, but does not have an obvious column or set of columns to use as a primary key, you might create a separate column with auto-increment values to use as the primary key. These unique IDs can serve as pointers to corresponding rows in other tables when you join tables using foreign keys.

## 10.3.3 SPATIAL Index Optimization

MySQL permits creation of `SPATIAL` indexes on `NOT NULL` geometry-valued columns (see [Section 13.4.10, “Creating Spatial Indexes”](#)). The optimizer checks the `SRID` attribute for indexed columns to determine which spatial reference system (SRS) to use for comparisons, and uses calculations appropriate to the SRS. (Prior to MySQL 9.1, the optimizer performs comparisons of `SPATIAL` index values using Cartesian calculations; the results of such operations are undefined if the column contains values with non-Cartesian SRIDs.)

For comparisons to work properly, each column in a `SPATIAL` index must be `SRID`-restricted. That is, the column definition must include an explicit `SRID` attribute, and all column values must have the same `SRID`.

The optimizer considers `SPATIAL` indexes only for `SRID`-restricted columns:

- Indexes on columns restricted to a Cartesian `SRID` enable Cartesian bounding box computations.
- Indexes on columns restricted to a geographic `SRID` enable geographic bounding box computations.

The optimizer ignores `SPATIAL` indexes on columns that have no `SRID` attribute (and thus are not `SRID`-restricted). MySQL still maintains such indexes, as follows:

- They are updated for table modifications (`INSERT`, `UPDATE`, `DELETE`, and so forth). Updates occur as though the index was Cartesian, even though the column might contain a mix of Cartesian and geographical values.
- They exist only for backward compatibility (for example, the ability to perform a dump in MySQL 8.4 and restore in MySQL 9.0). Because `SPATIAL` indexes on columns that are not `SRID`-restricted are of no use to the optimizer, each such column should be modified:
- Verify that all values within the column have the same `SRID`. To determine the `SRIDs` contained in a geometry column `col_name`, use the following query:

```
SELECT DISTINCT ST_SRID(col_name) FROM tbl_name;
```

If the query returns more than one row, the column contains a mix of SRIDs. In that case, modify its contents so all values have the same SRID.

- Redefine the column to have an explicit [SRID](#) attribute.
- Recreate the [SPATIAL](#) index.

### 10.3.4 Foreign Key Optimization

If a table has many columns, and you query many different combinations of columns, it might be efficient to split the less-frequently used data into separate tables with a few columns each, and relate them back to the main table by duplicating the numeric ID column from the main table. That way, each small table can have a primary key for fast lookups of its data, and you can query just the set of columns that you need using a join operation. Depending on how the data is distributed, the queries might perform less I/O and take up less cache memory because the relevant columns are packed together on disk. (To maximize performance, queries try to read as few data blocks as possible from disk; tables with only a few columns can fit more rows in each data block.)

### 10.3.5 Column Indexes

The most common type of index involves a single column, storing copies of the values from that column in a data structure, allowing fast lookups for the rows with the corresponding column values. The B-tree data structure lets the index quickly find a specific value, a set of values, or a range of values, corresponding to operators such as `=`, `>`, `≤`, [BETWEEN](#), [IN](#), and so on, in a [WHERE](#) clause.

The maximum number of indexes per table and the maximum index length is defined per storage engine. See [Chapter 17, The InnoDB Storage Engine](#), and [Chapter 18, Alternative Storage Engines](#). All storage engines support at least 16 indexes per table and a total index length of at least 256 bytes. Most storage engines have higher limits.

For additional information about column indexes, see [Section 15.1.15, “CREATE INDEX Statement”](#).

- [Index Prefixes](#)
- [FULLTEXT Indexes](#)
- [Spatial Indexes](#)
- [Indexes in the MEMORY Storage Engine](#)

### Index Prefixes

With `col_name(N)` syntax in an index specification for a string column, you can create an index that uses only the first *N* characters of the column. Indexing only a prefix of column values in this way can make the index file much smaller. When you index a [BLOB](#) or [TEXT](#) column, you *must* specify a prefix length for the index. For example:

```
CREATE TABLE test (blob_col BLOB, INDEX(blob_col(10)));
```

Prefixes can be up to 767 bytes long for [InnoDB](#) tables that use the [REDUNDANT](#) or [COMPACT](#) row format. The prefix length limit is 3072 bytes for [InnoDB](#) tables that use the [DYNAMIC](#) or [COMPRESSED](#) row format. For [MyISAM](#) tables, the prefix length limit is 1000 bytes.

#### Note

Prefix limits are measured in bytes, whereas the prefix length in [CREATE TABLE](#), [ALTER TABLE](#), and [CREATE INDEX](#) statements is interpreted as number of

characters for nonbinary string types ([CHAR](#), [VARCHAR](#), [TEXT](#)) and number of bytes for binary string types ([BINARY](#), [VARBINARY](#), [BLOB](#)). Take this into account when specifying a prefix length for a nonbinary string column that uses a multibyte character set.

If a search term exceeds the index prefix length, the index is used to exclude non-matching rows, and the remaining rows are examined for possible matches.

For additional information about index prefixes, see [Section 15.1.15, “CREATE INDEX Statement”](#).

## FULLTEXT Indexes

[FULLTEXT](#) indexes are used for full-text searches. Only the [InnoDB](#) and [MyISAM](#) storage engines support [FULLTEXT](#) indexes and only for [CHAR](#), [VARCHAR](#), and [TEXT](#) columns. Indexing always takes place over the entire column and column prefix indexing is not supported. For details, see [Section 14.9, “Full-Text Search Functions”](#).

Optimizations are applied to certain kinds of [FULLTEXT](#) queries against single [InnoDB](#) tables. Queries with these characteristics are particularly efficient:

- [FULLTEXT](#) queries that only return the document ID, or the document ID and the search rank.
- [FULLTEXT](#) queries that sort the matching rows in descending order of score and apply a [LIMIT](#) clause to take the top N matching rows. For this optimization to apply, there must be no [WHERE](#) clauses and only a single [ORDER BY](#) clause in descending order.
- [FULLTEXT](#) queries that retrieve only the [COUNT\(\\*\)](#) value of rows matching a search term, with no additional [WHERE](#) clauses. Code the [WHERE](#) clause as [WHERE MATCH\(text\) AGAINST \('other\\_text'\)](#), without any [> 0](#) comparison operator.

For queries that contain full-text expressions, MySQL evaluates those expressions during the optimization phase of query execution. The optimizer does not just look at full-text expressions and make estimates, it actually evaluates them in the process of developing an execution plan.

An implication of this behavior is that [EXPLAIN](#) for full-text queries is typically slower than for non-full-text queries for which no expression evaluation occurs during the optimization phase.

[EXPLAIN](#) for full-text queries may show [Select tables optimized away](#) in the [Extra](#) column due to matching occurring during optimization; in this case, no table access need occur during later execution.

## Spatial Indexes

You can create indexes on spatial data types. [MyISAM](#) and [InnoDB](#) support R-tree indexes on spatial types. Other storage engines use B-trees for indexing spatial types (except for [ARCHIVE](#), which does not support spatial type indexing).

## Indexes in the MEMORY Storage Engine

The [MEMORY](#) storage engine uses [HASH](#) indexes by default, but also supports [BTREE](#) indexes.

### 10.3.6 Multiple-Column Indexes

MySQL can create composite indexes (that is, indexes on multiple columns). An index may consist of up to 16 columns. For certain data types, you can index a prefix of the column (see [Section 10.3.5, “Column Indexes”](#)).

MySQL can use multiple-column indexes for queries that test all the columns in the index, or queries that test just the first column, the first two columns, the first three columns, and so on. If you specify the columns in the right order in the index definition, a single composite index can speed up several kinds of queries on the same table.

A multiple-column index can be considered a sorted array, the rows of which contain values that are created by concatenating the values of the indexed columns.

### Note

As an alternative to a composite index, you can introduce a column that is “hashed” based on information from other columns. If this column is short, reasonably unique, and indexed, it might be faster than a “wide” index on many columns. In MySQL, it is very easy to use this extra column:

```
SELECT * FROM tbl_name
WHERE hash_col=MD5(CONCAT(val1,val2))
AND col1=val1 AND col2=val2;
```

Suppose that a table has the following specification:

```
CREATE TABLE test (
 id INT NOT NULL,
 last_name CHAR(30) NOT NULL,
 first_name CHAR(30) NOT NULL,
 PRIMARY KEY (id),
 INDEX name (last_name,first_name)
);
```

The `name` index is an index over the `last_name` and `first_name` columns. The index can be used for lookups in queries that specify values in a known range for combinations of `last_name` and `first_name` values. It can also be used for queries that specify just a `last_name` value because that column is a leftmost prefix of the index (as described later in this section). Therefore, the `name` index is used for lookups in the following queries:

```
SELECT * FROM test WHERE last_name='Jones';

SELECT * FROM test
WHERE last_name='Jones' AND first_name='John';

SELECT * FROM test
WHERE last_name='Jones'
AND (first_name='John' OR first_name='Jon');

SELECT * FROM test
WHERE last_name='Jones'
AND first_name >='M' AND first_name < 'N';
```

However, the `name` index is *not* used for lookups in the following queries:

```
SELECT * FROM test WHERE first_name='John';

SELECT * FROM test
WHERE last_name='Jones' OR first_name='John';
```

Suppose that you issue the following `SELECT` statement:

```
SELECT * FROM tbl_name
WHERE col1=val1 AND col2=val2;
```

If a multiple-column index exists on `col1` and `col2`, the appropriate rows can be fetched directly. If separate single-column indexes exist on `col1` and `col2`, the optimizer attempts to use the Index Merge

optimization (see [Section 10.2.1.3, “Index Merge Optimization”](#)), or attempts to find the most restrictive index by deciding which index excludes more rows and using that index to fetch the rows.

If the table has a multiple-column index, any leftmost prefix of the index can be used by the optimizer to look up rows. For example, if you have a three-column index on `(col1, col2, col3)`, you have indexed search capabilities on `(col1)`, `(col1, col2)`, and `(col1, col2, col3)`.

MySQL cannot use the index to perform lookups if the columns do not form a leftmost prefix of the index. Suppose that you have the `SELECT` statements shown here:

```
SELECT * FROM tbl_name WHERE col1=val1;
SELECT * FROM tbl_name WHERE col1=val1 AND col2=val2;

SELECT * FROM tbl_name WHERE col2=val2;
SELECT * FROM tbl_name WHERE col2=val2 AND col3=val3;
```

If an index exists on `(col1, col2, col3)`, only the first two queries use the index. The third and fourth queries do involve indexed columns, but do not use an index to perform lookups because `(col2)` and `(col2, col3)` are not leftmost prefixes of `(col1, col2, col3)`.

## 10.3.7 Verifying Index Usage

Always check whether all your queries really use the indexes that you have created in the tables. Use the `EXPLAIN` statement, as described in [Section 10.8.1, “Optimizing Queries with EXPLAIN”](#).

## 10.3.8 InnoDB and MyISAM Index Statistics Collection

Storage engines collect statistics about tables for use by the optimizer. Table statistics are based on value groups, where a value group is a set of rows with the same key prefix value. For optimizer purposes, an important statistic is the average value group size.

MySQL uses the average value group size in the following ways:

- To estimate how many rows must be read for each `ref` access
- To estimate how many rows a partial join produces, that is, the number of rows produced by an operation of the form

```
(...) JOIN tbl_name ON tbl_name.key = expr
```

As the average value group size for an index increases, the index is less useful for those two purposes because the average number of rows per lookup increases: For the index to be good for optimization purposes, it is best that each index value target a small number of rows in the table. When a given index value yields a large number of rows, the index is less useful and MySQL is less likely to use it.

The average value group size is related to table cardinality, which is the number of value groups. The `SHOW INDEX` statement displays a cardinality value based on  $N/S$ , where  $N$  is the number of rows in the table and  $S$  is the average value group size. That ratio yields an approximate number of value groups in the table.

For a join based on the `<=>` comparison operator, `NULL` is not treated differently from any other value: `NULL <=> NULL`, just as `N <=> N` for any other  $N$ .

However, for a join based on the `=` operator, `NULL` is different from non-`NULL` values: `expr1 = expr2` is not true when `expr1` or `expr2` (or both) are `NULL`. This affects `ref` accesses for comparisons of the form `tbl_name.key = expr`: MySQL does not access the table if the current value of `expr` is `NULL`, because the comparison cannot be true.

For `=` comparisons, it does not matter how many `NULL` values are in the table. For optimization purposes, the relevant value is the average size of the non-`NULL` value groups. However, MySQL does not currently enable that average size to be collected or used.

For `InnoDB` and `MyISAM` tables, you have some control over collection of table statistics by means of the `innodb_stats_method` and `myisam_stats_method` system variables, respectively. These variables have three possible values, which differ as follows:

- When the variable is set to `nulls_equal`, all `NULL` values are treated as identical (that is, they all form a single value group).

If the `NULL` value group size is much higher than the average non-`NULL` value group size, this method skews the average value group size upward. This makes index appear to the optimizer to be less useful than it really is for joins that look for non-`NULL` values. Consequently, the `nulls_equal` method may cause the optimizer not to use the index for `ref` accesses when it should.

- When the variable is set to `nulls_unequal`, `NULL` values are not considered the same. Instead, each `NULL` value forms a separate value group of size 1.

If you have many `NULL` values, this method skews the average value group size downward. If the average non-`NULL` value group size is large, counting `NULL` values each as a group of size 1 causes the optimizer to overestimate the value of the index for joins that look for non-`NULL` values. Consequently, the `nulls_unequal` method may cause the optimizer to use this index for `ref` lookups when other methods may be better.

- When the variable is set to `nulls_ignored`, `NULL` values are ignored.

If you tend to use many joins that use `<=>` rather than `=`, `NULL` values are not special in comparisons and one `NULL` is equal to another. In this case, `nulls_equal` is the appropriate statistics method.

The `innodb_stats_method` system variable has a global value; the `myisam_stats_method` system variable has both global and session values. Setting the global value affects statistics collection for tables from the corresponding storage engine. Setting the session value affects statistics collection only for the current client connection. This means that you can force a table's statistics to be regenerated with a given method without affecting other clients by setting the session value of `myisam_stats_method`.

To regenerate `MyISAM` table statistics, you can use any of the following methods:

- Execute `myisamchk --stats_method=method_name --analyze`
- Change the table to cause its statistics to go out of date (for example, insert a row and then delete it), and then set `myisam_stats_method` and issue an `ANALYZE TABLE` statement

Some caveats regarding the use of `innodb_stats_method` and `myisam_stats_method`:

- You can force table statistics to be collected explicitly, as just described. However, MySQL may also collect statistics automatically. For example, if during the course of executing statements for a table, some of those statements modify the table, MySQL may collect statistics. (This may occur for bulk inserts or deletes, or some `ALTER TABLE` statements, for example.) If this happens, the statistics are collected using whatever value `innodb_stats_method` or `myisam_stats_method` has at the time. Thus, if you collect statistics using one method, but the system variable is set to the other method when a table's statistics are collected automatically later, the other method is used.
- There is no way to tell which method was used to generate statistics for a given table.
- These variables apply only to `InnoDB` and `MyISAM` tables. Other storage engines have only one method for collecting table statistics. Usually it is closer to the `nulls_equal` method.

## 10.3.9 Comparison of B-Tree and Hash Indexes

Understanding the B-tree and hash data structures can help predict how different queries perform on different storage engines that use these data structures in their indexes, particularly for the [MEMORY](#) storage engine that lets you choose B-tree or hash indexes.

- [B-Tree Index Characteristics](#)
- [Hash Index Characteristics](#)

### B-Tree Index Characteristics

A B-tree index can be used for column comparisons in expressions that use the `=`, `>`, `>=`, `<`, `<=`, or [BETWEEN](#) operators. The index also can be used for [LIKE](#) comparisons if the argument to [LIKE](#) is a constant string that does not start with a wildcard character. For example, the following [SELECT](#) statements use indexes:

```
SELECT * FROM tbl_name WHERE key_col LIKE 'Patrick%';
SELECT * FROM tbl_name WHERE key_col LIKE 'Pat%ck%';
```

In the first statement, only rows with `'Patrick' <= key_col < 'Patricl'` are considered. In the second statement, only rows with `'Pat' <= key_col < 'Pau'` are considered.

The following [SELECT](#) statements do not use indexes:

```
SELECT * FROM tbl_name WHERE key_col LIKE '%Patrick%';
SELECT * FROM tbl_name WHERE key_col LIKE other_col;
```

In the first statement, the [LIKE](#) value begins with a wildcard character. In the second statement, the [LIKE](#) value is not a constant.

If you use `... LIKE '%string%'` and *string* is longer than three characters, MySQL uses the *Turbo Boyer-Moore algorithm* to initialize the pattern for the string and then uses this pattern to perform the search more quickly.

A search using `col_name IS NULL` employs indexes if *col\_name* is indexed.

Any index that does not span all [AND](#) levels in the [WHERE](#) clause is not used to optimize the query. In other words, to be able to use an index, a prefix of the index must be used in every [AND](#) group.

The following [WHERE](#) clauses use indexes:

```
... WHERE index_part1=1 AND index_part2=2 AND other_column=3

/* index = 1 OR index = 2 */
... WHERE index=1 OR A=10 AND index=2

/* optimized like "index_part1='hello'" */
... WHERE index_part1='hello' AND index_part3=5

/* Can use index on index1 but not on index2 or index3 */
... WHERE index1=1 AND index2=2 OR index1=3 AND index3=3;
```

These [WHERE](#) clauses do *not* use indexes:

```
/* index_part1 is not used */
... WHERE index_part2=1 AND index_part3=2

/* Index is not used in both parts of the WHERE clause */
... WHERE index=1 OR A=10
```

```
/* No index spans all rows */
... WHERE index_part1=1 OR index_part2=10
```

Sometimes MySQL does not use an index, even if one is available. One circumstance under which this occurs is when the optimizer estimates that using the index would require MySQL to access a very large percentage of the rows in the table. (In this case, a table scan is likely to be much faster because it requires fewer seeks.) However, if such a query uses `LIMIT` to retrieve only some of the rows, MySQL uses an index anyway, because it can much more quickly find the few rows to return in the result.

## Hash Index Characteristics

Hash indexes have somewhat different characteristics from those just discussed:

- They are used only for equality comparisons that use the `=` or `<=>` operators (but are *very* fast). They are not used for comparison operators such as `<` that find a range of values. Systems that rely on this type of single-value lookup are known as “key-value stores”; to use MySQL for such applications, use hash indexes wherever possible.
- The optimizer cannot use a hash index to speed up `ORDER BY` operations. (This type of index cannot be used to search for the next entry in order.)
- MySQL cannot determine approximately how many rows there are between two values (this is used by the range optimizer to decide which index to use). This may affect some queries if you change a `MyISAM` or `InnoDB` table to a hash-indexed `MEMORY` table.
- Only whole keys can be used to search for a row. (With a B-tree index, any leftmost prefix of the key can be used to find rows.)

### 10.3.10 Use of Index Extensions

`InnoDB` automatically extends each secondary index by appending the primary key columns to it. Consider this table definition:

```
CREATE TABLE t1 (
 i1 INT NOT NULL DEFAULT 0,
 i2 INT NOT NULL DEFAULT 0,
 d DATE DEFAULT NULL,
 PRIMARY KEY (i1, i2),
 INDEX k_d (d)
) ENGINE = InnoDB;
```

This table defines the primary key on columns (`i1`, `i2`). It also defines a secondary index `k_d` on column (`d`), but internally `InnoDB` extends this index and treats it as columns (`d`, `i1`, `i2`).

The optimizer takes into account the primary key columns of the extended secondary index when determining how and whether to use that index. This can result in more efficient query execution plans and better performance.

The optimizer can use extended secondary indexes for `ref`, `range`, and `index_merge` index access, for Loose Index Scan access, for join and sorting optimization, and for `MIN()`/`MAX()` optimization.

The following example shows how execution plans are affected by whether the optimizer uses extended secondary indexes. Suppose that `t1` is populated with these rows:

```
INSERT INTO t1 VALUES
(1, 1, '1998-01-01'), (1, 2, '1999-01-01'),
(1, 3, '2000-01-01'), (1, 4, '2001-01-01'),
(1, 5, '2002-01-01'), (2, 1, '1998-01-01'),
(2, 2, '1999-01-01'), (2, 3, '2000-01-01'),
```

```
(2, 4, '2001-01-01'), (2, 5, '2002-01-01'),
(3, 1, '1998-01-01'), (3, 2, '1999-01-01'),
(3, 3, '2000-01-01'), (3, 4, '2001-01-01'),
(3, 5, '2002-01-01'), (4, 1, '1998-01-01'),
(4, 2, '1999-01-01'), (4, 3, '2000-01-01'),
(4, 4, '2001-01-01'), (4, 5, '2002-01-01'),
(5, 1, '1998-01-01'), (5, 2, '1999-01-01'),
(5, 3, '2000-01-01'), (5, 4, '2001-01-01'),
(5, 5, '2002-01-01');
```

Now consider this query:

```
EXPLAIN SELECT COUNT(*) FROM t1 WHERE i1 = 3 AND d = '2000-01-01'
```

The execution plan depends on whether the extended index is used.

When the optimizer does not consider index extensions, it treats the index `k_d` as only `(d)`. `EXPLAIN` for the query produces this result:

```
mysql> EXPLAIN SELECT COUNT(*) FROM t1 WHERE i1 = 3 AND d = '2000-01-01'\G
***** 1. row *****
 id: 1
 select_type: SIMPLE
 table: t1
 type: ref
possible_keys: PRIMARY,k_d
 key: k_d
 key_len: 4
 ref: const
 rows: 5
 Extra: Using where; Using index
```

When the optimizer takes index extensions into account, it treats `k_d` as `(d, i1, i2)`. In this case, it can use the leftmost index prefix `(d, i1)` to produce a better execution plan:

```
mysql> EXPLAIN SELECT COUNT(*) FROM t1 WHERE i1 = 3 AND d = '2000-01-01'\G
***** 1. row *****
 id: 1
 select_type: SIMPLE
 table: t1
 type: ref
possible_keys: PRIMARY,k_d
 key: k_d
 key_len: 8
 ref: const,const
 rows: 1
 Extra: Using index
```

In both cases, `key` indicates that the optimizer uses secondary index `k_d` but the `EXPLAIN` output shows these improvements from using the extended index:

- `key_len` goes from 4 bytes to 8 bytes, indicating that key lookups use columns `d` and `i1`, not just `d`.
- The `ref` value changes from `const` to `const,const` because the key lookup uses two key parts, not one.
- The `rows` count decreases from 5 to 1, indicating that InnoDB should need to examine fewer rows to produce the result.
- The `Extra` value changes from `Using where; Using index` to `Using index`. This means that rows can be read using only the index, without consulting columns in the data row.

Differences in optimizer behavior for use of extended indexes can also be seen with `SHOW STATUS`:

```
FLUSH TABLE t1;
FLUSH STATUS;
SELECT COUNT(*) FROM t1 WHERE i1 = 3 AND d = '2000-01-01';
SHOW STATUS LIKE 'handler_read%'
```

The preceding statements include `FLUSH TABLES` and `FLUSH STATUS` to flush the table cache and clear the status counters.

Without index extensions, `SHOW STATUS` produces this result:

Variable_name	Value
Handler_read_first	0
Handler_read_key	1
Handler_read_last	0
Handler_read_next	5
Handler_read_prev	0
Handler_read_rnd	0
Handler_read_rnd_next	0

With index extensions, `SHOW STATUS` produces this result. The `Handler_read_next` value decreases from 5 to 1, indicating more efficient use of the index:

Variable_name	Value
Handler_read_first	0
Handler_read_key	1
Handler_read_last	0
Handler_read_next	1
Handler_read_prev	0
Handler_read_rnd	0
Handler_read_rnd_next	0

The `use_index_extensions` flag of the `optimizer_switch` system variable permits control over whether the optimizer takes the primary key columns into account when determining how to use an InnoDB table's secondary indexes. By default, `use_index_extensions` is enabled. To check whether disabling use of index extensions can improve performance, use this statement:

```
SET optimizer_switch = 'use_index_extensions=off';
```

Use of index extensions by the optimizer is subject to the usual limits on the number of key parts in an index (16) and the maximum key length (3072 bytes).

### 10.3.11 Optimizer Use of Generated Column Indexes

MySQL supports indexes on generated columns. For example:

```
CREATE TABLE t1 (f1 INT, gc INT AS (f1 + 1) STORED, INDEX (gc));
```

The generated column, `gc`, is defined as the expression `f1 + 1`. The column is also indexed and the optimizer can take that index into account during execution plan construction. In the following query, the `WHERE` clause refers to `gc` and the optimizer considers whether the index on that column yields a more efficient plan:

```
SELECT * FROM t1 WHERE gc > 9;
```

The optimizer can use indexes on generated columns to generate execution plans, even in the absence of direct references in queries to those columns by name. This occurs if the `WHERE`, `ORDER BY`, or `GROUP`

[BY](#) clause refers to an expression that matches the definition of some indexed generated column. The following query does not refer directly to [gc](#) but does use an expression that matches the definition of [gc](#):

```
SELECT * FROM t1 WHERE f1 + 1 > 9;
```

The optimizer recognizes that the expression [f1](#) + 1 matches the definition of [gc](#) and that [gc](#) is indexed, so it considers that index during execution plan construction. You can see this using [EXPLAIN](#):

```
mysql> EXPLAIN SELECT * FROM t1 WHERE f1 + 1 > 9\G
***** 1. row *****
 id: 1
 select_type: SIMPLE
 table: t1
 partitions: NULL
 type: range
possible_keys: gc
 key: gc
 key_len: 5
 ref: NULL
 rows: 1
 filtered: 100.00
 Extra: Using index condition
```

In effect, the optimizer has replaced the expression [f1](#) + 1 with the name of the generated column that matches the expression. That is also apparent in the rewritten query available in the extended [EXPLAIN](#) information displayed by [SHOW WARNINGS](#):

```
mysql> SHOW WARNINGS\G
***** 1. row *****
 Level: Note
 Code: 1003
Message: /* select#1 */ select `test`.`t1`.`f1` AS `f1`,`test`.`t1`.`gc`
 AS `gc` from `test`.`t1` where (`test`.`t1`.`gc` > 9)
```

The following restrictions and conditions apply to the optimizer's use of generated column indexes:

- For a query expression to match a generated column definition, the expression must be identical and it must have the same result type. For example, if the generated column expression is [f1](#) + 1, the optimizer does not recognize a match if the query uses 1 + [f1](#), or if [f1](#) + 1 (an integer expression) is compared with a string.
- The optimization applies to these operators: =, <, <=, >, >=, [BETWEEN](#), and [IN\(\)](#).

For operators other than [BETWEEN](#) and [IN\(\)](#), either operand can be replaced by a matching generated column. For [BETWEEN](#) and [IN\(\)](#), only the first argument can be replaced by a matching generated column, and the other arguments must have the same result type. [BETWEEN](#) and [IN\(\)](#) are not yet supported for comparisons involving JSON values.

- The generated column must be defined as an expression that contains at least a function call or one of the operators mentioned in the preceding item. The expression cannot consist of a simple reference to another column. For example, [gc](#) INT AS ([f1](#)) STORED consists only of a column reference, so indexes on [gc](#) are not considered.
- For comparisons of strings to indexed generated columns that compute a value from a JSON function that returns a quoted string, [JSON\\_UNQUOTE\(\)](#) is needed in the column definition to remove the extra quotes from the function value. (For direct comparison of a string to the function result, the JSON comparator handles quote removal, but this does not occur for index lookups.) For example, instead of writing a column definition like this:

```
doc_name TEXT AS (JSON_EXTRACT(jdoc, '$.name')) STORED
```

Write it like this:

```
doc_name TEXT AS (JSON_UNQUOTE(JSON_EXTRACT(jdoc, '$.name'))) STORED
```

With the latter definition, the optimizer can detect a match for both of these comparisons:

```
... WHERE JSON_EXTRACT(jdoc, '$.name') = 'some_string' ...
... WHERE JSON_UNQUOTE(JSON_EXTRACT(jdoc, '$.name')) = 'some_string' ...
```

Without `JSON_UNQUOTE( )` in the column definition, the optimizer detects a match only for the first of those comparisons.

- If the optimizer picks the wrong index, an index hint can be used to disable it and force the optimizer to make a different choice.

### 10.3.12 Invisible Indexes

MySQL supports invisible indexes; that is, indexes that are not used by the optimizer. The feature applies to indexes other than primary keys (either explicit or implicit).

Indexes are visible by default. To control visibility explicitly for a new index, use a `VISIBLE` or `INVISIBLE` keyword as part of the index definition for `CREATE TABLE`, `CREATE INDEX`, or `ALTER TABLE`:

```
CREATE TABLE t1 (
 i INT,
 j INT,
 k INT,
 INDEX i_idx (i) INVISIBLE
) ENGINE = InnoDB;
CREATE INDEX j_idx ON t1 (j) INVISIBLE;
ALTER TABLE t1 ADD INDEX k_idx (k) INVISIBLE;
```

To alter the visibility of an existing index, use a `VISIBLE` or `INVISIBLE` keyword with the `ALTER TABLE ... ALTER INDEX` operation:

```
ALTER TABLE t1 ALTER INDEX i_idx INVISIBLE;
ALTER TABLE t1 ALTER INDEX i_idx VISIBLE;
```

Information about whether an index is visible or invisible is available from the Information Schema `STATISTICS` table or `SHOW INDEX` output. For example:

```
mysql> SELECT INDEX_NAME, IS_VISIBLE
 FROM INFORMATION_SCHEMA.STATISTICS
 WHERE TABLE_SCHEMA = 'db1' AND TABLE_NAME = 't1';
```

INDEX_NAME	IS_VISIBLE
i_idx	YES
j_idx	NO
k_idx	NO

Invisible indexes make it possible to test the effect of removing an index on query performance, without making a destructive change that must be undone should the index turn out to be required. Dropping and re-adding an index can be expensive for a large table, whereas making it invisible and visible are fast, in-place operations.

If an index made invisible actually is needed or used by the optimizer, there are several ways to notice the effect of its absence on queries for the table:

- Errors occur for queries that include index hints that refer to the invisible index.

- Performance Schema data shows an increase in workload for affected queries.
- Queries have different `EXPLAIN` execution plans.
- Queries appear in the slow query log that did not appear there previously.

The `use_invisible_indexes` flag of the `optimizer_switch` system variable controls whether the optimizer uses invisible indexes for query execution plan construction. If the flag is `off` (the default), the optimizer ignores invisible indexes (the same behavior as prior to the introduction of this flag). If the flag is `on`, invisible indexes remain invisible but the optimizer takes them into account for execution plan construction.

Using the `SET_VAR` optimizer hint to update the value of `optimizer_switch` temporarily, you can enable invisible indexes for the duration of a single query only, like this:

```
mysql> EXPLAIN SELECT /*+ SET_VAR(optimizer_switch = 'use_invisible_indexes=on') */
> i, j FROM t1 WHERE j >= 50\G
***** 1. row *****
 id: 1
 select_type: SIMPLE
 table: t1
 partitions: NULL
 type: range
possible_keys: j_idx
 key: j_idx
 key_len: 5
 ref: NULL
 rows: 2
 filtered: 100.00
 Extra: Using index condition

mysql> EXPLAIN SELECT i, j FROM t1 WHERE j >= 50\G
***** 1. row *****
 id: 1
 select_type: SIMPLE
 table: t1
 partitions: NULL
 type: ALL
possible_keys: NULL
 key: NULL
 key_len: NULL
 ref: NULL
 rows: 5
 filtered: 33.33
 Extra: Using where
```

Index visibility does not affect index maintenance. For example, an index continues to be updated per changes to table rows, and a unique index prevents insertion of duplicates into a column, regardless of whether the index is visible or invisible.

A table with no explicit primary key may still have an effective implicit primary key if it has any `UNIQUE` indexes on `NOT NULL` columns. In this case, the first such index places the same constraint on table rows as an explicit primary key and that index cannot be made invisible. Consider the following table definition:

```
CREATE TABLE t2 (
 i INT NOT NULL,
 j INT NOT NULL,
 UNIQUE j_idx (j)
) ENGINE = InnoDB;
```

The definition includes no explicit primary key, but the index on `NOT NULL` column `j` places the same constraint on rows as a primary key and cannot be made invisible:

```
mysql> ALTER TABLE t2 ALTER INDEX j_idx INVISIBLE;
ERROR 3522 (HY000): A primary key index cannot be invisible.
```

Now suppose that an explicit primary key is added to the table:

```
ALTER TABLE t2 ADD PRIMARY KEY (i);
```

The explicit primary key cannot be made invisible. In addition, the unique index on `j` no longer acts as an implicit primary key and as a result can be made invisible:

```
mysql> ALTER TABLE t2 ALTER INDEX j_idx INVISIBLE;
Query OK, 0 rows affected (0.03 sec)
```

### 10.3.13 Descending Indexes

MySQL supports descending indexes: `DESC` in an index definition is no longer ignored but causes storage of key values in descending order. Previously, indexes could be scanned in reverse order but at a performance penalty. A descending index can be scanned in forward order, which is more efficient. Descending indexes also make it possible for the optimizer to use multiple-column indexes when the most efficient scan order mixes ascending order for some columns and descending order for others.

Consider the following table definition, which contains two columns and four two-column index definitions for the various combinations of ascending and descending indexes on the columns:

```
CREATE TABLE t (
 c1 INT, c2 INT,
 INDEX idx1 (c1 ASC, c2 ASC),
 INDEX idx2 (c1 ASC, c2 DESC),
 INDEX idx3 (c1 DESC, c2 ASC),
 INDEX idx4 (c1 DESC, c2 DESC)
);
```

The table definition results in four distinct indexes. The optimizer can perform a forward index scan for each of the `ORDER BY` clauses and need not use a `filesort` operation:

```
ORDER BY c1 ASC, c2 ASC -- optimizer can use idx1
ORDER BY c1 DESC, c2 DESC -- optimizer can use idx4
ORDER BY c1 ASC, c2 DESC -- optimizer can use idx2
ORDER BY c1 DESC, c2 ASC -- optimizer can use idx3
```

Use of descending indexes is subject to these conditions:

- Descending indexes are supported only for the `InnoDB` storage engine, with these limitations:
  - Change buffering is not supported for a secondary index if the index contains a descending index key column or if the primary key includes a descending index column.
  - The `InnoDB` SQL parser does not use descending indexes. For `InnoDB` full-text search, this means that the index required on the `FTS_DOC_ID` column of the indexed table cannot be defined as a descending index. For more information, see [Section 17.6.2.4, “InnoDB Full-Text Indexes”](#).
- Descending indexes are supported for all data types for which ascending indexes are available.
- Descending indexes are supported for ordinary (nongenerated) and generated columns (both `VIRTUAL` and `STORED`).
- `DISTINCT` can use any index containing matching columns, including descending key parts.
- Indexes that have descending key parts are not used for `MIN()`/`MAX()` optimization of queries that invoke aggregate functions but do not have a `GROUP BY` clause.

- Descending indexes are supported for [BTREE](#) but not [HASH](#) indexes. Descending indexes are not supported for [FULLTEXT](#) or [SPATIAL](#) indexes.

Explicitly specified [ASC](#) and [DESC](#) designators for [HASH](#), [FULLTEXT](#), and [SPATIAL](#) indexes results in an error.

You can see in the [Extra](#) column of the output of [EXPLAIN](#) that the optimizer is able to use a descending index, as shown here:

```
mysql> CREATE TABLE t1 (
-> a INT,
-> b INT,
-> INDEX a_desc_b_asc (a DESC, b ASC)
->);

mysql> EXPLAIN SELECT * FROM t1 ORDER BY a ASC\G
***** 1. row *****
 id: 1
 select_type: SIMPLE
 table: t1
 partitions: NULL
 type: index
possible_keys: NULL
 key: a_desc_b_asc
 key_len: 10
 ref: NULL
 rows: 1
 filtered: 100.00
 Extra: Backward index scan; Using index
```

In [EXPLAIN FORMAT=TREE](#) output, use of a descending index is indicated by the addition of [\(reverse\)](#) following the name of the index, like this:

```
mysql> EXPLAIN FORMAT=TREE SELECT * FROM t1 ORDER BY a ASC\G
***** 1. row *****
EXPLAIN: -> Index scan on t1 using a_desc_b_asc (reverse) (cost=0.35 rows=1)
```

See also [EXPLAIN Extra Information](#).

## 10.3.14 Indexed Lookups from TIMESTAMP Columns

Temporal values are stored in [TIMESTAMP](#) columns as UTC values, and values inserted into and retrieved from [TIMESTAMP](#) columns are converted between the session time zone and UTC. (This is the same type of conversion performed by the [CONVERT\\_TZ\(\)](#) function. If the session time zone is UTC, there is effectively no time zone conversion.)

Due to conventions for local time zone changes such as Daylight Saving Time (DST), conversions between UTC and non-UTC time zones are not one-to-one in both directions. UTC values that are distinct may not be distinct in another time zone. The following example shows distinct UTC values that become identical in a non-UTC time zone:

```
mysql> CREATE TABLE tstable (ts TIMESTAMP);
mysql> SET time_zone = 'UTC'; -- insert UTC values
mysql> INSERT INTO tstable VALUES
 ('2018-10-28 00:30:00'),
 ('2018-10-28 01:30:00');
mysql> SELECT ts FROM tstable;
+-----+
| ts |
+-----+
| 2018-10-28 00:30:00 |
| 2018-10-28 01:30:00 |
```

```

+-----+
mysql> SET time_zone = 'MET'; -- retrieve non-UTC values
mysql> SELECT ts FROM tstable;
+-----+
| ts |
+-----+
| 2018-10-28 02:30:00 |
| 2018-10-28 02:30:00 |
+-----+

```

**Note**

To use named time zones such as 'MET' or 'Europe/Amsterdam', the time zone tables must be properly set up. For instructions, see [Section 7.1.15, “MySQL Server Time Zone Support”](#).

You can see that the two distinct UTC values are the same when converted to the 'MET' time zone. This phenomenon can lead to different results for a given `TIMESTAMP` column query, depending on whether the optimizer uses an index to execute the query.

Suppose that a query selects values from the table shown earlier using a `WHERE` clause to search the `ts` column for a single specific value such as a user-provided timestamp literal:

```

SELECT ts FROM tstable
WHERE ts = 'literal';

```

Suppose further that the query executes under these conditions:

- The session time zone is not UTC and has a DST shift. For example:

```
SET time_zone = 'MET';
```

- Unique UTC values stored in the `TIMESTAMP` column are not unique in the session time zone due to DST shifts. (The example shown earlier illustrates how this can occur.)
- The query specifies a search value that is within the hour of entry into DST in the session time zone.

Under those conditions, the comparison in the `WHERE` clause occurs in different ways for nonindexed and indexed lookups and leads to different results:

- If there is no index or the optimizer cannot use it, comparisons occur in the session time zone. The optimizer performs a table scan in which it retrieves each `ts` column value, converts it from UTC to the session time zone, and compares it to the search value (also interpreted in the session time zone):

```

mysql> SELECT ts FROM tstable
 WHERE ts = '2018-10-28 02:30:00';
+-----+
| ts |
+-----+
| 2018-10-28 02:30:00 |
| 2018-10-28 02:30:00 |
+-----+

```

Because the stored `ts` values are converted to the session time zone, it is possible for the query to return two timestamp values that are distinct as UTC values but equal in the session time zone: One value that occurs before the DST shift when clocks are changed, and one value that occurs after the DST shift.

- If there is a usable index, comparisons occur in UTC. The optimizer performs an index scan, first converting the search value from the session time zone to UTC, then comparing the result to the UTC index entries:

```
mysql> ALTER TABLE tstable ADD INDEX (ts);
mysql> SELECT ts FROM tstable
 WHERE ts = '2018-10-28 02:30:00';
```

ts
2018-10-28 02:30:00

In this case, the (converted) search value is matched only to index entries, and because the index entries for the distinct stored UTC values are also distinct, the search value can match only one of them.

Due to different optimizer operation for nonindexed and indexed lookups, the query produces different results in each case. The result from the nonindexed lookup returns all values that match in the session time zone. The indexed lookup cannot do so:

- It is performed within the storage engine, which knows only about UTC values.
- For the two distinct session time zone values that map to the same UTC value, the indexed lookup matches only the corresponding UTC index entry and returns only a single row.

In the preceding discussion, the data set stored in `tstable` happens to consist of distinct UTC values. In such cases, all index-using queries of the form shown match at most one index entry.

If the index is not `UNIQUE`, it is possible for the table (and the index) to store multiple instances of a given UTC value. For example, the `ts` column might contain multiple instances of the UTC value `'2018-10-28 00:30:00'`. In this case, the index-using query would return each of them (converted to the MET value `'2018-10-28 02:30:00'` in the result set). It remains true that index-using queries match the converted search value to a single value in the UTC index entries, rather than matching multiple UTC values that convert to the search value in the session time zone.

If it is important to return all `ts` values that match in the session time zone, the workaround is to suppress use of the index with an `IGNORE INDEX` hint:

```
mysql> SELECT ts FROM tstable
 IGNORE INDEX (ts)
 WHERE ts = '2018-10-28 02:30:00';
```

ts
2018-10-28 02:30:00
2018-10-28 02:30:00

The same lack of one-to-one mapping for time zone conversions in both directions occurs in other contexts as well, such as conversions performed with the `FROM_UNIXTIME()` and `UNIX_TIMESTAMP()` functions. See [Section 14.7, “Date and Time Functions”](#).

## 10.4 Optimizing Database Structure

In your role as a database designer, look for the most efficient way to organize your schemas, tables, and columns. As when tuning application code, you minimize I/O, keep related items together, and plan ahead so that performance stays high as the data volume increases. Starting with an efficient database design makes it easier for team members to write high-performing application code, and makes the database likely to endure as applications evolve and are rewritten.

### 10.4.1 Optimizing Data Size

Design your tables to minimize their space on the disk. This can result in huge improvements by reducing the amount of data written to and read from disk. Smaller tables normally require less main memory while their contents are being actively processed during query execution. Any space reduction for table data also results in smaller indexes that can be processed faster.

MySQL supports many different storage engines (table types) and row formats. For each table, you can decide which storage and indexing method to use. Choosing the proper table format for your application can give you a big performance gain. See [Chapter 17, The InnoDB Storage Engine](#), and [Chapter 18, Alternative Storage Engines](#).

You can get better performance for a table and minimize storage space by using the techniques listed here:

- [Table Columns](#)
- [Row Format](#)
- [Indexes](#)
- [Joins](#)
- [Normalization](#)

## Table Columns

- Use the most efficient (smallest) data types possible. MySQL has many specialized types that save disk space and memory. For example, use the smaller integer types if possible to get smaller tables. `MEDIUMINT` is often a better choice than `INT` because a `MEDIUMINT` column uses 25% less space.
- Declare columns to be `NOT NULL` if possible. It makes SQL operations faster, by enabling better use of indexes and eliminating overhead for testing whether each value is `NULL`. You also save some storage space, one bit per column. If you really need `NULL` values in your tables, use them. Just avoid the default setting that allows `NULL` values in every column.

## Row Format

- `InnoDB` tables are created using the `DYNAMIC` row format by default. To use a row format other than `DYNAMIC`, configure `innodb_default_row_format`, or specify the `ROW_FORMAT` option explicitly in a `CREATE TABLE` or `ALTER TABLE` statement.

The compact family of row formats, which includes `COMPACT`, `DYNAMIC`, and `COMPRESSED`, decreases row storage space at the cost of increasing CPU use for some operations. If your workload is a typical one that is limited by cache hit rates and disk speed it is likely to be faster. If it is a rare case that is limited by CPU speed, it might be slower.

The compact family of row formats also optimizes `CHAR` column storage when using a variable-length character set such as `utf8mb3` or `utf8mb4`. With `ROW_FORMAT=REDUNDANT`, `CHAR(N)` occupies  $N \times$  the maximum byte length of the character set. Many languages can be written primarily using single-byte `utf8mb3` or `utf8mb4` characters, so a fixed storage length often wastes space. With the compact family of rows formats, `InnoDB` allocates a variable amount of storage in the range of  $N$  to  $N \times$  the maximum byte length of the character set for these columns by stripping trailing spaces. The minimum storage length is  $N$  bytes to facilitate in-place updates in typical cases. For more information, see [Section 17.10, “InnoDB Row Formats”](#).

- To minimize space even further by storing table data in compressed form, specify `ROW_FORMAT=COMPRESSED` when creating `InnoDB` tables, or run the `mysampack` command on

an existing [MyISAM](#) table. ([InnoDB](#) compressed tables are readable and writable, while [MyISAM](#) compressed tables are read-only.)

- For [MyISAM](#) tables, if you do not have any variable-length columns ([VARCHAR](#), [TEXT](#), or [BLOB](#) columns), a fixed-size row format is used. This is faster but may waste some space. See [Section 18.2.3, “MyISAM Table Storage Formats”](#). You can hint that you want to have fixed length rows even if you have [VARCHAR](#) columns with the [CREATE TABLE](#) option [ROW\\_FORMAT=FIXED](#).

## Indexes

- The primary index of a table should be as short as possible. This makes identification of each row easy and efficient. For [InnoDB](#) tables, the primary key columns are duplicated in each secondary index entry, so a short primary key saves considerable space if you have many secondary indexes.
- Create only the indexes that you need to improve query performance. Indexes are good for retrieval, but slow down insert and update operations. If you access a table mostly by searching on a combination of columns, create a single composite index on them rather than a separate index for each column. The first part of the index should be the column most used. If you *always* use many columns when selecting from the table, the first column in the index should be the one with the most duplicates, to obtain better compression of the index.
- If it is very likely that a long string column has a unique prefix on the first number of characters, it is better to index only this prefix, using MySQL's support for creating an index on the leftmost part of the column (see [Section 15.1.15, “CREATE INDEX Statement”](#)). Shorter indexes are faster, not only because they require less disk space, but because they also give you more hits in the index cache, and thus fewer disk seeks. See [Section 7.1.1, “Configuring the Server”](#).

## Joins

- In some circumstances, it can be beneficial to split into two a table that is scanned very often. This is especially true if it is a dynamic-format table and it is possible to use a smaller static format table that can be used to find the relevant rows when scanning the table.
- Declare columns with identical information in different tables with identical data types, to speed up joins based on the corresponding columns.
- Keep column names simple, so that you can use the same name across different tables and simplify join queries. For example, in a table named [customer](#), use a column name of [name](#) instead of [customer\\_name](#). To make your names portable to other SQL servers, consider keeping them shorter than 18 characters.

## Normalization

- Normally, try to keep all data nonredundant (observing what is referred to in database theory as *third normal form*). Instead of repeating lengthy values such as names and addresses, assign them unique IDs, repeat these IDs as needed across multiple smaller tables, and join the tables in queries by referencing the IDs in the join clause.
- If speed is more important than disk space and the maintenance costs of keeping multiple copies of data, for example in a business intelligence scenario where you analyze all the data from large tables, you can relax the normalization rules, duplicating information or creating summary tables to gain more speed.

## 10.4.2 Optimizing MySQL Data Types

### 10.4.2.1 Optimizing for Numeric Data

- For unique IDs or other values that can be represented as either strings or numbers, prefer numeric columns to string columns. Since large numeric values can be stored in fewer bytes than the corresponding strings, it is faster and takes less memory to transfer and compare them.
- If you are using numeric data, it is faster in many cases to access information from a database (using a live connection) than to access a text file. Information in the database is likely to be stored in a more compact format than in the text file, so accessing it involves fewer disk accesses. You also save code in your application because you can avoid parsing the text file to find line and column boundaries.

### 10.4.2.2 Optimizing for Character and String Types

For character and string columns, follow these guidelines:

- Use binary collation order for fast comparison and sort operations, when you do not need language-specific collation features. You can use the [BINARY](#) operator to use binary collation within a particular query.
- When comparing values from different columns, declare those columns with the same character set and collation wherever possible, to avoid string conversions while running the query.
- For column values less than 8KB in size, use binary [VARCHAR](#) instead of [BLOB](#). The [GROUP BY](#) and [ORDER BY](#) clauses can generate temporary tables, and these temporary tables can use the [MEMORY](#) storage engine if the original table does not contain any [BLOB](#) columns.
- If a table contains string columns such as name and address, but many queries do not retrieve those columns, consider splitting the string columns into a separate table and using join queries with a foreign key when necessary. When MySQL retrieves any value from a row, it reads a data block containing all the columns of that row (and possibly other adjacent rows). Keeping each row small, with only the most frequently used columns, allows more rows to fit in each data block. Such compact tables reduce disk I/O and memory usage for common queries.
- When you use a randomly generated value as a primary key in an [InnoDB](#) table, prefix it with an ascending value such as the current date and time if possible. When consecutive primary values are physically stored near each other, [InnoDB](#) can insert and retrieve them faster.
- See [Section 10.4.2.1, “Optimizing for Numeric Data”](#) for reasons why a numeric column is usually preferable to an equivalent string column.

### 10.4.2.3 Optimizing for BLOB Types

- When storing a large blob containing textual data, consider compressing it first. Do not use this technique when the entire table is compressed by [InnoDB](#) or [MyISAM](#).
- For a table with several columns, to reduce memory requirements for queries that do not use the BLOB column, consider splitting the BLOB column into a separate table and referencing it with a join query when needed.
- Since the performance requirements to retrieve and display a BLOB value might be very different from other data types, you could put the BLOB-specific table on a different storage device or even a separate database instance. For example, to retrieve a BLOB might require a large sequential disk read that is better suited to a traditional hard drive than to an [SSD device](#).
- See [Section 10.4.2.2, “Optimizing for Character and String Types”](#) for reasons why a binary [VARCHAR](#) column is sometimes preferable to an equivalent BLOB column.
- Rather than testing for equality against a very long text string, you can store a hash of the column value in a separate column, index that column, and test the hashed value in queries. (Use the [MD5 \( \)](#) or [CRC32 \( \)](#) function to produce the hash value.) Since hash functions can produce duplicate results for

different inputs, you still include a clause `AND blob_column = long_string_value` in the query to guard against false matches; the performance benefit comes from the smaller, easily scanned index for the hashed values.

### 10.4.3 Optimizing for Many Tables

Some techniques for keeping individual queries fast involve splitting data across many tables. When the number of tables runs into the thousands or even millions, the overhead of dealing with all these tables becomes a new performance consideration.

#### 10.4.3.1 How MySQL Opens and Closes Tables

When you execute a `mysqladmin status` command, you should see something like this:

```
Uptime: 426 Running threads: 1 Questions: 11082
Reloads: 1 Open tables: 12
```

The `Open tables` value of 12 can be somewhat puzzling if you have fewer than 12 tables.

MySQL is multithreaded, so there may be many clients issuing queries for a given table simultaneously. To minimize the problem with multiple client sessions having different states on the same table, the table is opened independently by each concurrent session. This uses additional memory but normally increases performance. With `MyISAM` tables, one extra file descriptor is required for the data file for each client that has the table open. (By contrast, the index file descriptor is shared between all sessions.)

The `table_open_cache` and `max_connections` system variables affect the maximum number of files the server keeps open. If you increase one or both of these values, you may run up against a limit imposed by your operating system on the per-process number of open file descriptors. Many operating systems permit you to increase the open-files limit, although the method varies widely from system to system. Consult your operating system documentation to determine whether it is possible to increase the limit and how to do so.

`table_open_cache` is related to `max_connections`. For example, for 200 concurrent running connections, specify a table cache size of at least  $200 * N$ , where  $N$  is the maximum number of tables per join in any of the queries which you execute. You must also reserve some extra file descriptors for temporary tables and files.

Make sure that your operating system can handle the number of open file descriptors implied by the `table_open_cache` setting. If `table_open_cache` is set too high, MySQL may run out of file descriptors and exhibit symptoms such as refusing connections or failing to perform queries.

Also take into account that the `MyISAM` storage engine needs two file descriptors for each unique open table. To increase the number of file descriptors available to MySQL, set the `open_files_limit` system variable. See [Section B.3.2.16, “File Not Found and Similar Errors”](#).

The cache of open tables is kept at a level of `table_open_cache` entries. The server autosizes the cache size at startup. To set the size explicitly, set the `table_open_cache` system variable at startup. MySQL may temporarily open more tables than this to execute queries, as described later in this section.

MySQL closes an unused table and removes it from the table cache under the following circumstances:

- When the cache is full and a thread tries to open a table that is not in the cache.
- When the cache contains more than `table_open_cache` entries and a table in the cache is no longer being used by any threads.
- When a table-flushing operation occurs. This happens when someone issues a `FLUSH TABLES` statement or executes a `mysqladmin flush-tables` or `mysqladmin refresh` command.

When the table cache fills up, the server uses the following procedure to locate a cache entry to use:

- Tables not currently in use are released, beginning with the table least recently used.
- If a new table must be opened, but the cache is full and no tables can be released, the cache is temporarily extended as necessary. When the cache is in a temporarily extended state and a table goes from a used to unused state, the table is closed and released from the cache.

A [MyISAM](#) table is opened for each concurrent access. This means the table needs to be opened twice if two threads access the same table or if a thread accesses the table twice in the same query (for example, by joining the table to itself). Each concurrent open requires an entry in the table cache. The first open of any [MyISAM](#) table takes two file descriptors: one for the data file and one for the index file. Each additional use of the table takes only one file descriptor for the data file. The index file descriptor is shared among all threads.

If you are opening a table with the `HANDLER tbl_name OPEN` statement, a dedicated table object is allocated for the thread. This table object is not shared by other threads and is not closed until the thread calls `HANDLER tbl_name CLOSE` or the thread terminates. When this happens, the table is put back in the table cache (if the cache is not full). See [Section 15.2.5, “HANDLER Statement”](#).

To determine whether your table cache is too small, check the `Opened_tables` status variable, which indicates the number of table-opening operations since the server started:

```
mysql> SHOW GLOBAL STATUS LIKE 'Opened_tables';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Opened_tables | 2741 |
+-----+-----+
```

If the value is very large or increases rapidly, even when you have not issued many `FLUSH TABLES` statements, increase the `table_open_cache` value at server startup.

### 10.4.3.2 Disadvantages of Creating Many Tables in the Same Database

If you have many [MyISAM](#) tables in the same database directory, open, close, and create operations are slow. If you execute `SELECT` statements on many different tables, there is a little overhead when the table cache is full, because for every table that has to be opened, another must be closed. You can reduce this overhead by increasing the number of entries permitted in the table cache.

## 10.4.4 Internal Temporary Table Use in MySQL

In some cases, the server creates internal temporary tables while processing statements. Users have no direct control over when this occurs.

The server creates temporary tables under conditions such as these:

- Evaluation of [UNION](#) statements, with some exceptions described later.
- Evaluation of some views, such those that use the [TEMPTABLE](#) algorithm, [UNION](#), or aggregation.
- Evaluation of derived tables (see [Section 15.2.15.8, “Derived Tables”](#)).
- Evaluation of common table expressions (see [Section 15.2.20, “WITH \(Common Table Expressions\)”](#)).
- Tables created for subquery or semijoin materialization (see [Section 10.2.2, “Optimizing Subqueries, Derived Tables, View References, and Common Table Expressions”](#)).

- Evaluation of statements that contain an `ORDER BY` clause and a different `GROUP BY` clause, or for which the `ORDER BY` or `GROUP BY` contains columns from tables other than the first table in the join queue.
- Evaluation of `DISTINCT` combined with `ORDER BY` may require a temporary table.
- For queries that use the `SQL_SMALL_RESULT` modifier, MySQL uses an in-memory temporary table, unless the query also contains elements (described later) that require on-disk storage.
- To evaluate `INSERT ... SELECT` statements that select from and insert into the same table, MySQL creates an internal temporary table to hold the rows from the `SELECT`, then inserts those rows into the target table. See [Section 15.2.7.1, “INSERT ... SELECT Statement”](#).
- Evaluation of multiple-table `UPDATE` statements.
- Evaluation of `GROUP_CONCAT()` or `COUNT(DISTINCT)` expressions.
- Evaluation of window functions (see [Section 14.20, “Window Functions”](#)) uses temporary tables as necessary.

To determine whether a statement requires a temporary table, use `EXPLAIN` and check the `Extra` column to see whether it says `Using temporary` (see [Section 10.8.1, “Optimizing Queries with EXPLAIN”](#)). `EXPLAIN` does not necessarily say `Using temporary` for derived or materialized temporary tables. For statements that use window functions, `EXPLAIN` with `FORMAT=JSON` always provides information about the windowing steps. If the windowing functions use temporary tables, it is indicated for each step.

Some query conditions prevent the use of an in-memory temporary table, in which case the server uses an on-disk table instead:

- Presence of a `BLOB` or `TEXT` column in the table. The `TempTable` storage engine, which is the default storage engine for in-memory internal temporary tables in MySQL 9.1, supports binary large object types. See [Internal Temporary Table Storage Engine](#).
- Presence of any string column with a maximum length larger than 512 (bytes for binary strings, characters for nonbinary strings) in the `SELECT` list, if `UNION` or `UNION ALL` is used.
- The `SHOW COLUMNS` and `DESCRIBE` statements use `BLOB` as the type for some columns, thus the temporary table used for the results is an on-disk table.

The server does not use a temporary table for `UNION` statements that meet certain qualifications. Instead, it retains from temporary table creation only the data structures necessary to perform result column typecasting. The table is not fully instantiated and no rows are written to or read from it; rows are sent directly to the client. The result is reduced memory and disk requirements, and smaller delay before the first row is sent to the client because the server need not wait until the last query block is executed. `EXPLAIN` and optimizer trace output reflects this execution strategy: The `UNION RESULT` query block is not present because that block corresponds to the part that reads from the temporary table.

These conditions qualify a `UNION` for evaluation without a temporary table:

- The union is `UNION ALL`, not `UNION` or `UNION DISTINCT`.
- There is no global `ORDER BY` clause.
- The union is not the top-level query block of an `{INSERT | REPLACE} ... SELECT ...` statement.

## Internal Temporary Table Storage Engine

An internal temporary table can be held in memory and processed by the `TempTable` or `MEMORY` storage engine, or stored on disk by the `InnoDB` storage engine.

## Storage Engine for In-Memory Internal Temporary Tables

The `internal_tmp_mem_storage_engine` variable defines the storage engine used for in-memory internal temporary tables. Permitted values are `TempTable` (the default) and `MEMORY`.

### Note

Configuring a session setting for `internal_tmp_mem_storage_engine` requires the `SESSION_VARIABLES_ADMIN` or `SYSTEM_VARIABLES_ADMIN` privilege.

The `TempTable` storage engine provides efficient storage for `VARCHAR` and `VARBINARY` columns, and other binary large object types.

The following variables control `TempTable` storage engine limits and behavior:

- `tmp_table_size`: Defines the maximum size of any individual in-memory internal temporary table created using the `TempTable` storage engine. When the limit determined by `tmp_table_size` is reached, MySQL automatically converts the in-memory internal temporary table to an `InnoDB` on-disk internal temporary table. The default value is 16777216 bytes (16 MiB).

The `tmp_table_size` limit is intended to prevent individual queries from consuming an inordinate amount of global `TempTable` resources, which can affect the performance of concurrent queries that require such resources. Global `TempTable` resources are controlled by `temptable_max_ram` and `temptable_max_mmap`.

If `tmp_table_size` is less than `temptable_max_ram`, it is not possible for an in-memory temporary table to use more than `tmp_table_size`. If `tmp_table_size` is greater than the sum of `temptable_max_ram` and `temptable_max_mmap`, an in-memory temporary table cannot use more than the sum of the `temptable_max_ram` and `temptable_max_mmap` limits.

- `temptable_max_ram`: Defines the maximum amount of RAM that can be used by the `TempTable` storage engine before it starts allocating space from memory-mapped files or before MySQL starts using `InnoDB` on-disk internal temporary tables, depending on your configuration. If not set explicitly, the value of `temptable_max_ram` is 3% of the total memory available on the server, with a minimum of 1 GB and a maximum of 4 GB.

### Note

`temptable_max_ram` does not account for the thread-local memory block allocated to each thread that uses the `TempTable` storage engine. The size of the thread-local memory block depends on the size of the thread's first memory allocation request. If the request is less than 1MB, which it is in most cases, the thread-local memory block size is 1MB. If the request is greater than 1MB, the thread-local memory block is approximately the same size as the initial memory request. The thread-local memory block is held in thread-local storage until thread exit.

- `temptable_use_mmap`: Controls whether the `TempTable` storage engine allocates space from memory-mapped files or MySQL uses `InnoDB` on-disk internal temporary tables when the limit determined by `temptable_max_ram` is exceeded. The default value is `OFF`.

### Note

`temptable_use_mmap` is deprecated; expect support for it to be removed in a future version of MySQL. Setting `temptable_max_mmap=0` is equivalent to setting `temptable_use_mmap=OFF`.

- `temptable_max_mmap`: Sets the maximum amount of memory the `TempTable` storage engine is permitted to allocate from memory-mapped files before MySQL starts using `InnoDB` on-disk internal temporary tables. The default value is 0 (disabled). The limit is intended to address the risk of memory mapped files using too much space in the temporary directory (`tmpdir`). `temptable_max_mmap = 0` disables allocation from memory-mapped files, effectively disabling their use, regardless of the value of `temptable_use_mmap`.

Use of memory-mapped files by the `TempTable` storage engine is governed by these rules:

- Temporary files are created in the directory defined by the `tmpdir` variable.
- Temporary files are deleted immediately after they are created and opened, and therefore do not remain visible in the `tmpdir` directory. The space occupied by temporary files is held by the operating system while temporary files are open. The space is reclaimed when temporary files are closed by the `TempTable` storage engine, or when the `mysqld` process is shut down.
- Data is never moved between RAM and temporary files, within RAM, or between temporary files.
- New data is stored in RAM if space becomes available within the limit defined by `temptable_max_ram`. Otherwise, new data is stored in temporary files.
- If space becomes available in RAM after some of the data for a table is written to temporary files, it is possible for the remaining table data to be stored in RAM.

When using the `MEMORY` storage engine for in-memory temporary tables (`internal_tmp_mem_storage_engine=MEMORY`), MySQL automatically converts an in-memory temporary table to an on-disk table if it becomes too large. The maximum size of an in-memory temporary table is defined by the `tmp_table_size` or `max_heap_table_size` value, whichever is smaller. This differs from `MEMORY` tables explicitly created with `CREATE TABLE`. For such tables, only the `max_heap_table_size` variable determines how large a table can grow, and there is no conversion to on-disk format.

## Storage Engine for On-Disk Internal Temporary Tables

MySQL 9.1 uses only the `InnoDB` storage engine for on-disk internal temporary tables. (The `MYISAM` storage engine is no longer supported for this purpose.)

`InnoDB` on-disk internal temporary tables are created in session temporary tablespaces that reside in the data directory by default. For more information, see [Section 17.6.3.5, “Temporary Tablespaces”](#).

## Internal Temporary Table Storage Format

When in-memory internal temporary tables are managed by the `TempTable` storage engine, rows that include `VARCHAR` columns, `VARBINARY` columns, and other binary large object type columns are represented in memory by an array of cells, with each cell containing a `NULL` flag, the data length, and a data pointer. Column values are placed in consecutive order after the array, in a single region of memory, without padding. Each cell in the array uses 16 bytes of storage. The same storage format applies when the `TempTable` storage engine allocates space from memory-mapped files.

When in-memory internal temporary tables are managed by the `MEMORY` storage engine, fixed-length row format is used. `VARCHAR` and `VARBINARY` column values are padded to the maximum column length, in effect storing them as `CHAR` and `BINARY` columns.

Internal temporary tables on disk are always managed by `InnoDB`.

When using the `MEMORY` storage engine, statements can initially create an in-memory internal temporary table and then convert it to an on-disk table if the table becomes too large. In such cases, better

performance might be achieved by skipping the conversion and creating the internal temporary table on disk to begin with. The `big_tables` variable can be used to force disk storage of internal temporary tables.

## Monitoring Internal Temporary Table Creation

When an internal temporary table is created in memory or on disk, the server increments the `Created_tmp_tables` value. When an internal temporary table is created on disk, the server increments the `Created_tmp_disk_tables` value. If too many internal temporary tables are created on disk, consider adjusting the engine-specific limits described in [Internal Temporary Table Storage Engine](#).

### Note

Due to a known limitation, `Created_tmp_disk_tables` does not count on-disk temporary tables created in memory-mapped files. By default, the TempTable storage engine overflow mechanism creates internal temporary tables in memory-mapped files. See [Internal Temporary Table Storage Engine](#).

The `memory/temptable/physical_ram` and `memory/temptable/physical_disk` Performance Schema instruments can be used to monitor TempTable space allocation from memory and disk. `memory/temptable/physical_ram` reports the amount of allocated RAM. `memory/temptable/physical_disk` reports the amount of space allocated from disk when memory-mapped files are used as the TempTable overflow mechanism. If the `physical_disk` instrument reports a value other than 0 and memory-mapped files are used as the TempTable overflow mechanism, a TempTable memory limit was reached at some point. Data can be queried in Performance Schema memory summary tables such as `memory_summary_global_by_event_name`. See [Section 29.12.20.10, “Memory Summary Tables”](#).

## Monitoring Internal Temporary Table Conversion

When an internal temporary table is converted from in-memory to on-disk, the server increments system status variables to track these changes:

- `TempTable_count_hit_max_ram` is incremented when the `temptable_max_ram` limit is reached. This is specific to the TempTable storage engine, and is a global status variable.
- `Count_hit_tmp_table_size` is incremented under these conditions:
  - TempTable storage engine: if the `tmp_table_size` limit is reached.
  - MEMORY storage engine: if the smaller limit value of `tmp_table_size` or `max_heap_table_size` is reached.

This is a global and session status variable.

The `TempTable_count_hit_max_ram` and `Count_hit_tmp_table_size` server status variables were added in MySQL 9.1.0.

## 10.4.5 Limits on Number of Databases and Tables

MySQL has no limit on the number of databases. The underlying file system may have a limit on the number of directories.

MySQL has no limit on the number of tables. The underlying file system may have a limit on the number of files that represent tables. Individual storage engines may impose engine-specific constraints. InnoDB permits up to 4 billion tables.

## 10.4.6 Limits on Table Size

The effective maximum table size for MySQL databases is usually determined by operating system constraints on file sizes, not by MySQL internal limits. For up-to-date information operating system file size limits, refer to the documentation specific to your operating system.

Windows users, please note that FAT and VFAT (FAT32) are *not* considered suitable for production use with MySQL. Use NTFS instead.

If you encounter a full-table error, there are several reasons why it might have occurred:

- The disk might be full.
- You are using [InnoDB](#) tables and have run out of room in an [InnoDB](#) tablespace file. The maximum tablespace size is also the maximum size for a table. For tablespace size limits, see [Section 17.21, “InnoDB Limits”](#).

Generally, partitioning of tables into multiple tablespace files is recommended for tables larger than 1TB in size.

- You have hit an operating system file size limit. For example, you are using [MyISAM](#) tables on an operating system that supports files only up to 2GB in size and you have hit this limit for the data file or index file.
- You are using a [MyISAM](#) table and the space required for the table exceeds what is permitted by the internal pointer size. [MyISAM](#) permits data and index files to grow up to 256TB by default, but this limit can be changed up to the maximum permissible size of 65,536TB ( $256^7 - 1$  bytes).

If you need a [MyISAM](#) table that is larger than the default limit and your operating system supports large files, the [CREATE TABLE](#) statement supports [AVG\\_ROW\\_LENGTH](#) and [MAX\\_ROWS](#) options. See [Section 15.1.20, “CREATE TABLE Statement”](#). The server uses these options to determine how large a table to permit.

If the pointer size is too small for an existing table, you can change the options with [ALTER TABLE](#) to increase a table's maximum permissible size. See [Section 15.1.9, “ALTER TABLE Statement”](#).

```
ALTER TABLE tbl_name MAX_ROWS=1000000000 AVG_ROW_LENGTH=nnn;
```

You have to specify [AVG\\_ROW\\_LENGTH](#) only for tables with [BLOB](#) or [TEXT](#) columns; in this case, MySQL cannot optimize the space required based only on the number of rows.

To change the default size limit for [MyISAM](#) tables, set the [myisam\\_data\\_pointer\\_size](#), which sets the number of bytes used for internal row pointers. The value is used to set the pointer size for new tables if you do not specify the [MAX\\_ROWS](#) option. The value of [myisam\\_data\\_pointer\\_size](#) can be from 2 to 7. For example, for tables that use the dynamic storage format, a value of 4 permits tables up to 4GB; a value of 6 permits tables up to 256TB. Tables that use the fixed storage format have a larger maximum data length. For storage format characteristics, see [Section 18.2.3, “MyISAM Table Storage Formats”](#).

You can check the maximum data and index sizes by using this statement:

```
SHOW TABLE STATUS FROM db_name LIKE 'tbl_name';
```

You also can use [myisamchk -dv /path/to/table-index-file](#). See [Section 15.7.7, “SHOW Statements”](#), or [Section 6.6.4, “myisamchk — MyISAM Table-Maintenance Utility”](#).

Other ways to work around file-size limits for [MyISAM](#) tables are as follows:

- If your large table is read only, you can use [myisampack](#) to compress it. [myisampack](#) usually compresses a table by at least 50%, so you can have, in effect, much bigger tables. [myisampack](#)

also can merge multiple tables into a single table. See [Section 6.6.6, “myisampack — Generate Compressed, Read-Only MyISAM Tables”](#).

- MySQL includes a [MERGE](#) library that enables you to handle a collection of [MyISAM](#) tables that have identical structure as a single [MERGE](#) table. See [Section 18.7, “The MERGE Storage Engine”](#).
- You are using the [MEMORY \(HEAP\)](#) storage engine; in this case you need to increase the value of the [max\\_heap\\_table\\_size](#) system variable. See [Section 7.1.8, “Server System Variables”](#).

## 10.4.7 Limits on Table Column Count and Row Size

This section describes limits on the number of columns in tables and the size of individual rows.

- [Column Count Limits](#)
- [Row Size Limits](#)

### Column Count Limits

MySQL has hard limit of 4096 columns per table, but the effective maximum may be less for a given table. The exact column limit depends on several factors:

- The maximum row size for a table constrains the number (and possibly size) of columns because the total length of all columns cannot exceed this size. See [Row Size Limits](#).
- The storage requirements of individual columns constrain the number of columns that fit within a given maximum row size. Storage requirements for some data types depend on factors such as storage engine, storage format, and character set. See [Section 13.7, “Data Type Storage Requirements”](#).
- Storage engines may impose additional restrictions that limit table column count. For example, [InnoDB](#) has a limit of 1017 columns per table. See [Section 17.21, “InnoDB Limits”](#). For information about other storage engines, see [Chapter 18, Alternative Storage Engines](#).
- Functional key parts (see [Section 15.1.15, “CREATE INDEX Statement”](#)) are implemented as hidden virtual generated stored columns, so each functional key part in a table index counts against the table total column limit.

### Row Size Limits

The maximum row size for a given table is determined by several factors:

- The internal representation of a MySQL table has a maximum row size limit of 65,535 bytes, even if the storage engine is capable of supporting larger rows. [BLOB](#) and [TEXT](#) columns only contribute 9 to 12 bytes toward the row size limit because their contents are stored separately from the rest of the row.
- The maximum row size for an [InnoDB](#) table, which applies to data stored locally within a database page, is slightly less than half a page for 4KB, 8KB, 16KB, and 32KB [innodb\\_page\\_size](#) settings. For example, the maximum row size is slightly less than 8KB for the default 16KB [InnoDB](#) page size. For 64KB pages, the maximum row size is slightly less than 16KB. See [Section 17.21, “InnoDB Limits”](#).

If a row containing [variable-length columns](#) exceeds the [InnoDB](#) maximum row size, [InnoDB](#) selects variable-length columns for external off-page storage until the row fits within the [InnoDB](#) row size limit. The amount of data stored locally for variable-length columns that are stored off-page differs by row format. For more information, see [Section 17.10, “InnoDB Row Formats”](#).

- Different storage formats use different amounts of page header and trailer data, which affects the amount of storage available for rows.
  - For information about [InnoDB](#) row formats, see [Section 17.10, “InnoDB Row Formats”](#).

- For information about [MyISAM](#) storage formats, see [Section 18.2.3, “MyISAM Table Storage Formats”](#).

## Row Size Limit Examples

- The MySQL maximum row size limit of 65,535 bytes is demonstrated in the following [InnoDB](#) and [MyISAM](#) examples. The limit is enforced regardless of storage engine, even though the storage engine may be capable of supporting larger rows.

```
mysql> CREATE TABLE t (a VARCHAR(10000), b VARCHAR(10000),
 c VARCHAR(10000), d VARCHAR(10000), e VARCHAR(10000),
 f VARCHAR(10000), g VARCHAR(6000)) ENGINE=InnoDB CHARACTER SET latin1;
ERROR 1118 (42000): Row size too large. The maximum row size for the used
table type, not counting BLOBs, is 65535. This includes storage overhead,
check the manual. You have to change some columns to TEXT or BLOBs
```

```
mysql> CREATE TABLE t (a VARCHAR(10000), b VARCHAR(10000),
 c VARCHAR(10000), d VARCHAR(10000), e VARCHAR(10000),
 f VARCHAR(10000), g VARCHAR(6000)) ENGINE=MyISAM CHARACTER SET latin1;
ERROR 1118 (42000): Row size too large. The maximum row size for the used
table type, not counting BLOBs, is 65535. This includes storage overhead,
check the manual. You have to change some columns to TEXT or BLOBs
```

In the following [MyISAM](#) example, changing a column to [TEXT](#) avoids the 65,535-byte row size limit and permits the operation to succeed because [BLOB](#) and [TEXT](#) columns only contribute 9 to 12 bytes toward the row size.

```
mysql> CREATE TABLE t (a VARCHAR(10000), b VARCHAR(10000),
 c VARCHAR(10000), d VARCHAR(10000), e VARCHAR(10000),
 f VARCHAR(10000), g TEXT(6000)) ENGINE=MyISAM CHARACTER SET latin1;
Query OK, 0 rows affected (0.02 sec)
```

The operation succeeds for an [InnoDB](#) table because changing a column to [TEXT](#) avoids the MySQL 65,535-byte row size limit, and [InnoDB](#) off-page storage of variable-length columns avoids the [InnoDB](#) row size limit.

```
mysql> CREATE TABLE t (a VARCHAR(10000), b VARCHAR(10000),
 c VARCHAR(10000), d VARCHAR(10000), e VARCHAR(10000),
 f VARCHAR(10000), g TEXT(6000)) ENGINE=InnoDB CHARACTER SET latin1;
Query OK, 0 rows affected (0.02 sec)
```

- Storage for variable-length columns includes length bytes, which are counted toward the row size. For example, a [VARCHAR\(255\) CHARACTER SET utf8mb3](#) column takes two bytes to store the length of the value, so each value can take up to 767 bytes.

The statement to create table `t1` succeeds because the columns require 32,765 + 2 bytes and 32,766 + 2 bytes, which falls within the maximum row size of 65,535 bytes:

```
mysql> CREATE TABLE t1
 (c1 VARCHAR(32765) NOT NULL, c2 VARCHAR(32766) NOT NULL)
 ENGINE = InnoDB CHARACTER SET latin1;
Query OK, 0 rows affected (0.02 sec)
```

The statement to create table `t2` fails because, although the column length is within the maximum length of 65,535 bytes, two additional bytes are required to record the length, which causes the row size to exceed 65,535 bytes:

```
mysql> CREATE TABLE t2
 (c1 VARCHAR(65535) NOT NULL)
 ENGINE = InnoDB CHARACTER SET latin1;
ERROR 1118 (42000): Row size too large. The maximum row size for the used
table type, not counting BLOBs, is 65535. This includes storage overhead,
```

check the manual. You have to change some columns to TEXT or BLOBs

Reducing the column length to 65,533 or less permits the statement to succeed.

```
mysql> CREATE TABLE t2
 (c1 VARCHAR(65533) NOT NULL)
 ENGINE = InnoDB CHARACTER SET latin1;
Query OK, 0 rows affected (0.01 sec)
```

- For **MyISAM** tables, **NULL** columns require additional space in the row to record whether their values are **NULL**. Each **NULL** column takes one bit extra, rounded up to the nearest byte.

The statement to create table **t3** fails because **MyISAM** requires space for **NULL** columns in addition to the space required for variable-length column length bytes, causing the row size to exceed 65,535 bytes:

```
mysql> CREATE TABLE t3
 (c1 VARCHAR(32765) NULL, c2 VARCHAR(32766) NULL)
 ENGINE = MyISAM CHARACTER SET latin1;
ERROR 1118 (42000): Row size too large. The maximum row size for the used
table type, not counting BLOBs, is 65535. This includes storage overhead,
check the manual. You have to change some columns to TEXT or BLOBs
```

For information about **InnoDB** **NULL** column storage, see [Section 17.10, “InnoDB Row Formats”](#).

- **InnoDB** restricts row size (for data stored locally within the database page) to slightly less than half a database page for 4KB, 8KB, 16KB, and 32KB `innodb_page_size` settings, and to slightly less than 16KB for 64KB pages.

The statement to create table **t4** fails because the defined columns exceed the row size limit for a 16KB **InnoDB** page.

```
mysql> CREATE TABLE t4 (
 c1 CHAR(255),c2 CHAR(255),c3 CHAR(255),
 c4 CHAR(255),c5 CHAR(255),c6 CHAR(255),
 c7 CHAR(255),c8 CHAR(255),c9 CHAR(255),
 c10 CHAR(255),c11 CHAR(255),c12 CHAR(255),
 c13 CHAR(255),c14 CHAR(255),c15 CHAR(255),
 c16 CHAR(255),c17 CHAR(255),c18 CHAR(255),
 c19 CHAR(255),c20 CHAR(255),c21 CHAR(255),
 c22 CHAR(255),c23 CHAR(255),c24 CHAR(255),
 c25 CHAR(255),c26 CHAR(255),c27 CHAR(255),
 c28 CHAR(255),c29 CHAR(255),c30 CHAR(255),
 c31 CHAR(255),c32 CHAR(255),c33 CHAR(255)
) ENGINE=InnoDB ROW_FORMAT=DYNAMIC DEFAULT CHARSET latin1;
ERROR 1118 (42000): Row size too large (> 8126). Changing some columns to TEXT or BLOB may help.
In current row format, BLOB prefix of 0 bytes is stored inline.
```

## 10.5 Optimizing for InnoDB Tables

**InnoDB** is the storage engine that MySQL customers typically use in production databases where reliability and concurrency are important. **InnoDB** is the default storage engine in MySQL. This section explains how to optimize database operations for **InnoDB** tables.

### 10.5.1 Optimizing Storage Layout for InnoDB Tables

- Once your data reaches a stable size, or a growing table has increased by tens or some hundreds of megabytes, consider using the `OPTIMIZE TABLE` statement to reorganize the table and compact any wasted space. The reorganized tables require less disk I/O to perform full table scans. This is a straightforward technique that can improve performance when other techniques such as improving index usage or tuning application code are not practical.

`OPTIMIZE TABLE` copies the data part of the table and rebuilds the indexes. The benefits come from improved packing of data within indexes, and reduced fragmentation within the tablespaces and on disk. The benefits vary depending on the data in each table. You may find that there are significant gains for some and not for others, or that the gains decrease over time until you next optimize the table. This operation can be slow if the table is large or if the indexes being rebuilt do not fit into the buffer pool. The first run after adding a lot of data to a table is often much slower than later runs.

- In `InnoDB`, having a long `PRIMARY KEY` (either a single column with a lengthy value, or several columns that form a long composite value) wastes a lot of disk space. The primary key value for a row is duplicated in all the secondary index records that point to the same row. (See [Section 17.6.2.1, “Clustered and Secondary Indexes”](#).) Create an `AUTO_INCREMENT` column as the primary key if your primary key is long, or index a prefix of a long `VARCHAR` column instead of the entire column.
- Use the `VARCHAR` data type instead of `CHAR` to store variable-length strings or for columns with many `NULL` values. A `CHAR(N)` column always takes `N` characters to store data, even if the string is shorter or its value is `NULL`. Smaller tables fit better in the buffer pool and reduce disk I/O.

When using `COMPACT` row format (the default `InnoDB` format) and variable-length character sets, such as `utf8mb4` or `sjis`, `CHAR(N)` columns occupy a variable amount of space, but still at least `N` bytes.

- For tables that are big, or contain lots of repetitive text or numeric data, consider using `COMPRESSED` row format. Less disk I/O is required to bring data into the buffer pool, or to perform full table scans. Before making a permanent decision, measure the amount of compression you can achieve by using `COMPRESSED` versus `COMPACT` row format.

## 10.5.2 Optimizing InnoDB Transaction Management

To optimize `InnoDB` transaction processing, find the ideal balance between the performance overhead of transactional features and the workload of your server. For example, an application might encounter performance issues if it commits thousands of times per second, and different performance issues if it commits only every 2-3 hours.

- The default MySQL setting `AUTOCOMMIT=1` can impose performance limitations on a busy database server. Where practical, wrap several related data change operations into a single transaction, by issuing `SET AUTOCOMMIT=0` or a `START TRANSACTION` statement, followed by a `COMMIT` statement after making all the changes.

`InnoDB` must flush the log to disk at each transaction commit if that transaction made modifications to the database. When each change is followed by a commit (as with the default autocommit setting), the I/O throughput of the storage device puts a cap on the number of potential operations per second.

- Alternatively, for transactions that consist only of a single `SELECT` statement, turning on `AUTOCOMMIT` helps `InnoDB` to recognize read-only transactions and optimize them. See [Section 10.5.3, “Optimizing InnoDB Read-Only Transactions”](#) for requirements.
- Avoid performing rollbacks after inserting, updating, or deleting huge numbers of rows. If a big transaction is slowing down server performance, rolling it back can make the problem worse, potentially taking several times as long to perform as the original data change operations. Killing the database process does not help, because the rollback starts again on server startup.

To minimize the chance of this issue occurring:

- Increase the size of the `buffer pool` so that all the data change changes can be cached rather than immediately written to disk.

- Set `innodb_change_buffering=all` so that update and delete operations are buffered in addition to inserts.
- Consider issuing `COMMIT` statements periodically during the big data change operation, possibly breaking a single delete or update into multiple statements that operate on smaller numbers of rows.

To get rid of a runaway rollback once it occurs, increase the buffer pool so that the rollback becomes CPU-bound and runs fast, or kill the server and restart with `innodb_force_recovery=3`, as explained in [Section 17.18.2, “InnoDB Recovery”](#).

- If you can afford the loss of some of the latest committed transactions if an unexpected exit occurs, you can set the `innodb_flush_log_at_trx_commit` parameter to 0. InnoDB tries to flush the log once per second anyway, although the flush is not guaranteed.
- When rows are modified or deleted, the rows and associated [undo logs](#) are not physically removed immediately, or even immediately after the transaction commits. The old data is preserved until transactions that started earlier or concurrently are finished, so that those transactions can access the previous state of modified or deleted rows. Thus, a long-running transaction can prevent InnoDB from purging data that was changed by a different transaction.
- When rows are modified or deleted within a long-running transaction, other transactions using the `READ COMMITTED` and `REPEATABLE READ` isolation levels have to do more work to reconstruct the older data if they read those same rows.
- When a long-running transaction modifies a table, queries against that table from other transactions do not make use of the [covering index](#) technique. Queries that normally could retrieve all the result columns from a secondary index, instead look up the appropriate values from the table data.

If secondary index pages are found to have a `PAGE_MAX_TRX_ID` that is too new, or if records in the secondary index are delete-marked, InnoDB may need to look up records using a clustered index.

### 10.5.3 Optimizing InnoDB Read-Only Transactions

InnoDB can avoid the overhead associated with setting up the [transaction ID](#) (`TRX_ID` field) for transactions that are known to be read-only. A transaction ID is only needed for a [transaction](#) that might perform write operations or [locking reads](#) such as `SELECT ... FOR UPDATE`. Eliminating unnecessary transaction IDs reduces the size of internal data structures that are consulted each time a query or data change statement constructs a [read view](#).

InnoDB detects read-only transactions when:

- The transaction is started with the `START TRANSACTION READ ONLY` statement. In this case, attempting to make changes to the database (for InnoDB, MyISAM, or other types of tables) causes an error, and the transaction continues in read-only state:

```
ERROR 1792 (25006): Cannot execute statement in a READ ONLY transaction.
```

You can still make changes to session-specific temporary tables in a read-only transaction, or issue locking queries for them, because those changes and locks are not visible to any other transaction.

- The `autocommit` setting is turned on, so that the transaction is guaranteed to be a single statement, and the single statement making up the transaction is a “non-locking” `SELECT` statement. That is, a `SELECT` that does not use a `FOR UPDATE` or `LOCK IN SHARED MODE` clause.
- The transaction is started without the `READ ONLY` option, but no updates or statements that explicitly lock rows have been executed yet. Until updates or explicit locks are required, a transaction stays in read-only mode.

Thus, for a read-intensive application such as a report generator, you can tune a sequence of [InnoDB](#) queries by grouping them inside [START TRANSACTION READ ONLY](#) and [COMMIT](#), or by turning on the [autocommit](#) setting before running the [SELECT](#) statements, or simply by avoiding any data change statements interspersed with the queries.

For information about [START TRANSACTION](#) and [autocommit](#), see [Section 15.3.1, “START TRANSACTION, COMMIT, and ROLLBACK Statements”](#).

#### Note

Transactions that qualify as auto-commit, non-locking, and read-only (AC-NL-RO) are kept out of certain internal [InnoDB](#) data structures and are therefore not listed in [SHOW ENGINE INNODB STATUS](#) output.

## 10.5.4 Optimizing InnoDB Redo Logging

Consider the following guidelines for optimizing redo logging:

- Increase the size of your redo log files. When [InnoDB](#) has written redo log files full, it must write the modified contents of the buffer pool to disk in a [checkpoint](#). Small redo log files cause many unnecessary disk writes.

The redo log file size is determined by [innodb\\_redo\\_log\\_capacity](#). [InnoDB](#) tries to maintain 32 redo log files of the same size, with each file equal to  $1/32 * \text{innodb\_redo\_log\_capacity}$ . Therefore, changing the [innodb\\_redo\\_log\\_capacity](#) setting changes the size of the redo log files.

For information about modifying your redo log file configuration, see [Section 17.6.5, “Redo Log”](#).

- Consider increasing the size of the [log buffer](#). A large log buffer enables large [transactions](#) to run without a need to write the log to disk before the transactions [commit](#). Thus, if you have transactions that update, insert, or delete many rows, making the log buffer larger saves disk I/O. Log buffer size is configured using the [innodb\\_log\\_buffer\\_size](#) configuration option, which can be dynamically configured.
- Configure the [innodb\\_log\\_write\\_ahead\\_size](#) configuration option to avoid “read-on-write”. This option defines the write-ahead block size for the redo log. Set [innodb\\_log\\_write\\_ahead\\_size](#) to match the operating system or file system cache block size. Read-on-write occurs when redo log blocks are not entirely cached to the operating system or file system due to a mismatch between write-ahead block size for the redo log and operating system or file system cache block size.

Valid values for [innodb\\_log\\_write\\_ahead\\_size](#) are multiples of the [InnoDB](#) log file block size ( $2^n$ ). The minimum value is the [InnoDB](#) log file block size (512). Write-ahead does not occur when the minimum value is specified. The maximum value is equal to the [innodb\\_page\\_size](#) value. If you specify a value for [innodb\\_log\\_write\\_ahead\\_size](#) that is larger than the [innodb\\_page\\_size](#) value, the [innodb\\_log\\_write\\_ahead\\_size](#) setting is truncated to the [innodb\\_page\\_size](#) value.

Setting the [innodb\\_log\\_write\\_ahead\\_size](#) value too low in relation to the operating system or file system cache block size results in read-on-write. Setting the value too high may have a slight impact on [fsync](#) performance for log file writes due to several blocks being written at once.

- MySQL provides dedicated log writer threads for writing redo log records from the log buffer to the system buffers and flushing the system buffers to the redo log files. You can enable or disable log writer threads using the [innodb\\_log\\_writer\\_threads](#) variable. Dedicated log writer threads can improve performance on high-concurrency systems, but for low-concurrency systems, disabling dedicated log writer threads provides better performance.
- Optimize the use of spin delay by user threads waiting for flushed redo. Spin delay helps reduce latency. During periods of low concurrency, reducing latency may be less of a priority, and avoiding the use of

spin delay during these periods may reduce energy consumption. During periods of high concurrency, you may want to avoid expending processing power on spin delay so that it can be used for other work. The following system variables permit setting high and low watermark values that define boundaries for the use of spin delay.

- `innodb_log_wait_for_flush_spin_hwm`: Defines the maximum average log flush time beyond which user threads no longer spin while waiting for flushed redo. The default value is 400 microseconds.
- `innodb_log_spin_cpu_abs_lwm`: Defines the minimum amount of CPU usage below which user threads no longer spin while waiting for flushed redo. The value is expressed as a sum of CPU core usage. For example, The default value of 80 is 80% of a single CPU core. On a system with a multi-core processor, a value of 150 represents 100% usage of one CPU core plus 50% usage of a second CPU core.
- `innodb_log_spin_cpu_pct_hwm`: Defines the maximum amount of CPU usage above which user threads no longer spin while waiting for flushed redo. The value is expressed as a percentage of the combined total processing power of all CPU cores. The default value is 50%. For example, 100% usage of two CPU cores is 50% of the combined CPU processing power on a server with four CPU cores.

The `innodb_log_spin_cpu_pct_hwm` configuration option respects processor affinity. For example, if a server has 48 cores but the `mysqld` process is pinned to only four CPU cores, the other 44 CPU cores are ignored.

## 10.5.5 Bulk Data Loading for InnoDB Tables

These performance tips supplement the general guidelines for fast inserts in [Section 10.2.5.1, “Optimizing INSERT Statements”](#).

- When importing data into `InnoDB`, turn off autocommit mode, because it performs a log flush to disk for every insert. To disable autocommit during your import operation, surround it with `SET autocommit` and `COMMIT` statements:

```
SET autocommit=0;
... SQL import statements ...
COMMIT;
```

The `mysqldump` option `--opt` creates dump files that are fast to import into an `InnoDB` table, even without wrapping them with the `SET autocommit` and `COMMIT` statements.

- If you have `UNIQUE` constraints on secondary keys, you can speed up table imports by temporarily turning off the uniqueness checks during the import session:

```
SET unique_checks=0;
... SQL import statements ...
SET unique_checks=1;
```

For big tables, this saves a lot of disk I/O because `InnoDB` can use its change buffer to write secondary index records in a batch. Be certain that the data contains no duplicate keys.

- If you have `FOREIGN KEY` constraints in your tables, you can speed up table imports by turning off the foreign key checks for the duration of the import session:

```
SET foreign_key_checks=0;
... SQL import statements ...
SET foreign_key_checks=1;
```

For big tables, this can save a lot of disk I/O.

- Use the multiple-row `INSERT` syntax to reduce communication overhead between the client and the server if you need to insert many rows:

```
INSERT INTO yourtable VALUES (1,2), (5,5), ...;
```

This tip is valid for inserts into any table, not just InnoDB tables.

- When doing bulk inserts into tables with auto-increment columns, set `innodb_autoinc_lock_mode` to 2 (interleaved) instead of 1 (consecutive). See [Section 17.6.1.6, “AUTO\\_INCREMENT Handling in InnoDB”](#) for details.
- When performing bulk inserts, it is faster to insert rows in `PRIMARY KEY` order. InnoDB tables use a [clustered index](#), which makes it relatively fast to use data in the order of the `PRIMARY KEY`. Performing bulk inserts in `PRIMARY KEY` order is particularly important for tables that do not fit entirely within the buffer pool.
- For optimal performance when loading data into an InnoDB `FULLTEXT` index, follow this set of steps:
  1. Define a column `FTS_DOC_ID` at table creation time, of type `BIGINT UNSIGNED NOT NULL`, with a unique index named `FTS_DOC_ID_INDEX`. For example:

```
CREATE TABLE t1 (
 FTS_DOC_ID BIGINT unsigned NOT NULL AUTO_INCREMENT,
 title varchar(255) NOT NULL DEFAULT '',
 text mediumtext NOT NULL,
 PRIMARY KEY (`FTS_DOC_ID`)
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4;

CREATE UNIQUE INDEX FTS_DOC_ID_INDEX on t1(FTS_DOC_ID);
```

2. Load the data into the table.
3. Create the `FULLTEXT` index after the data is loaded.

#### Note

When adding `FTS_DOC_ID` column at table creation time, ensure that the `FTS_DOC_ID` column is updated when the `FULLTEXT` indexed column is updated, as the `FTS_DOC_ID` must increase monotonically with each `INSERT` or `UPDATE`. If you choose not to add the `FTS_DOC_ID` at table creation time and have InnoDB manage DOC IDs for you, InnoDB adds the `FTS_DOC_ID` as a hidden column with the next `CREATE FULLTEXT INDEX` call. This approach, however, requires a table rebuild which can impact performance.

- If loading data into a *new* MySQL instance, consider disabling redo logging using `ALTER INSTANCE {ENABLE|DISABLE} INNODB REDO_LOG` syntax. Disabling redo logging helps speed up data loading by avoiding redo log writes. For more information, see [Disabling Redo Logging](#).

#### Warning

This feature is intended only for loading data into a new MySQL instance. *Do not disable redo logging on a production system.* It is permitted to shutdown and restart the server while redo logging is disabled, but an unexpected server stoppage while redo logging is disabled can cause data loss and instance corruption.

- Use MySQL Shell to import data. MySQL Shell's parallel table import utility `util.importTable()` provides rapid data import to a MySQL relational table for large data files. MySQL Shell's dump loading utility `util.loadDump()` also offers parallel load capabilities. See [MySQL Shell Utilities](#).

## 10.5.6 Optimizing InnoDB Queries

To tune queries for [InnoDB](#) tables, create an appropriate set of indexes on each table. See [Section 10.3.1, “How MySQL Uses Indexes”](#) for details. Follow these guidelines for [InnoDB](#) indexes:

- Because each [InnoDB](#) table has a [primary key](#) (whether you request one or not), specify a set of primary key columns for each table, columns that are used in the most important and time-critical queries.
- Do not specify too many or too long columns in the primary key, because these column values are duplicated in each secondary index. When an index contains unnecessary data, the I/O to read this data and memory to cache it reduce the performance and scalability of the server.
- Do not create a separate [secondary index](#) for each column, because each query can only make use of one index. Indexes on rarely tested columns or columns with only a few different values might not be helpful for any queries. If you have many queries for the same table, testing different combinations of columns, try to create a small number of [concatenated indexes](#) rather than a large number of single-column indexes. If an index contains all the columns needed for the result set (known as a [covering index](#)), the query might be able to avoid reading the table data at all.
- If an indexed column cannot contain any [NULL](#) values, declare it as [NOT NULL](#) when you create the table. The optimizer can better determine which index is most effective to use for a query, when it knows whether each column contains [NULL](#) values.
- You can optimize single-query transactions for [InnoDB](#) tables, using the technique in [Section 10.5.3, “Optimizing InnoDB Read-Only Transactions”](#).

## 10.5.7 Optimizing InnoDB DDL Operations

- Many DDL operations on tables and indexes ([CREATE](#), [ALTER](#), and [DROP](#) statements) can be performed online. See [Section 17.12, “InnoDB and Online DDL”](#) for details.
- Online DDL support for adding secondary indexes means that you can generally speed up the process of creating and loading a table and associated indexes by creating the table without secondary indexes, then adding secondary indexes after the data is loaded.
- Use [TRUNCATE TABLE](#) to empty a table, not [DELETE FROM tbl\\_name](#). Foreign key constraints can make a [TRUNCATE](#) statement work like a regular [DELETE](#) statement, in which case a sequence of commands like [DROP TABLE](#) and [CREATE TABLE](#) might be fastest.
- Because the primary key is integral to the storage layout of each [InnoDB](#) table, and changing the definition of the primary key involves reorganizing the whole table, always set up the primary key as part of the [CREATE TABLE](#) statement, and plan ahead so that you do not need to [ALTER](#) or [DROP](#) the primary key afterward.

## 10.5.8 Optimizing InnoDB Disk I/O

If you follow best practices for database design and tuning techniques for SQL operations, but your database is still slow due to heavy disk I/O activity, consider these disk I/O optimizations. If the Unix `top` tool or the Windows Task Manager shows that the CPU usage percentage with your workload is less than 70%, your workload is probably disk-bound.

- Increase buffer pool size

When table data is cached in the [InnoDB](#) buffer pool, it can be accessed repeatedly by queries without requiring any disk I/O. Specify the size of the buffer pool with the [innodb\\_buffer\\_pool\\_size](#) option. This memory area is important enough that it is typically recommended that [innodb\\_buffer\\_pool\\_size](#) is configured to 50 to 75 percent of system memory. For more information see, [Section 10.12.3.1, “How MySQL Uses Memory”](#).

- Adjust the flush method

In some versions of GNU/Linux and Unix, flushing files to disk with the Unix [fsync\(\)](#) call and similar methods is surprisingly slow. If database write performance is an issue, conduct benchmarks with the [innodb\\_flush\\_method](#) parameter set to [O\\_DSYNC](#).

- Configure a threshold for operating system flushes

By default, when [InnoDB](#) creates a new data file, such as a new log file or tablespace file, the file is fully written to the operating system cache before it is flushed to disk, which can cause a large amount of disk write activity to occur at once. To force smaller, periodic flushes of data from the operating system cache, you can use the [innodb\\_fsync\\_threshold](#) variable to define a threshold value, in bytes. When the byte threshold is reached, the contents of the operating system cache are flushed to disk. The default value of 0 forces the default behavior, which is to flush data to disk only after a file is fully written to the cache.

Specifying a threshold to force smaller, periodic flushes may be beneficial in cases where multiple MySQL instances use the same storage devices. For example, creating a new MySQL instance and its associated data files could cause large surges of disk write activity, impeding the performance of other MySQL instances that use the same storage devices. Configuring a threshold helps avoid such surges in write activity.

- Use [fdatasync\(\)](#) instead of [fsync\(\)](#)

On platforms that support [fdatasync\(\)](#) system calls, the [innodb\\_use\\_fdatasync](#) variable permits using [fdatasync\(\)](#) instead of [fsync\(\)](#) for operating system flushes. An [fdatasync\(\)](#) system call does not flush changes to file metadata unless required for subsequent data retrieval, providing a potential performance benefit.

A subset of [innodb\\_flush\\_method](#) settings such as [fsync](#), [O\\_DSYNC](#), and [O\\_DIRECT](#) use [fsync\(\)](#) system calls. The [innodb\\_use\\_fdatasync](#) variable is applicable when using those settings.

- Use a noop or deadline I/O scheduler with native AIO on Linux

[InnoDB](#) uses the asynchronous I/O subsystem (native AIO) on Linux to perform read-ahead and write requests for data file pages. This behavior is controlled by the [innodb\\_use\\_native\\_aio](#) configuration option, which is enabled by default. With native AIO, the type of I/O scheduler has greater influence on I/O performance. Generally, noop and deadline I/O schedulers are recommended. Conduct benchmarks to determine which I/O scheduler provides the best results for your workload and environment. For more information, see [Section 17.8.6, “Using Asynchronous I/O on Linux”](#).

- Use direct I/O on Solaris 10 for x86\_64 architecture

When using the [InnoDB](#) storage engine on Solaris 10 for x86\_64 architecture (AMD Opteron), use direct I/O for [InnoDB](#)-related files to avoid degradation of [InnoDB](#) performance. To use direct I/O for an entire UFS file system used for storing [InnoDB](#)-related files, mount it with the [forcedirectio](#) option; see [mount\\_ufs\(1M\)](#). (The default on Solaris 10/x86\_64 is *not* to use this option.) To apply direct I/O only to [InnoDB](#) file operations rather than the whole file system, set [innodb\\_flush\\_method = O\\_DIRECT](#). With this setting, [InnoDB](#) calls [directio\(\)](#) instead of [fcntl\(\)](#) for I/O to data files (not for I/O to log files).

- Use raw storage for data and log files with Solaris 2.6 or later

When using the [InnoDB](#) storage engine with a large [innodb\\_buffer\\_pool\\_size](#) value on any release of Solaris 2.6 and up and any platform (sparc/x86/x64/amd64), conduct benchmarks with [InnoDB](#) data files and log files on raw devices or on a separate direct I/O UFS file system, using the [forcedirectio](#) mount option as described previously. (It is necessary to use the mount option rather than setting [innodb\\_flush\\_method](#) if you want direct I/O for the log files.) Users of the Veritas file system VxFS should use the [convosync=direct](#) mount option.

Do not place other MySQL data files, such as those for [MyISAM](#) tables, on a direct I/O file system. Executables or libraries *must not* be placed on a direct I/O file system.

- Use additional storage devices

Additional storage devices could be used to set up a RAID configuration. For related information, see [Section 10.12.1, “Optimizing Disk I/O”](#).

Alternatively, [InnoDB](#) tablespace data files and log files can be placed on different physical disks. For more information, refer to the following sections:

- [Section 17.8.1, “InnoDB Startup Configuration”](#)
  - [Section 17.6.1.2, “Creating Tables Externally”](#)
  - [Creating a General Tablespace](#)
  - [Section 17.6.1.4, “Moving or Copying InnoDB Tables”](#)
- Consider non-rotational storage

Non-rotational storage generally provides better performance for random I/O operations; and rotational storage for sequential I/O operations. When distributing data and log files across rotational and non-

rotational storage devices, consider the type of I/O operations that are predominantly performed on each file.

Random I/O-oriented files typically include [file-per-table](#) and [general tablespace](#) data files, [undo tablespace](#) files, and [temporary tablespace](#) files. Sequential I/O-oriented files include [InnoDB system tablespace](#) files, doublewrite files, and log files such as [binary log](#) files and [redo log](#) files.

Review settings for the following configuration options when using non-rotational storage:

- [innodb\\_checksum\\_algorithm](#)

The [crc32](#) option uses a faster checksum algorithm and is recommended for fast storage systems.

- [innodb\\_flush\\_neighbors](#)

Optimizes I/O for rotational storage devices. Disable it for non-rotational storage or a mix of rotational and non-rotational storage. It is disabled by default.

- [innodb\\_idle\\_flush\\_pct](#)

Permits placing a limit on page flushing during idle periods, which can help extend the life of non-rotational storage devices.

- [innodb\\_io\\_capacity](#)

The default setting of 10000 is generally sufficient.

- [innodb\\_io\\_capacity\\_max](#)

The default value of  $(2 * \text{innodb\_io\_capacity})$  is intended for most workloads.

- [innodb\\_log\\_compressed\\_pages](#)

If redo logs are on non-rotational storage, consider disabling this option to reduce logging. See [Disable logging of compressed pages](#).

- [innodb\\_log\\_file\\_size](#) (deprecated)

If redo logs are on non-rotational storage, configure this option to maximize caching and write combining.

- [innodb\\_redo\\_log\\_capacity](#)

If redo logs are on non-rotational storage, configure this option to maximize caching and write combining.

- [innodb\\_page\\_size](#)

Consider using a page size that matches the internal sector size of the disk. Early-generation SSD devices often have a 4KB sector size. Some newer devices have a 16KB sector size. The default

InnoDB page size is 16KB. Keeping the page size close to the storage device block size minimizes the amount of unchanged data that is rewritten to disk.

- `binlog_row_image`

If binary logs are on non-rotational storage and all tables have primary keys, consider setting this option to `minimal` to reduce logging.

Ensure that TRIM support is enabled for your operating system. It is typically enabled by default.

- Increase I/O capacity to avoid backlogs

If throughput drops periodically because of InnoDB `checkpoint` operations, consider increasing the value of the `innodb_io_capacity` configuration option. Higher values cause more frequent `flushing`, avoiding the backlog of work that can cause dips in throughput.

- Lower I/O capacity if flushing does not fall behind

If the system is not falling behind with InnoDB `flushing` operations, consider lowering the value of the `innodb_io_capacity` configuration option. Typically, you keep this option value as low as practical, but not so low that it causes periodic drops in throughput as mentioned in the preceding bullet. In a typical scenario where you could lower the option value, you might see a combination like this in the output from `SHOW ENGINE INNODB STATUS`:

- History list length low, below a few thousand.
- Insert buffer merges close to rows inserted.
- Modified pages in buffer pool consistently well below `innodb_max_dirty_pages_pct` of the buffer pool. (Measure at a time when the server is not doing bulk inserts; it is normal during bulk inserts for the modified pages percentage to rise significantly.)
- `Log sequence number - Last checkpoint` is at less than 7/8 or ideally less than 6/8 of the total size of the InnoDB log files.
- Store system tablespace files on Fusion-io devices

You can take advantage of a doublewrite buffer-related I/O optimization by storing the files that contain the doublewrite storage area on Fusion-io devices that support atomic writes. (The doublewrite buffer storage area resides in doublewrite files. See [Section 17.6.4, “Doublewrite Buffer”](#).) When doublewrite storage area files are placed on Fusion-io devices that support atomic writes, the doublewrite buffer is automatically disabled and Fusion-io atomic writes are used for all data files. This feature is only supported on Fusion-io hardware and is only enabled for Fusion-io NVMFS on Linux. To take full advantage of this feature, an `innodb_flush_method` setting of `O_DIRECT` is recommended.

#### Note

Because the doublewrite buffer setting is global, the doublewrite buffer is also disabled for data files that do not reside on Fusion-io hardware.

- Disable logging of compressed pages

When using the InnoDB table `compression` feature, images of re-compressed `pages` are written to the `redo log` when changes are made to compressed data. This behavior is controlled by `innodb_log_compressed_pages`, which is enabled by default to prevent corruption that can occur if a different version of the `zlib` compression algorithm is used during recovery. If you are certain that the

`zlib` version is not subject to change, disable `innodb_log_compressed_pages` to reduce redo log generation for workloads that modify compressed data.

## 10.5.9 Optimizing InnoDB Configuration Variables

Different settings work best for servers with light, predictable loads, versus servers that are running near full capacity all the time, or that experience spikes of high activity.

Because the `InnoDB` storage engine performs many of its optimizations automatically, many performance-tuning tasks involve monitoring to ensure that the database is performing well, and changing configuration options when performance drops. See [Section 17.16, “InnoDB Integration with MySQL Performance Schema”](#) for information about detailed `InnoDB` performance monitoring.

The main configuration steps you can perform include:

- Controlling the types of data change operations for which `InnoDB` buffers the changed data, to avoid frequent small disk writes. See [Configuring Change Buffering](#). Enabling change buffering can give better performance on IO-bound workloads, but can cause issues during recovery, bulk load, or during buffer pool resizing. Having it disabled (default as of MySQL 8.4) helps ensure stability even if it may lower performance.
- Turning the adaptive hash indexing feature on and off using the `innodb_adaptive_hash_index` option. See [Section 17.5.3, “Adaptive Hash Index”](#) for more information. You might change this setting during periods of unusual activity, then restore it to its original setting.
- Setting a limit on the number of concurrent threads that `InnoDB` processes, if context switching is a bottleneck. See [Section 17.8.4, “Configuring Thread Concurrency for InnoDB”](#).
- Controlling the amount of prefetching that `InnoDB` does with its read-ahead operations. When the system has unused I/O capacity, more read-ahead can improve the performance of queries. Too much read-ahead can cause periodic drops in performance on a heavily loaded system. See [Section 17.8.3.4, “Configuring InnoDB Buffer Pool Prefetching \(Read-Ahead\)”](#).
- Increasing the number of background threads for read or write operations, if you have a high-end I/O subsystem that is not fully utilized by the default values. See [Section 17.8.5, “Configuring the Number of Background InnoDB I/O Threads”](#).
- Controlling how much I/O `InnoDB` performs in the background. See [Section 17.8.7, “Configuring InnoDB I/O Capacity”](#). You might scale back this setting if you observe periodic drops in performance.
- Controlling the algorithm that determines when `InnoDB` performs certain types of background writes. See [Section 17.8.3.5, “Configuring Buffer Pool Flushing”](#). The algorithm works for some types of workloads but not others, so you might disable this feature if you observe periodic drops in performance.
- Taking advantage of multicore processors and their cache memory configuration, to minimize delays in context switching. See [Section 17.8.8, “Configuring Spin Lock Polling”](#).
- Preventing one-time operations such as table scans from interfering with the frequently accessed data stored in the `InnoDB` buffer cache. See [Section 17.8.3.3, “Making the Buffer Pool Scan Resistant”](#).
- Adjusting log files to a size that makes sense for reliability and crash recovery. `InnoDB` log files have often been kept small to avoid long startup times after a crash. Optimizations introduced in MySQL 5.5 speed up certain steps of the crash [recovery](#) process. In particular, scanning the [redo log](#) and applying the redo log are faster due to improved algorithms for memory management. If you have kept your log files artificially small to avoid long startup times, you can now consider increasing log file size to reduce the I/O that occurs due recycling of redo log records.

- Configuring the size and number of instances for the [InnoDB](#) buffer pool, especially important for systems with multi-gigabyte buffer pools. See [Section 17.8.3.2, “Configuring Multiple Buffer Pool Instances”](#).
- Increasing the maximum number of concurrent transactions, which dramatically improves scalability for the busiest databases. See [Section 17.6.6, “Undo Logs”](#).
- Moving purge operations (a type of garbage collection) into a background thread. See [Section 17.8.9, “Purge Configuration”](#). To effectively measure the results of this setting, tune the other I/O-related and thread-related configuration settings first.
- Reducing the amount of switching that [InnoDB](#) does between concurrent threads, so that SQL operations on a busy server do not queue up and form a “traffic jam”. Set a value for the [innodb\\_thread\\_concurrency](#) option, up to approximately 32 for a high-powered modern system. Increase the value for the [innodb\\_concurrency\\_tickets](#) option, typically to 5000 or so. This combination of options sets a cap on the number of threads that [InnoDB](#) processes at any one time, and allows each thread to do substantial work before being swapped out, so that the number of waiting threads stays low and operations can complete without excessive context switching.

### 10.5.10 Optimizing InnoDB for Systems with Many Tables

- If you have configured [non-persistent optimizer statistics](#) (a non-default configuration), [InnoDB](#) computes index [cardinality](#) values for a table the first time that table is accessed after startup, instead of storing such values in the table. This step can take significant time on systems that partition the data into many tables. Since this overhead only applies to the initial table open operation, to “warm up” a table for later use, access it immediately after startup by issuing a statement such as `SELECT 1 FROM tbl_name LIMIT 1`.

Optimizer statistics are persisted to disk by default, enabled by the [innodb\\_stats\\_persistent](#) configuration option. For information about persistent optimizer statistics, see [Section 17.8.10.1, “Configuring Persistent Optimizer Statistics Parameters”](#).

## 10.6 Optimizing for MyISAM Tables

The [MyISAM](#) storage engine performs best with read-mostly data or with low-concurrency operations, because table locks limit the ability to perform simultaneous updates. In MySQL, [InnoDB](#) is the default storage engine rather than [MyISAM](#).

### 10.6.1 Optimizing MyISAM Queries

Some general tips for speeding up queries on [MyISAM](#) tables:

- To help MySQL better optimize queries, use `ANALYZE TABLE` or run `myisamchk --analyze` on a table after it has been loaded with data. This updates a value for each index part that indicates the average number of rows that have the same value. (For unique indexes, this is always 1.) MySQL uses this to decide which index to choose when you join two tables based on a nonconstant expression. You can check the result from the table analysis by using `SHOW INDEX FROM tbl_name` and examining the [Cardinality](#) value. `myisamchk --description --verbose` shows index distribution information.
- To sort an index and data according to an index, use `myisamchk --sort-index --sort-records=1` (assuming that you want to sort on index 1). This is a good way to make queries faster if you have a unique index from which you want to read all rows in order according to the index. The first time you sort a large table this way, it may take a long time.
- Try to avoid complex `SELECT` queries on [MyISAM](#) tables that are updated frequently, to avoid problems with table locking that occur due to contention between readers and writers.

- **MyISAM** supports concurrent inserts: If a table has no free blocks in the middle of the data file, you can **INSERT** new rows into it at the same time that other threads are reading from the table. If it is important to be able to do this, consider using the table in ways that avoid deleting rows. Another possibility is to run **OPTIMIZE TABLE** to defragment the table after you have deleted a lot of rows from it. This behavior is altered by setting the `concurrent_insert` variable. You can force new rows to be appended (and therefore permit concurrent inserts), even in tables that have deleted rows. See [Section 10.11.3, “Concurrent Inserts”](#).
- For **MyISAM** tables that change frequently, try to avoid all variable-length columns (**VARCHAR**, **BLOB**, and **TEXT**). The table uses dynamic row format if it includes even a single variable-length column. See [Chapter 18, Alternative Storage Engines](#).
- It is normally not useful to split a table into different tables just because the rows become large. In accessing a row, the biggest performance hit is the disk seek needed to find the first byte of the row. After finding the data, most modern disks can read the entire row fast enough for most applications. The only cases where splitting up a table makes an appreciable difference is if it is a **MyISAM** table using dynamic row format that you can change to a fixed row size, or if you very often need to scan the table but do not need most of the columns. See [Chapter 18, Alternative Storage Engines](#).
- Use **ALTER TABLE ... ORDER BY** *expr1*, *expr2*, ... if you usually retrieve rows in *expr1*, *expr2*, ... order. By using this option after extensive changes to the table, you may be able to get higher performance.
- If you often need to calculate results such as counts based on information from a lot of rows, it may be preferable to introduce a new table and update the counter in real time. An update of the following form is very fast:

```
UPDATE tbl_name SET count_col=count_col+1 WHERE key_col=constant;
```

This is very important when you use MySQL storage engines such as **MyISAM** that has only table-level locking (multiple readers with single writers). This also gives better performance with most database systems, because the row locking manager in this case has less to do.

- Use **OPTIMIZE TABLE** periodically to avoid fragmentation with dynamic-format **MyISAM** tables. See [Section 18.2.3, “MyISAM Table Storage Formats”](#).
- Declaring a **MyISAM** table with the `DELAY_KEY_WRITE=1` table option makes index updates faster because they are not flushed to disk until the table is closed. The downside is that if something kills the server while such a table is open, you must ensure that the table is okay by running the server with the `myisam_recover_options` system variable set, or by running `myisamchk` before restarting the server. (However, even in this case, you should not lose anything by using `DELAY_KEY_WRITE`, because the key information can always be generated from the data rows.)
- Strings are automatically prefix- and end-space compressed in **MyISAM** indexes. See [Section 15.1.15, “CREATE INDEX Statement”](#).
- You can increase performance by caching queries or answers in your application and then executing many inserts or updates together. Locking the table during this operation ensures that the index cache is only flushed once after all updates.

## 10.6.2 Bulk Data Loading for MyISAM Tables

These performance tips supplement the general guidelines for fast inserts in [Section 10.2.5.1, “Optimizing INSERT Statements”](#).

- For a [MyISAM](#) table, you can use concurrent inserts to add rows at the same time that [SELECT](#) statements are running, if there are no deleted rows in middle of the data file. See [Section 10.11.3, “Concurrent Inserts”](#).
- With some extra work, it is possible to make [LOAD DATA](#) run even faster for a [MyISAM](#) table when the table has many indexes. Use the following procedure:
  1. Execute a [FLUSH TABLES](#) statement or a `mysqladmin flush-tables` command.
  2. Use `myisamchk --keys-used=0 -rq /path/to/db/tbl_name` to remove all use of indexes for the table.
  3. Insert data into the table with [LOAD DATA](#). This does not update any indexes and therefore is very fast.
  4. If you intend only to read from the table in the future, use `myisampack` to compress it. See [Section 18.2.3.3, “Compressed Table Characteristics”](#).
  5. Re-create the indexes with `myisamchk -rq /path/to/db/tbl_name`. This creates the index tree in memory before writing it to disk, which is much faster than updating the index during [LOAD DATA](#) because it avoids lots of disk seeks. The resulting index tree is also perfectly balanced.
  6. Execute a [FLUSH TABLES](#) statement or a `mysqladmin flush-tables` command.

[LOAD DATA](#) performs the preceding optimization automatically if the [MyISAM](#) table into which you insert data is empty. The main difference between automatic optimization and using the procedure explicitly is that you can let `myisamchk` allocate much more temporary memory for the index creation than you might want the server to allocate for index re-creation when it executes the [LOAD DATA](#) statement.

You can also disable or enable the nonunique indexes for a [MyISAM](#) table by using the following statements rather than `myisamchk`. If you use these statements, you can skip the [FLUSH TABLES](#) operations:

```
ALTER TABLE tbl_name DISABLE KEYS;
ALTER TABLE tbl_name ENABLE KEYS;
```

- To speed up [INSERT](#) operations that are performed with multiple statements for nontransactional tables, lock your tables:

```
LOCK TABLES a WRITE;
INSERT INTO a VALUES (1,23),(2,34),(4,33);
INSERT INTO a VALUES (8,26),(6,29);
...
UNLOCK TABLES;
```

This benefits performance because the index buffer is flushed to disk only once, after all [INSERT](#) statements have completed. Normally, there would be as many index buffer flushes as there are [INSERT](#) statements. Explicit locking statements are not needed if you can insert all rows with a single [INSERT](#).

Locking also lowers the total time for multiple-connection tests, although the maximum wait time for individual connections might go up because they wait for locks. Suppose that five clients attempt to perform inserts simultaneously as follows:

- Connection 1 does 1000 inserts
- Connections 2, 3, and 4 do 1 insert

- Connection 5 does 1000 inserts

If you do not use locking, connections 2, 3, and 4 finish before 1 and 5. If you use locking, connections 2, 3, and 4 probably do not finish before 1 or 5, but the total time should be about 40% faster.

`INSERT`, `UPDATE`, and `DELETE` operations are very fast in MySQL, but you can obtain better overall performance by adding locks around everything that does more than about five successive inserts or updates. If you do very many successive inserts, you could do a `LOCK TABLES` followed by an `UNLOCK TABLES` once in a while (each 1,000 rows or so) to permit other threads to access table. This would still result in a nice performance gain.

`INSERT` is still much slower for loading data than `LOAD DATA`, even when using the strategies just outlined.

- To increase performance for `MyISAM` tables, for both `LOAD DATA` and `INSERT`, enlarge the key cache by increasing the `key_buffer_size` system variable. See [Section 7.1.1, “Configuring the Server”](#).

### 10.6.3 Optimizing REPAIR TABLE Statements

`REPAIR TABLE` for `MyISAM` tables is similar to using `myisamchk` for repair operations, and some of the same performance optimizations apply:

- `myisamchk` has variables that control memory allocation. You may be able to its improve performance by setting these variables, as described in [Section 6.6.4.6, “myisamchk Memory Usage”](#).
- For `REPAIR TABLE`, the same principle applies, but because the repair is done by the server, you set server system variables instead of `myisamchk` variables. Also, in addition to setting memory-allocation variables, increasing the `myisam_max_sort_file_size` system variable increases the likelihood that the repair uses the faster filesort method and avoids the slower repair by key cache method. Set the variable to the maximum file size for your system, after checking to be sure that there is enough free space to hold a copy of the table files. The free space must be available in the file system containing the original table files.

Suppose that a `myisamchk` table-repair operation is done using the following options to set its memory-allocation variables:

```
--key_buffer_size=128M --myisam_sort_buffer_size=256M
--read_buffer_size=64M --write_buffer_size=64M
```

Some of those `myisamchk` variables correspond to server system variables:

<code>myisamchk</code> Variable	System Variable
<code>key_buffer_size</code>	<code>key_buffer_size</code>
<code>myisam_sort_buffer_size</code>	<code>myisam_sort_buffer_size</code>
<code>read_buffer_size</code>	<code>read_buffer_size</code>
<code>write_buffer_size</code>	none

Each of the server system variables can be set at runtime, and some of them (`myisam_sort_buffer_size`, `read_buffer_size`) have a session value in addition to a global value. Setting a session value limits the effect of the change to your current session and does not affect other users. Changing a global-only variable (`key_buffer_size`, `myisam_max_sort_file_size`) affects other users as well. For `key_buffer_size`, you must take into account that the buffer is shared with those users. For example, if you set the `myisamchk` `key_buffer_size` variable to 128MB, you could set the corresponding `key_buffer_size` system variable larger than that (if it is not already set larger), to permit key buffer use by activity in other sessions. However, changing the global key buffer size

invalidates the buffer, causing increased disk I/O and slowdown for other sessions. An alternative that avoids this problem is to use a separate key cache, assign to it the indexes from the table to be repaired, and deallocate it when the repair is complete. See [Section 10.10.2.2, “Multiple Key Caches”](#).

Based on the preceding remarks, a `REPAIR TABLE` operation can be done as follows to use settings similar to the `myisamchk` command. Here a separate 128MB key buffer is allocated and the file system is assumed to permit a file size of at least 100GB.

```
SET SESSION myisam_sort_buffer_size = 256*1024*1024;
SET SESSION read_buffer_size = 64*1024*1024;
SET GLOBAL myisam_max_sort_file_size = 100*1024*1024*1024;
SET GLOBAL repair_cache.key_buffer_size = 128*1024*1024;
CACHE INDEX tbl_name IN repair_cache;
LOAD INDEX INTO CACHE tbl_name;
REPAIR TABLE tbl_name ;
SET GLOBAL repair_cache.key_buffer_size = 0;
```

If you intend to change a global variable but want to do so only for the duration of a `REPAIR TABLE` operation to minimally affect other users, save its value in a user variable and restore it afterward. For example:

```
SET @old_myisam_sort_buffer_size = @@GLOBAL.myisam_max_sort_file_size;
SET GLOBAL myisam_max_sort_file_size = 100*1024*1024*1024;
REPAIR TABLE tbl_name ;
SET GLOBAL myisam_max_sort_file_size = @old_myisam_max_sort_file_size;
```

The system variables that affect `REPAIR TABLE` can be set globally at server startup if you want the values to be in effect by default. For example, add these lines to the server `my.cnf` file:

```
[mysqld]
myisam_sort_buffer_size=256M
key_buffer_size=1G
myisam_max_sort_file_size=100G
```

These settings do not include `read_buffer_size`. Setting `read_buffer_size` globally to a large value does so for all sessions and can cause performance to suffer due to excessive memory allocation for a server with many simultaneous sessions.

## 10.7 Optimizing for MEMORY Tables

Consider using `MEMORY` tables for noncritical data that is accessed often, and is read-only or rarely updated. Benchmark your application against equivalent `InnoDB` or `MyISAM` tables under a realistic workload, to confirm that any additional performance is worth the risk of losing data, or the overhead of copying data from a disk-based table at application start.

For best performance with `MEMORY` tables, examine the kinds of queries against each table, and specify the type to use for each associated index, either a B-tree index or a hash index. On the `CREATE INDEX` statement, use the clause `USING BTREE` or `USING HASH`. B-tree indexes are fast for queries that do greater-than or less-than comparisons through operators such as `>` or `BETWEEN`. Hash indexes are only fast for queries that look up single values through the `=` operator, or a restricted set of values through the `IN` operator. For why `USING BTREE` is often a better choice than the default `USING HASH`, see [Section 10.2.1.23, “Avoiding Full Table Scans”](#). For implementation details of the different types of `MEMORY` indexes, see [Section 10.3.9, “Comparison of B-Tree and Hash Indexes”](#).

## 10.8 Understanding the Query Execution Plan

Depending on the details of your tables, columns, indexes, and the conditions in your `WHERE` clause, the MySQL optimizer considers many techniques to efficiently perform the lookups involved in an SQL query. A query on a huge table can be performed without reading all the rows; a join involving several

tables can be performed without comparing every combination of rows. The set of operations that the optimizer chooses to perform the most efficient query is called the “query execution plan”, also known as the `EXPLAIN` plan. Your goals are to recognize the aspects of the `EXPLAIN` plan that indicate a query is optimized well, and to learn the SQL syntax and indexing techniques to improve the plan if you see some inefficient operations.

## 10.8.1 Optimizing Queries with EXPLAIN

The `EXPLAIN` statement provides information about how MySQL executes statements:

- `EXPLAIN` works with `SELECT`, `DELETE`, `INSERT`, `REPLACE`, and `UPDATE` statements.
- When `EXPLAIN` is used with an explainable statement, MySQL displays information from the optimizer about the statement execution plan. That is, MySQL explains how it would process the statement, including information about how tables are joined and in which order. For information about using `EXPLAIN` to obtain execution plan information, see [Section 10.8.2, “EXPLAIN Output Format”](#).
- When `EXPLAIN` is used with `FOR CONNECTION connection_id` rather than an explainable statement, it displays the execution plan for the statement executing in the named connection. See [Section 10.8.4, “Obtaining Execution Plan Information for a Named Connection”](#).
- For `SELECT` statements, `EXPLAIN` produces additional execution plan information that can be displayed using `SHOW WARNINGS`. See [Section 10.8.3, “Extended EXPLAIN Output Format”](#).
- `EXPLAIN` is useful for examining queries involving partitioned tables. See [Section 26.3.5, “Obtaining Information About Partitions”](#).
- The `FORMAT` option can be used to select the output format. `TRADITIONAL` presents the output in tabular format. This is the default if no `FORMAT` option is present. `JSON` format displays the information in JSON format.

With the help of `EXPLAIN`, you can see where you should add indexes to tables so that the statement executes faster by using indexes to find rows. You can also use `EXPLAIN` to check whether the optimizer joins the tables in an optimal order. To give a hint to the optimizer to use a join order corresponding to the order in which the tables are named in a `SELECT` statement, begin the statement with `SELECT STRAIGHT_JOIN` rather than just `SELECT`. (See [Section 15.2.13, “SELECT Statement”](#).) However, `STRAIGHT_JOIN` may prevent indexes from being used because it disables semijoin transformations. See [Optimizing IN and EXISTS Subquery Predicates with Semijoin Transformations](#).

The optimizer trace may sometimes provide information complementary to that of `EXPLAIN`. However, the optimizer trace format and content are subject to change between versions. For details, see [Section 10.15, “Tracing the Optimizer”](#).

If you have a problem with indexes not being used when you believe that they should be, run `ANALYZE TABLE` to update table statistics, such as cardinality of keys, that can affect the choices the optimizer makes. See [Section 15.7.3.1, “ANALYZE TABLE Statement”](#).

### Note

`EXPLAIN` can also be used to obtain information about the columns in a table. `EXPLAIN tbl_name` is synonymous with `DESCRIBE tbl_name` and `SHOW COLUMNS FROM tbl_name`. For more information, see [Section 15.8.1, “DESCRIBE Statement”](#), and [Section 15.7.7.6, “SHOW COLUMNS Statement”](#).

## 10.8.2 EXPLAIN Output Format

The `EXPLAIN` statement provides information about how MySQL executes statements. `EXPLAIN` works with `SELECT`, `DELETE`, `INSERT`, `REPLACE`, and `UPDATE` statements.

**EXPLAIN** returns a row of information for each table used in the **SELECT** statement. It lists the tables in the output in the order that MySQL would read them while processing the statement. This means that MySQL reads a row from the first table, then finds a matching row in the second table, and then in the third table, and so on. When all tables are processed, MySQL outputs the selected columns and backtracks through the table list until a table is found for which there are more matching rows. The next row is read from this table and the process continues with the next table.

#### Note

MySQL Workbench has a Visual Explain capability that provides a visual representation of **EXPLAIN** output. See [Tutorial: Using Explain to Improve Query Performance](#).

- [EXPLAIN Output Columns](#)
- [EXPLAIN Join Types](#)
- [EXPLAIN Extra Information](#)
- [EXPLAIN Output Interpretation](#)

## EXPLAIN Output Columns

This section describes the output columns produced by **EXPLAIN**. Later sections provide additional information about the **type** and **Extra** columns.

Each output row from **EXPLAIN** provides information about one table. Each row contains the values summarized in [Table 10.1, “EXPLAIN Output Columns”](#), and described in more detail following the table. Column names are shown in the table's first column; the second column provides the equivalent property name shown in the output when **FORMAT=JSON** is used.

**Table 10.1 EXPLAIN Output Columns**

Column	JSON Name	Meaning
<code>id</code>	<code>select_id</code>	The <b>SELECT</b> identifier
<code>select_type</code>	None	The <b>SELECT</b> type
<code>table</code>	<code>table_name</code>	The table for the output row
<code>partitions</code>	<code>partitions</code>	The matching partitions
<code>type</code>	<code>access_type</code>	The join type
<code>possible_keys</code>	<code>possible_keys</code>	The possible indexes to choose
<code>key</code>	<code>key</code>	The index actually chosen
<code>key_len</code>	<code>key_length</code>	The length of the chosen key
<code>ref</code>	<code>ref</code>	The columns compared to the index
<code>rows</code>	<code>rows</code>	Estimate of rows to be examined
<code>filtered</code>	<code>filtered</code>	Percentage of rows filtered by table condition
<b>Extra</b>	None	Additional information

#### Note

JSON properties which are **NULL** are not displayed in JSON-formatted **EXPLAIN** output.

- `id` (JSON name: `select_id`)

The `SELECT` identifier. This is the sequential number of the `SELECT` within the query. The value can be `NULL` if the row refers to the union result of other rows. In this case, the `table` column shows a value like `<unionM,N>` to indicate that the row refers to the union of the rows with `id` values of `M` and `N`.

- `select_type` (JSON name: none)

The type of `SELECT`, which can be any of those shown in the following table. A JSON-formatted `EXPLAIN` exposes the `SELECT` type as a property of a `query_block`, unless it is `SIMPLE` or `PRIMARY`. The JSON names (where applicable) are also shown in the table.

<code>select_type</code> Value	JSON Name	Meaning
<code>SIMPLE</code>	None	Simple <code>SELECT</code> (not using <code>UNION</code> or subqueries)
<code>PRIMARY</code>	None	Outermost <code>SELECT</code>
<code>UNION</code>	None	Second or later <code>SELECT</code> statement in a <code>UNION</code>
<code>DEPENDENT UNION</code>	<code>dependent (true)</code>	Second or later <code>SELECT</code> statement in a <code>UNION</code> , dependent on outer query
<code>UNION RESULT</code>	<code>union_result</code>	Result of a <code>UNION</code> .
<code>SUBQUERY</code>	None	First <code>SELECT</code> in subquery
<code>DEPENDENT SUBQUERY</code>	<code>dependent (true)</code>	First <code>SELECT</code> in subquery, dependent on outer query
<code>DERIVED</code>	None	Derived table
<code>DEPENDENT DERIVED</code>	<code>dependent (true)</code>	Derived table dependent on another table
<code>MATERIALIZED</code>	<code>materialized_from_subquery</code>	Materialized subquery
<code>UNCACHEABLE SUBQUERY</code>	<code>cacheable (false)</code>	A subquery for which the result cannot be cached and must be re-evaluated for each row of the outer query
<code>UNCACHEABLE UNION</code>	<code>cacheable (false)</code>	The second or later select in a <code>UNION</code> that belongs to an uncacheable subquery (see <code>UNCACHEABLE SUBQUERY</code> )

`DEPENDENT` typically signifies the use of a correlated subquery. See [Section 15.2.15.7, “Correlated Subqueries”](#).

`DEPENDENT SUBQUERY` evaluation differs from `UNCACHEABLE SUBQUERY` evaluation. For `DEPENDENT SUBQUERY`, the subquery is re-evaluated only once for each set of different values of the variables from its outer context. For `UNCACHEABLE SUBQUERY`, the subquery is re-evaluated for each row of the outer context.

When you specify `FORMAT=JSON` with `EXPLAIN`, the output has no single property directly equivalent to `select_type`; the `query_block` property corresponds to a given `SELECT`. Properties equivalent to most of the `SELECT` subquery types just shown are available (an example being

`materialized_from_subquery` for `MATERIALIZED`), and are displayed when appropriate. There are no JSON equivalents for `SIMPLE` or `PRIMARY`.

The `select_type` value for non-`SELECT` statements displays the statement type for affected tables. For example, `select_type` is `DELETE` for `DELETE` statements.

- `table` (JSON name: `table_name`)

The name of the table to which the row of output refers. This can also be one of the following values:

- `<unionM,N>`: The row refers to the union of the rows with `id` values of `M` and `N`.
- `<derivedN>`: The row refers to the derived table result for the row with an `id` value of `N`. A derived table may result, for example, from a subquery in the `FROM` clause.
- `<subqueryN>`: The row refers to the result of a materialized subquery for the row with an `id` value of `N`. See [Section 10.2.2.2, “Optimizing Subqueries with Materialization”](#).

- `partitions` (JSON name: `partitions`)

The partitions from which records would be matched by the query. The value is `NULL` for nonpartitioned tables. See [Section 26.3.5, “Obtaining Information About Partitions”](#).

- `type` (JSON name: `access_type`)

The join type. For descriptions of the different types, see [EXPLAIN Join Types](#).

- `possible_keys` (JSON name: `possible_keys`)

The `possible_keys` column indicates the indexes from which MySQL can choose to find the rows in this table. Note that this column is totally independent of the order of the tables as displayed in the output from `EXPLAIN`. That means that some of the keys in `possible_keys` might not be usable in practice with the generated table order.

If this column is `NULL` (or undefined in JSON-formatted output), there are no relevant indexes. In this case, you may be able to improve the performance of your query by examining the `WHERE` clause to check whether it refers to some column or columns that would be suitable for indexing. If so, create an appropriate index and check the query with `EXPLAIN` again. See [Section 15.1.9, “ALTER TABLE Statement”](#).

To see what indexes a table has, use `SHOW INDEX FROM tbl_name`.

- `key` (JSON name: `key`)

The `key` column indicates the key (index) that MySQL actually decided to use. If MySQL decides to use one of the `possible_keys` indexes to look up rows, that index is listed as the key value.

It is possible that `key` may name an index that is not present in the `possible_keys` value. This can happen if none of the `possible_keys` indexes are suitable for looking up rows, but all the columns selected by the query are columns of some other index. That is, the named index covers the selected

columns, so although it is not used to determine which rows to retrieve, an index scan is more efficient than a data row scan.

For [InnoDB](#), a secondary index might cover the selected columns even if the query also selects the primary key because [InnoDB](#) stores the primary key value with each secondary index. If `key` is `NULL`, MySQL found no index to use for executing the query more efficiently.

To force MySQL to use or ignore an index listed in the `possible_keys` column, use `FORCE INDEX`, `USE INDEX`, or `IGNORE INDEX` in your query. See [Section 10.9.4, “Index Hints”](#).

For [MyISAM](#) tables, running `ANALYZE TABLE` helps the optimizer choose better indexes. For [MyISAM](#) tables, `myisamchk --analyze` does the same. See [Section 15.7.3.1, “ANALYZE TABLE Statement”](#), and [Section 9.6, “MyISAM Table Maintenance and Crash Recovery”](#).

- `key_len` (JSON name: `key_length`)

The `key_len` column indicates the length of the key that MySQL decided to use. The value of `key_len` enables you to determine how many parts of a multiple-part key MySQL actually uses. If the `key` column says `NULL`, the `key_len` column also says `NULL`.

Due to the key storage format, the key length is one greater for a column that can be `NULL` than for a `NOT NULL` column.

- `ref` (JSON name: `ref`)

The `ref` column shows which columns or constants are compared to the index named in the `key` column to select rows from the table.

If the value is `func`, the value used is the result of some function. To see which function, use `SHOW WARNINGS` following `EXPLAIN` to see the extended `EXPLAIN` output. The function might actually be an operator such as an arithmetic operator.

- `rows` (JSON name: `rows`)

The `rows` column indicates the number of rows MySQL believes it must examine to execute the query.

For [InnoDB](#) tables, this number is an estimate, and may not always be exact.

- `filtered` (JSON name: `filtered`)

The `filtered` column indicates an estimated percentage of table rows that are filtered by the table condition. The maximum value is 100, which means no filtering of rows occurred. Values decreasing from 100 indicate increasing amounts of filtering. `rows` shows the estimated number of rows examined and `rows × filtered` shows the number of rows that are joined with the following table. For example, if `rows` is 1000 and `filtered` is 50.00 (50%), the number of rows to be joined with the following table is  $1000 \times 50\% = 500$ .

- `Extra` (JSON name: `none`)

This column contains additional information about how MySQL resolves the query. For descriptions of the different values, see [EXPLAIN Extra Information](#).

There is no single JSON property corresponding to the `Extra` column; however, values that can occur in this column are exposed as JSON properties, or as the text of the `message` property.

## EXPLAIN Join Types

The `type` column of `EXPLAIN` output describes how tables are joined. In JSON-formatted output, these are found as values of the `access_type` property. The following list describes the join types, ordered from the best type to the worst:

- `system`

The table has only one row (= system table). This is a special case of the `const` join type.

- `const`

The table has at most one matching row, which is read at the start of the query. Because there is only one row, values from the column in this row can be regarded as constants by the rest of the optimizer. `const` tables are very fast because they are read only once.

`const` is used when you compare all parts of a `PRIMARY KEY` or `UNIQUE` index to constant values. In the following queries, `tbl_name` can be used as a `const` table:

```
SELECT * FROM tbl_name WHERE primary_key=1;

SELECT * FROM tbl_name
WHERE primary_key_part1=1 AND primary_key_part2=2;
```

- `eq_ref`

One row is read from this table for each combination of rows from the previous tables. Other than the `system` and `const` types, this is the best possible join type. It is used when all parts of an index are used by the join and the index is a `PRIMARY KEY` or `UNIQUE NOT NULL` index.

`eq_ref` can be used for indexed columns that are compared using the `=` operator. The comparison value can be a constant or an expression that uses columns from tables that are read before this table. In the following examples, MySQL can use an `eq_ref` join to process `ref_table`:

```
SELECT * FROM ref_table,other_table
WHERE ref_table.key_column=other_table.column;

SELECT * FROM ref_table,other_table
WHERE ref_table.key_column_part1=other_table.column
AND ref_table.key_column_part2=1;
```

- `ref`

All rows with matching index values are read from this table for each combination of rows from the previous tables. `ref` is used if the join uses only a leftmost prefix of the key or if the key is not a `PRIMARY KEY` or `UNIQUE` index (in other words, if the join cannot select a single row based on the key value). If the key that is used matches only a few rows, this is a good join type.

`ref` can be used for indexed columns that are compared using the `=` or `<=>` operator. In the following examples, MySQL can use a `ref` join to process `ref_table`:

```
SELECT * FROM ref_table WHERE key_column=expr;

SELECT * FROM ref_table,other_table
WHERE ref_table.key_column=other_table.column;

SELECT * FROM ref_table,other_table
WHERE ref_table.key_column_part1=other_table.column
AND ref_table.key_column_part2=1;
```

- `fulltext`

The join is performed using a `FULLTEXT` index.

- `ref_or_null`

This join type is like `ref`, but with the addition that MySQL does an extra search for rows that contain `NULL` values. This join type optimization is used most often in resolving subqueries. In the following examples, MySQL can use a `ref_or_null` join to process `ref_table`:

```
SELECT * FROM ref_table
WHERE key_column=expr OR key_column IS NULL;
```

See [Section 10.2.1.15, “IS NULL Optimization”](#).

- `index_merge`

This join type indicates that the Index Merge optimization is used. In this case, the `key` column in the output row contains a list of indexes used, and `key_len` contains a list of the longest key parts for the indexes used. For more information, see [Section 10.2.1.3, “Index Merge Optimization”](#).

- `unique_subquery`

This type replaces `eq_ref` for some `IN` subqueries of the following form:

```
value IN (SELECT primary_key FROM single_table WHERE some_expr)
```

`unique_subquery` is just an index lookup function that replaces the subquery completely for better efficiency.

- `index_subquery`

This join type is similar to `unique_subquery`. It replaces `IN` subqueries, but it works for nonunique indexes in subqueries of the following form:

```
value IN (SELECT key_column FROM single_table WHERE some_expr)
```

- `range`

Only rows that are in a given range are retrieved, using an index to select the rows. The `key` column in the output row indicates which index is used. The `key_len` contains the longest key part that was used. The `ref` column is `NULL` for this type.

`range` can be used when a key column is compared to a constant using any of the `=`, `<>`, `>`, `>=`, `<`, `<=`, `IS NULL`, `<=>`, `BETWEEN`, `LIKE`, or `IN()` operators:

```
SELECT * FROM tbl_name
WHERE key_column = 10;

SELECT * FROM tbl_name
WHERE key_column BETWEEN 10 and 20;

SELECT * FROM tbl_name
WHERE key_column IN (10,20,30);

SELECT * FROM tbl_name
WHERE key_part1 = 10 AND key_part2 IN (10,20,30);
```

- `index`

The `index` join type is the same as `ALL`, except that the index tree is scanned. This occurs two ways:

- If the index is a covering index for the queries and can be used to satisfy all data required from the table, only the index tree is scanned. In this case, the `Extra` column says `Using index`. An index-only scan usually is faster than `ALL` because the size of the index usually is smaller than the table data.
- A full table scan is performed using reads from the index to look up data rows in index order. `Uses index` does not appear in the `Extra` column.

MySQL can use this join type when the query uses only columns that are part of a single index.

- `ALL`

A full table scan is done for each combination of rows from the previous tables. This is normally not good if the table is the first table not marked `const`, and usually very bad in all other cases. Normally, you can avoid `ALL` by adding indexes that enable row retrieval from the table based on constant values or column values from earlier tables.

## EXPLAIN Extra Information

The `Extra` column of `EXPLAIN` output contains additional information about how MySQL resolves the query. The following list explains the values that can appear in this column. Each item also indicates for JSON-formatted output which property displays the `Extra` value. For some of these, there is a specific property. The others display as the text of the `message` property.

If you want to make your queries as fast as possible, look out for `Extra` column values of `Using filesort` and `Using temporary`, or, in JSON-formatted `EXPLAIN` output, for `using_filesort` and `using_temporary_table` properties equal to `true`.

- `Backward index scan` (JSON: `backward_index_scan`)

The optimizer is able to use a descending index on an `InnoDB` table. Shown together with `Using index`. For more information, see [Section 10.3.13, “Descending Indexes”](#).

- `Child of 'table' pushed join@1` (JSON: `message` text)

This table is referenced as the child of `table` in a join that can be pushed down to the NDB kernel. Applies only in NDB Cluster, when pushed-down joins are enabled. See the description of the `ndb_join_pushdown` server system variable for more information and examples.

- `const row not found` (JSON property: `const_row_not_found`)

For a query such as `SELECT ... FROM tbl_name`, the table was empty.

- `Deleting all rows` (JSON property: `message`)

For `DELETE`, some storage engines (such as `MyISAM`) support a handler method that removes all table rows in a simple and fast way. This `Extra` value is displayed if the engine uses this optimization.

- `Distinct` (JSON property: `distinct`)

MySQL is looking for distinct values, so it stops searching for more rows for the current row combination after it has found the first matching row.

- `FirstMatch(tbl_name)` (JSON property: `first_match`)

The semijoin FirstMatch join shortcutting strategy is used for `tbl_name`.

- `Full scan on NULL key` (JSON property: `message`)

This occurs for subquery optimization as a fallback strategy when the optimizer cannot use an index-lookup access method.

- `Impossible HAVING` (JSON property: `message`)

The `HAVING` clause is always false and cannot select any rows.

- `Impossible WHERE` (JSON property: `message`)

The `WHERE` clause is always false and cannot select any rows.

- `Impossible WHERE noticed after reading const tables` (JSON property: `message`)

MySQL has read all `const` (and `system`) tables and notice that the `WHERE` clause is always false.

- `LooseScan(m..n)` (JSON property: `message`)

The semijoin LooseScan strategy is used. `m` and `n` are key part numbers.

- `No matching min/max row` (JSON property: `message`)

No row satisfies the condition for a query such as `SELECT MIN(...) FROM ... WHERE condition`.

- `no matching row in const table` (JSON property: `message`)

For a query with a join, there was an empty table or a table with no rows satisfying a unique index condition.

- `No matching rows after partition pruning` (JSON property: `message`)

For `DELETE` or `UPDATE`, the optimizer found nothing to delete or update after partition pruning. It is similar in meaning to `Impossible WHERE` for `SELECT` statements.

- `No tables used` (JSON property: `message`)

The query has no `FROM` clause, or has a `FROM DUAL` clause.

For `INSERT` or `REPLACE` statements, `EXPLAIN` displays this value when there is no `SELECT` part. For example, it appears for `EXPLAIN INSERT INTO t VALUES(10)` because that is equivalent to `EXPLAIN INSERT INTO t SELECT 10 FROM DUAL`.

- `Not exists` (JSON property: `message`)

MySQL was able to do a `LEFT JOIN` optimization on the query and does not examine more rows in this table for the previous row combination after it finds one row that matches the `LEFT JOIN` criteria. Here is an example of the type of query that can be optimized this way:

```
SELECT * FROM t1 LEFT JOIN t2 ON t1.id=t2.id
WHERE t2.id IS NULL;
```

Assume that `t2.id` is defined as `NOT NULL`. In this case, MySQL scans `t1` and looks up the rows in `t2` using the values of `t1.id`. If MySQL finds a matching row in `t2`, it knows that `t2.id` can never be `NULL`, and does not scan through the rest of the rows in `t2` that have the same `id` value. In other words, for each row in `t1`, MySQL needs to do only a single lookup in `t2`, regardless of how many rows actually match in `t2`.

This can also indicate that a `WHERE` condition of the form `NOT IN (subquery)` or `NOT EXISTS (subquery)` has been transformed internally into an antijoin. This removes the subquery and brings its tables into the plan for the topmost query, providing improved cost planning. By merging semijoins and antijoins, the optimizer can reorder tables in the execution plan more freely, in some cases resulting in a faster plan.

You can see when an antijoin transformation is performed for a given query by checking the `Message` column from `SHOW WARNINGS` following execution of `EXPLAIN`, or in the output of `EXPLAIN FORMAT=TREE`.

#### Note

An antijoin is the complement of a semijoin `table_a JOIN table_b ON condition`. The antijoin returns all rows from `table_a` for which there is *no* row in `table_b` which matches `condition`.

- `Plan is not ready yet` (JSON property: `none`)

This value occurs with `EXPLAIN FOR CONNECTION` when the optimizer has not finished creating the execution plan for the statement executing in the named connection. If execution plan output comprises multiple lines, any or all of them could have this `Extra` value, depending on the progress of the optimizer in determining the full execution plan.

- `Range checked for each record (index map: N)` (JSON property: `message`)

MySQL found no good index to use, but found that some of indexes might be used after column values from preceding tables are known. For each row combination in the preceding tables, MySQL checks whether it is possible to use a `range` or `index_merge` access method to retrieve rows. This is not very fast, but is faster than performing a join with no index at all. The applicability criteria are as described in [Section 10.2.1.2, “Range Optimization”](#), and [Section 10.2.1.3, “Index Merge Optimization”](#), with the exception that all column values for the preceding table are known and considered to be constants.

Indexes are numbered beginning with 1, in the same order as shown by `SHOW INDEX` for the table. The index map value `N` is a bitmask value that indicates which indexes are candidates. For example, a value of `0x19` (binary 11001) means that indexes 1, 4, and 5 are considered.

- `Recursive` (JSON property: `recursive`)

This indicates that the row applies to the recursive `SELECT` part of a recursive common table expression. See [Section 15.2.20, “WITH \(Common Table Expressions\)”](#).

- `Rematerialize` (JSON property: `rematerialize`)

`Rematerialize (X,...)` is displayed in the `EXPLAIN` row for table `T`, where `X` is any lateral derived table whose rematerialization is triggered when a new row of `T` is read. For example:

```
SELECT
...
FROM
 t,
 LATERAL (derived table that refers to t) AS dt
...
```

The content of the derived table is rematerialized to bring it up to date each time a new row of `t` is processed by the top query.

- `Scanned N databases` (JSON property: `message`)

This indicates how many directory scans the server performs when processing a query for `INFORMATION_SCHEMA` tables, as described in [Section 10.2.3, “Optimizing INFORMATION\\_SCHEMA Queries”](#). The value of `N` can be 0, 1, or `all`.

- `Select tables optimized away` (JSON property: `message`)

The optimizer determined 1) that at most one row should be returned, and 2) that to produce this row, a deterministic set of rows must be read. When the rows to be read can be read during the optimization phase (for example, by reading index rows), there is no need to read any tables during query execution.

The first condition is fulfilled when the query is implicitly grouped (contains an aggregate function but no `GROUP BY` clause). The second condition is fulfilled when one row lookup is performed per index used. The number of indexes read determines the number of rows to read.

Consider the following implicitly grouped query:

```
SELECT MIN(c1), MIN(c2) FROM t1;
```

Suppose that `MIN(c1)` can be retrieved by reading one index row and `MIN(c2)` can be retrieved by reading one row from a different index. That is, for each column `c1` and `c2`, there exists an index where the column is the first column of the index. In this case, one row is returned, produced by reading two deterministic rows.

This `Extra` value does not occur if the rows to read are not deterministic. Consider this query:

```
SELECT MIN(c2) FROM t1 WHERE c1 <= 10;
```

Suppose that `(c1, c2)` is a covering index. Using this index, all rows with `c1 <= 10` must be scanned to find the minimum `c2` value. By contrast, consider this query:

```
SELECT MIN(c2) FROM t1 WHERE c1 = 10;
```

In this case, the first index row with `c1 = 10` contains the minimum `c2` value. Only one row must be read to produce the returned row.

For storage engines that maintain an exact row count per table (such as `MyISAM`, but not `InnoDB`), this `Extra` value can occur for `COUNT(*)` queries for which the `WHERE` clause is missing or always true and there is no `GROUP BY` clause. (This is an instance of an implicitly grouped query where the storage engine influences whether a deterministic number of rows can be read.)

- `Skip_open_table`, `Open_frm_only`, `Open_full_table` (JSON property: `message`)

These values indicate file-opening optimizations that apply to queries for `INFORMATION_SCHEMA` tables.

- `Skip_open_table`: Table files do not need to be opened. The information is already available from the data dictionary.
- `Open_frm_only`: Only the data dictionary need be read for table information.
- `Open_full_table`: Unoptimized information lookup. Table information must be read from the data dictionary and by reading table files.

- `Start temporary`, `End temporary` (JSON property: `message`)

This indicates temporary table use for the semijoin Duplicate Weedout strategy.

- `unique row not found` (JSON property: `message`)

For a query such as `SELECT ... FROM tbl_name`, no rows satisfy the condition for a `UNIQUE` index or `PRIMARY KEY` on the table.

- `Using filesort` (JSON property: `using_filesort`)

MySQL must do an extra pass to find out how to retrieve the rows in sorted order. The sort is done by going through all rows according to the join type and storing the sort key and pointer to the row for all rows that match the `WHERE` clause. The keys then are sorted and the rows are retrieved in sorted order. See [Section 10.2.1.16, “ORDER BY Optimization”](#).

- `Using index` (JSON property: `using_index`)

The column information is retrieved from the table using only information in the index tree without having to do an additional seek to read the actual row. This strategy can be used when the query uses only columns that are part of a single index.

For `InnoDB` tables that have a user-defined clustered index, that index can be used even when `Using index` is absent from the `Extra` column. This is the case if `type` is `index` and `key` is `PRIMARY`.

Information about any covering indexes used is shown for `EXPLAIN FORMAT=TRADITIONAL` and `EXPLAIN FORMAT=JSON`. It is also shown for `EXPLAIN FORMAT=TREE`.

- `Using index condition` (JSON property: `using_index_condition`)

Tables are read by accessing index tuples and testing them first to determine whether to read full table rows. In this way, index information is used to defer (“push down”) reading full table rows unless it is necessary. See [Section 10.2.1.6, “Index Condition Pushdown Optimization”](#).

- `Using index for group-by` (JSON property: `using_index_for_group_by`)

Similar to the `Using index` table access method, `Using index for group-by` indicates that MySQL found an index that can be used to retrieve all columns of a `GROUP BY` or `DISTINCT` query without any extra disk access to the actual table. Additionally, the index is used in the most efficient way so that for each group, only a few index entries are read. For details, see [Section 10.2.1.17, “GROUP BY Optimization”](#).

- `Using index for skip scan` (JSON property: `using_index_for_skip_scan`)

Indicates that the Skip Scan access method is used. See [Skip Scan Range Access Method](#).

- `Using join buffer (Block Nested Loop)`, `Using join buffer (Batched Key Access)`, `Using join buffer (hash join)` (JSON property: `using_join_buffer`)

Tables from earlier joins are read in portions into the join buffer, and then their rows are used from the buffer to perform the join with the current table. `(Block Nested Loop)` indicates use of the Block Nested-Loop algorithm, `(Batched Key Access)` indicates use of the Batched Key Access algorithm, and `(hash join)` indicates use of a hash join. That is, the keys from the table on the preceding line of the `EXPLAIN` output are buffered, and the matching rows are fetched in batches from the table represented by the line in which `Using join buffer` appears.

In JSON-formatted output, the value of `using_join_buffer` is always one of `Block Nested Loop`, `Batched Key Access`, or `hash join`.

For more information about hash joins, see [Section 10.2.1.4, “Hash Join Optimization”](#).

See [Batched Key Access Joins](#), for information about the Batched Key Access algorithm.

- `Using MRR` (JSON property: `message`)

Tables are read using the Multi-Range Read optimization strategy. See [Section 10.2.1.11, “Multi-Range Read Optimization”](#).

- `Using sort_union(...), Using union(...), Using intersect(...)` (JSON property: `message`)

These indicate the particular algorithm showing how index scans are merged for the `index_merge` join type. See [Section 10.2.1.3, “Index Merge Optimization”](#).

- `Using temporary` (JSON property: `using_temporary_table`)

To resolve the query, MySQL needs to create a temporary table to hold the result. This typically happens if the query contains `GROUP BY` and `ORDER BY` clauses that list columns differently.

- `Using where` (JSON property: `attached_condition`)

A `WHERE` clause is used to restrict which rows to match against the next table or send to the client. Unless you specifically intend to fetch or examine all rows from the table, you may have something wrong in your query if the `Extra` value is not `Using where` and the table join type is `ALL` or `index`.

`Using where` has no direct counterpart in JSON-formatted output; the `attached_condition` property contains any `WHERE` condition used.

- `Using where with pushed condition` (JSON property: `message`)

This item applies to `NDB` tables *only*. It means that NDB Cluster is using the Condition Pushdown optimization to improve the efficiency of a direct comparison between a nonindexed column and a constant. In such cases, the condition is “pushed down” to the cluster’s data nodes and is evaluated on all data nodes simultaneously. This eliminates the need to send nonmatching rows over the network, and can speed up such queries by a factor of 5 to 10 times over cases where Condition Pushdown could be but is not used. For more information, see [Section 10.2.1.5, “Engine Condition Pushdown Optimization”](#).

- `Zero limit` (JSON property: `message`)

The query had a `LIMIT 0` clause and cannot select any rows.

## EXPLAIN Output Interpretation

You can get a good indication of how good a join is by taking the product of the values in the `rows` column of the `EXPLAIN` output. This should tell you roughly how many rows MySQL must examine to execute the query. If you restrict queries with the `max_join_size` system variable, this row product also is used to determine which multiple-table `SELECT` statements to execute and which to abort. See [Section 7.1.1, “Configuring the Server”](#).

The following example shows how a multiple-table join can be optimized progressively based on the information provided by `EXPLAIN`.

Suppose that you have the `SELECT` statement shown here and that you plan to examine it using `EXPLAIN`:

```
EXPLAIN SELECT tt.TicketNumber, tt.TimeIn,
 tt.ProjectReference, tt.EstimatedShipDate,
 tt.ActualShipDate, tt.ClientID,
 tt.ServiceCodes, tt.RepetitiveID,
 tt.CurrentProcess, tt.CurrentDPPerson,
 tt.RecordVolume, tt.DPPrinted, et.COUNTRY,
 et_1.COUNTRY, do.CUSTNAME
FROM tt, et, et AS et_1, do
WHERE tt.SubmitTime IS NULL
```

```

AND tt.ActualPC = et.EMPLOYID
AND tt.AssignedPC = et_1.EMPLOYID
AND tt.ClientID = do.CUSTNMBR;

```

For this example, make the following assumptions:

- The columns being compared have been declared as follows.

Table	Column	Data Type
tt	ActualPC	CHAR(10)
tt	AssignedPC	CHAR(10)
tt	ClientID	CHAR(10)
et	EMPLOYID	CHAR(15)
do	CUSTNMBR	CHAR(15)

- The tables have the following indexes.

Table	Index
tt	ActualPC
tt	AssignedPC
tt	ClientID
et	EMPLOYID (primary key)
do	CUSTNMBR (primary key)

- The `tt.ActualPC` values are not evenly distributed.

Initially, before any optimizations have been performed, the `EXPLAIN` statement produces the following information:

```

table type possible_keys key key_len ref rows Extra
et ALL PRIMARY NULL NULL NULL 74
do ALL PRIMARY NULL NULL NULL 2135
et_1 ALL PRIMARY NULL NULL NULL 74
tt ALL AssignedPC, NULL NULL NULL 3872
 ClientID,
 ActualPC
 Range checked for each record (index map: 0x23)

```

Because `type` is `ALL` for each table, this output indicates that MySQL is generating a Cartesian product of all the tables; that is, every combination of rows. This takes quite a long time, because the product of the number of rows in each table must be examined. For the case at hand, this product is  $74 \times 2135 \times 74 \times 3872 = 45,268,558,720$  rows. If the tables were bigger, you can only imagine how long it would take.

One problem here is that MySQL can use indexes on columns more efficiently if they are declared as the same type and size. In this context, `VARCHAR` and `CHAR` are considered the same if they are declared as the same size. `tt.ActualPC` is declared as `CHAR(10)` and `et.EMPLOYID` is `CHAR(15)`, so there is a length mismatch.

To fix this disparity between column lengths, use `ALTER TABLE` to lengthen `ActualPC` from 10 characters to 15 characters:

```
mysql> ALTER TABLE tt MODIFY ActualPC VARCHAR(15);
```

Now `tt.ActualPC` and `et.EMPLOYID` are both `VARCHAR(15)`. Executing the `EXPLAIN` statement again produces this result:

## Extended EXPLAIN Output Format

table	type	possible_keys	key	key_len	ref	rows	Extra
tt	ALL	AssignedPC, ClientID, ActualPC	NULL	NULL	NULL	3872	Using where
do	ALL	PRIMARY	NULL	NULL	NULL	2135	
		Range checked for each record (index map: 0x1)					
et_1	ALL	PRIMARY	NULL	NULL	NULL	74	
		Range checked for each record (index map: 0x1)					
et	eq_ref	PRIMARY	PRIMARY	15	tt.ActualPC	1	

This is not perfect, but is much better: The product of the `rows` values is less by a factor of 74. This version executes in a couple of seconds.

A second alteration can be made to eliminate the column length mismatches for the `tt.AssignedPC = et_1.EMPLOYID` and `tt.ClientID = do.CUSTNMBR` comparisons:

```
mysql> ALTER TABLE tt MODIFY AssignedPC VARCHAR(15),
 MODIFY ClientID VARCHAR(15);
```

After that modification, `EXPLAIN` produces the output shown here:

table	type	possible_keys	key	key_len	ref	rows	Extra
et	ALL	PRIMARY	NULL	NULL	NULL	74	
tt	ref	AssignedPC, ClientID, ActualPC	ActualPC	15	et.EMPLOYID	52	Using where
et_1	eq_ref	PRIMARY	PRIMARY	15	tt.AssignedPC	1	
do	eq_ref	PRIMARY	PRIMARY	15	tt.ClientID	1	

At this point, the query is optimized almost as well as possible. The remaining problem is that, by default, MySQL assumes that values in the `tt.ActualPC` column are evenly distributed, and that is not the case for the `tt` table. Fortunately, it is easy to tell MySQL to analyze the key distribution:

```
mysql> ANALYZE TABLE tt;
```

With the additional index information, the join is perfect and `EXPLAIN` produces this result:

table	type	possible_keys	key	key_len	ref	rows	Extra
tt	ALL	AssignedPC, ClientID, ActualPC	NULL	NULL	NULL	3872	Using where
et	eq_ref	PRIMARY	PRIMARY	15	tt.ActualPC	1	
et_1	eq_ref	PRIMARY	PRIMARY	15	tt.AssignedPC	1	
do	eq_ref	PRIMARY	PRIMARY	15	tt.ClientID	1	

The `rows` column in the output from `EXPLAIN` is an educated guess from the MySQL join optimizer. Check whether the numbers are even close to the truth by comparing the `rows` product with the actual number of rows that the query returns. If the numbers are quite different, you might get better performance by using `STRAIGHT_JOIN` in your `SELECT` statement and trying to list the tables in a different order in the `FROM` clause. (However, `STRAIGHT_JOIN` may prevent indexes from being used because it disables semijoin transformations. See [Optimizing IN and EXISTS Subquery Predicates with Semijoin Transformations](#).)

It is possible in some cases to execute statements that modify data when `EXPLAIN SELECT` is used with a subquery; for more information, see [Section 15.2.15.8, “Derived Tables”](#).

### 10.8.3 Extended EXPLAIN Output Format

The `EXPLAIN` statement produces extra (“extended”) information that is not part of `EXPLAIN` output but can be viewed by issuing a `SHOW WARNINGS` statement following `EXPLAIN`. Extended information is available for `SELECT`, `DELETE`, `INSERT`, `REPLACE`, and `UPDATE` statements.

The `Message` value in `SHOW WARNINGS` output displays how the optimizer qualifies table and column names in the `SELECT` statement, what the `SELECT` looks like after the application of rewriting and optimization rules, and possibly other notes about the optimization process.

The extended information displayable with a `SHOW WARNINGS` statement following `EXPLAIN` is produced only for `SELECT` statements. `SHOW WARNINGS` displays an empty result for other explainable statements (`DELETE`, `INSERT`, `REPLACE`, and `UPDATE`).

Here is an example of extended `EXPLAIN` output:

```
mysql> EXPLAIN
 SELECT t1.a, t1.a IN (SELECT t2.a FROM t2) FROM t1\G
***** 1. row *****
 id: 1
 select_type: PRIMARY
 table: t1
 type: index
possible_keys: NULL
 key: PRIMARY
 key_len: 4
 ref: NULL
 rows: 4
 filtered: 100.00
 Extra: Using index
***** 2. row *****
 id: 2
 select_type: SUBQUERY
 table: t2
 type: index
possible_keys: a
 key: a
 key_len: 5
 ref: NULL
 rows: 3
 filtered: 100.00
 Extra: Using index
2 rows in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
***** 1. row *****
 Level: Note
 Code: 1003
Message: /* select#1 */ select `test`.`t1`.`a` AS `a`,
 <in_optimizer>(`test`.`t1`.`a`,`test`.`t1`.`a` in
 (<materialize> (/* select#2 */ select `test`.`t2`.`a`
 from `test`.`t2` where 1 having 1),
 <primary_index_lookup>(`test`.`t1`.`a` in
 <temporary table> on <auto_key>
 where ((`test`.`t1`.`a` = `materialized-subquery`.`a`)))) AS `t1.a`
 IN (SELECT t2.a FROM t2)` from `test`.`t1`
1 row in set (0.00 sec)
```

Because the statement displayed by `SHOW WARNINGS` may contain special markers to provide information about query rewriting or optimizer actions, the statement is not necessarily valid SQL and is not intended to be executed. The output may also include rows with `Message` values that provide additional non-SQL explanatory notes about actions taken by the optimizer.

The following list describes special markers that can appear in the extended output displayed by `SHOW WARNINGS`:

- `<auto_key>`

An automatically generated key for a temporary table.

- `<cache>(expr)`

The expression (such as a scalar subquery) is executed once and the resulting value is saved in memory for later use. For results consisting of multiple values, a temporary table may be created and `<temporary table>` is shown instead.

- `<exists>(query fragment)`

The subquery predicate is converted to an `EXISTS` predicate and the subquery is transformed so that it can be used together with the `EXISTS` predicate.

- `<in_optimizer>(query fragment)`

This is an internal optimizer object with no user significance.

- `<index_lookup>(query fragment)`

The query fragment is processed using an index lookup to find qualifying rows.

- `<if>(condition, expr1, expr2)`

If the condition is true, evaluate to `expr1`, otherwise `expr2`.

- `<is_not_null_test>(expr)`

A test to verify that the expression does not evaluate to `NULL`.

- `<materialize>(query fragment)`

Subquery materialization is used.

- ``materialized-subquery`.col_name`

A reference to the column `col_name` in an internal temporary table materialized to hold the result from evaluating a subquery.

- `<primary_index_lookup>(query fragment)`

The query fragment is processed using a primary key lookup to find qualifying rows.

- `<ref_null_helper>(expr)`

This is an internal optimizer object with no user significance.

- `/* select#N */ select_stmt`

The `SELECT` is associated with the row in non-extended `EXPLAIN` output that has an `id` value of `N`.

- `outer_tables semi join (inner_tables)`

A semijoin operation. `inner_tables` shows the tables that were not pulled out. See [Optimizing IN and EXISTS Subquery Predicates with Semijoin Transformations](#).

- `<temporary table>`

This represents an internal temporary table created to cache an intermediate result.

When some tables are of `const` or `system` type, expressions involving columns from these tables are evaluated early by the optimizer and are not part of the displayed statement. However, with `FORMAT=JSON`, some `const` table accesses are displayed as a `ref` access that uses a const value.

## 10.8.4 Obtaining Execution Plan Information for a Named Connection

To obtain the execution plan for an explainable statement executing in a named connection, use this statement:

```
EXPLAIN [options] FOR CONNECTION connection_id;
```

`EXPLAIN FOR CONNECTION` returns the `EXPLAIN` information that is currently being used to execute a query in a given connection. Because of changes to data (and supporting statistics) it may produce a different result from running `EXPLAIN` on the equivalent query text. This difference in behavior can be useful in diagnosing more transient performance problems. For example, if you are running a statement in one session that is taking a long time to complete, using `EXPLAIN FOR CONNECTION` in another session may yield useful information about the cause of the delay.

*connection\_id* is the connection identifier, as obtained from the `INFORMATION_SCHEMA.PROCESSLIST` table or the `SHOW PROCESSLIST` statement. If you have the `PROCESS` privilege, you can specify the identifier for any connection. Otherwise, you can specify the identifier only for your own connections. In all cases, you must have sufficient privileges to explain the query on the specified connection.

If the named connection is not executing a statement, the result is empty. Otherwise, `EXPLAIN FOR CONNECTION` applies only if the statement being executed in the named connection is explainable. This includes `SELECT`, `DELETE`, `INSERT`, `REPLACE`, and `UPDATE`. (However, `EXPLAIN FOR CONNECTION` does not work for prepared statements, even prepared statements of those types.)

If the named connection is executing an explainable statement, the output is what you would obtain by using `EXPLAIN` on the statement itself.

If the named connection is executing a statement that is not explainable, an error occurs. For example, you cannot name the connection identifier for your current session because `EXPLAIN` is not explainable:

```
mysql> SELECT CONNECTION_ID();
+-----+
| CONNECTION_ID() |
+-----+
| 373 |
+-----+
1 row in set (0.00 sec)

mysql> EXPLAIN FOR CONNECTION 373;
ERROR 1889 (HY000): EXPLAIN FOR CONNECTION command is supported
only for SELECT/UPDATE/INSERT/DELETE/REPLACE
```

The `Com_explain_other` status variable indicates the number of `EXPLAIN FOR CONNECTION` statements executed.

## 10.8.5 Estimating Query Performance

In most cases, you can estimate query performance by counting disk seeks. For small tables, you can usually find a row in one disk seek (because the index is probably cached). For bigger tables, you can estimate that, using B-tree indexes, you need this many seeks to find a row:  $\log(\text{row\_count}) / \log(\text{index\_block\_length} / 3 * 2 / (\text{index\_length} + \text{data\_pointer\_length})) + 1$ .

In MySQL, an index block is usually 1,024 bytes and the data pointer is usually four bytes. For a 500,000-row table with a key value length of three bytes (the size of `MEDIUMINT`), the formula indicates  $\log(500,000) / \log(1024/3*2/(3+4)) + 1 = 4$  seeks.

This index would require storage of about  $500,000 * 7 * 3/2 = 5.2\text{MB}$  (assuming a typical index buffer fill ratio of 2/3), so you probably have much of the index in memory and so need only one or two calls to read data to find the row.

For writes, however, you need four seek requests to find where to place a new index value and normally two seeks to update the index and write the row.

The preceding discussion does not mean that your application performance slowly degenerates by  $\log N$ . As long as everything is cached by the OS or the MySQL server, things become only marginally slower as the table gets bigger. After the data gets too big to be cached, things start to go much slower until your applications are bound only by disk seeks (which increase by  $\log N$ ). To avoid this, increase the key cache size as the data grows. For `MyISAM` tables, the key cache size is controlled by the `key_buffer_size` system variable. See [Section 7.1.1, “Configuring the Server”](#).

## 10.9 Controlling the Query Optimizer

MySQL provides optimizer control through system variables that affect how query plans are evaluated, switchable optimizations, optimizer and index hints, and the optimizer cost model.

The server maintains histogram statistics about column values in the `column_statistics` data dictionary table (see [Section 10.9.6, “Optimizer Statistics”](#)). Like other data dictionary tables, this table is not directly accessible by users. Instead, you can obtain histogram information by querying `INFORMATION_SCHEMA.COLUMN_STATISTICS`, which is implemented as a view on the data dictionary table. You can also perform histogram management using the `ANALYZE TABLE` statement.

### 10.9.1 Controlling Query Plan Evaluation

The task of the query optimizer is to find an optimal plan for executing an SQL query. Because the difference in performance between “good” and “bad” plans can be orders of magnitude (that is, seconds versus hours or even days), most query optimizers, including that of MySQL, perform a more or less exhaustive search for an optimal plan among all possible query evaluation plans. For join queries, the number of possible plans investigated by the MySQL optimizer grows exponentially with the number of tables referenced in a query. For small numbers of tables (typically less than 7 to 10) this is not a problem. However, when larger queries are submitted, the time spent in query optimization may easily become the major bottleneck in the server's performance.

A more flexible method for query optimization enables the user to control how exhaustive the optimizer is in its search for an optimal query evaluation plan. The general idea is that the fewer plans that are investigated by the optimizer, the less time it spends in compiling a query. On the other hand, because the optimizer skips some plans, it may miss finding an optimal plan.

The behavior of the optimizer with respect to the number of plans it evaluates can be controlled using two system variables:

- The `optimizer_prune_level` variable tells the optimizer to skip certain plans based on estimates of the number of rows accessed for each table. Our experience shows that this kind of “educated guess” rarely misses optimal plans, and may dramatically reduce query compilation times. That is why this option is on (`optimizer_prune_level=1`) by default. However, if you believe that the optimizer missed a better query plan, this option can be switched off (`optimizer_prune_level=0`) with the risk that query compilation may take much longer. Note that, even with the use of this heuristic, the optimizer still explores a roughly exponential number of plans.
- The `optimizer_search_depth` variable tells how far into the “future” of each incomplete plan the optimizer should look to evaluate whether it should be expanded further. Smaller values of `optimizer_search_depth` may result in orders of magnitude smaller query compilation times. For example, queries with 12, 13, or more tables may easily require hours and even days to compile if `optimizer_search_depth` is close to the number of tables in the query. At the same time, if compiled with `optimizer_search_depth` equal to 3 or 4, the optimizer may compile in less than a minute for the same query. If you are unsure of what a reasonable value is for `optimizer_search_depth`, this variable can be set to 0 to tell the optimizer to determine the value automatically.

## 10.9.2 Switchable Optimizations

The `optimizer_switch` system variable enables control over optimizer behavior. Its value is a set of flags, each of which has a value of `on` or `off` to indicate whether the corresponding optimizer behavior is enabled or disabled. This variable has global and session values and can be changed at runtime. The global default can be set at server startup.

To see the current set of optimizer flags, select the variable value:

```
mysql> SELECT @@optimizer_switch\G
***** 1. row *****
@@optimizer_switch: index_merge=on,index_merge_union=on,
 index_merge_sort_union=on,index_merge_intersection=on,
 engine_condition_pushdown=on,index_condition_pushdown=on,
 mrr=on,mrr_cost_based=on,block_nested_loop=on,
 batched_key_access=off,materialization=on,semijoin=on,
 loosescan=on,firstmatch=on,duplicateweedout=on,
 subquery_materialization_cost_based=on,
 use_index_extensions=on,condition_fanout_filter=on,
 derived_merge=on,use_invisible_indexes=off,skip_scan=on,
 hash_join=on,subquery_to_derived=off,
 prefer_ordering_index=on,hypergraph_optimizer=off,
 derived_condition_pushdown=on,hash_set_operations=on

1 row in set (0.00 sec)
```

To change the value of `optimizer_switch`, assign a value consisting of a comma-separated list of one or more commands:

```
SET [GLOBAL|SESSION] optimizer_switch='command[,command]...';
```

Each `command` value should have one of the forms shown in the following table.

Command Syntax	Meaning
<code>default</code>	Reset every optimization to its default value
<code>opt_name=default</code>	Set the named optimization to its default value
<code>opt_name=off</code>	Disable the named optimization
<code>opt_name=on</code>	Enable the named optimization

The order of the commands in the value does not matter, although the `default` command is executed first if present. Setting an `opt_name` flag to `default` sets it to whichever of `on` or `off` is its default value. Specifying any given `opt_name` more than once in the value is not permitted and causes an error. Any errors in the value cause the assignment to fail with an error, leaving the value of `optimizer_switch` unchanged.

The following list describes the permissible `opt_name` flag names, grouped by optimization strategy:

- Batched Key Access Flags
  - `batched_key_access` (default `off`)

Controls use of BKA join algorithm.

For `batched_key_access` to have any effect when set to `on`, the `mrr` flag must also be `on`. Currently, the cost estimation for MRR is too pessimistic. Hence, it is also necessary for `mrr_cost_based` to be `off` for BKA to be used.

For more information, see [Section 10.2.1.12, “Block Nested-Loop and Batched Key Access Joins”](#).

- Block Nested-Loop Flags

- `block_nested_loop` (default `on`)

Controls use of hash joins, as do the `BNL` and `NO_BNL` optimizer hints.

For more information, see [Section 10.2.1.12, “Block Nested-Loop and Batched Key Access Joins”](#).

- Condition Filtering Flags

- `condition_fanout_filter` (default `on`)

Controls use of condition filtering.

For more information, see [Section 10.2.1.13, “Condition Filtering”](#).

- Derived Condition Pushdown Flags

- `derived_condition_pushdown` (default `on`)

Controls derived condition pushdown.

For more information, see [Section 10.2.2.5, “Derived Condition Pushdown Optimization”](#)

- Derived Table Merging Flags

- `derived_merge` (default `on`)

Controls merging of derived tables and views into outer query block.

The `derived_merge` flag controls whether the optimizer attempts to merge derived tables, view references, and common table expressions into the outer query block, assuming that no other rule prevents merging; for example, an `ALGORITHM` directive for a view takes precedence over the `derived_merge` setting. By default, the flag is `on` to enable merging.

For more information, see [Section 10.2.2.4, “Optimizing Derived Tables, View References, and Common Table Expressions with Merging or Materialization”](#).

- Engine Condition Pushdown Flags

- `engine_condition_pushdown` (default `on`)

Controls engine condition pushdown.

For more information, see [Section 10.2.1.5, “Engine Condition Pushdown Optimization”](#).

- Hash Join Flags

- `hash_join` (default `on`)

Has no effect in MySQL 9.1. Use the `block_nested_loop` flag, instead.

For more information, see [Section 10.2.1.4, “Hash Join Optimization”](#).

- Index Condition Pushdown Flags

- `index_condition_pushdown` (default `on`)

Controls index condition pushdown.

For more information, see [Section 10.2.1.6, “Index Condition Pushdown Optimization”](#).

- Index Extensions Flags

- `use_index_extensions` (default `on`)

Controls use of index extensions.

For more information, see [Section 10.3.10, “Use of Index Extensions”](#).

- Index Merge Flags

- `index_merge` (default `on`)

Controls all Index Merge optimizations.

- `index_merge_intersection` (default `on`)

Controls the Index Merge Intersection Access optimization.

- `index_merge_sort_union` (default `on`)

Controls the Index Merge Sort-Union Access optimization.

- `index_merge_union` (default `on`)

Controls the Index Merge Union Access optimization.

For more information, see [Section 10.2.1.3, “Index Merge Optimization”](#).

- Index Visibility Flags

- `use_invisible_indexes` (default `off`)

Controls use of invisible indexes.

For more information, see [Section 10.3.12, “Invisible Indexes”](#).

- Limit Optimization Flags

- `prefer_ordering_index` (default `on`)

Controls whether, in the case of a query having an `ORDER BY` or `GROUP BY` with a `LIMIT` clause, the optimizer tries to use an ordered index instead of an unordered index, a filesort, or some other optimization. This optimization is performed by default whenever the optimizer determines that using it would allow for faster execution of the query.

Because the algorithm that makes this determination cannot handle every conceivable case (due in part to the assumption that the distribution of data is always more or less uniform), there are cases in which this optimization may not be desirable. This optimization can be disabled by setting the `prefer_ordering_index` flag to `off`.

For more information and examples, see [Section 10.2.1.19, “LIMIT Query Optimization”](#).

- Multi-Range Read Flags

- `mrr` (default `on`)

Controls the Multi-Range Read strategy.

- `mrr_cost_based` (default `on`)

Controls use of cost-based MRR if `mrr=on`.

For more information, see [Section 10.2.1.11, “Multi-Range Read Optimization”](#).

- Semijoin Flags

- `duplicateweedout` (default `on`)

Controls the semijoin Duplicate Weedout strategy.

- `firstmatch` (default `on`)

Controls the semijoin FirstMatch strategy.

- `loosescan` (default `on`)

Controls the semijoin LooseScan strategy (not to be confused with Loose Index Scan for `GROUP BY`).

- `semijoin` (default `on`)

Controls all semijoin strategies.

This also applies to the antijoin optimization.

The `semijoin`, `firstmatch`, `loosescan`, and `duplicateweedout` flags enable control over semijoin strategies. The `semijoin` flag controls whether semijoins are used. If it is set to `on`, the `firstmatch` and `loosescan` flags enable finer control over the permitted semijoin strategies.

If the `duplicateweedout` semijoin strategy is disabled, it is not used unless all other applicable strategies are also disabled.

If `semijoin` and `materialization` are both `on`, semijoins also use materialization where applicable. These flags are `on` by default.

For more information, see [Optimizing IN and EXISTS Subquery Predicates with Semijoin Transformations](#).

- Set Operations Flags

- `hash_set_operations` (default `on`)

Enables the hash table optimization for set operations involving `EXCEPT` and `INTERSECT`); enabled by default. Otherwise, temporary table based de-duplication is used, as in previous versions of MySQL.

The amount of memory used for hashing by this optimization can be controlled using the `set_operations_buffer_size` system variable; increasing this generally results in faster execution times for statements using these operations.

- Skip Scan Flags

- `skip_scan` (default `on`)

Controls use of Skip Scan access method.

For more information, see [Skip Scan Range Access Method](#).

- Subquery Materialization Flags

- `materialization` (default `on`)

Controls materialization (including semijoin materialization).

- `subquery_materialization_cost_based` (default `on`)

Use cost-based materialization choice.

The `materialization` flag controls whether subquery materialization is used. If `semi_join` and `materialization` are both `on`, semijoins also use materialization where applicable. These flags are `on` by default.

The `subquery_materialization_cost_based` flag enables control over the choice between subquery materialization and `IN-to-EXISTS` subquery transformation. If the flag is `on` (the default), the optimizer performs a cost-based choice between subquery materialization and `IN-to-EXISTS` subquery transformation if either method could be used. If the flag is `off`, the optimizer chooses subquery materialization over `IN-to-EXISTS` subquery transformation.

For more information, see [Section 10.2.2, “Optimizing Subqueries, Derived Tables, View References, and Common Table Expressions”](#).

- Subquery Transformation Flags

- `subquery_to_derived` (default `off`)

The optimizer is able in many cases to transform a scalar subquery in a `SELECT`, `WHERE`, `JOIN`, or `HAVING` clause into a left outer join on a derived table. (Depending on the nullability of the derived table, this can sometimes be simplified further to an inner join.) This can be done for a subquery which meets the following conditions:

- The subquery does not make use of any nondeterministic functions, such as `RAND()`.
  - The subquery is not an `ANY` or `ALL` subquery which can be rewritten to use `MIN()` or `MAX()`.
  - The parent query does not set a user variable, since rewriting it may affect the order of execution, which could lead to unexpected results if the variable is accessed more than once in the same query.
  - The subquery should not be correlated, that is, it should not reference a column from a table in the outer query, or contain an aggregate that is evaluated in the outer query.

This optimization can also be applied to a table subquery which is the argument to `IN`, `NOT IN`, `EXISTS`, or `NOT EXISTS`, that does not contain a `GROUP BY`.

The default value for this flag is `off`, since, in most cases, enabling this optimization does not produce any noticeable improvement in performance (and in many cases can even make queries run more

slowly), but you can enable the optimization by setting the `subquery_to_derived` flag to `on`. It is primarily intended for use in testing.

Example, using a scalar subquery:

```
d
mysql> CREATE TABLE t1(a INT);

mysql> CREATE TABLE t2(a INT);

mysql> INSERT INTO t1 VALUES ROW(1), ROW(2), ROW(3), ROW(4);

mysql> INSERT INTO t2 VALUES ROW(1), ROW(2);

mysql> SELECT * FROM t1
 -> WHERE t1.a > (SELECT COUNT(a) FROM t2);
+-----+
| a |

```

As can be seen from executing `SHOW WARNINGS` immediately following the second `EXPLAIN` statement, with the optimization enabled, the query `SELECT * FROM t1 WHERE t1.a > (SELECT COUNT(a) FROM t2)` is rewritten in a form similar to what is shown here:

```

SELECT t1.a FROM t1
 JOIN (SELECT COUNT(t2.a) AS c FROM t2) AS d
 WHERE t1.a > d.c;

```

Example, using a query with `IN (subquery)`:

```

mysql> DROP TABLE IF EXISTS t1, t2;

mysql> CREATE TABLE t1 (a INT, b INT);
mysql> CREATE TABLE t2 (a INT, b INT);

mysql> INSERT INTO t1 VALUES ROW(1,10), ROW(2,20), ROW(3,30);

```

```
mysql> INSERT INTO t2
-> VALUES ROW(1,10), ROW(2,20), ROW(3,30), ROW(1,110), ROW(2,120), ROW(3,130);

mysql> SELECT * FROM t1
-> WHERE t1.b < 0
-> OR
-> t1.a IN (SELECT t2.a + 1 FROM t2);

+-----+-----+
| a | b |
+-----+-----+
| 2 | 20 |
| 3 | 30 |
+-----+-----+

mysql> SET @@optimizer_switch="subquery_to_derived=off";

mysql> EXPLAIN SELECT * FROM t1
-> WHERE t1.b < 0
-> OR
-> t1.a IN (SELECT t2.a + 1 FROM t2)\G
***** 1. row *****
 id: 1
 select_type: PRIMARY
 table: t1
 partitions: NULL

 Extra: Using temporary

```

Checking and simplifying the result of `SHOW WARNINGS` after executing `EXPLAIN` on this query shows that, when the `subquery_to_derived` flag enabled, `SELECT * FROM t1 WHERE t1.b < 0 OR t1.a IN (SELECT t2.a + 1 FROM t2)` is rewritten in a form similar to what is shown here:

```

SELECT a, b FROM t1
 LEFT JOIN (SELECT DISTINCT a + 1 AS e FROM t2) d
 ON t1.a = d.e
 WHERE t1.b < 0
 OR
 d.e IS NOT NULL;

```

Example, using a query with `EXISTS (subquery)` and the same tables and data as in the previous example:

```

mysql> SELECT * FROM t1
-> WHERE t1.b < 0
-> OR
-> EXISTS(SELECT * FROM t2 WHERE t2.a = t1.a + 1);
+-----+-----+
| a | b |
+-----+-----+
| 1 | 10 |
| 2 | 20 |
+-----+-----+

mysql> SET @@optimizer_switch="subquery_to_derived=off";

mysql> EXPLAIN SELECT * FROM t1
-> WHERE t1.b < 0
-> OR
-> EXISTS(SELECT * FROM t2 WHERE t2.a = t1.a + 1)\G
***** 1. row *****
 id: 1
 select_type: PRIMARY
 table: t1
 partitions: NULL
 type: ALL
possible_keys: NULL
 key: NULL
 key_len: NULL

```

```

 ref: NULL
 rows: 3

```

If we execute `SHOW WARNINGS` after running `EXPLAIN` on the query `SELECT * FROM t1 WHERE t1.b < 0 OR EXISTS(SELECT * FROM t2 WHERE t2.a = t1.a + 1)` when

`subquery_to_derived` has been enabled, and simplify the second row of the result, we see that it has been rewritten in a form which resembles this:

```
SELECT a, b FROM t1
LEFT JOIN (SELECT DISTINCT 1 AS e1, t2.a AS e2 FROM t2) d
ON t1.a + 1 = d.e2
WHERE t1.b < 0
 OR
 d.e1 IS NOT NULL;
```

For more information, see [Section 10.2.2.4, “Optimizing Derived Tables, View References, and Common Table Expressions with Merging or Materialization”](#), as well as [Section 10.2.1.19, “LIMIT Query Optimization”](#), and [Optimizing IN and EXISTS Subquery Predicates with Semijoin Transformations](#).

When you assign a value to `optimizer_switch`, flags that are not mentioned keep their current values. This makes it possible to enable or disable specific optimizer behaviors in a single statement without affecting other behaviors. The statement does not depend on what other optimizer flags exist and what their values are. Suppose that all Index Merge optimizations are enabled:

```
mysql> SELECT @@optimizer_switch\G
***** 1. row *****
@@optimizer_switch: index_merge=on,index_merge_union=on,
 index_merge_sort_union=on,index_merge_intersection=on,
 engine_condition_pushdown=on,index_condition_pushdown=on,
 mrr=on,mrr_cost_based=on,block_nested_loop=on,
 batched_key_access=off,materialization=on,semijoin=on,
 loosescan=on, firstmatch=on,
 subquery_materialization_cost_based=on,
 use_index_extensions=on,condition_fanout_filter=on,
 derived_merge=on,use_invisible_indexes=off,skip_scan=on,
 hash_join=on,subquery_to_derived=off,
 prefer_ordering_index=on
```

If the server is using the Index Merge Union or Index Merge Sort-Union access methods for certain queries and you want to check whether the optimizer can perform better without them, set the variable value like this:

```
mysql> SET optimizer_switch='index_merge_union=off,index_merge_sort_union=off';

mysql> SELECT @@optimizer_switch\G
***** 1. row *****
@@optimizer_switch: index_merge=on,index_merge_union=off,
 index_merge_sort_union=off,index_merge_intersection=on,
 engine_condition_pushdown=on,index_condition_pushdown=on,
 mrr=on,mrr_cost_based=on,block_nested_loop=on,

 loosescan=on, firstmatch=on,
 subquery_materialization_cost_based=on,
 use_index_extensions=on,condition_fanout_filter=on,
 derived_merge=on,use_invisible_indexes=off,skip_scan=on,
 hash_join=on,subquery_to_derived=off,
 prefer_ordering_index=on
```

## 10.9.3 Optimizer Hints

One means of control over optimizer strategies is to set the `optimizer_switch` system variable (see [Section 10.9.2, “Switchable Optimizations”](#)). Changes to this variable affect execution of all subsequent queries; to affect one query differently from another, it is necessary to change `optimizer_switch` before each one.

Another way to control the optimizer is by using optimizer hints, which can be specified within individual statements. Because optimizer hints apply on a per-statement basis, they provide finer control over

statement execution plans than can be achieved using [optimizer\\_switch](#). For example, you can enable an optimization for one table in a statement and disable the optimization for a different table. Hints within a statement take precedence over [optimizer\\_switch](#) flags.

Examples:

```
SELECT /*+ NO_RANGE_OPTIMIZATION(t3 PRIMARY, f2_idx) */ f1
 FROM t3 WHERE f1 > 30 AND f1 < 33;
SELECT /*+ BKA(t1) NO_BKA(t2) */ * FROM t1 INNER JOIN t2 WHERE ...;
SELECT /*+ NO_ICP(t1, t2) */ * FROM t1 INNER JOIN t2 WHERE ...;
SELECT /*+ SEMIJOIN(FIRSTMATCH, LOOSESCAN) */ * FROM t1 ...;
EXPLAIN SELECT /*+ NO_ICP(t1) */ * FROM t1 WHERE ...;
SELECT /*+ MERGE(dt) */ * FROM (SELECT * FROM t1) AS dt;
INSERT /*+ SET_VAR(foreign_key_checks=OFF) */ INTO t2 VALUES(2);
```

Optimizer hints, described here, differ from index hints, described in [Section 10.9.4, “Index Hints”](#). Optimizer and index hints may be used separately or together.

## Optimizer Hint Overview

Optimizer hints apply at different scope levels:

- Global: The hint affects the entire statement
- Query block: The hint affects a particular query block within a statement
- Table-level: The hint affects a particular table within a query block
- Index-level: The hint affects a particular index within a table

The following table summarizes the available optimizer hints, the optimizer strategies they affect, and the scope or scopes at which they apply. More details are given later.

**Table 10.2 Optimizer Hints Available**

Hint Name	Description	Applicable Scopes
<a href="#">BKA</a> , <a href="#">NO_BKA</a>	Affects Batched Key Access join processing	Query block, table
<a href="#">BNL</a> , <a href="#">NO_BNL</a>	Affects hash join optimization	Query block, table

Hint Name	Description	Applicable Scopes
<code>DERIVED_CONDITION_PUSHDOWN</code> , <code>NO_DERIVED_CONDITION_PUSHDOWN</code>	Use or ignore the derived condition pushdown optimization for materialized derived tables	Query block, table
<code>GROUP_INDEX</code> , <code>NO_GROUP_INDEX</code>	Use or ignore the specified index or indexes for index scans in <code>GROUP BY</code> operations	Index
<code>HASH_JOIN</code> , <code>NO_HASH_JOIN</code>	Affects Hash Join optimization (No effect in MySQL 9.1)	Query block, table
<code>INDEX</code> , <code>NO_INDEX</code>	Acts as the combination of <code>JOIN_INDEX</code> , <code>GROUP_INDEX</code> , and <code>ORDER_INDEX</code> , or as the combination of <code>NO_JOIN_INDEX</code> , <code>NO_GROUP_INDEX</code> , and <code>NO_ORDER_INDEX</code>	Index
<code>INDEX_MERGE</code> , <code>NO_INDEX_MERGE</code>	Affects Index Merge optimization	Table, index
<code>JOIN_FIXED_ORDER</code>	Use table order specified in <code>FROM</code> clause for join order	Query block
<code>JOIN_INDEX</code> , <code>NO_JOIN_INDEX</code>	Use or ignore the specified index or indexes for any access method	Index
<code>JOIN_ORDER</code>	Use table order specified in hint for join order	Query block
<code>JOIN_PREFIX</code>	Use table order specified in hint for first tables of join order	Query block
<code>JOIN_SUFFIX</code>	Use table order specified in hint for last tables of join order	Query block
<code>MAX_EXECUTION_TIME</code>	Limits statement execution time	Global
<code>MERGE</code> , <code>NO_MERGE</code>	Affects derived table/view merging into outer query block	Table
<code>MRR</code> , <code>NO_MRR</code>	Affects Multi-Range Read optimization	Table, index
<code>NO_ICP</code>	Affects Index Condition Pushdown optimization	Table, index
<code>NO_RANGE_OPTIMIZATION</code>	Affects range optimization	Table, index
<code>ORDER_INDEX</code> , <code>NO_ORDER_INDEX</code>	Use or ignore the specified index or indexes for sorting rows	Index
<code>QB_NAME</code>	Assigns name to query block	Query block
<code>RESOURCE_GROUP</code>	Set resource group during statement execution	Global
<code>SEMIJOIN</code> , <code>NO_SEMIJOIN</code>	Affects semijoin and antijoin strategies	Query block
<code>SKIP_SCAN</code> , <code>NO_SKIP_SCAN</code>	Affects Skip Scan optimization	Table, index
<code>SET_VAR</code>	Set variable during statement execution	Global

Hint Name	Description	Applicable Scopes
<a href="#">SUBQUERY</a>	Affects materialization, <a href="#">IN</a> -to- <a href="#">EXISTS</a> subquery strategies	Query block

Disabling an optimization prevents the optimizer from using it. Enabling an optimization means the optimizer is free to use the strategy if it applies to statement execution, not that the optimizer necessarily uses it.

## Optimizer Hint Syntax

MySQL supports comments in SQL statements as described in [Section 11.7, “Comments”](#). Optimizer hints must be specified within `/*+ ... */` comments. That is, optimizer hints use a variant of `/* ... */` C-style comment syntax, with a `+` character following the `/*` comment opening sequence. Examples:

```
/*+ BKA(t1) */
/*+ BNL(t1, t2) */
/*+ NO_RANGE_OPTIMIZATION(t4 PRIMARY) */
/*+ QB_NAME(qb2) */
```

Whitespace is permitted after the `+` character.

The parser recognizes optimizer hint comments after the initial keyword of [SELECT](#), [UPDATE](#), [INSERT](#), [REPLACE](#), and [DELETE](#) statements. Hints are permitted in these contexts:

- At the beginning of query and data change statements:

```
SELECT /*+ ... */ ...
INSERT /*+ ... */ ...
REPLACE /*+ ... */ ...
UPDATE /*+ ... */ ...
DELETE /*+ ... */ ...
```

- At the beginning of query blocks:

```
(SELECT /*+ ... */ ...)
(SELECT ...) UNION (SELECT /*+ ... */ ...)
(SELECT /*+ ... */ ...) UNION (SELECT /*+ ... */ ...)
UPDATE ... WHERE x IN (SELECT /*+ ... */ ...)
INSERT ... SELECT /*+ ... */ ...
```

- In hintable statements prefaced by [EXPLAIN](#). For example:

```
EXPLAIN SELECT /*+ ... */ ...
EXPLAIN UPDATE ... WHERE x IN (SELECT /*+ ... */ ...)
```

The implication is that you can use [EXPLAIN](#) to see how optimizer hints affect execution plans. Use [SHOW WARNINGS](#) immediately after [EXPLAIN](#) to see how hints are used. The extended [EXPLAIN](#) output displayed by a following [SHOW WARNINGS](#) indicates which hints were used. Ignored hints are not displayed.

A hint comment may contain multiple hints, but a query block cannot contain multiple hint comments. This is valid:

```
SELECT /*+ BNL(t1) BKA(t2) */ ...
```

But this is invalid:

```
SELECT /*+ BNL(t1) */ /* BKA(t2) */ ...
```

When a hint comment contains multiple hints, the possibility of duplicates and conflicts exists. The following general guidelines apply. For specific hint types, additional rules may apply, as indicated in the hint descriptions.

- Duplicate hints: For a hint such as `/*+ MRR(idx1) MRR(idx1) */`, MySQL uses the first hint and issues a warning about the duplicate hint.
- Conflicting hints: For a hint such as `/*+ MRR(idx1) NO_MRR(idx1) */`, MySQL uses the first hint and issues a warning about the second conflicting hint.

Query block names are identifiers and follow the usual rules about what names are valid and how to quote them (see [Section 11.2, “Schema Object Names”](#)).

Hint names, query block names, and strategy names are not case-sensitive. References to table and index names follow the usual identifier case-sensitivity rules (see [Section 11.2.3, “Identifier Case Sensitivity”](#)).

## Join-Order Optimizer Hints

Join-order hints affect the order in which the optimizer joins tables.

Syntax of the `JOIN_FIXED_ORDER` hint:

```
hint_name ([@query_block_name])
```

Syntax of other join-order hints:

```
hint_name([@query_block_name] tbl_name [, tbl_name] ...)
hint_name(tbl_name[@query_block_name] [, tbl_name[@query_block_name]] ...)
```

The syntax refers to these terms:

- `hint_name`: These hint names are permitted:
  - `JOIN_FIXED_ORDER`: Force the optimizer to join tables using the order in which they appear in the `FROM` clause. This is the same as specifying `SELECT STRAIGHT_JOIN`.
  - `JOIN_ORDER`: Instruct the optimizer to join tables using the specified table order. The hint applies to the named tables. The optimizer may place tables that are not named anywhere in the join order, including between specified tables.
  - `JOIN_PREFIX`: Instruct the optimizer to join tables using the specified table order for the first tables of the join execution plan. The hint applies to the named tables. The optimizer places all other tables after the named tables.
  - `JOIN_SUFFIX`: Instruct the optimizer to join tables using the specified table order for the last tables of the join execution plan. The hint applies to the named tables. The optimizer places all other tables before the named tables.
- `tbl_name`: The name of a table used in the statement. A hint that names tables applies to all tables that it names. The `JOIN_FIXED_ORDER` hint names no tables and applies to all tables in the `FROM` clause of the query block in which it occurs.

If a table has an alias, hints must refer to the alias, not the table name.

Table names in hints cannot be qualified with schema names.

- `query_block_name`: The query block to which the hint applies. If the hint includes no leading `@query_block_name`, the hint applies to the query block in which it occurs. For

`tbl_name@query_block_name` syntax, the hint applies to the named table in the named query block. To assign a name to a query block, see [Optimizer Hints for Naming Query Blocks](#).

Example:

```
SELECT
/*+ JOIN_PREFIX(t2, t5@subq2, t4@subq1)
 JOIN_ORDER(t4@subq1, t3)
 JOIN_SUFFIX(t1) */
COUNT(*) FROM t1 JOIN t2 JOIN t3
 WHERE t1.f1 IN (SELECT /*+ QB_NAME(subq1) */ f1 FROM t4)
 AND t2.f1 IN (SELECT /*+ QB_NAME(subq2) */ f1 FROM t5);
```

Hints control the behavior of semijoin tables that are merged to the outer query block. If subqueries `subq1` and `subq2` are converted to semijoins, tables `t4@subq1` and `t5@subq2` are merged to the outer query block. In this case, the hint specified in the outer query block controls the behavior of `t4@subq1`, `t5@subq2` tables.

The optimizer resolves join-order hints according to these principles:

- Multiple hint instances

Only one `JOIN_PREFIX` and `JOIN_SUFFIX` hint of each type are applied. Any later hints of the same type are ignored with a warning. `JOIN_ORDER` can be specified several times.

Examples:

```
/*+ JOIN_PREFIX(t1) JOIN_PREFIX(t2) */
```

The second `JOIN_PREFIX` hint is ignored with a warning.

```
/*+ JOIN_PREFIX(t1) JOIN_SUFFIX(t2) */
```

Both hints are applicable. No warning occurs.

```
/*+ JOIN_ORDER(t1, t2) JOIN_ORDER(t2, t3) */
```

Both hints are applicable. No warning occurs.

- Conflicting hints

In some cases hints can conflict, such as when `JOIN_ORDER` and `JOIN_PREFIX` have table orders that are impossible to apply at the same time:

```
SELECT /*+ JOIN_ORDER(t1, t2) JOIN_PREFIX(t2, t1) */ ... FROM t1, t2;
```

In this case, the first specified hint is applied and subsequent conflicting hints are ignored with no warning. A valid hint that is impossible to apply is silently ignored with no warning.

- Ignored hints

A hint is ignored if a table specified in the hint has a circular dependency.

Example:

```
/*+ JOIN_ORDER(t1, t2) JOIN_PREFIX(t2, t1) */
```

The `JOIN_ORDER` hint sets table `t2` dependent on `t1`. The `JOIN_PREFIX` hint is ignored because table `t1` cannot be dependent on `t2`. Ignored hints are not displayed in extended `EXPLAIN` output.

- Interaction with `const` tables

The MySQL optimizer places `const` tables first in the join order, and the position of a `const` table cannot be affected by hints. References to `const` tables in join-order hints are ignored, although the hint is still applicable. For example, these are equivalent:

```
JOIN_ORDER(t1, const_tbl, t2)
JOIN_ORDER(t1, t2)
```

Accepted hints shown in extended `EXPLAIN` output include `const` tables as they were specified.

- Interaction with types of join operations

MySQL supports several type of joins: `LEFT`, `RIGHT`, `INNER`, `CROSS`, `STRAIGHT_JOIN`. A hint that conflicts with the specified type of join is ignored with no warning.

Example:

```
SELECT /*+ JOIN_PREFIX(t1, t2) */FROM t2 LEFT JOIN t1;
```

Here a conflict occurs between the requested join order in the hint and the order required by the `LEFT JOIN`. The hint is ignored with no warning.

## Table-Level Optimizer Hints

Table-level hints affect:

- Use of the Block Nested-Loop (BNL) and Batched Key Access (BKA) join-processing algorithms (see [Section 10.2.1.12, “Block Nested-Loop and Batched Key Access Joins”](#)).
- Whether derived tables, view references, or common table expressions should be merged into the outer query block, or materialized using an internal temporary table.
- Use of the derived table condition pushdown optimization. See [Section 10.2.2.5, “Derived Condition Pushdown Optimization”](#).

These hint types apply to specific tables, or all tables in a query block.

Syntax of table-level hints:

```
hint_name([@query_block_name] [tbl_name [, tbl_name] ...])
hint_name([tbl_name@query_block_name [, tbl_name@query_block_name] ...])
```

The syntax refers to these terms:

- `hint_name`: These hint names are permitted:
  - `BKA`, `NO_BKA`: Enable or disable batched key access for the specified tables.
  - `BNL`, `NO_BNL`: Enable and disable the hash join optimization.
  - `DERIVED_CONDITION_PUSHDOWN`, `NO_DERIVED_CONDITION_PUSHDOWN`: Enable or disable use of derived table condition pushdown for the specified tables. For more information, see [Section 10.2.2.5, “Derived Condition Pushdown Optimization”](#).
  - `HASH_JOIN`, `NO_HASH_JOIN`: These hints have no effect in MySQL 9.1; use `BNL` or `NO_BNL` instead.
  - `MERGE`, `NO_MERGE`: Enable merging for the specified tables, view references or common table expressions; or disable merging and use materialization instead.

**Note**

To use a block nested loop or batched key access hint to enable join buffering for any inner table of an outer join, join buffering must be enabled for all inner tables of the outer join.

- *tbl\_name*: The name of a table used in the statement. The hint applies to all tables that it names. If the hint names no tables, it applies to all tables of the query block in which it occurs.

If a table has an alias, hints must refer to the alias, not the table name.

Table names in hints cannot be qualified with schema names.

- *query\_block\_name*: The query block to which the hint applies. If the hint includes no leading *@query\_block\_name*, the hint applies to the query block in which it occurs. For *tbl\_name@query\_block\_name* syntax, the hint applies to the named table in the named query block. To assign a name to a query block, see [Optimizer Hints for Naming Query Blocks](#).

**Examples:**

```
SELECT /*+ NO_BKA(t1, t2) */ t1.* FROM t1 INNER JOIN t2 INNER JOIN t3;
SELECT /*+ NO_BNL() BKA(t1) */ t1.* FROM t1 INNER JOIN t2 INNER JOIN t3;
SELECT /*+ NO_MERGE(dt) */ * FROM (SELECT * FROM t1) AS dt;
```

A table-level hint applies to tables that receive records from previous tables, not sender tables. Consider this statement:

```
SELECT /*+ BNL(t2) */ FROM t1, t2;
```

If the optimizer chooses to process *t1* first, it applies a Block Nested-Loop join to *t2* by buffering the rows from *t1* before starting to read from *t2*. If the optimizer instead chooses to process *t2* first, the hint has no effect because *t2* is a sender table.

For the *MERGE* and *NO\_MERGE* hints, these precedence rules apply:

- A hint takes precedence over any optimizer heuristic that is not a technical constraint. (If providing a hint as a suggestion has no effect, the optimizer has a reason for ignoring it.)
- A hint takes precedence over the *derived\_merge* flag of the *optimizer\_switch* system variable.
- For view references, an *ALGORITHM={MERGE|TEMPTABLE}* clause in the view definition takes precedence over a hint specified in the query referencing the view.

## Index-Level Optimizer Hints

Index-level hints affect which index-processing strategies the optimizer uses for particular tables or indexes. These hint types affect use of Index Condition Pushdown (ICP), Multi-Range Read (MRR), Index Merge, and range optimizations (see [Section 10.2.1, “Optimizing SELECT Statements”](#)).

Syntax of index-level hints:

```
hint_name([@query_block_name] tbl_name [index_name [, index_name] ...])
hint_name(tbl_name@query_block_name [index_name [, index_name] ...])
```

The syntax refers to these terms:

- *hint\_name*: These hint names are permitted:

- `GROUP_INDEX`, `NO_GROUP_INDEX`: Enable or disable the specified index or indexes for index scans for `GROUP BY` operations. Equivalent to the index hints `FORCE INDEX FOR GROUP BY`, `IGNORE INDEX FOR GROUP BY`.
- `INDEX`, `NO_INDEX`: Acts as the combination of `JOIN_INDEX`, `GROUP_INDEX`, and `ORDER_INDEX`, forcing the server to use the specified index or indexes for any and all scopes, or as the combination of `NO_JOIN_INDEX`, `NO_GROUP_INDEX`, and `NO_ORDER_INDEX`, which causes the server to ignore the specified index or indexes for any and all scopes. Equivalent to `FORCE INDEX`, `IGNORE INDEX`.
- `INDEX_MERGE`, `NO_INDEX_MERGE`: Enable or disable the Index Merge access method for the specified table or indexes. For information about this access method, see [Section 10.2.1.3, “Index Merge Optimization”](#). These hints apply to all three Index Merge algorithms.

The `INDEX_MERGE` hint forces the optimizer to use Index Merge for the specified table using the specified set of indexes. If no index is specified, the optimizer considers all possible index combinations and selects the least expensive one. The hint may be ignored if the index combination is inapplicable to the given statement.

The `NO_INDEX_MERGE` hint disables Index Merge combinations that involve any of the specified indexes. If the hint specifies no indexes, Index Merge is not permitted for the table.

- `JOIN_INDEX`, `NO_JOIN_INDEX`: Forces MySQL to use or ignore the specified index or indexes for any access method, such as `ref`, `range`, `index_merge`, and so on. Equivalent to `FORCE INDEX FOR JOIN`, `IGNORE INDEX FOR JOIN`.
- `MRR`, `NO_MRR`: Enable or disable MRR for the specified table or indexes. MRR hints apply only to `InnoDB` and `MyISAM` tables. For information about this access method, see [Section 10.2.1.11, “Multi-Range Read Optimization”](#).
- `NO_ICP`: Disable ICP for the specified table or indexes. By default, ICP is a candidate optimization strategy, so there is no hint for enabling it. For information about this access method, see [Section 10.2.1.6, “Index Condition Pushdown Optimization”](#).
- `NO_RANGE_OPTIMIZATION`: Disable index range access for the specified table or indexes. This hint also disables Index Merge and Loose Index Scan for the table or indexes. By default, range access is a candidate optimization strategy, so there is no hint for enabling it.

This hint may be useful when the number of ranges may be high and range optimization would require many resources.

- `ORDER_INDEX`, `NO_ORDER_INDEX`: Cause MySQL to use or to ignore the specified index or indexes for sorting rows. Equivalent to `FORCE INDEX FOR ORDER BY`, `IGNORE INDEX FOR ORDER BY`.
- `SKIP_SCAN`, `NO_SKIP_SCAN`: Enable or disable the Skip Scan access method for the specified table or indexes. For information about this access method, see [Skip Scan Range Access Method](#).

The `SKIP_SCAN` hint forces the optimizer to use Skip Scan for the specified table using the specified set of indexes. If no index is specified, the optimizer considers all possible indexes and selects the least expensive one. The hint may be ignored if the index is inapplicable to the given statement.

The `NO_SKIP_SCAN` hint disables Skip Scan for the specified indexes. If the hint specifies no indexes, Skip Scan is not permitted for the table.

- `tbl_name`: The table to which the hint applies.

- `index_name`: The name of an index in the named table. The hint applies to all indexes that it names. If the hint names no indexes, it applies to all indexes in the table.

To refer to a primary key, use the name `PRIMARY`. To see the index names for a table, use `SHOW INDEX`.

- `query_block_name`: The query block to which the hint applies. If the hint includes no leading `@query_block_name`, the hint applies to the query block in which it occurs. For `tbl_name@query_block_name` syntax, the hint applies to the named table in the named query block. To assign a name to a query block, see [Optimizer Hints for Naming Query Blocks](#).

Examples:

```
SELECT /*+ INDEX_MERGE(t1 f3, PRIMARY) */ f2 FROM t1
 WHERE f1 = 'o' AND f2 = f3 AND f3 <= 4;
SELECT /*+ MRR(t1) */ * FROM t1 WHERE f2 <= 3 AND 3 <= f3;
SELECT /*+ NO_RANGE_OPTIMIZATION(t3 PRIMARY, f2_idx) */ f1
 FROM t3 WHERE f1 > 30 AND f1 < 33;
INSERT INTO t3(f1, f2, f3)
 (SELECT /*+ NO_ICP(t2) */ t2.f1, t2.f2, t2.f3 FROM t1,t2
 WHERE t1.f1=t2.f1 AND t2.f2 BETWEEN t1.f1
 AND t1.f2 AND t2.f2 + 1 >= t1.f1 + 1);
SELECT /*+ SKIP_SCAN(t1 PRIMARY) */ f1, f2
 FROM t1 WHERE f2 > 40;
```

The following examples use the Index Merge hints, but other index-level hints follow the same principles regarding hint ignoring and precedence of optimizer hints in relation to the `optimizer_switch` system variable or index hints.

Assume that table `t1` has columns `a`, `b`, `c`, and `d`; and that indexes named `i_a`, `i_b`, and `i_c` exist on `a`, `b`, and `c`, respectively:

```
SELECT /*+ INDEX_MERGE(t1 i_a, i_b, i_c)*/ * FROM t1
 WHERE a = 1 AND b = 2 AND c = 3 AND d = 4;
```

Index Merge is used for (`i_a`, `i_b`, `i_c`) in this case.

```
SELECT /*+ INDEX_MERGE(t1 i_a, i_b, i_c)*/ * FROM t1
 WHERE b = 1 AND c = 2 AND d = 3;
```

Index Merge is used for (`i_b`, `i_c`) in this case.

```
/*+ INDEX_MERGE(t1 i_a, i_b) NO_INDEX_MERGE(t1 i_b) */
```

`NO_INDEX_MERGE` is ignored because there is a preceding hint for the same table.

```
/*+ NO_INDEX_MERGE(t1 i_a, i_b) INDEX_MERGE(t1 i_b) */
```

`INDEX_MERGE` is ignored because there is a preceding hint for the same table.

For the `INDEX_MERGE` and `NO_INDEX_MERGE` optimizer hints, these precedence rules apply:

- If an optimizer hint is specified and is applicable, it takes precedence over the Index Merge-related flags of the `optimizer_switch` system variable.

```
SET optimizer_switch='index_merge_intersection=off';
SELECT /*+ INDEX_MERGE(t1 i_b, i_c) */ * FROM t1
 WHERE b = 1 AND c = 2 AND d = 3;
```

The hint takes precedence over `optimizer_switch`. Index Merge is used for (`i_b`, `i_c`) in this case.

```
SET optimizer_switch='index_merge_intersection=on';
```

```
SELECT /*+ INDEX_MERGE(t1 i_b) */ * FROM t1
WHERE b = 1 AND c = 2 AND d = 3;
```

The hint specifies only one index, so it is inapplicable, and the `optimizer_switch` flag (`on`) applies. Index Merge is used if the optimizer assesses it to be cost efficient.

```
SET optimizer_switch='index_merge_intersection=off';
SELECT /*+ INDEX_MERGE(t1 i_b) */ * FROM t1
WHERE b = 1 AND c = 2 AND d = 3;
```

The hint specifies only one index, so it is inapplicable, and the `optimizer_switch` flag (`off`) applies. Index Merge is not used.

- The index-level optimizer hints `GROUP_INDEX`, `INDEX`, `JOIN_INDEX`, and `ORDER_INDEX` all take precedence over the equivalent `FORCE INDEX` hints; that is, they cause the `FORCE INDEX` hints to be ignored. Likewise, the `NO_GROUP_INDEX`, `NO_INDEX`, `NO_JOIN_INDEX`, and `NO_ORDER_INDEX` hints all take precedence over any `IGNORE INDEX` equivalents, also causing them to be ignored.

The index-level optimizer hints `GROUP_INDEX`, `NO_GROUP_INDEX`, `INDEX`, `NO_INDEX`, `JOIN_INDEX`, `NO_JOIN_INDEX`, `ORDER_INDEX`, and `NO_ORDER_INDEX` hints all take precedence over all other optimizer hints, including other index-level optimizer hints. Any other optimizer hints are applied only to the indexes permitted by these.

The `GROUP_INDEX`, `INDEX`, `JOIN_INDEX`, and `ORDER_INDEX` hints are all equivalent to `FORCE INDEX` and not to `USE INDEX`. This is because using one or more of these hints means that a table scan is used only if there is no way to use one of the named indexes to find rows in the table. To cause MySQL to use the same index or set of indexes as with a given instance of `USE INDEX`, you can use `NO_INDEX`, `NO_JOIN_INDEX`, `NO_GROUP_INDEX`, `NO_ORDER_INDEX`, or some combination of these.

To replicate the effect that `USE INDEX` has in the query `SELECT a,c FROM t1 USE INDEX FOR ORDER BY (i_a) ORDER BY a`, you can use the `NO_ORDER_INDEX` optimizer hint to cover all indexes on the table except the one that is desired like this:

```
SELECT /*+ NO_ORDER_INDEX(t1 i_b,i_c) */ a,c
FROM t1
ORDER BY a;
```

Attempting to combine `NO_ORDER_INDEX` for the table as a whole with `USE INDEX FOR ORDER BY` does not work to do this, because `NO_ORDER_BY` causes `USE INDEX` to be ignored, as shown here:

```
mysql> EXPLAIN SELECT /*+ NO_ORDER_INDEX(t1) */ a,c FROM t1
-> USE INDEX FOR ORDER BY (i_a) ORDER BY a\G
***** 1. row *****
 id: 1
 select_type: SIMPLE
 table: t1
 partitions: NULL
 type: ALL
possible_keys: NULL
 key: NULL
 key_len: NULL
 ref: NULL
 rows: 256
 filtered: 100.00
 Extra: Using filesort
```

- The `USE INDEX`, `FORCE INDEX`, and `IGNORE INDEX` index hints have higher priority than the `INDEX_MERGE` and `NO_INDEX_MERGE` optimizer hints.

```
/*+ INDEX_MERGE(t1 i_a, i_b, i_c) */ ... IGNORE INDEX i_a
```

`IGNORE INDEX` takes precedence over `INDEX_MERGE`, so index `i_a` is excluded from the possible ranges for Index Merge.

```
/*+ NO_INDEX_MERGE(t1 i_a, i_b) */ ... FORCE INDEX i_a, i_b
```

Index Merge is disallowed for `i_a`, `i_b` because of `FORCE INDEX`, but the optimizer is forced to use either `i_a` or `i_b` for `range` or `ref` access. There are no conflicts; both hints are applicable.

- If an `IGNORE INDEX` hint names multiple indexes, those indexes are unavailable for Index Merge.
- The `FORCE INDEX` and `USE INDEX` hints make only the named indexes to be available for Index Merge.

```
SELECT /*+ INDEX_MERGE(t1 i_a, i_b, i_c) */ a FROM t1
FORCE INDEX (i_a, i_b) WHERE c = 'h' AND a = 2 AND b = 'b';
```

The Index Merge intersection access algorithm is used for `(i_a, i_b)`. The same is true if `FORCE INDEX` is changed to `USE INDEX`.

## Subquery Optimizer Hints

Subquery hints affect whether to use semijoin transformations and which semijoin strategies to permit, and, when semijoins are not used, whether to use subquery materialization or `IN-to-EXISTS` transformations. For more information about these optimizations, see [Section 10.2.2, “Optimizing Subqueries, Derived Tables, View References, and Common Table Expressions”](#).

Syntax of hints that affect semijoin strategies:

```
hint_name([@query_block_name] [strategy [, strategy] ...])
```

The syntax refers to these terms:

- `hint_name`: These hint names are permitted:
  - `SEMIJOIN`, `NO_SEMIJOIN`: Enable or disable the named semijoin strategies.
- `strategy`: A semijoin strategy to be enabled or disabled. These strategy names are permitted: `DUPSWEEDOUT`, `FIRSTMATCH`, `LOOSESCAN`, `MATERIALIZATION`.

For `SEMIJOIN` hints, if no strategies are named, semijoin is used if possible based on the strategies enabled according to the `optimizer_switch` system variable. If strategies are named but inapplicable for the statement, `DUPSWEEDOUT` is used.

For `NO_SEMIJOIN` hints, if no strategies are named, semijoin is not used. If strategies are named that rule out all applicable strategies for the statement, `DUPSWEEDOUT` is used.

If one subquery is nested within another and both are merged into a semijoin of an outer query, any specification of semijoin strategies for the innermost query are ignored. `SEMIJOIN` and `NO_SEMIJOIN` hints can still be used to enable or disable semijoin transformations for such nested subqueries.

If `DUPSWEEDOUT` is disabled, on occasion the optimizer may generate a query plan that is far from optimal. This occurs due to heuristic pruning during greedy search, which can be avoided by setting `optimizer_prune_level=0`.

Examples:

```
SELECT /*+ NO_SEMIJOIN(@subq1 FIRSTMATCH, LOOSECAN) */ * FROM t2
 WHERE t2.a IN (SELECT /*+ QB_NAME(subq1) */ a FROM t3);
SELECT /*+ SEMIJOIN(@subq1 MATERIALIZATION, DUPSWEEDOUT) */ * FROM t2
 WHERE t2.a IN (SELECT /*+ QB_NAME(subq1) */ a FROM t3);
```

Syntax of hints that affect whether to use subquery materialization or [IN-to-EXISTS](#) transformations:

```
SUBQUERY([@query_block_name] strategy)
```

The hint name is always [SUBQUERY](#).

For [SUBQUERY](#) hints, these *strategy* values are permitted: [INTOEXISTS](#), [MATERIALIZATION](#).

Examples:

```
SELECT id, a IN (SELECT /*+ SUBQUERY(MATERIALIZATION) */ a FROM t1) FROM t2;
SELECT * FROM t2 WHERE t2.a IN (SELECT /*+ SUBQUERY(INTOEXISTS) */ a FROM t1);
```

For semijoin and [SUBQUERY](#) hints, a leading [@query\\_block\\_name](#) specifies the query block to which the hint applies. If the hint includes no leading [@query\\_block\\_name](#), the hint applies to the query block in which it occurs. To assign a name to a query block, see [Optimizer Hints for Naming Query Blocks](#).

If a hint comment contains multiple subquery hints, the first is used. If there are other following hints of that type, they produce a warning. Following hints of other types are silently ignored.

## Statement Execution Time Optimizer Hints

The [MAX\\_EXECUTION\\_TIME](#) hint is permitted only for [SELECT](#) statements. It places a limit *N* (a timeout value in milliseconds) on how long a statement is permitted to execute before the server terminates it:

```
MAX_EXECUTION_TIME(N)
```

Example with a timeout of 1 second (1000 milliseconds):

```
SELECT /*+ MAX_EXECUTION_TIME(1000) */ * FROM t1 INNER JOIN t2 WHERE ...
```

The [MAX\\_EXECUTION\\_TIME\(N\)](#) hint sets a statement execution timeout of *N* milliseconds. If this option is absent or *N* is 0, the statement timeout established by the [max\\_execution\\_time](#) system variable applies.

The [MAX\\_EXECUTION\\_TIME](#) hint is applicable as follows:

- For statements with multiple [SELECT](#) keywords, such as unions or statements with subqueries, [MAX\\_EXECUTION\\_TIME](#) applies to the entire statement and must appear after the first [SELECT](#).
- It applies to read-only [SELECT](#) statements. Statements that are not read only are those that invoke a stored function that modifies data as a side effect.
- It does not apply to [SELECT](#) statements in stored programs and is ignored.

## Variable-Setting Hint Syntax

The [SET\\_VAR](#) hint sets the session value of a system variable temporarily (for the duration of a single statement). Examples:

```
SELECT /*+ SET_VAR(sort_buffer_size = 16M) */ name FROM people ORDER BY name;
INSERT /*+ SET_VAR(foreign_key_checks=OFF) */ INTO t2 VALUES(2);
SELECT /*+ SET_VAR(optimizer_switch = 'mrr_cost_based=off') */ 1;
```

Syntax of the `SET_VAR` hint:

```
SET_VAR(var_name = value)
```

*var\_name* names a system variable that has a session value (although not all such variables can be named, as explained later). *value* is the value to assign to the variable; the value must be a scalar.

`SET_VAR` makes a temporary variable change, as demonstrated by these statements:

```
mysql> SELECT @@unique_checks;
+-----+
| @@unique_checks |
+-----+
| 1 |
+-----+
mysql> SELECT /*+ SET_VAR(unique_checks=OFF) */ @@unique_checks;
+-----+
| @@unique_checks |
+-----+
| 0 |
+-----+
mysql> SELECT @@unique_checks;
+-----+
| @@unique_checks |
+-----+
| 1 |
+-----+
```

With `SET_VAR`, there is no need to save and restore the variable value. This enables you to replace multiple statements by a single statement. Consider this sequence of statements:

```
SET @saved_val = @@SESSION.var_name;
SET @@SESSION.var_name = value;
SELECT ...
SET @@SESSION.var_name = @saved_val;
```

The sequence can be replaced by this single statement:

```
SELECT /*+ SET_VAR(var_name = value) ...
```

Standalone `SET` statements permit any of these syntaxes for naming session variables:

```
SET SESSION var_name = value;
SET @@SESSION.var_name = value;
SET @@.var_name = value;
```

Because the `SET_VAR` hint applies only to session variables, session scope is implicit, and `SESSION`, `@@SESSION.`, and `@@` are neither needed nor permitted. Including explicit session-indicator syntax results in the `SET_VAR` hint being ignored with a warning.

Not all session variables are permitted for use with `SET_VAR`. Individual system variable descriptions indicate whether each variable is hintable; see [Section 7.1.8, “Server System Variables”](#). You can also check a system variable at runtime by attempting to use it with `SET_VAR`. If the variable is not hintable, a warning occurs:

```
mysql> SELECT /*+ SET_VAR(collation_server = 'utf8mb4') */ 1;
+----+
| 1 |
+----+
| 1 |
+----+
1 row in set, 1 warning (0.00 sec)
```

```
mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Warning
Code: 4537
Message: Variable 'collation_server' cannot be set using SET_VAR hint.
```

[SET\\_VAR](#) syntax permits setting only a single variable, but multiple hints can be given to set multiple variables:

```
SELECT /*+ SET_VAR(optimizer_switch = 'mrr_cost_based=off')
 SET_VAR(max_heap_table_size = 1G) */ 1;
```

If several hints with the same variable name appear in the same statement, the first one is applied and the others are ignored with a warning:

```
SELECT /*+ SET_VAR(max_heap_table_size = 1G)
 SET_VAR(max_heap_table_size = 3G) */ 1;
```

In this case, the second hint is ignored with a warning that it is conflicting.

A [SET\\_VAR](#) hint is ignored with a warning if no system variable has the specified name or the variable value is incorrect:

```
SELECT /*+ SET_VAR(max_size = 1G) */ 1;
SELECT /*+ SET_VAR(optimizer_switch = 'mrr_cost_based=yes') */ 1;
```

For the first statement, there is no [max\\_size](#) variable. For the second statement, [mrr\\_cost\\_based](#) takes values of [on](#) or [off](#), so attempting to set it to [yes](#) is incorrect. In each case, the hint is ignored with a warning.

The [SET\\_VAR](#) hint is permitted only at the statement level. If used in a subquery, the hint is ignored with a warning.

Replicas ignore [SET\\_VAR](#) hints in replicated statements to avoid the potential for security issues.

## Resource Group Hint Syntax

The [RESOURCE\\_GROUP](#) optimizer hint is used for resource group management (see [Section 7.1.16, “Resource Groups”](#)). This hint assigns the thread that executes a statement to the named resource group temporarily (for the duration of the statement). It requires the [RESOURCE\\_GROUP\\_ADMIN](#) or [RESOURCE\\_GROUP\\_USER](#) privilege.

Examples:

```
SELECT /*+ RESOURCE_GROUP(USR_default) */ name FROM people ORDER BY name;
INSERT /*+ RESOURCE_GROUP(Batch) */ INTO t2 VALUES(2);
```

Syntax of the [RESOURCE\\_GROUP](#) hint:

```
RESOURCE_GROUP (group_name)
```

[group\\_name](#) indicates the resource group to which the thread should be assigned for the duration of statement execution. If the group is nonexistent, a warning occurs and the hint is ignored.

The [RESOURCE\\_GROUP](#) hint must appear after the initial statement keyword ([SELECT](#), [INSERT](#), [REPLACE](#), [UPDATE](#), or [DELETE](#)).

An alternative to [RESOURCE\\_GROUP](#) is the [SET RESOURCE GROUP](#) statement, which nontemporarily assigns threads to a resource group. See [Section 15.7.2.4, “SET RESOURCE GROUP Statement”](#).

## Optimizer Hints for Naming Query Blocks

Table-level, index-level, and subquery optimizer hints permit specific query blocks to be named as part of their argument syntax. To create these names, use the `QB_NAME` hint, which assigns a name to the query block in which it occurs:

```
QB_NAME(name)
```

`QB_NAME` hints can be used to make explicit in a clear way which query blocks other hints apply to. They also permit all non-query block name hints to be specified within a single hint comment for easier understanding of complex statements. Consider the following statement:

```
SELECT ...
 FROM (SELECT ...
 FROM (SELECT ... FROM ...)) ...
```

`QB_NAME` hints assign names to query blocks in the statement:

```
SELECT /*+ QB_NAME(qb1) */ ...
 FROM (SELECT /*+ QB_NAME(qb2) */ ...
 FROM (SELECT /*+ QB_NAME(qb3) */ ... FROM ...)) ...
```

Then other hints can use those names to refer to the appropriate query blocks:

```
SELECT /*+ QB_NAME(qb1) MRR(@qb1 t1) BKA(@qb2) NO_MRR(@qb3t1 idx1, id2) */ ...
 FROM (SELECT /*+ QB_NAME(qb2) */ ...
 FROM (SELECT /*+ QB_NAME(qb3) */ ... FROM ...)) ...
```

The resulting effect is as follows:

- `MRR(@qb1 t1)` applies to table `t1` in query block `qb1`.
- `BKA(@qb2)` applies to query block `qb2`.
- `NO_MRR(@qb3 t1 idx1, id2)` applies to indexes `idx1` and `idx2` in table `t1` in query block `qb3`.

Query block names are identifiers and follow the usual rules about what names are valid and how to quote them (see [Section 11.2, “Schema Object Names”](#)). For example, a query block name that contains spaces must be quoted, which can be done using backticks:

```
SELECT /*+ BKA(@`my hint name`) */ ...
 FROM (SELECT /*+ QB_NAME(`my hint name`) */ ...) ...
```

If the `ANSI_QUOTES` SQL mode is enabled, it is also possible to quote query block names within double quotation marks:

```
SELECT /*+ BKA(@"my hint name") */ ...
 FROM (SELECT /*+ QB_NAME("my hint name") */ ...) ...
```

### 10.9.4 Index Hints

Index hints give the optimizer information about how to choose indexes during query processing. Index hints, described here, differ from optimizer hints, described in [Section 10.9.3, “Optimizer Hints”](#). Index and optimizer hints may be used separately or together.

Index hints apply to `SELECT` and `UPDATE` statements. They also work with multi-table `DELETE` statements, but not with single-table `DELETE`, as shown later in this section.

Index hints are specified following a table name. (For the general syntax for specifying tables in a `SELECT` statement, see [Section 15.2.13.2, “JOIN Clause”](#).) The syntax for referring to an individual table, including index hints, looks like this:

```
tbl_name [[AS] alias] [index_hint_list]

index_hint_list:
 index_hint [index_hint] ...

index_hint:
 USE {INDEX|KEY}
 [FOR {JOIN|ORDER BY|GROUP BY}] ([index_list])
 | {IGNORE|FORCE} {INDEX|KEY}
 [FOR {JOIN|ORDER BY|GROUP BY}] (index_list)

index_list:
 index_name [, index_name] ...
```

The `USE INDEX (index_list)` hint tells MySQL to use only one of the named indexes to find rows in the table. The alternative syntax `IGNORE INDEX (index_list)` tells MySQL to not use some particular index or indexes. These hints are useful if `EXPLAIN` shows that MySQL is using the wrong index from the list of possible indexes.

The `FORCE INDEX` hint acts like `USE INDEX (index_list)`, with the addition that a table scan is assumed to be *very* expensive. In other words, a table scan is used only if there is no way to use one of the named indexes to find rows in the table.

#### Note

MySQL 9.1 supports the index-level optimizer hints `JOIN_INDEX`, `GROUP_INDEX`, `ORDER_INDEX`, and `INDEX`, which are equivalent to and intended to supersede `FORCE INDEX` index hints, as well as the `NO_JOIN_INDEX`, `NO_GROUP_INDEX`, `NO_ORDER_INDEX`, and `NO_INDEX` optimizer hints, which are equivalent to and intended to supersede `IGNORE INDEX` index hints. Thus, you should expect `USE INDEX`, `FORCE INDEX`, and `IGNORE INDEX` to be deprecated in a future release of MySQL, and at some time thereafter to be removed altogether.

These index-level optimizer hints are supported with both single-table and multi-table `DELETE` statements.

For more information, see [Index-Level Optimizer Hints](#).

Each hint requires index names, not column names. To refer to a primary key, use the name `PRIMARY`. To see the index names for a table, use the `SHOW INDEX` statement or the Information Schema `STATISTICS` table.

An `index_name` value need not be a full index name. It can be an unambiguous prefix of an index name. If a prefix is ambiguous, an error occurs.

#### Examples:

```
SELECT * FROM table1 USE INDEX (col1_index,col2_index)
WHERE col1=1 AND col2=2 AND col3=3;

SELECT * FROM table1 IGNORE INDEX (col3_index)
WHERE col1=1 AND col2=2 AND col3=3;
```

The syntax for index hints has the following characteristics:

- It is syntactically valid to omit `index_list` for `USE INDEX`, which means “use no indexes.” Omitting `index_list` for `FORCE INDEX` or `IGNORE INDEX` is a syntax error.
- You can specify the scope of an index hint by adding a `FOR` clause to the hint. This provides more fine-grained control over optimizer selection of an execution plan for various phases of query processing.

To affect only the indexes used when MySQL decides how to find rows in the table and how to process joins, use `FOR JOIN`. To influence index usage for sorting or grouping rows, use `FOR ORDER BY` or `FOR GROUP BY`.

- You can specify multiple index hints:

```
SELECT * FROM t1 USE INDEX (i1) IGNORE INDEX FOR ORDER BY (i2) ORDER BY a;
```

It is not an error to name the same index in several hints (even within the same hint):

```
SELECT * FROM t1 USE INDEX (i1) USE INDEX (i1,i1);
```

However, it is an error to mix `USE INDEX` and `FORCE INDEX` for the same table:

```
SELECT * FROM t1 USE INDEX FOR JOIN (i1) FORCE INDEX FOR JOIN (i2);
```

If an index hint includes no `FOR` clause, the scope of the hint is to apply to all parts of the statement. For example, this hint:

```
IGNORE INDEX (i1)
```

is equivalent to this combination of hints:

```
IGNORE INDEX FOR JOIN (i1)
IGNORE INDEX FOR ORDER BY (i1)
IGNORE INDEX FOR GROUP BY (i1)
```

When index hints are processed, they are collected in a single list by type (`USE`, `FORCE`, `IGNORE`) and by scope (`FOR JOIN`, `FOR ORDER BY`, `FOR GROUP BY`). For example:

```
SELECT * FROM t1
 USE INDEX () IGNORE INDEX (i2) USE INDEX (i1) USE INDEX (i2);
```

is equivalent to:

```
SELECT * FROM t1
 USE INDEX (i1,i2) IGNORE INDEX (i2);
```

The index hints then are applied for each scope in the following order:

- `{USE|FORCE} INDEX` is applied if present. (If not, the optimizer-determined set of indexes is used.)
- `IGNORE INDEX` is applied over the result of the previous step. For example, the following two queries are equivalent:

```
SELECT * FROM t1 USE INDEX (i1) IGNORE INDEX (i2) USE INDEX (i2);
SELECT * FROM t1 USE INDEX (i1);
```

For `FULLTEXT` searches, index hints work as follows:

- For natural language mode searches, index hints are silently ignored. For example, `IGNORE INDEX (i1)` is ignored with no warning and the index is still used.
- For boolean mode searches, index hints with `FOR ORDER BY` or `FOR GROUP BY` are silently ignored. Index hints with `FOR JOIN` or no `FOR` modifier are honored. In contrast to how hints apply for non-`FULLTEXT` searches, the hint is used for all phases of query execution (finding rows and retrieval, grouping, and ordering). This is true even if the hint is given for a non-`FULLTEXT` index.

For example, the following two queries are equivalent:

```
SELECT * FROM t
```

```

USE INDEX (index1)
IGNORE INDEX FOR ORDER BY (index1)
IGNORE INDEX FOR GROUP BY (index1)
WHERE ... IN BOOLEAN MODE ... ;

SELECT * FROM t
USE INDEX (index1)
WHERE ... IN BOOLEAN MODE ... ;

```

Index hints work with `DELETE` statements, but only if you use multi-table `DELETE` syntax, as shown here:

```

mysql> EXPLAIN DELETE FROM t1 USE INDEX(col2)
-> WHERE col1 BETWEEN 1 AND 100 AND COL2 BETWEEN 1 AND 100\G
ERROR 1064 (42000): You have an error in your SQL syntax; check the manual that
corresponds to your MySQL server version for the right syntax to use near 'use
index(col2) where col1 between 1 and 100 and col2 between 1 and 100' at line 1

mysql> EXPLAIN DELETE t1.* FROM t1 USE INDEX(col2)
-> WHERE col1 BETWEEN 1 AND 100 AND COL2 BETWEEN 1 AND 100\G
***** 1. row *****
 id: 1
 select_type: DELETE
 table: t1
 partitions: NULL
 type: range
possible_keys: col2
 key: col2
 key_len: 5
 ref: NULL
 rows: 72
 filtered: 11.11
 Extra: Using where
1 row in set, 1 warning (0.00 sec)

```

## 10.9.5 The Optimizer Cost Model

To generate execution plans, the optimizer uses a cost model that is based on estimates of the cost of various operations that occur during query execution. The optimizer has a set of compiled-in default “cost constants” available to it to make decisions regarding execution plans.

The optimizer also has a database of cost estimates to use during execution plan construction. These estimates are stored in the `server_cost` and `engine_cost` tables in the `mysql` system database and are configurable at any time. The intent of these tables is to make it possible to easily adjust the cost estimates that the optimizer uses when it attempts to arrive at query execution plans.

- [Cost Model General Operation](#)
- [The Cost Model Database](#)
- [Making Changes to the Cost Model Database](#)

### Cost Model General Operation

The configurable optimizer cost model works like this:

- The server reads the cost model tables into memory at startup and uses the in-memory values at runtime. Any non-`NULL` cost estimate specified in the tables takes precedence over the corresponding compiled-in default cost constant. Any `NULL` estimate indicates to the optimizer to use the compiled-in default.
- At runtime, the server may re-read the cost tables. This occurs when a storage engine is dynamically loaded or when a `FLUSH OPTIMIZER_COSTS` statement is executed.

- Cost tables enable server administrators to easily adjust cost estimates by changing entries in the tables. It is also easy to revert to a default by setting an entry's cost to `NULL`. The optimizer uses the in-memory cost values, so changes to the tables should be followed by `FLUSH OPTIMIZER_COSTS` to take effect.
- The in-memory cost estimates that are current when a client session begins apply throughout that session until it ends. In particular, if the server re-reads the cost tables, any changed estimates apply only to subsequently started sessions. Existing sessions are unaffected.
- Cost tables are specific to a given server instance. The server does not replicate cost table changes to replicas.

### The Cost Model Database

The optimizer cost model database consists of two tables in the `mysql` system database that contain cost estimate information for operations that occur during query execution:

- `server_cost`: Optimizer cost estimates for general server operations
- `engine_cost`: Optimizer cost estimates for operations specific to particular storage engines

The `server_cost` table contains these columns:

- `cost_name`

The name of a cost estimate used in the cost model. The name is not case-sensitive. If the server does not recognize the cost name when it reads this table, it writes a warning to the error log.

- `cost_value`

The cost estimate value. If the value is non-`NULL`, the server uses it as the cost. Otherwise, it uses the default estimate (the compiled-in value). DBAs can change a cost estimate by updating this column. If the server finds that the cost value is invalid (nonpositive) when it reads this table, it writes a warning to the error log.

To override a default cost estimate (for an entry that specifies `NULL`), set the cost to a non-`NULL` value. To revert to the default, set the value to `NULL`. Then execute `FLUSH OPTIMIZER_COSTS` to tell the server to re-read the cost tables.

- `last_update`

The time of the last row update.

- `comment`

A descriptive comment associated with the cost estimate. DBAs can use this column to provide information about why a cost estimate row stores a particular value.

- `default_value`

The default (compiled-in) value for the cost estimate. This column is a read-only generated column that retains its value even if the associated cost estimate is changed. For rows added to the table at runtime, the value of this column is `NULL`.

The primary key for the `server_cost` table is the `cost_name` column, so it is not possible to create multiple entries for any cost estimate.

The server recognizes these `cost_name` values for the `server_cost` table:

- `disk temptable_create_cost`, `disk temptable_row_cost`

The cost estimates for internally created temporary tables stored in a disk-based storage engine (either [InnoDB](#) or [MyISAM](#)). Increasing these values increases the cost estimate of using internal temporary tables and makes the optimizer prefer query plans with less use of them. For information about such tables, see [Section 10.4.4, “Internal Temporary Table Use in MySQL”](#).

The larger default values for these disk parameters compared to the default values for the corresponding memory parameters ([memory\\_temptable\\_create\\_cost](#), [memory\\_temptable\\_row\\_cost](#)) reflects the greater cost of processing disk-based tables.

- [key\\_compare\\_cost](#)

The cost of comparing record keys. Increasing this value causes a query plan that compares many keys to become more expensive. For example, a query plan that performs a [filesort](#) becomes relatively more expensive compared to a query plan that avoids sorting by using an index.

- [memory\\_temptable\\_create\\_cost](#), [memory\\_temptable\\_row\\_cost](#)

The cost estimates for internally created temporary tables stored in the [MEMORY](#) storage engine. Increasing these values increases the cost estimate of using internal temporary tables and makes the optimizer prefer query plans with less use of them. For information about such tables, see [Section 10.4.4, “Internal Temporary Table Use in MySQL”](#).

The smaller default values for these memory parameters compared to the default values for the corresponding disk parameters ([disk\\_temptable\\_create\\_cost](#), [disk\\_temptable\\_row\\_cost](#)) reflects the lesser cost of processing memory-based tables.

- [row\\_evaluate\\_cost](#)

The cost of evaluating record conditions. Increasing this value causes a query plan that examines many rows to become more expensive compared to a query plan that examines fewer rows. For example, a table scan becomes relatively more expensive compared to a range scan that reads fewer rows.

The [engine\\_cost](#) table contains these columns:

- [engine\\_name](#)

The name of the storage engine to which this cost estimate applies. The name is not case-sensitive. If the value is [default](#), it applies to all storage engines that have no named entry of their own. If the server does not recognize the engine name when it reads this table, it writes a warning to the error log.

- [device\\_type](#)

The device type to which this cost estimate applies. The column is intended for specifying different cost estimates for different storage device types, such as hard disk drives versus solid state drives. Currently, this information is not used and 0 is the only permitted value.

- [cost\\_name](#)

Same as in the [server\\_cost](#) table.

- [cost\\_value](#)

Same as in the [server\\_cost](#) table.

- [last\\_update](#)

Same as in the [server\\_cost](#) table.

- `comment`

Same as in the `server_cost` table.

- `default_value`

The default (compiled-in) value for the cost estimate. This column is a read-only generated column that retains its value even if the associated cost estimate is changed. For rows added to the table at runtime, the value of this column is `NULL`, with the exception that if the row has the same `cost_name` value as one of the original rows, the `default_value` column has the same value as that row.

The primary key for the `engine_cost` table is a tuple comprising the (`cost_name`, `engine_name`, `device_type`) columns, so it is not possible to create multiple entries for any combination of values in those columns.

The server recognizes these `cost_name` values for the `engine_cost` table:

- `io_block_read_cost`

The cost of reading an index or data block from disk. Increasing this value causes a query plan that reads many disk blocks to become more expensive compared to a query plan that reads fewer disk blocks. For example, a table scan becomes relatively more expensive compared to a range scan that reads fewer blocks.

- `memory_block_read_cost`

Similar to `io_block_read_cost`, but represents the cost of reading an index or data block from an in-memory database buffer.

If the `io_block_read_cost` and `memory_block_read_cost` values differ, the execution plan may change between two runs of the same query. Suppose that the cost for memory access is less than the cost for disk access. In that case, at server startup before data has been read into the buffer pool, you may get a different plan than after the query has been run because then the data is in memory.

## Making Changes to the Cost Model Database

For DBAs who wish to change the cost model parameters from their defaults, try doubling or halving the value and measuring the effect.

Changes to the `io_block_read_cost` and `memory_block_read_cost` parameters are most likely to yield worthwhile results. These parameter values enable cost models for data access methods to take into account the costs of reading information from different sources; that is, the cost of reading information from disk versus reading information already in a memory buffer. For example, all other things being equal, setting `io_block_read_cost` to a value larger than `memory_block_read_cost` causes the optimizer to prefer query plans that read information already held in memory to plans that must read from disk.

This example shows how to change the default value for `io_block_read_cost`:

```
UPDATE mysql.engine_cost
SET cost_value = 2.0
WHERE cost_name = 'io_block_read_cost';
FLUSH OPTIMIZER_COSTS;
```

This example shows how to change the value of `io_block_read_cost` only for the `InnoDB` storage engine:

```
INSERT INTO mysql.engine_cost
VALUES ('InnoDB', 0, 'io_block_read_cost', 3.0,
CURRENT_TIMESTAMP, 'Using a slower disk for InnoDB');
FLUSH OPTIMIZER_COSTS;
```

## 10.9.6 Optimizer Statistics

The `column_statistics` data dictionary table stores histogram statistics about column values, for use by the optimizer in constructing query execution plans. To perform histogram management, use the `ANALYZE TABLE` statement.

The `column_statistics` table has these characteristics:

- The table contains statistics for columns of all data types except geometry types (spatial data) and `JSON`.
- The table is persistent so that column statistics need not be created each time the server starts.
- The server performs updates to the table; users do not.

The `column_statistics` table is not directly accessible by users because it is part of the data dictionary. Histogram information is available using `INFORMATION_SCHEMA.COLUMN_STATISTICS`, which is implemented as a view on the data dictionary table. `COLUMN_STATISTICS` has these columns:

- `SCHEMA_NAME`, `TABLE_NAME`, `COLUMN_NAME`: The names of the schema, table, and column for which the statistics apply.
- `HISTOGRAM`: A `JSON` value describing the column statistics, stored as a histogram.

Column histograms contain buckets for parts of the range of values stored in the column. Histograms are `JSON` objects to permit flexibility in the representation of column statistics. Here is a sample histogram object:

```
{
 "buckets": [
 [
 1,
 0.3333333333333333
],
 [
 2,
 0.6666666666666666
],
 [
 3,
 1
]
],
 "null-values": 0,
 "last-updated": "2017-03-24 13:32:40.000000",
 "sampling-rate": 1,
 "histogram-type": "singleton",
 "number-of-buckets-specified": 128,
 "data-type": "int",
 "collation-id": 8
}
```

Histogram objects have these keys:

- `buckets`: The histogram buckets. Bucket structure depends on the histogram type.

For `singleton` histograms, buckets contain two values:

- Value 1: The value for the bucket. The type depends on the column data type.
- Value 2: A double representing the cumulative frequency for the value. For example, .25 and .75 indicate that 25% and 75% of the values in the column are less than or equal to the bucket value.

For `equi-height` histograms, buckets contain four values:

- Values 1, 2: The lower and upper inclusive values for the bucket. The type depends on the column data type.
- Value 3: A double representing the cumulative frequency for the value. For example, .25 and .75 indicate that 25% and 75% of the values in the column are less than or equal to the bucket upper value.
- Value 4: The number of distinct values in the range from the bucket lower value to its upper value.
- `null-values`: A number between 0.0 and 1.0 indicating the fraction of column values that are SQL `NULL` values. If 0, the column contains no `NULL` values.
- `last-updated`: When the histogram was generated, as a UTC value in `YYYY-MM-DD hh:mm:ss.uuuuuu` format.
- `sampling-rate`: A number between 0.0 and 1.0 indicating the fraction of data that was sampled to create the histogram. A value of 1 means that all of the data was read (no sampling).
- `histogram-type`: The histogram type:
  - `singleton`: One bucket represents one single value in the column. This histogram type is created when the number of distinct values in the column is less than or equal to the number of buckets specified in the `ANALYZE TABLE` statement that generated the histogram.
  - `equi-height`: One bucket represents a range of values. This histogram type is created when the number of distinct values in the column is greater than the number of buckets specified in the `ANALYZE TABLE` statement that generated the histogram.
- `number-of-buckets-specified`: The number of buckets specified in the `ANALYZE TABLE` statement that generated the histogram.
- `data-type`: The type of data this histogram contains. This is needed when reading and parsing histograms from persistent storage into memory. The value is one of `int`, `uint` (unsigned integer), `double`, `decimal`, `datetime`, or `string` (includes character and binary strings).
- `collation-id`: The collation ID for the histogram data. It is mostly meaningful when the `data-type` value is `string`. Values correspond to `ID` column values in the Information Schema `COLLATIONS` table.

To extract particular values from the histogram objects, you can use `JSON` operations. For example:

```
mysql> SELECT
 TABLE_NAME, COLUMN_NAME,
 HISTOGRAM->>'$.data-type' AS 'data-type',
 JSON_LENGTH(HISTOGRAM->>'$.buckets') AS 'bucket-count'
 FROM INFORMATION_SCHEMA.COLUMN_STATISTICS;
```

TABLE_NAME	COLUMN_NAME	data-type	bucket-count
country	Population	int	226
city	Population	int	1024
countrylanguage	Language	string	457

The optimizer uses histogram statistics, if applicable, for columns of any data type for which statistics are collected. The optimizer applies histogram statistics to determine row estimates based on the selectivity (filtering effect) of column value comparisons against constant values. Predicates of these forms qualify for histogram use:

```

col_name = constant
col_name <> constant
col_name != constant
col_name > constant
col_name < constant
col_name >= constant
col_name <= constant
col_name IS NULL
col_name IS NOT NULL
col_name BETWEEN constant AND constant
col_name NOT BETWEEN constant AND constant
col_name IN (constant[, constant] ...)
col_name NOT IN (constant[, constant] ...)

```

For example, these statements contain predicates that qualify for histogram use:

```

SELECT * FROM orders WHERE amount BETWEEN 100.0 AND 300.0;
SELECT * FROM tbl WHERE col1 = 15 AND col2 > 100;

```

The requirement for comparison against a constant value includes functions that are constant, such as `ABS()` and `FLOOR()`:

```

SELECT * FROM tbl WHERE col1 < ABS(-34);

```

Histogram statistics are useful primarily for nonindexed columns. Adding an index to a column for which histogram statistics are applicable might also help the optimizer make row estimates. The tradeoffs are:

- An index must be updated when table data is modified.
- A histogram is created or updated only on demand, so it adds no overhead when table data is modified. On the other hand, the statistics become progressively more out of date when table modifications occur, until the next time they are updated.

The optimizer prefers range optimizer row estimates to those obtained from histogram statistics. If the optimizer determines that the range optimizer applies, it does not use histogram statistics.

For columns that are indexed, row estimates can be obtained for equality comparisons using index dives (see [Section 10.2.1.2, “Range Optimization”](#)). In this case, histogram statistics are not necessarily useful because index dives can yield better estimates.

In some cases, use of histogram statistics may not improve query execution (for example, if the statistics are out of date). To check whether this is the case, use `ANALYZE TABLE` to regenerate the histogram statistics, then run the query again.

Alternatively, to disable histogram statistics, use `ANALYZE TABLE` to drop them. A different method of disabling histogram statistics is to turn off the `condition_fanout_filter` flag of the `optimizer_switch` system variable (although this may disable other optimizations as well):

```

SET optimizer_switch='condition_fanout_filter=off';

```

If histogram statistics are used, the resulting effect is visible using `EXPLAIN`. Consider the following query, where no index is available for column `col1`:

```

SELECT * FROM t1 WHERE col1 < 24;

```

If histogram statistics indicate that 57% of the rows in `t1` satisfy the `col1 < 24` predicate, filtering can occur even in the absence of an index, and `EXPLAIN` shows 57.00 in the `filtered` column.

## 10.10 Buffering and Caching

MySQL uses several strategies that cache information in memory buffers to increase performance.

## 10.10.1 InnoDB Buffer Pool Optimization

[InnoDB](#) maintains a storage area called the [buffer pool](#) for caching data and indexes in memory. Knowing how the [InnoDB](#) buffer pool works, and taking advantage of it to keep frequently accessed data in memory, is an important aspect of MySQL tuning.

For an explanation of the inner workings of the [InnoDB](#) buffer pool, an overview of its LRU replacement algorithm, and general configuration information, see [Section 17.5.1, “Buffer Pool”](#).

For additional [InnoDB](#) buffer pool configuration and tuning information, see these sections:

- [Section 17.8.3.4, “Configuring InnoDB Buffer Pool Prefetching \(Read-Ahead\)”](#)
- [Section 17.8.3.5, “Configuring Buffer Pool Flushing”](#)
- [Section 17.8.3.3, “Making the Buffer Pool Scan Resistant”](#)
- [Section 17.8.3.2, “Configuring Multiple Buffer Pool Instances”](#)
- [Section 17.8.3.6, “Saving and Restoring the Buffer Pool State”](#)
- [Section 17.8.3.1, “Configuring InnoDB Buffer Pool Size”](#)

## 10.10.2 The MyISAM Key Cache

To minimize disk I/O, the [MyISAM](#) storage engine exploits a strategy that is used by many database management systems. It employs a cache mechanism to keep the most frequently accessed table blocks in memory:

- For index blocks, a special structure called the *key cache* (or *key buffer*) is maintained. The structure contains a number of block buffers where the most-used index blocks are placed.
- For data blocks, MySQL uses no special cache. Instead it relies on the native operating system file system cache.

This section first describes the basic operation of the [MyISAM](#) key cache. Then it discusses features that improve key cache performance and that enable you to better control cache operation:

- Multiple sessions can access the cache concurrently.
- You can set up multiple key caches and assign table indexes to specific caches.

To control the size of the key cache, use the [key\\_buffer\\_size](#) system variable. If this variable is set equal to zero, no key cache is used. The key cache also is not used if the [key\\_buffer\\_size](#) value is too small to allocate the minimal number of block buffers (8).

When the key cache is not operational, index files are accessed using only the native file system buffering provided by the operating system. (In other words, table index blocks are accessed using the same strategy as that employed for table data blocks.)

An index block is a contiguous unit of access to the [MyISAM](#) index files. Usually the size of an index block is equal to the size of nodes of the index B-tree. (Indexes are represented on disk using a B-tree data structure. Nodes at the bottom of the tree are leaf nodes. Nodes above the leaf nodes are nonleaf nodes.)

All block buffers in a key cache structure are the same size. This size can be equal to, greater than, or less than the size of a table index block. Usually one these two values is a multiple of the other.

When data from any table index block must be accessed, the server first checks whether it is available in some block buffer of the key cache. If it is, the server accesses data in the key cache rather than on disk.

That is, it reads from the cache or writes into it rather than reading from or writing to disk. Otherwise, the server chooses a cache block buffer containing a different table index block (or blocks) and replaces the data there by a copy of required table index block. As soon as the new index block is in the cache, the index data can be accessed.

If it happens that a block selected for replacement has been modified, the block is considered “dirty.” In this case, prior to being replaced, its contents are flushed to the table index from which it came.

Usually the server follows an *LRU (Least Recently Used)* strategy: When choosing a block for replacement, it selects the least recently used index block. To make this choice easier, the key cache module maintains all used blocks in a special list (*LRU chain*) ordered by time of use. When a block is accessed, it is the most recently used and is placed at the end of the list. When blocks need to be replaced, blocks at the beginning of the list are the least recently used and become the first candidates for eviction.

The [InnoDB](#) storage engine also uses an LRU algorithm, to manage its buffer pool. See [Section 17.5.1, “Buffer Pool”](#).

### 10.10.2.1 Shared Key Cache Access

Threads can access key cache buffers simultaneously, subject to the following conditions:

- A buffer that is not being updated can be accessed by multiple sessions.
- A buffer that is being updated causes sessions that need to use it to wait until the update is complete.
- Multiple sessions can initiate requests that result in cache block replacements, as long as they do not interfere with each other (that is, as long as they need different index blocks, and thus cause different cache blocks to be replaced).

Shared access to the key cache enables the server to improve throughput significantly.

### 10.10.2.2 Multiple Key Caches

#### Note

As of MySQL 9.1, the compound-part structured-variable syntax discussed here for referring to multiple [MyISAM](#) key caches is deprecated.

Shared access to the key cache improves performance but does not eliminate contention among sessions entirely. They still compete for control structures that manage access to the key cache buffers. To reduce key cache access contention further, MySQL also provides multiple key caches. This feature enables you to assign different table indexes to different key caches.

Where there are multiple key caches, the server must know which cache to use when processing queries for a given [MyISAM](#) table. By default, all [MyISAM](#) table indexes are cached in the default key cache. To assign table indexes to a specific key cache, use the [CACHE INDEX](#) statement (see [Section 15.7.8.2, “CACHE INDEX Statement”](#)). For example, the following statement assigns indexes from the tables `t1`, `t2`, and `t3` to the key cache named `hot_cache`:

```
mysql> CACHE INDEX t1, t2, t3 IN hot_cache;
```

Table	Op	Msg_type	Msg_text
test.t1	assign_to_keycache	status	OK
test.t2	assign_to_keycache	status	OK
test.t3	assign_to_keycache	status	OK

The key cache referred to in a `CACHE INDEX` statement can be created by setting its size with a `SET GLOBAL` parameter setting statement or by using server startup options. For example:

```
mysql> SET GLOBAL keycache1.key_buffer_size=128*1024;
```

To destroy a key cache, set its size to zero:

```
mysql> SET GLOBAL keycache1.key_buffer_size=0;
```

You cannot destroy the default key cache. Any attempt to do this is ignored:

```
mysql> SET GLOBAL key_buffer_size = 0;

mysql> SHOW VARIABLES LIKE 'key_buffer_size';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| key_buffer_size | 8384512 |
+-----+-----+
```

Key cache variables are structured system variables that have a name and components. For `keycache1.key_buffer_size`, `keycache1` is the cache variable name and `key_buffer_size` is the cache component. See [Section 7.1.9.5, “Structured System Variables”](#), for a description of the syntax used for referring to structured key cache system variables.

By default, table indexes are assigned to the main (default) key cache created at the server startup. When a key cache is destroyed, all indexes assigned to it are reassigned to the default key cache.

For a busy server, you can use a strategy that involves three key caches:

- A “hot” key cache that takes up 20% of the space allocated for all key caches. Use this for tables that are heavily used for searches but that are not updated.
- A “cold” key cache that takes up 20% of the space allocated for all key caches. Use this cache for medium-sized, intensively modified tables, such as temporary tables.
- A “warm” key cache that takes up 60% of the key cache space. Employ this as the default key cache, to be used by default for all other tables.

One reason the use of three key caches is beneficial is that access to one key cache structure does not block access to the others. Statements that access tables assigned to one cache do not compete with statements that access tables assigned to another cache. Performance gains occur for other reasons as well:

- The hot cache is used only for retrieval queries, so its contents are never modified. Consequently, whenever an index block needs to be pulled in from disk, the contents of the cache block chosen for replacement need not be flushed first.
- For an index assigned to the hot cache, if there are no queries requiring an index scan, there is a high probability that the index blocks corresponding to nonleaf nodes of the index B-tree remain in the cache.
- An update operation most frequently executed for temporary tables is performed much faster when the updated node is in the cache and need not be read from disk first. If the size of the indexes of the temporary tables are comparable with the size of cold key cache, the probability is very high that the updated node is in the cache.

The `CACHE INDEX` statement sets up an association between a table and a key cache, but the association is lost each time the server restarts. If you want the association to take effect each time the server starts, one way to accomplish this is to use an option file: Include variable settings that configure your key

caches, and an `init_file` system variable that names a file containing `CACHE INDEX` statements to be executed. For example:

```
key_buffer_size = 4G
hot_cache.key_buffer_size = 2G
cold_cache.key_buffer_size = 2G
init_file=/path/to/data-directory/mysql_init.sql
```

The statements in `mysql_init.sql` are executed each time the server starts. The file should contain one SQL statement per line. The following example assigns several tables each to `hot_cache` and `cold_cache`:

```
CACHE INDEX db1.t1, db1.t2, db2.t3 IN hot_cache
CACHE INDEX db1.t4, db2.t5, db2.t6 IN cold_cache
```

### 10.10.2.3 Midpoint Insertion Strategy

By default, the key cache management system uses a simple LRU strategy for choosing key cache blocks to be evicted, but it also supports a more sophisticated method called the *midpoint insertion strategy*.

When using the midpoint insertion strategy, the LRU chain is divided into two parts: a hot sublist and a warm sublist. The division point between two parts is not fixed, but the key cache management system takes care that the warm part is not “too short,” always containing at least `key_cache_division_limit` percent of the key cache blocks. `key_cache_division_limit` is a component of structured key cache variables, so its value is a parameter that can be set per cache.

When an index block is read from a table into the key cache, it is placed at the end of the warm sublist. After a certain number of hits (accesses of the block), it is promoted to the hot sublist. At present, the number of hits required to promote a block (3) is the same for all index blocks.

A block promoted into the hot sublist is placed at the end of the list. The block then circulates within this sublist. If the block stays at the beginning of the sublist for a long enough time, it is demoted to the warm sublist. This time is determined by the value of the `key_cache_age_threshold` component of the key cache.

The threshold value prescribes that, for a key cache containing  $N$  blocks, the block at the beginning of the hot sublist not accessed within the last  $N * \text{key\_cache\_age\_threshold} / 100$  hits is to be moved to the beginning of the warm sublist. It then becomes the first candidate for eviction, because blocks for replacement always are taken from the beginning of the warm sublist.

The midpoint insertion strategy enables you to keep more-valued blocks always in the cache. If you prefer to use the plain LRU strategy, leave the `key_cache_division_limit` value set to its default of 100.

The midpoint insertion strategy helps to improve performance when execution of a query that requires an index scan effectively pushes out of the cache all the index blocks corresponding to valuable high-level B-tree nodes. To avoid this, you must use a midpoint insertion strategy with the `key_cache_division_limit` set to much less than 100. Then valuable frequently hit nodes are preserved in the hot sublist during an index scan operation as well.

### 10.10.2.4 Index Preloading

If there are enough blocks in a key cache to hold blocks of an entire index, or at least the blocks corresponding to its nonleaf nodes, it makes sense to preload the key cache with index blocks before starting to use it. Preloading enables you to put the table index blocks into a key cache buffer in the most efficient way: by reading the index blocks from disk sequentially.

Without preloading, the blocks are still placed into the key cache as needed by queries. Although the blocks stay in the cache, because there are enough buffers for all of them, they are fetched from disk in random order, and not sequentially.

To preload an index into a cache, use the `LOAD INDEX INTO CACHE` statement. For example, the following statement preloads nodes (index blocks) of indexes of the tables `t1` and `t2`:

```
mysql> LOAD INDEX INTO CACHE t1, t2 IGNORE LEAVES;
```

Table	Op	Msg_type	Msg_text
test.t1	preload_keys	status	OK
test.t2	preload_keys	status	OK

The `IGNORE LEAVES` modifier causes only blocks for the nonleaf nodes of the index to be preloaded. Thus, the statement shown preloads all index blocks from `t1`, but only blocks for the nonleaf nodes from `t2`.

If an index has been assigned to a key cache using a `CACHE INDEX` statement, preloading places index blocks into that cache. Otherwise, the index is loaded into the default key cache.

### 10.10.2.5 Key Cache Block Size

It is possible to specify the size of the block buffers for an individual key cache using the `key_cache_block_size` variable. This permits tuning of the performance of I/O operations for index files.

The best performance for I/O operations is achieved when the size of read buffers is equal to the size of the native operating system I/O buffers. But setting the size of key nodes equal to the size of the I/O buffer does not always ensure the best overall performance. When reading the big leaf nodes, the server pulls in a lot of unnecessary data, effectively preventing reading other leaf nodes.

To control the size of blocks in the `.MYI` index file of `MyISAM` tables, use the `--myisam-block-size` option at server startup.

### 10.10.2.6 Restructuring a Key Cache

A key cache can be restructured at any time by updating its parameter values. For example:

```
mysql> SET GLOBAL cold_cache.key_buffer_size=4*1024*1024;
```

If you assign to either the `key_buffer_size` or `key_cache_block_size` key cache component a value that differs from the component's current value, the server destroys the cache's old structure and creates a new one based on the new values. If the cache contains any dirty blocks, the server saves them to disk before destroying and re-creating the cache. Restructuring does not occur if you change other key cache parameters.

When restructuring a key cache, the server first flushes the contents of any dirty buffers to disk. After that, the cache contents become unavailable. However, restructuring does not block queries that need to use indexes assigned to the cache. Instead, the server directly accesses the table indexes using native file system caching. File system caching is not as efficient as using a key cache, so although queries execute, a slowdown can be anticipated. After the cache has been restructured, it becomes available again for caching indexes assigned to it, and the use of file system caching for the indexes ceases.

## 10.10.3 Caching of Prepared Statements and Stored Programs

For certain statements that a client might execute multiple times during a session, the server converts the statement to an internal structure and caches that structure to be used during execution. Caching enables the server to perform more efficiently because it avoids the overhead of reconverting the statement should it be needed again during the session. Conversion and caching occurs for these statements:

- Prepared statements, both those processed at the SQL level (using the `PREPARE` statement) and those processed using the binary client/server protocol (using the `mysql_stmt_prepare()` C API function). The `max_prepared_stmt_count` system variable controls the total number of statements the server caches. (The sum of the number of prepared statements across all sessions.)
- Stored programs (stored procedures and functions, triggers, and events). In this case, the server converts and caches the entire program body. The `stored_program_cache` system variable indicates the approximate number of stored programs the server caches per session.

The server maintains caches for prepared statements and stored programs on a per-session basis. Statements cached for one session are not accessible to other sessions. When a session ends, the server discards any statements cached for it.

When the server uses a cached internal statement structure, it must take care that the structure does not go out of date. Metadata changes can occur for an object used by the statement, causing a mismatch between the current object definition and the definition as represented in the internal statement structure. Metadata changes occur for DDL statements such as those that create, drop, alter, rename, or truncate tables, or that analyze, optimize, or repair tables. Table content changes (for example, with `INSERT` or `UPDATE`) do not change metadata, nor do `SELECT` statements.

Here is an illustration of the problem. Suppose that a client prepares this statement:

```
PREPARE s1 FROM 'SELECT * FROM t1';
```

The `SELECT *` expands in the internal structure to the list of columns in the table. If the set of columns in the table is modified with `ALTER TABLE`, the prepared statement goes out of date. If the server does not detect this change the next time the client executes `s1`, the prepared statement returns incorrect results.

To avoid problems caused by metadata changes to tables or views referred to by the prepared statement, the server detects these changes and automatically reprepares the statement when it is next executed. That is, the server reparses the statement and rebuilds the internal structure. Reparsing also occurs after referenced tables or views are flushed from the table definition cache, either implicitly to make room for new entries in the cache, or explicitly due to `FLUSH TABLES`.

Similarly, if changes occur to objects used by a stored program, the server reparses affected statements within the program.

The server also detects metadata changes for objects in expressions. These might be used in statements specific to stored programs, such as `DECLARE CURSOR` or flow-control statements such as `IF`, `CASE`, and `RETURN`.

To avoid reparsing entire stored programs, the server reparses affected statements or expressions within a program only as needed. Examples:

- Suppose that metadata for a table or view is changed. Reparsing occurs for a `SELECT *` within the program that accesses the table or view, but not for a `SELECT *` that does not access the table or view.
- When a statement is affected, the server reparses it only partially if possible. Consider this `CASE` statement:

```
CASE case_expr
 WHEN when_expr1 ...
 WHEN when_expr2 ...
 WHEN when_expr3 ...
 ...
END CASE
```

If a metadata change affects only `WHEN when_expr3`, that expression is reparsed. `case_expr` and the other `WHEN` expressions are not reparsed.

Reparsing uses the default database and SQL mode that were in effect for the original conversion to internal form.

The server attempts reparsing up to three times. An error occurs if all attempts fail.

Reparsing is automatic, but to the extent that it occurs, diminishes prepared statement and stored program performance.

For prepared statements, the `Com_stmt_reprepare` status variable tracks the number of re Preparations.

## 10.11 Optimizing Locking Operations

MySQL manages contention for table contents using [locking](#):

- Internal locking is performed within the MySQL server itself to manage contention for table contents by multiple threads. This type of locking is internal because it is performed entirely by the server and involves no other programs. See [Section 10.11.1, “Internal Locking Methods”](#).
- External locking occurs when the server and other programs lock [MyISAM](#) table files to coordinate among themselves which program can access the tables at which time. See [Section 10.11.5, “External Locking”](#).

### 10.11.1 Internal Locking Methods

This section discusses internal locking; that is, locking performed within the MySQL server itself to manage contention for table contents by multiple sessions. This type of locking is internal because it is performed entirely by the server and involves no other programs. For locking performed on MySQL files by other programs, see [Section 10.11.5, “External Locking”](#).

- [Row-Level Locking](#)
- [Table-Level Locking](#)
- [Choosing the Type of Locking](#)

#### Row-Level Locking

MySQL uses [row-level locking](#) for [InnoDB](#) tables to support simultaneous write access by multiple sessions, making them suitable for multi-user, highly concurrent, and OLTP applications.

To avoid [deadlocks](#) when performing multiple concurrent write operations on a single [InnoDB](#) table, acquire necessary locks at the start of the transaction by issuing a `SELECT ... FOR UPDATE` statement for each group of rows expected to be modified, even if the data change statements come later in the transaction. If transactions modify or lock more than one table, issue the applicable statements in the same order within each transaction. Deadlocks affect performance rather than representing a serious error, because [InnoDB](#) automatically [detects](#) deadlock conditions by default and rolls back one of the affected transactions.

On high concurrency systems, deadlock detection can cause a slowdown when numerous threads wait for the same lock. At times, it may be more efficient to disable deadlock detection and rely on the `innodb_lock_wait_timeout` setting for transaction rollback when a deadlock occurs. Deadlock detection can be disabled using the `innodb_deadlock_detect` configuration option.

Advantages of row-level locking:

- Fewer lock conflicts when different sessions access different rows.
- Fewer changes for rollbacks.

- Possible to lock a single row for a long time.

## Table-Level Locking

MySQL uses [table-level locking](#) for [MyISAM](#), [MEMORY](#), and [MERGE](#) tables, permitting only one session to update those tables at a time. This locking level makes these storage engines more suitable for read-only, read-mostly, or single-user applications.

These storage engines avoid [deadlocks](#) by always requesting all needed locks at once at the beginning of a query and always locking the tables in the same order. The tradeoff is that this strategy reduces concurrency; other sessions that want to modify the table must wait until the current data change statement finishes.

Advantages of table-level locking:

- Relatively little memory required (row locking requires memory per row or group of rows locked)
- Fast when used on a large part of the table because only a single lock is involved.
- Fast if you often do [GROUP BY](#) operations on a large part of the data or must scan the entire table frequently.

MySQL grants table write locks as follows:

1. If there are no locks on the table, put a write lock on it.
2. Otherwise, put the lock request in the write lock queue.

MySQL grants table read locks as follows:

1. If there are no write locks on the table, put a read lock on it.
2. Otherwise, put the lock request in the read lock queue.

Table updates are given higher priority than table retrievals. Therefore, when a lock is released, the lock is made available to the requests in the write lock queue and then to the requests in the read lock queue. This ensures that updates to a table are not “starved” even when there is heavy [SELECT](#) activity for the table. However, if there are many updates for a table, [SELECT](#) statements wait until there are no more updates.

For information on altering the priority of reads and writes, see [Section 10.11.2, “Table Locking Issues”](#).

You can analyze the table lock contention on your system by checking the [Table\\_locks\\_immediate](#) and [Table\\_locks\\_waited](#) status variables, which indicate the number of times that requests for table locks could be granted immediately and the number that had to wait, respectively:

```
mysql> SHOW STATUS LIKE 'Table%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Table_locks_immediate | 1151552 |
| Table_locks_waited | 15324 |
+-----+-----+
```

The Performance Schema lock tables also provide locking information. See [Section 29.12.13, “Performance Schema Lock Tables”](#).

The [MyISAM](#) storage engine supports concurrent inserts to reduce contention between readers and writers for a given table: If a [MyISAM](#) table has no free blocks in the middle of the data file, rows are always inserted at the end of the data file. In this case, you can freely mix concurrent [INSERT](#) and [SELECT](#)

statements for a [MyISAM](#) table without locks. That is, you can insert rows into a [MyISAM](#) table at the same time other clients are reading from it. Holes can result from rows having been deleted from or updated in the middle of the table. If there are holes, concurrent inserts are disabled but are enabled again automatically when all holes have been filled with new data. To control this behavior, use the [concurrent\\_insert](#) system variable. See [Section 10.11.3, “Concurrent Inserts”](#).

If you acquire a table lock explicitly with [LOCK TABLES](#), you can request a [READ LOCAL](#) lock rather than a [READ](#) lock to enable other sessions to perform concurrent inserts while you have the table locked.

To perform many [INSERT](#) and [SELECT](#) operations on a table [t1](#) when concurrent inserts are not possible, you can insert rows into a temporary table [temp\\_t1](#) and update the real table with the rows from the temporary table:

```
mysql> LOCK TABLES t1 WRITE, temp_t1 WRITE;
mysql> INSERT INTO t1 SELECT * FROM temp_t1;
mysql> DELETE FROM temp_t1;
mysql> UNLOCK TABLES;
```

## Choosing the Type of Locking

Generally, table locks are superior to row-level locks in the following cases:

- Most statements for the table are reads.
- Statements for the table are a mix of reads and writes, where writes are updates or deletes for a single row that can be fetched with one key read:

```
UPDATE tbl_name SET column=value WHERE unique_key_col=key_value;
DELETE FROM tbl_name WHERE unique_key_col=key_value;
```

- [SELECT](#) combined with concurrent [INSERT](#) statements, and very few [UPDATE](#) or [DELETE](#) statements.
- Many scans or [GROUP BY](#) operations on the entire table without any writers.

With higher-level locks, you can more easily tune applications by supporting locks of different types, because the lock overhead is less than for row-level locks.

Options other than row-level locking:

- Versioning (such as that used in MySQL for concurrent inserts) where it is possible to have one writer at the same time as many readers. This means that the database or table supports different views for the data depending on when access begins. Other common terms for this are “time travel,” “copy on write,” or “copy on demand.”
- Copy on demand is in many cases superior to row-level locking. However, in the worst case, it can use much more memory than using normal locks.
- Instead of using row-level locks, you can employ application-level locks, such as those provided by [GET\\_LOCK\(\)](#) and [RELEASE\\_LOCK\(\)](#) in MySQL. These are advisory locks, so they work only with applications that cooperate with each other. See [Section 14.14, “Locking Functions”](#).

## 10.11.2 Table Locking Issues

[InnoDB](#) tables use row-level locking so that multiple sessions and applications can read from and write to the same table simultaneously, without making each other wait or producing inconsistent results. For this storage engine, avoid using the [LOCK TABLES](#) statement, because it does not offer any extra protection, but instead reduces concurrency. The automatic row-level locking makes these tables suitable for your busiest databases with your most important data, while also simplifying application logic since you do not need to lock and unlock tables. Consequently, the [InnoDB](#) storage engine is the default in MySQL.

MySQL uses table locking (instead of page, row, or column locking) for all storage engines except [InnoDB](#). The locking operations themselves do not have much overhead. But because only one session can write to a table at any one time, for best performance with these other storage engines, use them primarily for tables that are queried often and rarely inserted into or updated.

- [Performance Considerations Favoring InnoDB](#)
- [Workarounds for Locking Performance Issues](#)

## Performance Considerations Favoring InnoDB

When choosing whether to create a table using [InnoDB](#) or a different storage engine, keep in mind the following disadvantages of table locking:

- Table locking enables many sessions to read from a table at the same time, but if a session wants to write to a table, it must first get exclusive access, meaning it might have to wait for other sessions to finish with the table first. During the update, all other sessions that want to access this particular table must wait until the update is done.
- Table locking causes problems when a session is waiting because the disk is full and free space needs to become available before the session can proceed. In this case, all sessions that want to access the problem table are also put in a waiting state until more disk space is made available.
- A [SELECT](#) statement that takes a long time to run prevents other sessions from updating the table in the meantime, making the other sessions appear slow or unresponsive. While a session is waiting to get exclusive access to the table for updates, other sessions that issue [SELECT](#) statements queue up behind it, reducing concurrency even for read-only sessions.

## Workarounds for Locking Performance Issues

The following items describe some ways to avoid or reduce contention caused by table locking:

- Consider switching the table to the [InnoDB](#) storage engine, either using [CREATE TABLE ... ENGINE=INNODB](#) during setup, or using [ALTER TABLE ... ENGINE=INNODB](#) for an existing table. See [Chapter 17, The InnoDB Storage Engine](#) for more details about this storage engine.
- Optimize [SELECT](#) statements to run faster so that they lock tables for a shorter time. You might have to create some summary tables to do this.
- Start `mysqld` with `--low-priority-updates`. For storage engines that use only table-level locking (such as [MyISAM](#), [MEMORY](#), and [MERGE](#)), this gives all statements that update (modify) a table lower priority than [SELECT](#) statements. In this case, the second [SELECT](#) statement in the preceding scenario would execute before the [UPDATE](#) statement, and would not wait for the first [SELECT](#) to finish.
- To specify that all updates issued in a specific connection should be done with low priority, set the `low_priority_updates` server system variable equal to 1.
- To give a specific [INSERT](#), [UPDATE](#), or [DELETE](#) statement lower priority, use the `LOW_PRIORITY` attribute.
- To give a specific [SELECT](#) statement higher priority, use the `HIGH_PRIORITY` attribute. See [Section 15.2.13, “SELECT Statement”](#).
- Start `mysqld` with a low value for the `max_write_lock_count` system variable to force MySQL to temporarily elevate the priority of all [SELECT](#) statements that are waiting for a table after a specific number of write locks to the table occur (for example, for insert operations). This permits read locks after a certain number of write locks.

- If you have problems with mixed `SELECT` and `DELETE` statements, the `LIMIT` option to `DELETE` may help. See [Section 15.2.2, “DELETE Statement”](#).
- Using `SQL_BUFFER_RESULT` with `SELECT` statements can help to make the duration of table locks shorter. See [Section 15.2.13, “SELECT Statement”](#).
- Splitting table contents into separate tables may help, by allowing queries to run against columns in one table, while updates are confined to columns in a different table.
- You could change the locking code in `mysys/thr_lock.c` to use a single queue. In this case, write locks and read locks would have the same priority, which might help some applications.

### 10.11.3 Concurrent Inserts

The `MyISAM` storage engine supports concurrent inserts to reduce contention between readers and writers for a given table: If a `MyISAM` table has no holes in the data file (deleted rows in the middle), an `INSERT` statement can be executed to add rows to the end of the table at the same time that `SELECT` statements are reading rows from the table. If there are multiple `INSERT` statements, they are queued and performed in sequence, concurrently with the `SELECT` statements. The results of a concurrent `INSERT` may not be visible immediately.

The `concurrent_insert` system variable can be set to modify the concurrent-insert processing. By default, the variable is set to `AUTO` (or 1) and concurrent inserts are handled as just described. If `concurrent_insert` is set to `NEVER` (or 0), concurrent inserts are disabled. If the variable is set to `ALWAYS` (or 2), concurrent inserts at the end of the table are permitted even for tables that have deleted rows. See also the description of the `concurrent_insert` system variable.

If you are using the binary log, concurrent inserts are converted to normal inserts for `CREATE ... SELECT` or `INSERT ... SELECT` statements. This is done to ensure that you can re-create an exact copy of your tables by applying the log during a backup operation. See [Section 7.4.4, “The Binary Log”](#). In addition, for those statements a read lock is placed on the selected-from table such that inserts into that table are blocked. The effect is that concurrent inserts for that table must wait as well.

With `LOAD DATA`, if you specify `CONCURRENT` with a `MyISAM` table that satisfies the condition for concurrent inserts (that is, it contains no free blocks in the middle), other sessions can retrieve data from the table while `LOAD DATA` is executing. Use of the `CONCURRENT` option affects the performance of `LOAD DATA` a bit, even if no other session is using the table at the same time.

If you specify `HIGH_PRIORITY`, it overrides the effect of the `--low-priority-updates` option if the server was started with that option. It also causes concurrent inserts not to be used.

For `LOCK TABLE`, the difference between `READ LOCAL` and `READ` is that `READ LOCAL` permits nonconflicting `INSERT` statements (concurrent inserts) to execute while the lock is held. However, this cannot be used if you are going to manipulate the database using processes external to the server while you hold the lock.

### 10.11.4 Metadata Locking

MySQL uses metadata locking to manage concurrent access to database objects and to ensure data consistency. Metadata locking applies not just to tables, but also to schemas, stored programs (procedures, functions, triggers, scheduled events), tablespaces, user locks acquired with the `GET_LOCK()` function (see [Section 14.14, “Locking Functions”](#)), and locks acquired with the locking service described in [Section 7.6.9.1, “The Locking Service”](#).

The Performance Schema `metadata_locks` table exposes metadata lock information, which can be useful for seeing which sessions hold locks, are blocked waiting for locks, and so forth. For details, see [Section 29.12.13.3, “The metadata\\_locks Table”](#).

Metadata locking does involve some overhead, which increases as query volume increases. Metadata contention increases the more that multiple queries attempt to access the same objects.

Metadata locking is not a replacement for the table definition cache, and its mutexes and locks differ from the `LOCK_open` mutex. The following discussion provides some information about how metadata locking works.

- [Metadata Lock Acquisition](#)
- [Metadata Lock Release](#)

## Metadata Lock Acquisition

If there are multiple waiters for a given lock, the highest-priority lock request is satisfied first, with an exception related to the `max_write_lock_count` system variable. Write lock requests have higher priority than read lock requests. However, if `max_write_lock_count` is set to some low value (say, 10), read lock requests may be preferred over pending write lock requests if the read lock requests have already been passed over in favor of 10 write lock requests. Normally this behavior does not occur because `max_write_lock_count` by default has a very large value.

Statements acquire metadata locks one by one, not simultaneously, and perform deadlock detection in the process.

DML statements normally acquire locks in the order in which tables are mentioned in the statement.

DDL statements, `LOCK TABLES`, and other similar statements try to reduce the number of possible deadlocks between concurrent DDL statements by acquiring locks on explicitly named tables in name order. Locks might be acquired in a different order for implicitly used tables (such as tables in foreign key relationships that also must be locked).

For example, `RENAME TABLE` is a DDL statement that acquires locks in name order:

- This `RENAME TABLE` statement renames `tbla` to something else, and renames `tblc` to `tbla`:

```
RENAME TABLE tbla TO tblb, tblc TO tbla;
```

The statement acquires metadata locks, in order, on `tbla`, `tblc`, and `tblb` (because `tblb` follows `tblc` in name order):

- This slightly different statement also renames `tbla` to something else, and renames `tblc` to `tbla`:

```
RENAME TABLE tbla TO tblc, tblc TO tbla;
```

In this case, the statement acquires metadata locks, in order, on `tbla`, `tblc`, and `tblb` (because `tblb` precedes `tblc` in name order):

Both statements acquire locks on `tbla` and `tblc`, in that order, but differ in whether the lock on the remaining table name is acquired before or after `tblc`.

Metadata lock acquisition order can make a difference in operation outcome when multiple transactions execute concurrently, as the following example illustrates.

Begin with two tables `x` and `x_new` that have identical structure. Three clients issue statements that involve these tables:

Client 1:

```
LOCK TABLE x WRITE, x_new WRITE;
```

The statement requests and acquires write locks in name order on `x` and `x_new`.

Client 2:

```
INSERT INTO x VALUES(1);
```

The statement requests and blocks waiting for a write lock on `x`.

Client 3:

```
RENAME TABLE x TO x_old, x_new TO x;
```

The statement requests exclusive locks in name order on `x`, `x_new`, and `x_old`, but blocks waiting for the lock on `x`.

Client 1:

```
UNLOCK TABLES;
```

The statement releases the write locks on `x` and `x_new`. The exclusive lock request for `x` by Client 3 has higher priority than the write lock request by Client 2, so Client 3 acquires its lock on `x`, then also on `x_new` and `x_old`, performs the renaming, and releases its locks. Client 2 then acquires its lock on `x`, performs the insert, and releases its lock.

Lock acquisition order results in the `RENAME TABLE` executing before the `INSERT`. The `x` into which the insert occurs is the table that was named `x_new` when Client 2 issued the insert and was renamed to `x` by Client 3:

```
mysql> SELECT * FROM x;
+-----+
| i |
+-----+
| 1 |
+-----+

mysql> SELECT * FROM x_old;
Empty set (0.01 sec)
```

Now begin instead with tables named `x` and `new_x` that have identical structure. Again, three clients issue statements that involve these tables:

Client 1:

```
LOCK TABLE x WRITE, new_x WRITE;
```

The statement requests and acquires write locks in name order on `new_x` and `x`.

Client 2:

```
INSERT INTO x VALUES(1);
```

The statement requests and blocks waiting for a write lock on `x`.

Client 3:

```
RENAME TABLE x TO old_x, new_x TO x;
```

The statement requests exclusive locks in name order on `new_x`, `old_x`, and `x`, but blocks waiting for the lock on `new_x`.

Client 1:

```
UNLOCK TABLES;
```

The statement releases the write locks on `x` and `new_x`. For `x`, the only pending request is by Client 2, so Client 2 acquires its lock, performs the insert, and releases the lock. For `new_x`, the only pending request

is by Client 3, which is permitted to acquire that lock (and also the lock on `old_x`). The rename operation still blocks for the lock on `x` until the Client 2 insert finishes and releases its lock. Then Client 3 acquires the lock on `x`, performs the rename, and releases its lock.

In this case, lock acquisition order results in the `INSERT` executing before the `RENAME TABLE`. The `x` into which the insert occurs is the original `x`, now renamed to `old_x` by the rename operation:

```
mysql> SELECT * FROM x;
Empty set (0.01 sec)

mysql> SELECT * FROM old_x;
+-----+
| i |
+-----+
| 1 |
+-----+
```

If order of lock acquisition in concurrent statements makes a difference to an application in operation outcome, as in the preceding example, you may be able to adjust the table names to affect the order of lock acquisition.

Metadata locks are extended, as necessary, to tables related by a foreign key constraint to prevent conflicting DML and DDL operations from executing concurrently on the related tables. When updating a parent table, a metadata lock is taken on the child table while updating foreign key metadata. Foreign key metadata is owned by the child table.

## Metadata Lock Release

To ensure transaction serializability, the server must not permit one session to perform a data definition language (DDL) statement on a table that is used in an uncompleted explicitly or implicitly started transaction in another session. The server achieves this by acquiring metadata locks on tables used within a transaction and deferring release of those locks until the transaction ends. A metadata lock on a table prevents changes to the table's structure. This locking approach has the implication that a table that is being used by a transaction within one session cannot be used in DDL statements by other sessions until the transaction ends.

This principle applies not only to transactional tables, but also to nontransactional tables. Suppose that a session begins a transaction that uses transactional table `t` and nontransactional table `nt` as follows:

```
START TRANSACTION;
SELECT * FROM t;
SELECT * FROM nt;
```

The server holds metadata locks on both `t` and `nt` until the transaction ends. If another session attempts a DDL or write lock operation on either table, it blocks until metadata lock release at transaction end. For example, a second session blocks if it attempts any of these operations:

```
DROP TABLE t;
ALTER TABLE t ...;
DROP TABLE nt;
ALTER TABLE nt ...;
LOCK TABLE t ... WRITE;
```

The same behavior applies for The `LOCK TABLES ... READ`. That is, explicitly or implicitly started transactions that update any table (transactional or nontransactional) block and are blocked by `LOCK TABLES ... READ` for that table.

If the server acquires metadata locks for a statement that is syntactically valid but fails during execution, it does not release the locks early. Lock release is still deferred to the end of the transaction because the failed statement is written to the binary log and the locks protect log consistency.

In autocommit mode, each statement is in effect a complete transaction, so metadata locks acquired for the statement are held only to the end of the statement.

Metadata locks acquired during a `PREPARE` statement are released once the statement has been prepared, even if preparation occurs within a multiple-statement transaction.

For XA transactions in `PREPARED` state, metadata locks are maintained across client disconnects and server restarts, until an `XA COMMIT` or `XA ROLLBACK` is executed.

## 10.11.5 External Locking

External locking is the use of file system locking to manage contention for `MyISAM` database tables by multiple processes. External locking is used in situations where a single process such as the MySQL server cannot be assumed to be the only process that requires access to tables. Here are some examples:

- If you run multiple servers that use the same database directory (not recommended), each server must have external locking enabled.
- If you use `myisamchk` to perform table maintenance operations on `MyISAM` tables, you must either ensure that the server is not running, or that the server has external locking enabled so that it locks table files as necessary to coordinate with `myisamchk` for access to the tables. The same is true for use of `myisampack` to pack `MyISAM` tables.

If the server is run with external locking enabled, you can use `myisamchk` at any time for read operations such as checking tables. In this case, if the server tries to update a table that `myisamchk` is using, the server waits for `myisamchk` to finish before it continues.

If you use `myisamchk` for write operations such as repairing or optimizing tables, or if you use `myisampack` to pack tables, you *must* always ensure that the `mysqld` server is not using the table. If you do not stop `mysqld`, at least do a `mysqladmin flush-tables` before you run `myisamchk`. Your tables *may become corrupted* if the server and `myisamchk` access the tables simultaneously.

With external locking in effect, each process that requires access to a table acquires a file system lock for the table files before proceeding to access the table. If all necessary locks cannot be acquired, the process is blocked from accessing the table until the locks can be obtained (after the process that currently holds the locks releases them).

External locking affects server performance because the server must sometimes wait for other processes before it can access tables.

External locking is unnecessary if you run a single server to access a given data directory (which is the usual case) and if no other programs such as `myisamchk` need to modify tables while the server is running. If you only *read* tables with other programs, external locking is not required, although `myisamchk` might report warnings if the server changes tables while `myisamchk` is reading them.

With external locking disabled, to use `myisamchk`, you must either stop the server while `myisamchk` executes or else lock and flush the tables before running `myisamchk`. To avoid this requirement, use the `CHECK TABLE` and `REPAIR TABLE` statements to check and repair `MyISAM` tables.

For `mysqld`, external locking is controlled by the value of the `skip_external_locking` system variable. When this variable is enabled, external locking is disabled, and vice versa. External locking is disabled by default.

Use of external locking can be controlled at server startup by using the `--external-locking` or `--skip-external-locking` option.

If you do use external locking option to enable updates to [MyISAM](#) tables from many MySQL processes, do not start the server with the `delay_key_write` system variable set to `ALL` or use the `DELAY_KEY_WRITE=1` table option for any shared tables. Otherwise, index corruption can occur.

The easiest way to satisfy this condition is to always use `--external-locking` together with `--delay-key-write=OFF`. (This is not done by default because in many setups it is useful to have a mixture of the preceding options.)

## 10.12 Optimizing the MySQL Server

This section discusses optimization techniques for the database server, primarily dealing with system configuration rather than tuning SQL statements. The information in this section is appropriate for DBAs who want to ensure performance and scalability across the servers they manage; for developers constructing installation scripts that include setting up the database; and people running MySQL themselves for development, testing, and so on who want to maximize their own productivity.

### 10.12.1 Optimizing Disk I/O

This section describes ways to configure storage devices when you can devote more and faster storage hardware to the database server. For information about optimizing an [InnoDB](#) configuration to improve I/O performance, see [Section 10.5.8, “Optimizing InnoDB Disk I/O”](#).

- Disk seeks are a huge performance bottleneck. This problem becomes more apparent when the amount of data starts to grow so large that effective caching becomes impossible. For large databases where you access data more or less randomly, you can be sure that you need at least one disk seek to read and a couple of disk seeks to write things. To minimize this problem, use disks with low seek times.
- Increase the number of available disk spindles (and thereby reduce the seek overhead) by either symlinking files to different disks or striping the disks:
  - Using symbolic links

This means that, for [MyISAM](#) tables, you symlink the index file and data files from their usual location in the data directory to another disk (that may also be striped). This makes both the seek and read times better, assuming that the disk is not used for other purposes as well. See [Section 10.12.2, “Using Symbolic Links”](#).

Symbolic links are not supported for use with [InnoDB](#) tables. However, it is possible to place [InnoDB](#) data and log files on different physical disks. For more information, see [Section 10.5.8, “Optimizing InnoDB Disk I/O”](#).

- Striping

Striping means that you have many disks and put the first block on the first disk, the second block on the second disk, and the  $N$ -th block on the  $(N \bmod \text{number\_of\_disks})$  disk, and so on. This means if your normal data size is less than the stripe size (or perfectly aligned), you get much better performance. Striping is very dependent on the operating system and the stripe size, so benchmark your application with different stripe sizes. See [Section 10.13.2, “Using Your Own Benchmarks”](#).

The speed difference for striping is very dependent on the parameters. Depending on how you set the striping parameters and number of disks, you may get differences measured in orders of magnitude. You have to choose to optimize for random or sequential access.

- For reliability, you may want to use RAID 0+1 (striping plus mirroring), but in this case, you need  $2 \times N$  drives to hold  $N$  drives of data. This is probably the best option if you have the money for it. However, you may also have to invest in some volume-management software to handle it efficiently.

- A good option is to vary the RAID level according to how critical a type of data is. For example, store semi-important data that can be regenerated on a RAID 0 disk, but store really important data such as host information and logs on a RAID 0+1 or RAID *N* disk. RAID *N* can be a problem if you have many writes, due to the time required to update the parity bits.
- You can also set the parameters for the file system that the database uses:

If you do not need to know when files were last accessed (which is not really useful on a database server), you can mount your file systems with the `-o noatime` option. That skips updates to the last access time in inodes on the file system, which avoids some disk seeks.

On many operating systems, you can set a file system to be updated asynchronously by mounting it with the `-o async` option. If your computer is reasonably stable, this should give you better performance without sacrificing too much reliability. (This flag is on by default on Linux.)

### Using NFS with MySQL

You should be cautious when considering whether to use NFS with MySQL. Potential issues, which vary by operating system and NFS version, include the following:

- MySQL data and log files placed on NFS volumes becoming locked and unavailable for use. Locking issues may occur in cases where multiple instances of MySQL access the same data directory or where MySQL is shut down improperly, due to a power outage, for example. NFS version 4 addresses underlying locking issues with the introduction of advisory and lease-based locking. However, sharing a data directory among MySQL instances is not recommended.
- Data inconsistencies introduced due to messages received out of order or lost network traffic. To avoid this issue, use TCP with `hard` and `intr` mount options.
- Maximum file size limitations. NFS Version 2 clients can only access the lowest 2GB of a file (signed 32 bit offset). NFS Version 3 clients support larger files (up to 64 bit offsets). The maximum supported file size also depends on the local file system of the NFS server.

Using NFS within a professional SAN environment or other storage system tends to offer greater reliability than using NFS outside of such an environment. However, NFS within a SAN environment may be slower than directly attached or bus-attached non-rotational storage.

If you choose to use NFS, NFS Version 4 or later is recommended, as is testing your NFS setup thoroughly before deploying into a production environment.

### 10.12.2 Using Symbolic Links

You can move databases or tables from the database directory to other locations and replace them with symbolic links to the new locations. You might want to do this, for example, to move a database to a file system with more free space or increase the speed of your system by spreading your tables to different disks.

For **InnoDB** tables, use the `DATA DIRECTORY` clause of the `CREATE TABLE` statement instead of symbolic links, as explained in [Section 17.6.1.2, “Creating Tables Externally”](#). This new feature is a supported, cross-platform technique.

The recommended way to do this is to symlink entire database directories to a different disk. Symlink **MyISAM** tables only as a last resort.

To determine the location of your data directory, use this statement:

```
SHOW VARIABLES LIKE 'datadir';
```

### 10.12.2.1 Using Symbolic Links for Databases on Unix

On Unix, symlink a database using this procedure:

1. Create the database using `CREATE DATABASE`:

```
mysql> CREATE DATABASE mydb1;
```

Using `CREATE DATABASE` creates the database in the MySQL data directory and permits the server to update the data dictionary with information about the database directory.

2. Stop the server to ensure that no activity occurs in the new database while it is being moved.
3. Move the database directory to some disk where you have free space. For example, use `tar` or `mv`. If you use a method that copies rather than moves the database directory, remove the original database directory after copying it.
4. Create a soft link in the data directory to the moved database directory:

```
$> ln -s /path/to/mydb1 /path/to/datadir
```

The command creates a symlink named `mydb1` in the data directory.

5. Restart the server.

### 10.12.2.2 Using Symbolic Links for MyISAM Tables on Unix

#### Note

Symbolic link support as described here, along with the `--symbolic-links` option that controls it, and is deprecated; expect these to be removed in a future version of MySQL. In addition, the option is disabled by default.

Symlinks are fully supported only for `MyISAM` tables. For files used by tables for other storage engines, you may get strange problems if you try to use symbolic links. For `InnoDB` tables, use the alternative technique explained in [Section 17.6.1.2, “Creating Tables Externally”](#) instead.

Do not symlink tables on systems that do not have a fully operational `realpath()` call. (Linux and Solaris support `realpath()`.) To determine whether your system supports symbolic links, check the value of the `have_symlink` system variable using this statement:

```
SHOW VARIABLES LIKE 'have_symlink';
```

The handling of symbolic links for `MyISAM` tables works as follows:

- In the data directory, you always have the data (`.MYD`) file and the index (`.MYI`) file. The data file and index file can be moved elsewhere and replaced in the data directory by symlinks.
- You can symlink the data file and the index file independently to different directories.
- To instruct a running MySQL server to perform the symlinking, use the `DATA DIRECTORY` and `INDEX DIRECTORY` options to `CREATE TABLE`. See [Section 15.1.20, “CREATE TABLE Statement”](#). Alternatively, if `mysqld` is not running, symlinking can be accomplished manually using `ln -s` from the command line.

#### Note

The path used with either or both of the `DATA DIRECTORY` and `INDEX DIRECTORY` options may not include the MySQL `data` directory. (Bug #32167)

- `myisamchk` does not replace a symlink with the data file or index file. It works directly on the file to which the symlink points. Any temporary files are created in the directory where the data file or index file is located. The same is true for the `ALTER TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` statements.

#### Note

When you drop a table that is using symlinks, *both the symlink and the file to which the symlink points are dropped*. This is an extremely good reason *not* to run `mysqld` as the `root` operating system user or permit operating system users to have write access to MySQL database directories.

- If you rename a table with `ALTER TABLE ... RENAME` or `RENAME TABLE` and you do not move the table to another database, the symlinks in the database directory are renamed to the new names and the data file and index file are renamed accordingly.
- If you use `ALTER TABLE ... RENAME` or `RENAME TABLE` to move a table to another database, the table is moved to the other database directory. If the table name changed, the symlinks in the new database directory are renamed to the new names and the data file and index file are renamed accordingly.
- If you are not using symlinks, start `mysqld` with the `--skip-symbolic-links` option to ensure that no one can use `mysqld` to drop or rename a file outside of the data directory.

These table symlink operations are not supported:

- `ALTER TABLE` ignores the `DATA DIRECTORY` and `INDEX DIRECTORY` table options.

### 10.12.2.3 Using Symbolic Links for Databases on Windows

On Windows, symbolic links can be used for database directories. This enables you to put a database directory at a different location (for example, on a different disk) by setting up a symbolic link to it. Use of database symlinks on Windows is similar to their use on Unix, although the procedure for setting up the link differs.

Suppose that you want to place the database directory for a database named `mydb` at `D:\data\mydb`. To do this, create a symbolic link in the MySQL data directory that points to `D:\data\mydb`. However, before creating the symbolic link, make sure that the `D:\data\mydb` directory exists by creating it if necessary. If you already have a database directory named `mydb` in the data directory, move it to `D:\data`. Otherwise, the symbolic link has no effect. To avoid problems, make sure that the server is not running when you move the database directory.

On Windows, you can create a symlink using the `mklink` command. This command requires administrative privileges.

1. Make sure that the desired path to the database exists. For this example, we use `D:\data\mydb`, and a database named `mydb`.
2. If the database does not already exist, issue `CREATE DATABASE mydb` in the `mysql` client to create it.
3. Stop the MySQL service.
4. Using Windows Explorer or the command line, move the directory `mydb` from the data directory to `D:\data`, replacing the directory of the same name.
5. If you are not already using the command prompt, open it, and change location to the data directory, like this:

```
C:\> cd \path\to\datadir
```

If your MySQL installation is in the default location, you can use this:

```
C:\> cd C:\ProgramData\MySQL\MySQL Server 9.1\Data
```

6. In the data directory, create a symlink named `mydb` that points to the location of the database directory:

```
C:\> mklink /d mydb D:\data\mydb
```

7. Start the MySQL service.

After this, all tables created in the database `mydb` are created in `D:\data\mydb`.

Alternatively, on any version of Windows supported by MySQL, you can create a symbolic link to a MySQL database by creating a `.sym` file in the data directory that contains the path to the destination directory. The file should be named `db_name.sym`, where `db_name` is the database name.

Support for database symbolic links on Windows using `.sym` files is enabled by default. If you do not need `.sym` file symbolic links, you can disable support for them by starting `mysqld` with the `--skip-symbolic-links` option. To determine whether your system supports `.sym` file symbolic links, check the value of the `have_symlink` system variable using this statement:

```
SHOW VARIABLES LIKE 'have_symlink';
```

To create a `.sym` file symlink, use this procedure:

1. Change location into the data directory:

```
C:\> cd \path\to\datadir
```

2. In the data directory, create a text file named `mydb.sym` that contains this path name: `D:\data\mydb`

#### Note

The path name to the new database and tables should be absolute. If you specify a relative path, the location is relative to the `mydb.sym` file.

After this, all tables created in the database `mydb` are created in `D:\data\mydb`.

## 10.12.3 Optimizing Memory Use

### 10.12.3.1 How MySQL Uses Memory

MySQL allocates buffers and caches to improve performance of database operations. The default configuration is designed to permit a MySQL server to start on a virtual machine that has approximately 512MB of RAM. You can improve MySQL performance by increasing the values of certain cache and buffer-related system variables. You can also modify the default configuration to run MySQL on systems with limited memory.

The following list describes some of the ways that MySQL uses memory. Where applicable, relevant system variables are referenced. Some items are storage engine or feature specific.

- The `InnoDB` buffer pool is a memory area that holds cached `InnoDB` data for tables, indexes, and other auxiliary buffers. For efficiency of high-volume read operations, the buffer pool is divided into `pages` that can potentially hold multiple rows. For efficiency of cache management, the buffer pool is implemented as a linked list of pages; data that is rarely used is aged out of the cache, using a variation of the `LRU` algorithm. For more information, see [Section 17.5.1, “Buffer Pool”](#).

The size of the buffer pool is important for system performance:

- **InnoDB** allocates memory for the entire buffer pool at server startup, using `malloc()` operations. The `innodb_buffer_pool_size` system variable defines the buffer pool size. Typically, a recommended `innodb_buffer_pool_size` value is 50 to 75 percent of system memory. `innodb_buffer_pool_size` can be configured dynamically, while the server is running. For more information, see [Section 17.8.3.1, “Configuring InnoDB Buffer Pool Size”](#).
- On systems with a large amount of memory, you can improve concurrency by dividing the buffer pool into multiple [buffer pool instances](#). The `innodb_buffer_pool_instances` system variable defines the number of buffer pool instances.
- A buffer pool that is too small may cause excessive churning as pages are flushed from the buffer pool only to be required again a short time later.
- A buffer pool that is too large may cause swapping due to competition for memory.
- The storage engine interface enables the optimizer to provide information about the size of the record buffer to be used for scans that the optimizer estimates are likely to read multiple rows. The buffer size can vary based on the size of the estimate. **InnoDB** uses this variable-size buffering capability to take advantage of row prefetching, and to reduce the overhead of latching and B-tree navigation.
- All threads share the **MyISAM** key buffer. The `key_buffer_size` system variable determines its size.

For each **MyISAM** table the server opens, the index file is opened once; the data file is opened once for each concurrently running thread that accesses the table. For each concurrent thread, a table structure, column structures for each column, and a buffer of size  $3 * N$  are allocated (where  $N$  is the maximum row length, not counting **BLOB** columns). A **BLOB** column requires five to eight bytes plus the length of the **BLOB** data. The **MyISAM** storage engine maintains one extra row buffer for internal use.

- The `myisam_use_mmap` system variable can be set to 1 to enable memory-mapping for all **MyISAM** tables.
- If an internal in-memory temporary table becomes too large (as determined by `tmp_table_size` and `max_heap_table_size`), MySQL automatically converts the table from in-memory to on-disk format, which uses the **InnoDB** storage engine. Reaching this limit also increments `Count_hit_tmp_table_size`. You can increase the permissible temporary table size as described in [Section 10.4.4, “Internal Temporary Table Use in MySQL”](#).

For **MEMORY** tables explicitly created with `CREATE TABLE`, only the `max_heap_table_size` system variable determines how large a table can grow, and there is no conversion to on-disk format.

- The [MySQL Performance Schema](#) is a feature for monitoring MySQL server execution at a low level. The Performance Schema dynamically allocates memory incrementally, scaling its memory use to actual server load, instead of allocating required memory during server startup. Once memory is allocated, it is not freed until the server is restarted. For more information, see [Section 29.17, “The Performance Schema Memory-Allocation Model”](#).
- Each thread that the server uses to manage client connections requires some thread-specific space. The following list indicates these and which system variables control their size:
  - A stack (`thread_stack`)
  - A connection buffer (`net_buffer_length`)
  - A result buffer (`net_buffer_length`)

The connection buffer and result buffer each begin with a size equal to `net_buffer_length` bytes, but are dynamically enlarged up to `max_allowed_packet` bytes as needed. The result buffer shrinks to `net_buffer_length` bytes after each SQL statement. While a statement is running, a copy of the current statement string is also allocated.

Each connection thread uses memory for computing statement digests. The server allocates `max_digest_length` bytes per session. See [Section 29.10, “Performance Schema Statement Digests and Sampling”](#).

- All threads share the same base memory.
- When a thread is no longer needed, the memory allocated to it is released and returned to the system unless the thread goes back into the thread cache. In that case, the memory remains allocated.
- Each request that performs a sequential scan of a table allocates a *read buffer*. The `read_buffer_size` system variable determines the buffer size.
- When reading rows in an arbitrary sequence (for example, following a sort), a *random-read buffer* may be allocated to avoid disk seeks. The `read_rnd_buffer_size` system variable determines the buffer size.
- All joins are executed in a single pass, and most joins can be done without even using a temporary table. Most temporary tables are memory-based hash tables. Temporary tables with a large row length (calculated as the sum of all column lengths) or that contain `BLOB` columns are stored on disk.
- Most requests that perform a sort allocate a sort buffer and zero to two temporary files depending on the result set size. See [Section B.3.3.5, “Where MySQL Stores Temporary Files”](#).
- Almost all parsing and calculating is done in thread-local and reusable memory pools. No memory overhead is needed for small items, thus avoiding the normal slow memory allocation and freeing. Memory is allocated only for unexpectedly large strings.
- For each table having `BLOB` columns, a buffer is enlarged dynamically to read in larger `BLOB` values. If you scan a table, the buffer grows as large as the largest `BLOB` value.
- MySQL requires memory and descriptors for the table cache. Handler structures for all in-use tables are saved in the table cache and managed as “First In, First Out” (FIFO). The `table_open_cache` system variable defines the initial table cache size; see [Section 10.4.3.1, “How MySQL Opens and Closes Tables”](#).

MySQL also requires memory for the table definition cache. The `table_definition_cache` system variable defines the number of table definitions that can be stored in the table definition cache. If you use a large number of tables, you can create a large table definition cache to speed up the opening of tables. The table definition cache takes less space and does not use file descriptors, unlike the table cache.

- A `FLUSH TABLES` statement or `mysqladmin flush-tables` command closes all tables that are not in use at once and marks all in-use tables to be closed when the currently executing thread finishes. This effectively frees most in-use memory. `FLUSH TABLES` does not return until all tables have been closed.
- The server caches information in memory as a result of `GRANT`, `CREATE USER`, `CREATE SERVER`, and `INSTALL PLUGIN` statements. This memory is not released by the corresponding `REVOKE`, `DROP USER`, `DROP SERVER`, and `UNINSTALL PLUGIN` statements, so for a server that executes many instances of the statements that cause caching, there is an increase in cached memory use unless it is freed with `FLUSH PRIVILEGES`.
- In a replication topology, the following settings affect memory usage, and can be adjusted as required:

- The `max_allowed_packet` system variable on a replication source limits the maximum message size that the source sends to its replicas for processing. This setting defaults to 64M.
- The system variable `replica_pending_jobs_size_max` on a multithreaded replica sets the maximum amount of memory that is made available for holding messages awaiting processing. This setting defaults to 128M. The memory is only allocated when needed, but it might be used if your replication topology handles large transactions sometimes. It is a soft limit, and larger transactions can be processed.
- The `rpl_read_size` system variable on a replication source or replica controls the minimum amount of data in bytes that is read from the binary log files and relay log files. The default is 8192 bytes. A buffer the size of this value is allocated for each thread that reads from the binary log and relay log files, including dump threads on sources and coordinator threads on replicas.
- The `binlog_transaction_dependency_history_size` system variable limits the number of row hashes held as an in-memory history.
- The `max_binlog_cache_size` system variable specifies the upper limit of memory usage by an individual transaction.
- The `max_binlog_stmt_cache_size` system variable specifies the upper limit of memory usage by the statement cache.

`ps` and other system status programs may report that `mysqld` uses a lot of memory. This may be caused by thread stacks on different memory addresses. For example, the Solaris version of `ps` counts the unused memory between stacks as used memory. To verify this, check available swap with `swap -s`. We test `mysqld` with several memory-leakage detectors (both commercial and Open Source), so there should be no memory leaks.

### 10.12.3.2 Monitoring MySQL Memory Usage

The following example demonstrates how to use [Performance Schema](#) and [sys schema](#) to monitor MySQL memory usage.

Most Performance Schema memory instrumentation is disabled by default. Instruments can be enabled by updating the `ENABLED` column of the Performance Schema `setup_instruments` table. Memory instruments have names in the form of `memory/code_area/instrument_name`, where `code_area` is a value such as `sql` or `innodb`, and `instrument_name` is the instrument detail.

1. To view available MySQL memory instruments, query the Performance Schema `setup_instruments` table. The following query returns hundreds of memory instruments for all code areas.

```
mysql> SELECT * FROM performance_schema.setup_instruments
 WHERE NAME LIKE '%memory%';
```

You can narrow results by specifying a code area. For example, you can limit results to [InnoDB](#) memory instruments by specifying `innodb` as the code area.

```
mysql> SELECT * FROM performance_schema.setup_instruments
 WHERE NAME LIKE '%memory/innodb%';
```

NAME	ENABLED	TIMED
memory/innodb/adaptive hash index	NO	NO
memory/innodb/buf_buf_pool	NO	NO
memory/innodb/dict_stats_bg_recalc_pool_t	NO	NO
memory/innodb/dict_stats_index_map_t	NO	NO

memory/innodb/dict_stats_n_diff_on_level	NO	NO
memory/innodb/other	NO	NO
memory/innodb/row_log_buf	NO	NO
memory/innodb/row_merge_sort	NO	NO
memory/innodb/std	NO	NO
memory/innodb/trx_sys_t::rw_trx_ids	NO	NO
...		

Depending on your MySQL installation, code areas may include `performance_schema`, `sql`, `client`, `innodb`, `myisam`, `csv`, `memory`, `blackhole`, `archive`, `partition`, and others.

- To enable memory instruments, add a `performance-schema-instrument` rule to your MySQL configuration file. For example, to enable all memory instruments, add this rule to your configuration file and restart the server:

```
performance-schema-instrument='memory/%=COUNTED'
```

#### Note

Enabling memory instruments at startup ensures that memory allocations that occur at startup are counted.

After restarting the server, the `ENABLED` column of the Performance Schema `setup_instruments` table should report `YES` for memory instruments that you enabled. The `TIMED` column in the `setup_instruments` table is ignored for memory instruments because memory operations are not timed.

```
mysql> SELECT * FROM performance_schema.setup_instruments
 WHERE NAME LIKE '%memory/innodb%';
```

NAME	ENABLED	TIMED
memory/innodb/adaptive hash index	NO	NO
memory/innodb/buf_buf_pool	NO	NO
memory/innodb/dict_stats_bg_recalc_pool_t	NO	NO
memory/innodb/dict_stats_index_map_t	NO	NO
memory/innodb/dict_stats_n_diff_on_level	NO	NO
memory/innodb/other	NO	NO
memory/innodb/row_log_buf	NO	NO
memory/innodb/row_merge_sort	NO	NO
memory/innodb/std	NO	NO
memory/innodb/trx_sys_t::rw_trx_ids	NO	NO
...		

- Query memory instrument data. In this example, memory instrument data is queried in the Performance Schema `memory_summary_global_by_event_name` table, which summarizes data by `EVENT_NAME`. The `EVENT_NAME` is the name of the instrument.

The following query returns memory data for the `InnoDB` buffer pool. For column descriptions, see [Section 29.12.20.10, “Memory Summary Tables”](#).

```
mysql> SELECT * FROM performance_schema.memory_summary_global_by_event_name
 WHERE EVENT_NAME LIKE 'memory/innodb/buf_buf_pool'\G
```

EVENT_NAME:	memory/innodb/buf_buf_pool
COUNT_ALLOC:	1
COUNT_FREE:	0
SUM_NUMBER_OF_BYTES_ALLOC:	137428992
SUM_NUMBER_OF_BYTES_FREE:	0
LOW_COUNT_USED:	0
CURRENT_COUNT_USED:	1
HIGH_COUNT_USED:	1
LOW_NUMBER_OF_BYTES_USED:	0
CURRENT_NUMBER_OF_BYTES_USED:	137428992

```
HIGH_NUMBER_OF_BYTES_USED: 137428992
```

The same underlying data can be queried using the `sys` schema `memory_global_by_current_bytes` table, which shows current memory usage within the server globally, broken down by allocation type.

```
mysql> SELECT * FROM sys.memory_global_by_current_bytes
 WHERE event_name LIKE 'memory/innodb/buf_buf_pool'\G
***** 1. row *****
 event_name: memory/innodb/buf_buf_pool
 current_count: 1
 current_alloc: 131.06 MiB
current_avg_alloc: 131.06 MiB
 high_count: 1
 high_alloc: 131.06 MiB
 high_avg_alloc: 131.06 MiB
```

This `sys` schema query aggregates currently allocated memory (`current_alloc`) by code area:

```
mysql> SELECT SUBSTRING_INDEX(event_name,'/',2) AS
 code_area, FORMAT_BYTES(SUM(current_alloc))
 AS current_alloc
FROM sys.x$memory_global_by_current_bytes
GROUP BY SUBSTRING_INDEX(event_name,'/',2)
ORDER BY SUM(current_alloc) DESC;
```

code_area	current_alloc
memory/innodb	843.24 MiB
memory/performance_schema	81.29 MiB
memory/mysys	8.20 MiB
memory/sql	2.47 MiB
memory/memory	174.01 KiB
memory/myisam	46.53 KiB
memory/blackhole	512 bytes
memory/federated	512 bytes
memory/csv	512 bytes
memory/vio	496 bytes

For more information about `sys` schema, see [Chapter 30, MySQL sys Schema](#).

### 10.12.3.3 Enabling Large Page Support

Some hardware and operating system architectures support memory pages greater than the default (usually 4KB). The actual implementation of this support depends on the underlying hardware and operating system. Applications that perform a lot of memory accesses may obtain performance improvements by using large pages due to reduced Translation Lookaside Buffer (TLB) misses.

In MySQL, large pages can be used by `InnoDB`, to allocate memory for its buffer pool and additional memory pool.

Standard use of large pages in MySQL attempts to use the largest size supported, up to 4MB. Under Solaris, a “super large pages” feature enables uses of pages up to 256MB. This feature is available for recent SPARC platforms. It can be enabled or disabled by using the `--super-large-pages` or `--skip-super-large-pages` option.

MySQL also supports the Linux implementation of large page support (which is called HugeTLB in Linux).

Before large pages can be used on Linux, the kernel must be enabled to support them and it is necessary to configure the HugeTLB memory pool. For reference, the HugeTLB API is documented in the [Documentation/vm/hugetlbpage.txt](#) file of your Linux sources.

The kernels for some recent systems such as Red Hat Enterprise Linux may have the large pages feature enabled by default. To check whether this is true for your kernel, use the following command and look for output lines containing “huge”:

```
$> grep -i huge /proc/meminfo
AnonHugePages: 2658304 kB
ShmemHugePages: 0 kB
HugePages_Total: 0
HugePages_Free: 0
HugePages_Rsvd: 0
HugePages_Surp: 0
Hugepagesize: 2048 kB
Hugetlb: 0 kB
```

The nonempty command output indicates that large page support is present, but the zero values indicate that no pages are configured for use.

If your kernel needs to be reconfigured to support large pages, consult the [hugetlbpage.txt](#) file for instructions.

Assuming that your Linux kernel has large page support enabled, configure it for use by MySQL using the following steps:

1. Determine the number of large pages needed. This is the size of the InnoDB buffer pool divided by the large page size, which we can calculate as `innodb_buffer_pool_size / Hugepagesize`. Assuming the default value for the `innodb_buffer_pool_size` (128MB) and using the `Hugepagesize` value obtained from `/proc/meminfo` (2MB), this is 128MB / 2MB, or 64 Huge Pages. We call this value *P*.
2. As system root, open the file `/etc/sysctl.conf` in a text editor, and add the line shown here, where *P* is the number of large pages obtained in the previous step:

```
vm.nr_hugepages=P
```

Using the actual value obtained previously, the additional line should look like this:

```
vm.nr_hugepages=66
```

Save the updated file.

3. As system root, run the following command:

```
$> sudo sysctl -p
```

#### Note

On some systems the large pages file may be named slightly differently; for example, some distributions call it `nr_hugepages`. In the event `sysctl` returns an error relating to the file name, check the name of the corresponding file in `/proc/sys/vm` and use that instead.

To verify the large page configuration, check `/proc/meminfo` again as described previously. Now you should see some additional nonzero values in the output, similar to this:

```
$> grep -i huge /proc/meminfo
AnonHugePages: 2686976 kB
ShmemHugePages: 0 kB
HugePages_Total: 233
HugePages_Free: 233
HugePages_Rsvd: 0
HugePages_Surp: 0
```

```
Hugepagesize: 2048 kB
Hugetlb: 477184 kB
```

4. Optionally, you may wish to compact the Linux VM. You can do this using a sequence of commands, possibly in a script file, similar to what is shown here:

```
sync
sync
sync
echo 3 > /proc/sys/vm/drop_caches
echo 1 > /proc/sys/vm/compact_memory
```

See your operating platform documentation for more information about how to do this.

5. Check any configuration files such as `my.cnf` used by the server, and make sure that `innodb_buffer_pool_chunk_size` is set larger than the huge page size. The default for this variable is 128M.
6. Large page support in the MySQL server is disabled by default. To enable it, start the server with `--large-pages`. You can also do so by adding the following line to the `[mysqld]` section of the server `my.cnf` file:

```
large-pages=ON
```

With this option enabled, `InnoDB` uses large pages automatically for its buffer pool and additional memory pool. If `InnoDB` cannot do this, it falls back to use of traditional memory and writes a warning to the error log: `Warning: Using conventional memory pool`.

You can verify that MySQL is now using large pages by checking `/proc/meminfo` again after restarting `mysqld`, like this:

```
$> grep -i huge /proc/meminfo
AnonHugePages: 2516992 kB
ShmemHugePages: 0 kB
HugePages_Total: 233
HugePages_Free: 222
HugePages_Rsvd: 55
HugePages_Surp: 0
Hugepagesize: 2048 kB
Hugetlb: 477184 kB
```

## 10.13 Measuring Performance (Benchmarking)

To measure performance, consider the following factors:

- Whether you are measuring the speed of a single operation on a quiet system, or how a set of operations (a “workload”) works over a period of time. With simple tests, you usually test how changing one aspect (a configuration setting, the set of indexes on a table, the SQL clauses in a query) affects performance. Benchmarks are typically long-running and elaborate performance tests, where the results could dictate high-level choices such as hardware and storage configuration, or how soon to upgrade to a new MySQL version.
- For benchmarking, sometimes you must simulate a heavy database workload to get an accurate picture.
- Performance can vary depending on so many different factors that a difference of a few percentage points might not be a decisive victory. The results might shift the opposite way when you test in a different environment.
- Certain MySQL features help or do not help performance depending on the workload. For completeness, always test performance with those features turned on and turned off. The most important feature to try with each workload is the `adaptive hash index` for `InnoDB` tables.

This section progresses from simple and direct measurement techniques that a single developer can do, to more complicated ones that require additional expertise to perform and interpret the results.

### 10.13.1 Measuring the Speed of Expressions and Functions

To measure the speed of a specific MySQL expression or function, invoke the `BENCHMARK()` function using the `mysql` client program. Its syntax is `BENCHMARK(loop_count,expr)`. The return value is always zero, but `mysql` prints a line displaying approximately how long the statement took to execute. For example:

```
mysql> SELECT BENCHMARK(1000000,1+1);
+-----+
| BENCHMARK(1000000,1+1) |
+-----+
| 0 |
+-----+
1 row in set (0.32 sec)
```

This result was obtained on a Pentium II 400MHz system. It shows that MySQL can execute 1,000,000 simple addition expressions in 0.32 seconds on that system.

The built-in MySQL functions are typically highly optimized, but there may be some exceptions. `BENCHMARK()` is an excellent tool for finding out if some function is a problem for your queries.

### 10.13.2 Using Your Own Benchmarks

Benchmark your application and database to find out where the bottlenecks are. After fixing one bottleneck (or by replacing it with a “dummy” module), you can proceed to identify the next bottleneck. Even if the overall performance for your application currently is acceptable, you should at least make a plan for each bottleneck and decide how to solve it if someday you really need the extra performance.

A free benchmark suite is the Open Source Database Benchmark, available at <http://osdb.sourceforge.net/>.

It is very common for a problem to occur only when the system is very heavily loaded. We have had many customers who contact us when they have a (tested) system in production and have encountered load problems. In most cases, performance problems turn out to be due to issues of basic database design (for example, table scans are not good under high load) or problems with the operating system or libraries. Most of the time, these problems would be much easier to fix if the systems were not already in production.

To avoid problems like this, benchmark your whole application under the worst possible load:

- The `mysqlslap` program can be helpful for simulating a high load produced by multiple clients issuing queries simultaneously. See [Section 6.5.7, “mysqlslap — A Load Emulation Client”](#).
- You can also try benchmarking packages such as SysBench and DBT2, available at <https://launchpad.net/sysbench>, and <http://osdlbdt.sourceforge.net/#dbt2>.

These programs or packages can bring a system to its knees, so be sure to use them only on your development systems.

### 10.13.3 Measuring Performance with performance\_schema

You can query the tables in the `performance_schema` database to see real-time information about the performance characteristics of your server and the applications it is running. See [Chapter 29, MySQL Performance Schema](#) for details.

## 10.14 Examining Server Thread (Process) Information

To ascertain what your MySQL server is doing, it can be helpful to examine the process list, which indicates the operations currently being performed by the set of threads executing within the server. For example:

```
mysql> SHOW PROCESSLIST\G
***** 1. row *****
 Id: 5
 User: event_scheduler
 Host: localhost
 db: NULL
Command: Daemon
 Time: 2756681
 State: Waiting on empty queue
 Info: NULL
***** 2. row *****
 Id: 20
 User: me
 Host: localhost:52943
 db: test
Command: Query
 Time: 0
 State: starting
 Info: SHOW PROCESSLIST
```

Threads can be killed with the [KILL](#) statement. See [Section 15.7.8.4, “KILL Statement”](#).

## 10.14.1 Accessing the Process List

The following discussion enumerates the sources of process information, the privileges required to see process information, and describes the content of process list entries.

- [Sources of Process Information](#)
- [Privileges Required to Access the Process List](#)
- [Content of Process List Entries](#)

### Sources of Process Information

Process information is available from these sources:

- The `SHOW PROCESSLIST` statement: [Section 15.7.7.30, “SHOW PROCESSLIST Statement”](#)
- The `mysqladmin processlist` command: [Section 6.5.2, “mysqladmin — A MySQL Server Administration Program”](#)
- The `INFORMATION_SCHEMA PROCESSLIST` table: [Section 28.3.23, “The INFORMATION\\_SCHEMA PROCESSLIST Table”](#)
- The Performance Schema `processlist` table: [Section 29.12.22.8, “The processlist Table”](#)
- The Performance Schema `threads` table columns with names having a prefix of `PROCESSLIST_`: [Section 29.12.22.9, “The threads Table”](#)
- The `sys` schema `processlist` and `session` views: [Section 30.4.3.22, “The processlist and x\\$processlist Views”](#), and [Section 30.4.3.33, “The session and x\\$session Views”](#)

The `threads` table compares to `SHOW PROCESSLIST`, `INFORMATION_SCHEMA PROCESSLIST`, and `mysqladmin processlist` as follows:

- Access to the `threads` table does not require a mutex and has minimal impact on server performance. The other sources have negative performance consequences because they require a mutex.

**Note**

An alternative implementation for `SHOW PROCESSLIST` is available based on the Performance Schema `processlist` table, which, like the `threads` table, does not require a mutex and has better performance characteristics. For details, see [Section 29.12.22.8, “The processlist Table”](#).

- The `threads` table displays background threads, which the other sources do not. It also provides additional information for each thread that the other sources do not, such as whether the thread is a foreground or background thread, and the location within the server associated with the thread. This means that the `threads` table can be used to monitor thread activity the other sources cannot.
- You can enable or disable Performance Schema thread monitoring, as described in [Section 29.12.22.9, “The threads Table”](#).

For these reasons, DBAs who perform server monitoring using one of the other thread information sources may wish to monitor using the `threads` table instead.

The `sys` schema `processlist` view presents information from the Performance Schema `threads` table in a more accessible format. The `sys` schema `session` view presents information about user sessions like the `sys` schema `processlist` view, but with background processes filtered out.

## Privileges Required to Access the Process List

For most sources of process information, if you have the `PROCESS` privilege, you can see all threads, even those belonging to other users. Otherwise (without the `PROCESS` privilege), nonanonymous users have access to information about their own threads but not threads for other users, and anonymous users have no access to thread information.

The Performance Schema `threads` table also provides thread information, but table access uses a different privilege model. See [Section 29.12.22.9, “The threads Table”](#).

## Content of Process List Entries

Each process list entry contains several pieces of information. The following list describes them using the labels from `SHOW PROCESSLIST` output. Other process information sources use similar labels.

- `Id` is the connection identifier for the client associated with the thread.
- `User` and `Host` indicate the account associated with the thread.
- `db` is the default database for the thread, or `NULL` if none has been selected.
- `Command` and `State` indicate what the thread is doing.

Most states correspond to very quick operations. If a thread stays in a given state for many seconds, there might be a problem that needs to be investigated.

The following sections list the possible `Command` values, and `State` values grouped by category. The meaning for some of these values is self-evident. For others, additional description is provided.

**Note**

Applications that examine process list information should be aware that the commands and states are subject to change.

- `Time` indicates how long the thread has been in its current state. The thread's notion of the current time may be altered in some cases: The thread can change the time with `SET TIMESTAMP = value`. For

a replica SQL thread, the value is the number of seconds between the timestamp of the last replicated event and the real time of the replica host. See [Section 19.2.3, “Replication Threads”](#).

- `Info` indicates the statement the thread is executing, or `NULL` if it is executing no statement. For `SHOW PROCESSLIST`, this value contains only the first 100 characters of the statement. To see complete statements, use `SHOW FULL PROCESSLIST` (or query a different process information source).

## 10.14.2 Thread Command Values

A thread can have any of the following `Command` values:

- `Binlog Dump`

This is a thread on a replication source for sending binary log contents to a replica.

- `Change user`

The thread is executing a change user operation.

- `Close stmt`

The thread is closing a prepared statement.

- `Connect`

Used by replication receiver threads connected to the source, and by replication worker threads.

- `Connect Out`

A replica is connecting to its source.

- `Create DB`

The thread is executing a create database operation.

- `Daemon`

This thread is internal to the server, not a thread that services a client connection.

- `Debug`

The thread is generating debugging information.

- `Delayed insert`

The thread is a delayed insert handler.

- `Drop DB`

The thread is executing a drop database operation.

- `Error`

- `Execute`

The thread is executing a prepared statement.

- `Fetch`

The thread is fetching the results from executing a prepared statement.

- `Field List`  
The thread is retrieving information for table columns.
- `Init DB`  
The thread is selecting a default database.
- `Kill`  
The thread is killing another thread.
- `Long Data`  
The thread is retrieving long data in the result of executing a prepared statement.
- `Ping`  
The thread is handling a server ping request.
- `Prepare`  
The thread is preparing a prepared statement.
- `Processlist`  
The thread is producing information about server threads.
- `Query`  
Employed for user clients while executing queries by single-threaded replication applier threads, as well as by the replication coordinator thread.
- `Quit`  
The thread is terminating.
- `Refresh`  
The thread is flushing table, logs, or caches, or resetting status variable or replication server information.
- `Register Slave`  
The thread is registering a replica server.
- `Reset stmt`  
The thread is resetting a prepared statement.
- `Set option`  
The thread is setting or resetting a client statement execution option.
- `Shutdown`  
The thread is shutting down the server.
- `Sleep`  
The thread is waiting for the client to send a new statement to it.

- `Statistics`

The thread is producing server status information.

- `Time`

Unused.

### 10.14.3 General Thread States

The following list describes thread `State` values that are associated with general query processing and not more specialized activities such as replication. Many of these are useful only for finding bugs in the server.

- `After create`

This occurs when the thread creates a table (including internal temporary tables), at the end of the function that creates the table. This state is used even if the table could not be created due to some error.

- `altering table`

The server is in the process of executing an in-place `ALTER TABLE`.

- `Analyzing`

The thread is calculating a `MyISAM` table key distributions (for example, for `ANALYZE TABLE`).

- `checking permissions`

The thread is checking whether the server has the required privileges to execute the statement.

- `Checking table`

The thread is performing a table check operation.

- `cleaning up`

The thread has processed one command and is preparing to free memory and reset certain state variables.

- `closing tables`

The thread is flushing the changed table data to disk and closing the used tables. This should be a fast operation. If not, verify that you do not have a full disk and that the disk is not in very heavy use.

- `committing alter table to storage engine`

The server has finished an in-place `ALTER TABLE` and is committing the result.

- `converting HEAP to ondisk`

The thread is converting an internal temporary table from a `MEMORY` table to an on-disk table.

- `copy to tmp table`

The thread is processing an `ALTER TABLE` statement. This state occurs after the table with the new structure has been created but before rows are copied into it.

For a thread in this state, the Performance Schema can be used to obtain about the progress of the copy operation. See [Section 29.12.5, “Performance Schema Stage Event Tables”](#).

- `Copying to group table`

If a statement has different `ORDER BY` and `GROUP BY` criteria, the rows are sorted by group and copied to a temporary table.

- `Copying to tmp table`

The server is copying to a temporary table in memory.

- `Copying to tmp table on disk`

The server is copying to a temporary table on disk. The temporary result set has become too large (see [Section 10.4.4, “Internal Temporary Table Use in MySQL”](#)). Consequently, the thread is changing the temporary table from in-memory to disk-based format to save memory.

- `Creating index`

The thread is processing `ALTER TABLE ... ENABLE KEYS` for a `MyISAM` table.

- `Creating sort index`

The thread is processing a `SELECT` that is resolved using an internal temporary table.

- `creating table`

The thread is creating a table. This includes creation of temporary tables.

- `Creating tmp table`

The thread is creating a temporary table in memory or on disk. If the table is created in memory but later is converted to an on-disk table, the state during that operation is `Copying to tmp table on disk`.

- `deleting from main table`

The server is executing the first part of a multiple-table delete. It is deleting only from the first table, and saving columns and offsets to be used for deleting from the other (reference) tables.

- `deleting from reference tables`

The server is executing the second part of a multiple-table delete and deleting the matched rows from the other tables.

- `discard_or_import_tablespace`

The thread is processing an `ALTER TABLE ... DISCARD TABLESPACE` or `ALTER TABLE ... IMPORT TABLESPACE` statement.

- `end`

This occurs at the end but before the cleanup of `ALTER TABLE`, `CREATE VIEW`, `DELETE`, `INSERT`, `SELECT`, or `UPDATE` statements.

For the `end` state, the following operations could be happening:

- Writing an event to the binary log

- Freeing memory buffers, including for blobs
- `executing`

The thread has begun executing a statement.
- `Execution of init_command`

The thread is executing statements in the value of the `init_command` system variable.
- `freeing items`

The thread has executed a command. This state is usually followed by `cleaning up`.
- `FULLTEXT initialization`

The server is preparing to perform a natural-language full-text search.
- `init`

This occurs before the initialization of `ALTER TABLE`, `DELETE`, `INSERT`, `SELECT`, or `UPDATE` statements. Actions taken by the server in this state include flushing the binary log and the `InnoDB` log.
- `Killed`

Someone has sent a `KILL` statement to the thread and it should abort next time it checks the kill flag. The flag is checked in each major loop in MySQL, but in some cases it might still take a short time for the thread to die. If the thread is locked by some other thread, the kill takes effect as soon as the other thread releases its lock.
- `Locking system tables`

The thread is trying to lock a system table (for example, a time zone or log table).
- `logging slow query`

The thread is writing a statement to the slow-query log.
- `login`

The initial state for a connection thread until the client has been authenticated successfully.
- `manage keys`

The server is enabling or disabling a table index.
- `Opening system tables`

The thread is trying to open a system table (for example, a time zone or log table).
- `Opening tables`

The thread is trying to open a table. This is should be very fast procedure, unless something prevents opening. For example, an `ALTER TABLE` or a `LOCK TABLE` statement can prevent opening a table until the statement is finished. It is also worth checking that your `table_open_cache` value is large enough.

For system tables, the `Opening system tables` state is used instead.
- `optimizing`

The server is performing initial optimizations for a query.

- `preparing`

This state occurs during query optimization.

- `preparing for alter table`

The server is preparing to execute an in-place `ALTER TABLE`.

- `Purging old relay logs`

The thread is removing unneeded relay log files.

- `query end`

This state occurs after processing a query but before the `freeing items` state.

- `Receiving from client`

The server is reading a packet from the client.

- `Removing duplicates`

The query was using `SELECT DISTINCT` in such a way that MySQL could not optimize away the distinct operation at an early stage. Because of this, MySQL requires an extra stage to remove all duplicated rows before sending the result to the client.

- `removing tmp table`

The thread is removing an internal temporary table after processing a `SELECT` statement. This state is not used if no temporary table was created.

- `rename`

The thread is renaming a table.

- `rename result table`

The thread is processing an `ALTER TABLE` statement, has created the new table, and is renaming it to replace the original table.

- `Reopen tables`

The thread got a lock for the table, but noticed after getting the lock that the underlying table structure changed. It has freed the lock, closed the table, and is trying to reopen it.

- `Repair by sorting`

The repair code is using a sort to create indexes.

- `Repair done`

The thread has completed a multithreaded repair for a `MyISAM` table.

- `Repair with keycache`

The repair code is using creating keys one by one through the key cache. This is much slower than `Repair by sorting`.

- `Rolling back`

The thread is rolling back a transaction.

- `Saving state`

For `MyISAM` table operations such as repair or analysis, the thread is saving the new table state to the `.MYI` file header. State includes information such as number of rows, the `AUTO_INCREMENT` counter, and key distributions.

- `Searching rows for update`

The thread is doing a first phase to find all matching rows before updating them. This has to be done if the `UPDATE` is changing the index that is used to find the involved rows.

- `Sending data`

This state is now included in the `Executing` state.

- `Sending to client`

The server is writing a packet to the client.

- `setup`

The thread is beginning an `ALTER TABLE` operation.

- `Sorting for group`

The thread is doing a sort to satisfy a `GROUP BY`.

- `Sorting for order`

The thread is doing a sort to satisfy an `ORDER BY`.

- `Sorting index`

The thread is sorting index pages for more efficient access during a `MyISAM` table optimization operation.

- `Sorting result`

For a `SELECT` statement, this is similar to `Creating sort index`, but for nontemporary tables.

- `starting`

The first stage at the beginning of statement execution.

- `statistics`

The server is calculating statistics to develop a query execution plan. If a thread is in this state for a long time, the server is probably disk-bound performing other work.

- `System lock`

The thread has called `mysql_lock_tables()` and the thread state has not been updated since. This is a very general state that can occur for many reasons.

For example, the thread is going to request or is waiting for an internal or external system lock for the table. This can occur when `InnoDB` waits for a table-level lock during execution of `LOCK TABLES`. If

this state is being caused by requests for external locks and you are not using multiple `mysqld` servers that are accessing the same `MyISAM` tables, you can disable external system locks with the `--skip-external-locking` option. However, external locking is disabled by default, so it is likely that this option has no effect. For `SHOW PROFILE`, this state means the thread is requesting the lock (not waiting for it).

For system tables, the `Locking system tables` state is used instead.

- `update`

The thread is getting ready to start updating the table.

- `Updating`

The thread is searching for rows to update and is updating them.

- `updating main table`

The server is executing the first part of a multiple-table update. It is updating only the first table, and saving columns and offsets to be used for updating the other (reference) tables.

- `updating reference tables`

The server is executing the second part of a multiple-table update and updating the matched rows from the other tables.

- `User lock`

The thread is going to request or is waiting for an advisory lock requested with a `GET_LOCK()` call. For `SHOW PROFILE`, this state means the thread is requesting the lock (not waiting for it).

- `User sleep`

The thread has invoked a `SLEEP()` call.

- `Waiting for commit lock`

`FLUSH TABLES WITH READ LOCK` is waiting for a commit lock.

- `waiting for handler commit`

The thread is waiting for a transaction to commit versus other parts of query processing.

- `Waiting for tables`

The thread got a notification that the underlying structure for a table has changed and it needs to reopen the table to get the new structure. However, to reopen the table, it must wait until all other threads have closed the table in question.

This notification takes place if another thread has used `FLUSH TABLES` or one of the following statements on the table in question: `FLUSH TABLES tbl_name`, `ALTER TABLE`, `RENAME TABLE`, `REPAIR TABLE`, `ANALYZE TABLE`, or `OPTIMIZE TABLE`.

- `Waiting for table flush`

The thread is executing `FLUSH TABLES` and is waiting for all threads to close their tables, or the thread got a notification that the underlying structure for a table has changed and it needs to reopen the table to get the new structure. However, to reopen the table, it must wait until all other threads have closed the table in question.

This notification takes place if another thread has used `FLUSH TABLES` or one of the following statements on the table in question: `FLUSH TABLES tbl_name`, `ALTER TABLE`, `RENAME TABLE`, `REPAIR TABLE`, `ANALYZE TABLE`, or `OPTIMIZE TABLE`.

- `Waiting for lock_type lock`

The server is waiting to acquire a `THR_LOCK` lock or a lock from the metadata locking subsystem, where `lock_type` indicates the type of lock.

This state indicates a wait for a `THR_LOCK`:

- `Waiting for table level lock`

These states indicate a wait for a metadata lock:

- `Waiting for event metadata lock`
- `Waiting for global read lock`
- `Waiting for schema metadata lock`
- `Waiting for stored function metadata lock`
- `Waiting for stored procedure metadata lock`
- `Waiting for table metadata lock`
- `Waiting for trigger metadata lock`

For information about table lock indicators, see [Section 10.11.1, “Internal Locking Methods”](#). For information about metadata locking, see [Section 10.11.4, “Metadata Locking”](#). To see which locks are blocking lock requests, use the Performance Schema lock tables described at [Section 29.12.13, “Performance Schema Lock Tables”](#).

- `Waiting on cond`

A generic state in which the thread is waiting for a condition to become true. No specific state information is available.

- `Writing to net`

The server is writing a packet to the network.

## 10.14.4 Replication Source Thread States

The following list shows the most common states you may see in the `State` column for the `Binlog Dump` thread of the replication source. If you see no `Binlog Dump` threads on a source, this means that replication is not running; that is, that no replicas are currently connected.

Set the `terminology_use_previous` system variable with session scope to support individual functions, or global scope to be a default for all new sessions. When global scope is used, the slow query log contains the old versions of the names.

- `Finished reading one binlog; switching to next binlog`

The thread has finished reading a binary log file and is opening the next one to send to the replica.

- `Master has sent all binlog to slave; waiting for more updates`  
`Source has sent all binlog to replica; waiting for more updates`

The thread has read all remaining updates from the binary logs and sent them to the replica. The thread is now idle, waiting for new events to appear in the binary log resulting from new updates occurring on the source.

- `Sending binlog event to slave`  
`Sending binlog event to replica`

Binary logs consist of *events*, where an event is usually an update plus some other information. The thread has read an event from the binary log and is now sending it to the replica.

- `Waiting to finalize termination`

A very brief state that occurs as the thread is stopping.

## 10.14.5 Replication I/O (Receiver) Thread States

The following list shows the most common states you see in the `State` column for a replication I/O (receiver) thread on a replica server. This state also appears in the `Replica_IO_State` column displayed by `SHOW REPLICA STATUS`, so you can get a good view of what is happening by using that statement.

Set the `terminology_use_previous` system variable with session scope to support individual functions, or global scope to be a default for all new sessions. When global scope is used, the slow query log contains the old versions of the names.

- `Checking master version`  
`Checking source version`

A state that occurs very briefly, after the connection to the source is established.

- `Connecting to master`  
`Connecting to source`

The thread is attempting to connect to the source.

- `Queueing master event to the relay log`  
`Queueing source event to the relay log`

The thread has read an event and is copying it to the relay log so that the SQL thread can process it.

- `Reconnecting after a failed binlog dump request`

The thread is trying to reconnect to the source.

- `Reconnecting after a failed master event read`  
`Reconnecting after a failed source event read`

The thread is trying to reconnect to the source. When connection is established again, the state becomes `Waiting for master to send event`.

- `Registering slave on master`

#### Registering replica on source

A state that occurs very briefly after the connection to the source is established.

- `Requesting binlog dump`

A state that occurs very briefly, after the connection to the source is established. The thread sends to the source a request for the contents of its binary logs, starting from the requested binary log file name and position.

- `Waiting for its turn to commit`

A state that occurs when the replica thread is waiting for older worker threads to commit if `replica_preserve_commit_order` is enabled.

- `Waiting for master to send event`

`Waiting for source to send event`

The thread has connected to the source and is waiting for binary log events to arrive. This can last for a long time if the source is idle. If the wait lasts for `replica_net_timeout` seconds, a timeout occurs. At that point, the thread considers the connection to be broken and makes an attempt to reconnect.

- `Waiting for master update`

`Waiting for source update`

The initial state before `Connecting to master` or `Connecting to source`.

- `Waiting for slave mutex on exit`

`Waiting for replica mutex on exit`

A state that occurs briefly as the thread is stopping.

- `Waiting for the slave SQL thread to free enough relay log space`

`Waiting for the replica SQL thread to free enough relay log space`

You are using a nonzero `relay_log_space_limit` value, and the relay logs have grown large enough that their combined size exceeds this value. The I/O (receiver) thread is waiting until the SQL (applier) thread frees enough space by processing relay log contents so that it can delete some relay log files.

- `Waiting to reconnect after a failed binlog dump request`

If the binary log dump request failed (due to disconnection), the thread goes into this state while it sleeps, then tries to reconnect periodically. The interval between retries can be specified using the `CHANGE REPLICATION SOURCE TO`.

- `Waiting to reconnect after a failed master event read`

`Waiting to reconnect after a failed source event read`

An error occurred while reading (due to disconnection). The thread is sleeping for the number of seconds set by the `CHANGE REPLICATION SOURCE TO` statement before attempting to reconnect.

## 10.14.6 Replication SQL Thread States

The following list shows the most common states you may see in the `State` column for a replication SQL thread on a replica server.

Set the `terminology_use_previous` system variable with session scope to support individual functions, or global scope to be a default for all new sessions. When global scope is used, the slow query log contains the old versions of the names.

- `Making temporary file (append) before replaying LOAD DATA INFILE`

The thread is executing a `LOAD DATA` statement and is appending the data to a temporary file containing the data from which the replica reads rows.

- `Making temporary file (create) before replaying LOAD DATA INFILE`

The thread is executing a `LOAD DATA` statement and is creating a temporary file containing the data from which the replica reads rows. This state can only be encountered if the original `LOAD DATA` statement was logged by a source running a version of MySQL lower than MySQL 5.0.3.

- `Reading event from the relay log`

The thread has read an event from the relay log so that the event can be processed.

- `Slave has read all relay log; waiting for more updates`

`Replica has read all relay log; waiting for more updates`

The thread has processed all events in the relay log files, and is now waiting for the I/O (receiver) thread to write new events to the relay log.

- `Waiting for an event from Coordinator`

Using the multithreaded replica (`replica_parallel_workers` is greater than 1), one of the replica worker threads is waiting for an event from the coordinator thread.

- `Waiting for slave mutex on exit`

`Waiting for replica mutex on exit`

A very brief state that occurs as the thread is stopping.

- `Waiting for Slave Workers to free pending events`

`Waiting for Replica Workers to free pending events`

This waiting action occurs when the total size of events being processed by Workers exceeds the size of the `replica_pending_jobs_size_max` system variable. The Coordinator resumes scheduling when the size drops below this limit. This state occurs only when `replica_parallel_workers` is set greater than 0.

- `Waiting for the next event in relay log`

The initial state before `Reading event from the relay log`.

- `Waiting until SOURCE_DELAY seconds after source executed event`

The SQL thread has read an event but is waiting for the replica delay to lapse. This delay is set with the `SOURCE_DELAY` option of the `CHANGE REPLICATION SOURCE TO`.

The `Info` column for the SQL thread may also show the text of a statement. This indicates that the thread has read an event from the relay log, extracted the statement from it, and may be executing it.

### 10.14.7 Replication Connection Thread States

These thread states occur on a replica server but are associated with connection threads, not with the I/O or SQL threads.

- `Changing master`

`Changing replication source`

The thread is processing a `CHANGE REPLICATION SOURCE TO` statement.

- `Killing slave`

The thread is processing a `STOP REPLICA` statement.

- `Opening master dump table`

This state occurs after `Creating table from master dump`.

- `Reading master dump table data`

This state occurs after `Opening master dump table`.

- `Rebuilding the index on master dump table`

This state occurs after `Reading master dump table data`.

### 10.14.8 NDB Cluster Thread States

- `Committing events to binlog`
- `Opening mysql.ndb_apply_status`
- `Processing events`

The thread is processing events for binary logging.

- `Processing events from schema table`

The thread is doing the work of schema replication.

- `Shutting down`
- `Syncing ndb table schema operation and binlog`

This is used to have a correct binary log of schema operations for NDB.

- `Waiting for allowed to take ndbcluster global schema lock`

The thread is waiting for permission to take a global schema lock.

- `Waiting for event from ndbcluster`

The server is acting as an SQL node in an NDB Cluster, and is connected to a cluster management node.

- `Waiting for first event from ndbcluster`
- `Waiting for ndbcluster binlog update to reach current position`
- `Waiting for ndbcluster global schema lock`

The thread is waiting for a global schema lock held by another thread to be released.

- `Waiting for ndbcluster to start`
- `Waiting for schema epoch`

The thread is waiting for a schema epoch (that is, a global checkpoint).

## 10.14.9 Event Scheduler Thread States

These states occur for the Event Scheduler thread, threads that are created to execute scheduled events, or threads that terminate the scheduler.

- `Clearing`

The scheduler thread or a thread that was executing an event is terminating and is about to end.

- `Initialized`

The scheduler thread or a thread that executes an event has been initialized.

- `Waiting for next activation`

The scheduler has a nonempty event queue but the next activation is in the future.

- `Waiting for scheduler to stop`

The thread issued `SET GLOBAL event_scheduler=OFF` and is waiting for the scheduler to stop.

- `Waiting on empty queue`

The scheduler's event queue is empty and it is sleeping.

## 10.15 Tracing the Optimizer

The MySQL optimizer includes the capability to perform tracing; the interface is provided by a set of `optimizer_trace_XXX` system variables and the `INFORMATION_SCHEMA.OPTIMIZER_TRACE` table.

### 10.15.1 Typical Usage

To perform optimizer tracing entails the following steps:

1. Enable tracing by executing `SET optimizer_trace="enabled=ON"`.
2. Execute the statement to be traced. See [Section 10.15.3, “Traceable Statements”](#), for a listing of statements which can be traced.
3. Examine the contents of the `INFORMATION_SCHEMA.OPTIMIZER_TRACE` table.
4. To examine traces for multiple queries, repeat the previous two steps as needed.
5. To disable tracing after you have finished, execute `SET optimizer_trace="enabled=OFF"`.

You can trace only statements which are executed within the current session; you cannot see traces from other sessions.

## 10.15.2 System Variables Controlling Tracing

The following system variables affect optimizer tracing:

- `optimizer_trace`: Enables or disables optimizer tracing. See [Section 10.15.8, “The `optimizer\_trace` System Variable](#)”.
- `optimizer_trace_features`: Enables or disables selected features of the MySQL Optimizer, using the syntax shown here:

```
SET optimizer_trace_features=option=value[,option=value][,...]

option:
 {greedy_search | range_optimizer | dynamic_range | repeated_subselect}

value:
 {on | off | default}
```

See [Section 10.15.10, “Selecting Optimizer Features to Trace](#)”, for more information on the effects of these.

- `optimizer_trace_max_mem_size`: Maximum amount of memory that can be used for storing all traces.
- `optimizer_trace_limit`: The maximum number of optimizer traces to be shown. See [Section 10.15.4, “Tuning Trace Purging](#)”, for more information.
- `optimizer_trace_offset`: Offset of the first trace shown. See [Section 10.15.4, “Tuning Trace Purging](#)”.
- `end_markers_in_json`: If set to `1`, causes the trace to repeat the key (if present) near the closing bracket. This also affects the output of `EXPLAIN FORMAT=JSON` in those versions of MySQL which support this statement. See [Section 10.15.9, “The `end\_markers\_in\_json` System Variable](#)”.

## 10.15.3 Traceable Statements

Statements which are traceable are listed here:

- `SELECT`
- `INSERT`
- `REPLACE`
- `UPDATE`
- `DELETE`
- `EXPLAIN` with any of the preceding statements
- `SET`
- `DO`
- `DECLARE`, `CASE`, `IF`, and `RETURN` as used in stored routines
- `CALL`

Tracing is supported for both `INSERT` and `REPLACE` statements using `VALUES`, `VALUES ROW`, or `SELECT`.

Traces of multi-table `UPDATE` and `DELETE` statements are supported.

Tracing of `SET optimizer_trace` is not supported.

For statements which are prepared and executed in separate steps, preparation and execution are traced separately.

## 10.15.4 Tuning Trace Purging

By default, each new trace overwrites the previous trace. Thus, if a statement contains substatements (such as invoking stored procedures, stored functions, or triggers), the topmost statement and substatements each generate one trace, but at the end of execution, the trace for only the last substatement is visible.

A user who wants to see the trace of a different substatement can enable or disable tracing for the desired substatement, but this requires editing the routine code, which may not always be possible. Another solution is to tune trace purging. This is done by setting the `optimizer_trace_offset` and `optimizer_trace_limit` system variables, like this:

```
SET optimizer_trace_offset=offset, optimizer_trace_limit=limit;
```

`offset` is a signed integer (default `-1`); `limit` is a positive integer (default `1`). Such a `SET` statement has the following effects:

- All traces previously stored are cleared from memory.
- A subsequent `SELECT` from the `OPTIMIZER_TRACE` table returns the first `limit` traces of the `offset` oldest stored traces (if `offset >= 0`), or the first `limit` traces of the `-offset` newest stored traces (if `offset < 0`).

Examples:

- `SET optimizer_trace_offset=-1, optimizer_trace_limit=1`: The most recent trace is shown (the default).
- `SET optimizer_trace_offset=-2, optimizer_trace_limit=1`: The next-to-last trace is shown.
- `SET optimizer_trace_offset=-5, optimizer_trace_limit=5`: The last five traces are shown.

Negative values for `offset` can thus prove useful when the substatements of interest are the last few in a stored routine. For example:

```
SET optimizer_trace_offset=-5, optimizer_trace_limit=5;

CALL stored_routine(); # more than 5 substatements in this routine

SELECT * FROM information_schema.OPTIMIZER_TRACE; # see only the last 5 traces
```

A positive `offset` can be useful when one knows that the interesting substatements are the first few in a stored routine.

The more accurately these two variables are set, the less memory is used. For example, `SET optimizer_trace_offset=0, optimizer_trace_limit=5` requires sufficient memory to store

five traces, so if only the three first are needed, it is better to use `SET optimizer_trace_offset=0, optimizer_trace_limit=3`, since tracing stops after `limit` traces. A stored routine may have a loop which executes many substatements and thus generates many traces, which can use a lot of memory; in such cases, choosing appropriate values for `offset` and `limit` can restrict tracing to, for example, a single iteration of the loop. This also decreases the impact of tracing on execution speed.

If `offset` is greater than or equal to 0, only `limit` traces are kept in memory. If `offset` is less than 0, that is not true: instead, `-offset` traces are kept in memory. Even if `limit` is smaller than `-offset`, excluding the last statement, the last statement must still be traced because it will be within the limit after executing one more statement. Since an offset less than 0 is counted from the end, the “window” moves as more statements execute.

Using `optimizer_trace_offset` and `optimizer_trace_limit`, which are restrictions at the trace producer level, provide better (greater) speed and (less) memory usage than setting offsets or limits at the trace consumer (SQL) level with `SELECT * FROM OPTIMIZER_TRACE LIMIT limit OFFSET offset`, which saves almost nothing.

### 10.15.5 Tracing Memory Usage

Each stored trace is a string, which is extended (using `realloc()`) as optimization progresses by appending more data to it. The `optimizer_trace_max_mem_size` server system variable sets a limit on the total amount of memory used by all traces currently being stored. If this limit is reached, the current trace is not extended, which means the trace is incomplete; in this case the `MISSING_BYTES_BEYOND_MAX_MEM_SIZE` column shows the number of bytes missing from the trace.

### 10.15.6 Privilege Checking

In complex scenarios where the query uses SQL SECURITY DEFINER views or stored routines, it may be that a user is denied from seeing the trace of its query because it lacks some extra privileges on those objects. In that case, the trace will be shown as empty and the `INSUFFICIENT_PRIVILEGES` column will show "1".

### 10.15.7 Interaction with the --debug Option

Anything written to the trace is automatically written to the debug file.

### 10.15.8 The optimizer\_trace System Variable

The `optimizer_trace` system variable has these on/off switches:

- `enabled`: Enables (`ON`) or disables (`OFF`) tracing
- `one_line`: If set to `ON`, the trace contains no whitespace, thus conserving space. This renders the trace difficult to read for humans, still usable by JSON parsers, since they ignore whitespace.

### 10.15.9 The end\_markers\_in\_json System Variable

When reading a very large JSON document, it can be difficult to pair its closing bracket and opening brackets; setting `end_markers_in_json=ON` repeats the structure's key, if it has one, near the closing bracket. This variable affects both optimizer traces and the output of `EXPLAIN FORMAT=JSON`.

#### Note

If `end_markers_in_json` is enabled, the repetition of the key means the result is not a valid JSON document, and causes JSON parsers to throw an error.

### 10.15.10 Selecting Optimizer Features to Trace

Some features in the optimizer can be invoked many times during statement optimization and execution, and thus can make the trace grow beyond reason. They are:

- *Greedy search*: With an *N*-table join, this could explore factorial(*N*) plans.
- *Range optimizer*
- *Dynamic range optimization*: Shown as `range checked for each record` in `EXPLAIN` output; each outer row causes a re-run of the range optimizer.
- *Subqueries*: A subquery in which the `WHERE` clause may be executed once per row.

Those features can be excluded from tracing by setting one or more switches of the `optimizer_trace_features` system variable to `OFF`. These switches are listed here:

- `greedy_search`: Greedy search is not traced.
- `range_optimizer`: The range optimizer is not traced.
- `dynamic_range`: Only the first call to the range optimizer on this `JOIN_TAB: :SQL_SELECT` is traced.
- `repeated_subselect`: Only the first execution of this `Item_subselect` is traced.

### 10.15.11 Trace General Structure

A trace follows the actual execution path very closely; for each join, there is a join preparation object, a join optimization object, and a join execution object. Query transformations (`IN` to `EXISTS`, outer join to inner join, and so on), simplifications (elimination of clauses), and equality propagation are shown in subobjects. Calls to the range optimizer, cost evaluations, reasons why an access path is chosen over another one, or why a sorting method is chosen over another one, are shown as well.

### 10.15.12 Example

Here we take an example from the test suite.

```
#
Tracing of ORDER BY & GROUP BY simplification.
#
SET optimizer_trace="enabled=on",end_markers_in_json=on; # make readable
SET optimizer_trace_max_mem_size=1000000; # avoid small default

CREATE TABLE t1 (
 pk INT, col_int_key INT,
 col_varchar_key VARCHAR(1),
 col_varchar_nokey VARCHAR(1)
);

INSERT INTO t1 VALUES
 (10,7,'v','v'),(11,0,'s','s'),(12,9,'l','l'),(13,3,'y','y'),(14,4,'c','c'),
 (15,2,'i','i'),(16,5,'h','h'),(17,3,'q','q'),(18,1,'a','a'),(19,3,'v','v'),
 (20,6,'u','u'),(21,7,'s','s'),(22,5,'y','y'),(23,1,'z','z'),(24,204,'h','h'),
 (25,224,'p','p'),(26,9,'e','e'),(27,5,'i','i'),(28,0,'y','y'),(29,3,'w','w');

CREATE TABLE t2 (
 pk INT, col_int_key INT,
 col_varchar_key VARCHAR(1),
 col_varchar_nokey VARCHAR(1),
 PRIMARY KEY (pk)
);

INSERT INTO t2 VALUES
```

## Example

```
(1,4,'b','b'),(2,8,'y','y'),(3,0,'p','p'),(4,0,'f','f'),(5,0,'p','p'),
(6,7,'d','d'),(7,7,'f','f'),(8,5,'j','j'),(9,3,'e','e'),(10,188,'u','u'),
(11,4,'v','v'),(12,9,'u','u'),(13,6,'i','i'),(14,1,'x','x'),(15,5,'l','l'),
(16,6,'q','q'),(17,2,'n','n'),(18,4,'r','r'),(19,231,'c','c'),(20,4,'h','h'),
(21,3,'k','k'),(22,3,'t','t'),(23,7,'t','t'),(24,6,'k','k'),(25,7,'g','g'),
(26,9,'z','z'),(27,4,'n','n'),(28,4,'j','j'),(29,2,'l','l'),(30,1,'d','d'),
(31,2,'t','t'),(32,194,'y','y'),(33,2,'i','i'),(34,3,'j','j'),(35,8,'r','r'),
(36,4,'b','b'),(37,9,'o','o'),(38,4,'k','k'),(39,5,'a','a'),(40,5,'f','f'),
(41,9,'t','t'),(42,3,'c','c'),(43,8,'c','c'),(44,0,'r','r'),(45,98,'k','k'),
(46,3,'l','l'),(47,1,'o','o'),(48,0,'t','t'),(49,189,'v','v'),(50,8,'x','x'),
(51,3,'j','j'),(52,3,'x','x'),(53,9,'k','k'),(54,6,'o','o'),(55,8,'z','z'),
(56,3,'n','n'),(57,9,'c','c'),(58,5,'d','d'),(59,9,'s','s'),(60,2,'j','j'),
(61,2,'w','w'),(62,5,'f','f'),(63,8,'p','p'),(64,6,'o','o'),(65,9,'f','f'),
(66,0,'x','x'),(67,3,'q','q'),(68,6,'g','g'),(69,5,'x','x'),(70,8,'p','p'),
(71,2,'q','q'),(72,120,'q','q'),(73,25,'v','v'),(74,1,'g','g'),(75,3,'l','l'),
(76,1,'w','w'),(77,3,'h','h'),(78,153,'c','c'),(79,5,'o','o'),(80,9,'o','o'),
(81,1,'v','v'),(82,8,'y','y'),(83,7,'d','d'),(84,6,'p','p'),(85,2,'z','z'),
(86,4,'t','t'),(87,7,'b','b'),(88,3,'y','y'),(89,8,'k','k'),(90,4,'c','c'),
(91,6,'z','z'),(92,1,'t','t'),(93,7,'o','o'),(94,1,'u','u'),(95,0,'t','t'),
(96,2,'k','k'),(97,7,'u','u'),(98,2,'b','b'),(99,1,'m','m'),(100,5,'o','o');
```

```
SELECT SUM(alias2.col_varchar_nokey) AS c1, alias2.pk AS c2
FROM t1 AS alias1
STRAIGHT_JOIN t2 AS alias2
ON alias2.pk = alias1.col_int_key
WHERE alias1.pk
GROUP BY c2
ORDER BY alias1.col_int_key, alias2.pk;
```

c1	c2
0	1
0	2
0	3
0	4
0	5
0	6
0	7
0	9

### Note

For reference, the complete trace is shown uninterrupted at the end of this section.

Now we can examine the trace, whose first column ([QUERY](#)), containing the original statement to be traced, is shown here:

```
SELECT * FROM INFORMATION_SCHEMA.OPTIMIZER_TRACE\G
***** 1. row *****
QUERY: SELECT SUM(alias2.col_varchar_nokey) AS c1, alias2.pk AS c2
FROM t1 AS alias1
STRAIGHT_JOIN t2 AS alias2
ON alias2.pk = alias1.col_int_key
WHERE alias1.pk
GROUP BY c2
ORDER BY alias1.col_int_key, alias2.pk
```

This can be useful mark when several traces are stored.

The [TRACE](#) column begins by showing that execution of the statement is made up of discrete steps, like this:

```
"steps": [
```

```
{
```

This is followed by the preparation of the join for the first (and only) [SELECT](#) in the statement being traced, as shown here:

```
"steps": [
 {
 "expanded_query": "/* select#1 */ select \
 sum(`test`.`alias2`.`col_varchar_nokey`) AS \
 `SUM(alias2.col_varchar_nokey)`, `test`.`alias2`.`pk` AS `field2` \
 from (`test`.`t1` `alias1` straight_join `test`.`t2` `alias2` \
 on((`test`.`alias2`.`pk` = `test`.`alias1`.`col_int_key`))) \
 where `test`.`alias1`.`pk` \
 group by `test`.`alias2`.`pk` \
 order by `test`.`alias1`.`col_int_key`, `test`.`alias2`.`pk`"
 }
] /* steps */
} /* join_preparation */
},
```

The output just shown displays the query as it is used for preparing the join; all columns (fields) have been resolved to their databases and tables, and each [SELECT](#) is annotated with a sequence number, which can be useful when studying subqueries.

The next portion of the trace shows how the join is optimized, starting with condition processing:

```
{
 "join_optimization": {
 "select#": 1,
 "steps": [
 {
 "condition_processing": {
 "condition": "WHERE",
 "original_condition": "(`test`.`alias1`.`pk` and \
 (`test`.`alias2`.`pk` = `test`.`alias1`.`col_int_key`))",
 "steps": [
 {
 "transformation": "equality_propagation",
 "resulting_condition": "(`test`.`alias1`.`pk` and \
 multiple equal(`test`.`alias2`.`pk`, \
 `test`.`alias1`.`col_int_key`))"
 },
 {
 "transformation": "constant_propagation",
 "resulting_condition": "(`test`.`alias1`.`pk` and \
 multiple equal(`test`.`alias2`.`pk`, \
 `test`.`alias1`.`col_int_key`))"
 },
 {
 "transformation": "trivial_condition_removal",
 "resulting_condition": "(`test`.`alias1`.`pk` and \
 multiple equal(`test`.`alias2`.`pk`, \
 `test`.`alias1`.`col_int_key`))"
 }
] /* steps */
 } /* condition_processing */
 },

```

Next, the optimizer checks for possible [ref](#) accesses, and identifies one:

```
{
 "ref_optimizer_key_uses": [
 {
 "database": "test",
 "table": "alias2",
 "field": "pk",

```

## Example

```
 "equals": "`test`.`alias1`.`col_int_key`",
 "null_rejecting": true
 }
] /* ref_optimizer_key_uses */
},
```

A [ref](#) access which rejects [NULL](#) has been identified: no [NULL](#) in `test.alias1.col_int_key` can have a match. (Observe that it could have a match, were the operator a null-safe equals `<=>`).

Next, for every table in the query, we estimate the cost of, and number of records returned by, a table scan or a range access.

We need to find an optimal order for the tables. Normally, greedy search is used, but since the statement uses a straight join, only the requested order is explored, and one or more access methods are selected. As shown in this portion of the trace, we can choose a table scan:

```
{
"records_estimation": [
 {
 "database": "test",
 "table": "alias1",
 "const_keys_added": {
 "keys": [
] /* keys */,
 "cause": "group_by"
 } /* const_keys_added */,
 "range_analysis": {
 "table_scan": {
 "records": 20,
 "cost": 8.1977
 } /* table_scan */
 } /* range_analysis */
 },
 {
 "database": "test",
 "table": "alias2",
 "const_keys_added": {
 "keys": [
 "PRIMARY"
] /* keys */,
 "cause": "group_by"
 } /* const_keys_added */,
 "range_analysis": {
 "table_scan": {
 "records": 100,
 "cost": 24.588
 } /* table_scan */,
 "potential_range_indices": [
 {
 "index": "PRIMARY",
 "usable": true,
 "key_parts": [
 "pk"
] /* key_parts */
 }
] /* potential_range_indices */,
 "setup_range_conditions": [
] /* setup_range_conditions */,
 "group_index_range": {
 "chosen": false,
 "cause": "not_single_table"
 } /* group_index_range */
 } /* range_analysis */
 }
] /* records_estimation */
},
```

As just shown in the second portion of the range analysis, it is not possible to use `GROUP_MIN_MAX` because it accepts only one table, and we have two in the join. This means that no range access is possible.

The optimizer estimates that reading the first table, and applying any required conditions to it, yields 20 rows:

```
{
 "considered_execution_plans": [
 {
 "database": "test",
 "table": "alias1",
 "best_access_path": {
 "considered_access_paths": [
 {
 "access_type": "scan",
 "records": 20,
 "cost": 2.0977,
 "chosen": true
 }
] /* considered_access_paths */
 } /* best_access_path */,
 "cost_for_plan": 6.0977,
 "records_for_plan": 20,
 }
]
}
```

For `alias2`, we choose `ref` access on the primary key rather than a table scan, because the number of records returned by the latter (75) is far greater than that returned by `ref` access (1), as shown here:

```
 "rest_of_plan": [
 {
 "database": "test",
 "table": "alias2",
 "best_access_path": {
 "considered_access_paths": [
 {
 "access_type": "ref",
 "index": "PRIMARY",
 "records": 1,
 "cost": 20.2,
 "chosen": true
 },
 {
 "access_type": "scan",
 "using_join_cache": true,
 "records": 75,
 "cost": 7.4917,
 "chosen": false
 }
] /* considered_access_paths */
 } /* best_access_path */,
 "cost_for_plan": 30.098,
 "records_for_plan": 20,
 "chosen": true
 }
] /* rest_of_plan */
 }
] /* considered_execution_plans */
},
```

Now that the order of tables is fixed, we can split the `WHERE` condition into chunks which can be tested early (pushdown of conditions down the join tree):

```
{
 "attaching_conditions_to_tables": {
 "original_condition": "((`test`.`alias2`.`pk` = \
 `test`.`alias1`.`col_int_key`) and `test`.`alias1`.`pk`)",
 }
}
```

## Example

```
"attached_conditions_computation": [
] /* attached_conditions_computation */,
"attached_conditions_summary": [
{
 "database": "test",
 "table": "alias1",
 "attached": "(`test`.`alias1`.`pk` and \
(`test`.`alias1`.`col_int_key` is not null))"
},
],
```

This condition can be tested on rows of `alias1` without reading rows from `alias2`.

```
{
 "database": "test",
 "table": "alias2",
 "attached": null
}
] /* attached_conditions_summary */
} /* attaching_conditions_to_tables */
},
{
```

Now we try to simplify the `ORDER BY`:

```
"clause_processing": {
 "clause": "ORDER BY",
 "original_clause": "`test`.`alias1`.`col_int_key`,`test`.`alias2`.`pk`",
 "items": [
 {
 "item": "`test`.`alias1`.`col_int_key`"
 },
 {
 "item": "`test`.`alias2`.`pk`",
 "eq_ref_to_preceding_items": true
 }
] /* items */,
}
```

Because the `WHERE` clause contains `alias2.pk=alias1.col_int_key`, ordering by both columns is unnecessary; we can order by the first column alone, since the second column is always equal to it.

```
"resulting_clause_is_simple": true,
"resulting_clause": "`test`.`alias1`.`col_int_key`"
} /* clause_processing */
},
```

The shorter `ORDER BY` clause (which is not visible in the output of `EXPLAIN`) can be implemented as an index scan, since it uses only a single column of one table.

```
{
 "clause_processing": {
 "clause": "GROUP BY",
 "original_clause": "`test`.`alias2`.`pk`",
 "items": [
 {
 "item": "`test`.`alias2`.`pk`"
 }
] /* items */,
 "resulting_clause_is_simple": false,
 "resulting_clause": "`test`.`alias2`.`pk`"
 } /* clause_processing */
},
{
 "refine_plan": [
 {
 "database": "test",
 "table": "alias1",
 "scan_type": "table"
 }
]
}
```

```

 },
 {
 "database": "test",
 "table": "alias2"
 }
] /* refine_plan */
}
] /* steps */
} /* join_optimization */
},
{

```

Now the join is executed:

```

 "join_execution": {
 "select#": 1,
 "steps": [
] /* steps */
 } /* join_execution */
 }
] /* steps */
} 0 0

```

All traces have the same basic structure. If a statement uses subqueries, there can be multiple preparations, optimizations, and executions, as well as subquery-specific transformations.

The complete trace is shown here:

```

mysql> SELECT * FROM INFORMATION_SCHEMA.OPTIMIZER_TRACE\G

### 10.15.13 Displaying Traces in Other Applications

Examining a trace in the `mysql` command-line client can be made less difficult using the `pager less` command (or your operating platform's equivalent). An alternative can be to send the trace to a file, similarly to what is shown here:

```

SELECT TRACE INTO DUMPFILE file
FROM INFORMATION_SCHEMA.OPTIMIZER_TRACE;

```

You can then pass this file to a JSON-aware text editor or other viewer, such as the [JsonView add-on for Firefox and Chrome](#), which shows objects in color and allows objects to be expanded or collapsed.

`INTO DUMPFILE` is preferable to `INTO OUTFILE` for this purpose, since the latter escapes newlines. As noted previously, you should ensure that `end_markers_in_json` is `OFF` when executing the `SELECT INTO` statement, so that the output is valid JSON.

### 10.15.14 Preventing the Use of Optimizer Trace

If, for some reason, you wish to prevent users from seeing traces of their queries, start the server with the options shown here:

```
--maximum-optimizer-trace-max-mem-size=0 --optimizer-trace-max-mem-size=0
```

This sets the maximum size to 0 and prevents users from changing this limit, thus truncating all traces to 0 bytes.

### 10.15.15 Testing Optimizer Trace

This feature is tested in `mysql-test/suite/opt_trace` and `unittest/gunit/opt_trace-t`.

### 10.15.16 Optimizer Trace Implementation

See the files `sql/opt_trace*`, starting with `sql/opt_trace.h`. A trace is started by creating an instance of `Opt_trace_start`; information is added to this trace by creating instances of `Opt_trace_object` and `Opt_trace_array`, and by using the `add()` methods of these classes.

This chapter discusses the rules for writing the following elements of [SQL](#) statements when using MySQL:

- Literal values such as strings and numbers
- Identifiers such as database, table, and column names
- Keywords and reserved words
- User-defined and system variables
- Expressions
- Query attributes
- Comments

## 11.1 Literal Values

This section describes how to write literal values in MySQL. These include strings, numbers, hexadecimal and bit values, boolean values, and [NULL](#). The section also covers various nuances that you may encounter when dealing with these basic types in MySQL.

### 11.1.1 String Literals

A string is a sequence of bytes or characters, enclosed within either single quote ( `'` ) or double quote ( `"` ) characters. Examples:

```
'a string'
```

```
"another string"
```

Quoted strings placed next to each other are concatenated to a single string. The following lines are equivalent:

```
'a string'
'a' ' ' 'string'
```

If the [ANSI\\_QUOTES](#) SQL mode is enabled, string literals can be quoted only within single quotation marks because a string quoted within double quotation marks is interpreted as an identifier.

A *binary string* is a string of bytes. Every binary string has a character set and collation named [binary](#). A *nonbinary string* is a string of characters. It has a character set other than [binary](#) and a collation that is compatible with the character set.

For both types of strings, comparisons are based on the numeric values of the string unit. For binary strings, the unit is the byte; comparisons use numeric byte values. For nonbinary strings, the unit is the character and some character sets support multibyte characters; comparisons use numeric character code values. Character code ordering is a function of the string collation. (For more information, see [Section 12.8.5](#), “The binary Collation Compared to `_bin` Collations”.)

#### Note

Within the `mysql` client, binary strings display using hexadecimal notation, depending on the value of the `--binary-as-hex`. For more information about that option, see [Section 6.5.1](#), “`mysql` — The MySQL Command-Line Client”.

A character string literal may have an optional character set introducer and [COLLATE](#) clause, to designate it as a string that uses a particular character set and collation:

```
[_charset_name]'string' [COLLATE collation_name]
```

Examples:

```
SELECT _latin1'string';
SELECT _binary'string';
SELECT _utf8mb4'string' COLLATE utf8mb4_danish_ci;
```

You can use `N'literal'` (or `n'literal'`) to create a string in the national character set. These statements are equivalent:

```
SELECT N'some text';
SELECT n'some text';
SELECT _utf8'some text';
```

For information about these forms of string syntax, see [Section 12.3.7](#), “The National Character Set”, and [Section 12.3.8](#), “Character Set Introducers”.

Within a string, certain sequences have special meaning unless the [NO\\_BACKSLASH\\_ESCAPES](#) SQL mode is enabled. Each of these sequences begins with a backslash (`\`), known as the *escape character*. MySQL recognizes the escape sequences shown in [Table 11.1](#), “Special Character Escape Sequences”. For all other escape sequences, backslash is ignored. That is, the escaped character is interpreted as if it was not escaped. For example, `\x` is just `x`. These sequences are case-sensitive. For example, `\b` is interpreted as a backspace, but `\B` is interpreted as `B`. Escape processing is done according to the character set indicated by the [character\\_set\\_connection](#) system variable. This is true even for strings that are preceded by an introducer that indicates a different character set, as discussed in [Section 12.3.6](#), “Character String Literal Character Set and Collation”.

Table 11.1 Special Character Escape Sequences

Escape Sequence	Character Represented by Sequence
<code>\0</code>	An ASCII NUL ( <code>\x'00'</code> ) character
<code>\'</code>	A single quote ( <code>'</code> ) character
<code>\"</code>	A double quote ( <code>"</code> ) character
<code>\b</code>	A backspace character
<code>\n</code>	A newline (linefeed) character
<code>\r</code>	A carriage return character
<code>\t</code>	A tab character
<code>\z</code>	ASCII 26 (Control+Z); see note following the table
<code>\\</code>	A backslash ( <code>\</code> ) character
<code>\%</code>	A <code>%</code> character; see note following the table
<code>\_</code>	A <code>_</code> character; see note following the table

The ASCII 26 character can be encoded as `\z` to enable you to work around the problem that ASCII 26 stands for END-OF-FILE on Windows. ASCII 26 within a file causes problems if you try to use `mysql db_name < file_name`.

The `\%` and `\_` sequences are used to search for literal instances of `%` and `_` in pattern-matching contexts where they would otherwise be interpreted as wildcard characters. See the description of the `LIKE` operator in [Section 14.8.1, “String Comparison Functions and Operators”](#). If you use `\%` or `\_` outside of pattern-matching contexts, they evaluate to the strings `\%` and `\_`, not to `%` and `_`.

There are several ways to include quote characters within a string:

- A `'` inside a string quoted with `'` may be written as `''`.
- A `"` inside a string quoted with `"` may be written as `""`.
- Precede the quote character by an escape character (`\`).
- A `'` inside a string quoted with `"` needs no special treatment and need not be doubled or escaped. In the same way, `"` inside a string quoted with `'` needs no special treatment.

The following `SELECT` statements demonstrate how quoting and escaping work:

```
mysql> SELECT 'hello', '"hello"', '"\"hello\""', 'hel'lo', '\hello';
+-----+-----+-----+-----+
| hello | "hello" | "\"hello\"" | hel'lo | 'hello |
+-----+-----+-----+-----+

mysql> SELECT "hello", "'hello'", "'\"hello'\"", "hel"lo", "\"hello";
+-----+-----+-----+-----+
| hello | 'hello' | '"hello"' | hel"lo | "hello |
+-----+-----+-----+-----+

mysql> SELECT 'This\nIs\nFour\nLines';
+-----+
| This
Is
Four
Lines |
+-----+
```

```
mysql> SELECT 'disappearing\ backslash';
+-----+
| disappearing backslash |
+-----+
```

To insert binary data into a string column (such as a [BLOB](#) column), you should represent certain characters by escape sequences. Backslash (\) and the quote character used to quote the string must be escaped. In certain client environments, it may also be necessary to escape [NUL](#) or Control+Z. The `mysql` client truncates quoted strings containing [NUL](#) characters if they are not escaped, and Control+Z may be taken for END-OF-FILE on Windows if not escaped. For the escape sequences that represent each of these characters, see [Table 11.1, “Special Character Escape Sequences”](#).

When writing application programs, any string that might contain any of these special characters must be properly escaped before the string is used as a data value in an SQL statement that is sent to the MySQL server. You can do this in two ways:

- Process the string with a function that escapes the special characters. In a C program, you can use the `mysql_real_escape_string_quote()` C API function to escape characters. See [mysql\\_real\\_escape\\_string\\_quote\(\)](#). Within SQL statements that construct other SQL statements, you can use the `QUOTE()` function. The Perl DBI interface provides a `quote` method to convert special characters to the proper escape sequences. See [Section 31.9, “MySQL Perl API”](#). Other language interfaces may provide a similar capability.
- As an alternative to explicitly escaping special characters, many MySQL APIs provide a placeholder capability that enables you to insert special markers into a statement string, and then bind data values to them when you issue the statement. In this case, the API takes care of escaping special characters in the values for you.

## 11.1.2 Numeric Literals

Number literals include exact-value (integer and [DECIMAL](#)) literals and approximate-value (floating-point) literals.

Integers are represented as a sequence of digits. Numbers may include `.` as a decimal separator. Numbers may be preceded by `-` or `+` to indicate a negative or positive value, respectively. Numbers represented in scientific notation with a mantissa and exponent are approximate-value numbers.

Exact-value numeric literals have an integer part or fractional part, or both. They may be signed. Examples: `1`, `.2`, `3.4`, `-5`, `-6.78`, `+9.10`.

Approximate-value numeric literals are represented in scientific notation with a mantissa and exponent. Either or both parts may be signed. Examples: `1.2E3`, `1.2E-3`, `-1.2E3`, `-1.2E-3`.

Two numbers that look similar may be treated differently. For example, `2.34` is an exact-value (fixed-point) number, whereas `2.34E0` is an approximate-value (floating-point) number.

The [DECIMAL](#) data type is a fixed-point type and calculations are exact. In MySQL, the [DECIMAL](#) type has several synonyms: [NUMERIC](#), [DEC](#), [FIXED](#). The integer types also are exact-value types. For more information about exact-value calculations, see [Section 14.25, “Precision Math”](#).

The [FLOAT](#) and [DOUBLE](#) data types are floating-point types and calculations are approximate. In MySQL, types that are synonymous with [FLOAT](#) or [DOUBLE](#) are [DOUBLE PRECISION](#) and [REAL](#).

An integer may be used in floating-point context; it is interpreted as the equivalent floating-point number.

### 11.1.3 Date and Time Literals

- [Standard SQL and ODBC Date and Time Literals](#)
- [String and Numeric Literals in Date and Time Context](#)

Date and time values can be represented in several formats, such as quoted strings or as numbers, depending on the exact type of the value and other factors. For example, in contexts where MySQL expects a date, it interprets any of '2015-07-21', '20150721', and 20150721 as a date.

This section describes the acceptable formats for date and time literals. For more information about the temporal data types, such as the range of permitted values, see [Section 13.2, “Date and Time Data Types”](#).

#### Standard SQL and ODBC Date and Time Literals

Standard SQL requires temporal literals to be specified using a type keyword and a string. The space between the keyword and string is optional.

```
DATE 'str'
TIME 'str'
TIMESTAMP 'str'
```

MySQL recognizes but, unlike standard SQL, does not require the type keyword. Applications that are to be standard-compliant should include the type keyword for temporal literals.

MySQL also recognizes the ODBC syntax corresponding to the standard SQL syntax:

```
{ d 'str' }
{ t 'str' }
{ ts 'str' }
```

MySQL uses the type keywords and the ODBC constructions to produce [DATE](#), [TIME](#), and [DATETIME](#) values, respectively, including a trailing fractional seconds part if specified. The [TIMESTAMP](#) syntax produces a [DATETIME](#) value in MySQL because [DATETIME](#) has a range that more closely corresponds to the standard SQL [TIMESTAMP](#) type, which has a year range from 0001 to 9999. (The MySQL [TIMESTAMP](#) year range is 1970 to 2038.)

#### String and Numeric Literals in Date and Time Context

MySQL recognizes [DATE](#) values in these formats:

- As a string in either 'YYYY-MM-DD' or 'YY-MM-DD' format. A “relaxed” syntax is permitted, but is deprecated: Any punctuation character may be used as the delimiter between date parts. For example, '2012-12-31', '2012/12/31', '2012^12^31', and '2012@12@31' are equivalent. Using any character other than the dash (-) as the delimiter raises a warning, as shown here:

```
mysql> SELECT DATE'2012@12@31';
+-----+
| DATE'2012@12@31' |
+-----+
| 2012-12-31 |
+-----+
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Warning
Code: 4095
Message: Delimiter '@' in position 4 in datetime value '2012@12@31' at row 1 is
deprecated. Prefer the standard '-'.

```

```
1 row in set (0.00 sec)
```

- As a string with no delimiters in either 'YYYYMMDD' or 'YYMMDD' format, provided that the string makes sense as a date. For example, '20070523' and '070523' are interpreted as '2007-05-23', but '071332' is illegal (it has nonsensical month and day parts) and becomes '0000-00-00'.
- As a number in either YYYYMMDD or YYMMDD format, provided that the number makes sense as a date. For example, 19830905 and 830905 are interpreted as '1983-09-05'.

MySQL recognizes DATETIME and TIMESTAMP values in these formats:

- As a string in either 'YYYY-MM-DD hh:mm:ss' or 'YY-MM-DD hh:mm:ss' format. MySQL also permits a “relaxed” syntax here, although this is deprecated: Any punctuation character may be used as the delimiter between date parts or time parts. For example, '2012-12-31 11:30:45', '2012^12^31 11+30+45', '2012/12/31 11\*30\*45', and '2012@12@31 11^30^45' are equivalent. Use of any characters as delimiters in such values, other than the dash (-) for the date part and the colon (:) for the time part, raises a warning, as shown here:

```
mysql> SELECT TIMESTAMP'2012^12^31 11*30*45';
+-----+
| TIMESTAMP'2012^12^31 11*30*45' |
+-----+
| 2012-12-31 11:30:45 |
+-----+
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Warning
Code: 4095
Message: Delimiter '^' in position 4 in datetime value '2012^12^31 11*30*45' at
row 1 is deprecated. Prefer the standard '-'.
1 row in set (0.00 sec)
```

The only delimiter recognized between a date and time part and a fractional seconds part is the decimal point.

The date and time parts can be separated by T rather than a space. For example, '2012-12-31 11:30:45' '2012-12-31T11:30:45' are equivalent.

Previously, MySQL supported arbitrary numbers of leading and trailing whitespace characters in date and time values, as well as between the date and time parts of DATETIME and TIMESTAMP values. In MySQL 9.1, this behavior is deprecated, and the presence of excess whitespace characters triggers a warning, as shown here:

```
mysql> SELECT TIMESTAMP'2012-12-31 11-30-45';
+-----+
| TIMESTAMP'2012-12-31 11-30-45' |
+-----+
| 2012-12-31 11:30:45 |
+-----+
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Warning
Code: 4096
Message: Delimiter ' ' in position 11 in datetime value '2012-12-31 11-30-45'
at row 1 is superfluous and is deprecated. Please remove.
1 row in set (0.00 sec)
```

A warning is also raised when whitespace characters other than the space character is used, like this:

```
mysql> SELECT TIMESTAMP'2021-06-06
 '> 11:15:25';
+-----+
| TIMESTAMP'2021-06-06
 11:15:25' |
+-----+
| 2021-06-06 11:15:25 |
+-----+
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Warning
Code: 4095
Message: Delimiter '\n' in position 10 in datetime value '2021-06-06
11:15:25' at row 1 is deprecated. Prefer the standard ' '.
1 row in set (0.00 sec)
```

Only one such warning is raised per temporal value, even though multiple issues may exist with delimiters, whitespace, or both, as shown in the following series of statements:

```
mysql> SELECT TIMESTAMP'2012!-12-31 11:30:45';
+-----+
| TIMESTAMP'2012!-12-31 11:30:45' |
+-----+
| 2012-12-31 11:30:45 |
+-----+
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Warning
Code: 4095
Message: Delimiter '!' in position 4 in datetime value '2012!-12-31 11:30:45'
at row 1 is deprecated. Prefer the standard '-'.
1 row in set (0.00 sec)

mysql> SELECT TIMESTAMP'2012-12-31 11:30:45';
+-----+
| TIMESTAMP'2012-12-31 11:30:45' |
+-----+
| 2012-12-31 11:30:45 |
+-----+
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Warning
Code: 4096
Message: Delimiter ' ' in position 11 in datetime value '2012-12-31 11:30:45'
at row 1 is superfluous and is deprecated. Please remove.
1 row in set (0.00 sec)

mysql> SELECT TIMESTAMP'2012-12-31 11:30:45';
+-----+
| TIMESTAMP'2012-12-31 11:30:45' |
+-----+
| 2012-12-31 11:30:45 |
+-----+
1 row in set (0.00 sec)
```

- As a string with no delimiters in either 'YYYYMMDDhhmmss' or 'YYMMDDhhmmss' format, provided that the string makes sense as a date. For example, '20070523091528' and '070523091528' are interpreted as '2007-05-23 09:15:28', but '071122129015' is illegal (it has a nonsensical minute part) and becomes '0000-00-00 00:00:00'.

- As a number in either `YYYYMMDDhhmmss` or `YYMMDDhhmmss` format, provided that the number makes sense as a date. For example, `19830905132800` and `830905132800` are interpreted as `'1983-09-05 13:28:00'`.

A `DATETIME` or `TIMESTAMP` value can include a trailing fractional seconds part in up to microseconds (6 digits) precision. The fractional part should always be separated from the rest of the time by a decimal point; no other fractional seconds delimiter is recognized. For information about fractional seconds support in MySQL, see [Section 13.2.6, “Fractional Seconds in Time Values”](#).

Dates containing two-digit year values are ambiguous because the century is unknown. MySQL interprets two-digit year values using these rules:

- Year values in the range `70-99` become `1970-1999`.
- Year values in the range `00-69` become `2000-2069`.

See also [Section 13.2.9, “2-Digit Years in Dates”](#).

For values specified as strings that include date part delimiters, it is unnecessary to specify two digits for month or day values that are less than 10. `'2015-6-9'` is the same as `'2015-06-09'`. Similarly, for values specified as strings that include time part delimiters, it is unnecessary to specify two digits for hour, minute, or second values that are less than 10. `'2015-10-30 1:2:3'` is the same as `'2015-10-30 01:02:03'`.

Values specified as numbers should be 6, 8, 12, or 14 digits long. If a number is 8 or 14 digits long, it is assumed to be in `YYYYMMDD` or `YYYYMMDDhhmmss` format and that the year is given by the first 4 digits. If the number is 6 or 12 digits long, it is assumed to be in `YYMMDD` or `YYMMDDhhmmss` format and that the year is given by the first 2 digits. Numbers that are not one of these lengths are interpreted as though padded with leading zeros to the closest length.

Values specified as nondelimited strings are interpreted according to their length. For a string 8 or 14 characters long, the year is assumed to be given by the first 4 characters. Otherwise, the year is assumed to be given by the first 2 characters. The string is interpreted from left to right to find year, month, day, hour, minute, and second values, for as many parts as are present in the string. This means you should not use strings that have fewer than 6 characters. For example, if you specify `'9903'`, thinking that represents March, 1999, MySQL converts it to the “zero” date value. This occurs because the year and month values are `99` and `03`, but the day part is completely missing. However, you can explicitly specify a value of zero to represent missing month or day parts. For example, to insert the value `'1999-03-00'`, use `'990300'`.

MySQL recognizes `TIME` values in these formats:

- As a string in `'D hh:mm:ss'` format. You can also use one of the following “relaxed” syntaxes: `'hh:mm:ss'`, `'hh:mm'`, `'D hh:mm'`, `'D hh'`, or `'ss'`. Here `D` represents days and can have a value from 0 to 34.
- As a string with no delimiters in `'hhmmss'` format, provided that it makes sense as a time. For example, `'101112'` is understood as `'10:11:12'`, but `'109712'` is illegal (it has a nonsensical minute part) and becomes `'00:00:00'`.
- As a number in `hhmmss` format, provided that it makes sense as a time. For example, `101112` is understood as `'10:11:12'`. The following alternative formats are also understood: `ss`, `mmss`, or `hhmmss`.

A trailing fractional seconds part is recognized in the `'D hh:mm:ss.fraction'`, `'hh:mm:ss.fraction'`, `'hhmmss.fraction'`, and `hhmmss.fraction` time formats, where `fraction` is the fractional part in up to microseconds (6 digits) precision. The fractional part should

always be separated from the rest of the time by a decimal point; no other fractional seconds delimiter is recognized. For information about fractional seconds support in MySQL, see [Section 13.2.6, “Fractional Seconds in Time Values”](#).

For `TIME` values specified as strings that include a time part delimiter, it is unnecessary to specify two digits for hours, minutes, or seconds values that are less than 10. `'8:3:2'` is the same as `'08:03:02'`.

You can specify a time zone offset when inserting `TIMESTAMP` and `DATETIME` values into a table. The offset is appended to the time part of a datetime literal, with no intervening spaces, and uses the same format used for setting the `time_zone` system variable, with the following exceptions:

- For hour values less than 10, a leading zero is required.
- The value `'-00:00'` is rejected.
- Time zone names such as `'EET'` and `'Asia/Shanghai'` cannot be used; `'SYSTEM'` also cannot be used in this context.

The value inserted must not have a zero for the month part, the day part, or both parts. This is enforced regardless of the server SQL mode setting.

This example illustrates inserting datetime values with time zone offsets into `TIMESTAMP` and `DATETIME` columns using different `time_zone` settings, and then retrieving them:

```
mysql> CREATE TABLE ts (
-> id INTEGER NOT NULL AUTO_INCREMENT PRIMARY KEY,
-> col TIMESTAMP NOT NULL
->) AUTO_INCREMENT = 1;

mysql> CREATE TABLE dt (
-> id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
-> col DATETIME NOT NULL
->) AUTO_INCREMENT = 1;

mysql> SET @@time_zone = 'SYSTEM';

mysql> INSERT INTO ts (col) VALUES ('2020-01-01 10:10:10'),
-> ('2020-01-01 10:10:10+05:30'), ('2020-01-01 10:10:10-08:00');

mysql> SET @@time_zone = '+00:00';

mysql> INSERT INTO ts (col) VALUES ('2020-01-01 10:10:10'),
-> ('2020-01-01 10:10:10+05:30'), ('2020-01-01 10:10:10-08:00');

mysql> SET @@time_zone = 'SYSTEM';

mysql> INSERT INTO dt (col) VALUES ('2020-01-01 10:10:10'),
-> ('2020-01-01 10:10:10+05:30'), ('2020-01-01 10:10:10-08:00');

mysql> SET @@time_zone = '+00:00';

mysql> INSERT INTO dt (col) VALUES ('2020-01-01 10:10:10'),
-> ('2020-01-01 10:10:10+05:30'), ('2020-01-01 10:10:10-08:00');

mysql> SET @@time_zone = 'SYSTEM';

mysql> SELECT @@system_time_zone;
+-----+
| @@system_time_zone |
+-----+
| EST |
+-----+
```

```
mysql> SELECT col, UNIX_TIMESTAMP(col) FROM dt ORDER BY id;
```

col	UNIX_TIMESTAMP(col)
2020-01-01 10:10:10	1577891410
2019-12-31 23:40:10	1577853610
2020-01-01 13:10:10	1577902210
2020-01-01 10:10:10	1577891410
2020-01-01 04:40:10	1577871610
2020-01-01 18:10:10	1577920210

```
mysql> SELECT col, UNIX_TIMESTAMP(col) FROM ts ORDER BY id;
```

col	UNIX_TIMESTAMP(col)
2020-01-01 10:10:10	1577891410
2019-12-31 23:40:10	1577853610
2020-01-01 13:10:10	1577902210
2020-01-01 05:10:10	1577873410
2019-12-31 23:40:10	1577853610
2020-01-01 13:10:10	1577902210

The offset is not displayed when selecting a datetime value, even if one was used when inserting it.

The range of supported offset values is `-13:59` to `+14:00`, inclusive.

Datetime literals that include time zone offsets are accepted as parameter values by prepared statements.

### 11.1.4 Hexadecimal Literals

Hexadecimal literal values are written using `X'val'` or `0xval` notation, where `val` contains hexadecimal digits (`0..9`, `A..F`). Lettercase of the digits and of any leading `x` does not matter. A leading `0x` is case-sensitive and cannot be written as `0X`.

Legal hexadecimal literals:

```
X'01AF'
X'01af'
x'01AF'
x'01af'
0x01AF
0x01af
```

Illegal hexadecimal literals:

```
X'0G' (G is not a hexadecimal digit)
0X01AF (0X must be written as 0x)
```

Values written using `X'val'` notation must contain an even number of digits or a syntax error occurs. To correct the problem, pad the value with a leading zero:

```
mysql> SET @s = X'FFF';
ERROR 1064 (42000): You have an error in your SQL syntax;
check the manual that corresponds to your MySQL server
version for the right syntax to use near 'X'FFF''

mysql> SET @s = X'0FFF';
Query OK, 0 rows affected (0.00 sec)
```

Values written using `0xval` notation that contain an odd number of digits are treated as having an extra leading `0`. For example, `0xaaa` is interpreted as `0x0aaa`.

By default, a hexadecimal literal is a binary string, where each pair of hexadecimal digits represents a character:

```
mysql> SELECT X'4D7953514C', CHARSET(X'4D7953514C');
+-----+-----+
| X'4D7953514C' | CHARSET(X'4D7953514C') |
+-----+-----+
| MySQL | binary |
+-----+-----+
mysql> SELECT 0x5461626c65, CHARSET(0x5461626c65);
+-----+-----+
| 0x5461626c65 | CHARSET(0x5461626c65) |
+-----+-----+
| Table | binary |
+-----+-----+
```

A hexadecimal literal may have an optional character set introducer and `COLLATE` clause, to designate it as a string that uses a particular character set and collation:

```
[_charset_name] X'val' [COLLATE collation_name]
```

Examples:

```
SELECT _latin1 X'4D7953514C';
SELECT _utf8mb4 0x4D7953514C COLLATE utf8mb4_danish_ci;
```

The examples use `X'val'` notation, but `0xval` notation permits introducers as well. For information about introducers, see [Section 12.3.8, “Character Set Introducers”](#).

In numeric contexts, MySQL treats a hexadecimal literal like a `BIGINT UNSIGNED` (64-bit unsigned integer). To ensure numeric treatment of a hexadecimal literal, use it in numeric context. Ways to do this include adding 0 or using `CAST(... AS UNSIGNED)`. For example, a hexadecimal literal assigned to a user-defined variable is a binary string by default. To assign the value as a number, use it in numeric context:

```
mysql> SET @v1 = X'41';
mysql> SET @v2 = X'41'+0;
mysql> SET @v3 = CAST(X'41' AS UNSIGNED);
mysql> SELECT @v1, @v2, @v3;
+-----+-----+-----+
| @v1 | @v2 | @v3 |
+-----+-----+-----+
| A | 65 | 65 |
+-----+-----+-----+
```

An empty hexadecimal value (`X''`) evaluates to a zero-length binary string. Converted to a number, it produces 0:

```
mysql> SELECT CHARSET(X''), LENGTH(X'');
+-----+-----+
| CHARSET(X'') | LENGTH(X'') |
+-----+-----+
| binary | 0 |
+-----+-----+
mysql> SELECT X''+0;
+-----+
| X''+0 |
+-----+
| 0 |
+-----+
```

The `X'val'` notation is based on standard SQL. The `0x` notation is based on ODBC, for which hexadecimal strings are often used to supply values for `BLOB` columns.

To convert a string or a number to a string in hexadecimal format, use the `HEX( )` function:

```
mysql> SELECT HEX('cat');
+-----+
| HEX('cat') |
+-----+
| 636174 |
+-----+
mysql> SELECT X'636174';
+-----+
| X'636174' |
+-----+
| cat |
+-----+
```

For hexadecimal literals, bit operations are considered numeric context, but bit operations permit numeric or binary string arguments in MySQL 9.1 and higher. To explicitly specify binary string context for hexadecimal literals, use a `_binary` introducer for at least one of the arguments:

```
mysql> SET @v1 = X'000D' | X'0BC0';
mysql> SET @v2 = _binary X'000D' | X'0BC0';
mysql> SELECT HEX(@v1), HEX(@v2);
+-----+-----+
| HEX(@v1) | HEX(@v2) |
+-----+-----+
| BCD | 0BCD |
+-----+-----+
```

The displayed result appears similar for both bit operations, but the result without `_binary` is a `BIGINT` value, whereas the result with `_binary` is a binary string. Due to the difference in result types, the displayed values differ: High-order 0 digits are not displayed for the numeric result.

## 11.1.5 Bit-Value Literals

Bit-value literals are written using `b'val'` or `0bval` notation. `val` is a binary value written using zeros and ones. Lettercase of any leading `b` does not matter. A leading `0b` is case-sensitive and cannot be written as `0B`.

Legal bit-value literals:

```
b'01'
B'01'
0b01
```

Illegal bit-value literals:

```
b'2' (2 is not a binary digit)
0B01 (0B must be written as 0b)
```

By default, a bit-value literal is a binary string:

```
mysql> SELECT b'1000001', CHARSET(b'1000001');
+-----+-----+
| b'1000001' | CHARSET(b'1000001') |
+-----+-----+
| A | binary |
+-----+-----+
mysql> SELECT 0b1100001, CHARSET(0b1100001);
+-----+-----+
| 0b1100001 | CHARSET(0b1100001) |
+-----+-----+
| a | binary |
+-----+-----+
```

A bit-value literal may have an optional character set introducer and `COLLATE` clause, to designate it as a string that uses a particular character set and collation:

```
[_charset_name] b'val' [COLLATE collation_name]
```

Examples:

```
SELECT _latin1 b'1000001';
SELECT _utf8mb4 0b1000001 COLLATE utf8mb4_danish_ci;
```

The examples use `b'val'` notation, but `0bval` notation permits introducers as well. For information about introducers, see [Section 12.3.8, “Character Set Introducers”](#).

In numeric contexts, MySQL treats a bit literal like an integer. To ensure numeric treatment of a bit literal, use it in numeric context. Ways to do this include adding 0 or using `CAST(... AS UNSIGNED)`. For example, a bit literal assigned to a user-defined variable is a binary string by default. To assign the value as a number, use it in numeric context:

```
mysql> SET @v1 = b'1100001';
mysql> SET @v2 = b'1100001'+0;
mysql> SET @v3 = CAST(b'1100001' AS UNSIGNED);
mysql> SELECT @v1, @v2, @v3;
+-----+-----+-----+
| @v1 | @v2 | @v3 |
+-----+-----+-----+
| a | 97 | 97 |
+-----+-----+-----+
```

An empty bit value (`b''`) evaluates to a zero-length binary string. Converted to a number, it produces 0:

```
mysql> SELECT CHARSET(b''), LENGTH(b'');
+-----+-----+
| CHARSET(b'') | LENGTH(b'') |
+-----+-----+
| binary | 0 |
+-----+-----+
mysql> SELECT b''+0;
+-----+
| b''+0 |
+-----+
| 0 |
+-----+
```

Bit-value notation is convenient for specifying values to be assigned to `BIT` columns:

```
mysql> CREATE TABLE t (b BIT(8));
mysql> INSERT INTO t SET b = b'11111111';
mysql> INSERT INTO t SET b = b'1010';
mysql> INSERT INTO t SET b = b'0101';
```

Bit values in result sets are returned as binary values, which may not display well. To convert a bit value to printable form, use it in numeric context or use a conversion function such as `BIN()` or `HEX()`. High-order 0 digits are not displayed in the converted value.

```
mysql> SELECT b+0, BIN(b), OCT(b), HEX(b) FROM t;
+-----+-----+-----+-----+
| b+0 | BIN(b) | OCT(b) | HEX(b) |
+-----+-----+-----+-----+
| 255 | 11111111 | 377 | FF |
| 10 | 1010 | 12 | A |
+-----+-----+-----+-----+
```

	5		101		5		5	
+	-----	+	-----	+	-----	+	-----	+

For bit literals, bit operations are considered numeric context, but bit operations permit numeric or binary string arguments in MySQL 9.1 and higher. To explicitly specify binary string context for bit literals, use a `_binary` introducer for at least one of the arguments:

```
mysql> SET @v1 = b'000010101' | b'000101010';
mysql> SET @v2 = _binary b'000010101' | _binary b'000101010';
mysql> SELECT HEX(@v1), HEX(@v2);
```

+	-----	+	-----	+
	HEX(@v1)		HEX(@v2)	
+	-----	+	-----	+
	3F		003F	
+	-----	+	-----	+

The displayed result appears similar for both bit operations, but the result without `_binary` is a `BIGINT` value, whereas the result with `_binary` is a binary string. Due to the difference in result types, the displayed values differ: High-order 0 digits are not displayed for the numeric result.

## 11.1.6 Boolean Literals

The constants `TRUE` and `FALSE` evaluate to `1` and `0`, respectively. The constant names can be written in any lettercase.

```
mysql> SELECT TRUE, true, FALSE, false;
-> 1, 1, 0, 0
```

## 11.1.7 NULL Values

The `NULL` value means “no data.” `NULL` can be written in any lettercase.

Be aware that the `NULL` value is different from values such as `0` for numeric types or the empty string for string types. For more information, see [Section B.3.4.3, “Problems with NULL Values”](#).

For text file import or export operations performed with `LOAD DATA` or `SELECT ... INTO OUTFILE`, `NULL` is represented by the `\N` sequence. See [Section 15.2.9, “LOAD DATA Statement”](#).

For sorting with `ORDER BY`, `NULL` values sort before other values for ascending sorts, after other values for descending sorts.

## 11.2 Schema Object Names

Certain objects within MySQL, including database, table, index, column, alias, view, stored procedure, partition, tablespace, resource group and other object names are known as identifiers. This section describes the permissible syntax for identifiers in MySQL. [Section 11.2.1, “Identifier Length Limits”](#), indicates the maximum length of each type of identifier. [Section 11.2.3, “Identifier Case Sensitivity”](#), describes which types of identifiers are case-sensitive and under what conditions.

An identifier may be quoted or unquoted. If an identifier contains special characters or is a reserved word, you *must* quote it whenever you refer to it. (Exception: A reserved word that follows a period in a qualified name must be an identifier, so it need not be quoted.) Reserved words are listed at [Section 11.3, “Keywords and Reserved Words”](#).

Internally, identifiers are converted to and are stored as Unicode (UTF-8). The permissible Unicode characters in identifiers are those in the Basic Multilingual Plane (BMP). Supplementary characters are not permitted. Identifiers thus may contain these characters:

- Permitted characters in unquoted identifiers:
  - ASCII: [0-9,a-z,A-Z\$\_] (basic Latin letters, digits 0-9, dollar, underscore)
  - Extended: U+0080 .. U+FFFF
- Permitted characters in quoted identifiers include the full Unicode Basic Multilingual Plane (BMP), except U+0000:
  - ASCII: U+0001 .. U+007F
  - Extended: U+0080 .. U+FFFF
- ASCII NUL (U+0000) and supplementary characters (U+10000 and higher) are not permitted in quoted or unquoted identifiers.
- Identifiers may begin with a digit but unless quoted may not consist solely of digits.
- Database, table, and column names cannot end with space characters.
- Use of the dollar sign as the first character in the unquoted name of a database, table, view, column, stored program, or alias is deprecated, including such names used with qualifiers (see [Section 11.2.2, “Identifier Qualifiers”](#)). An unquoted identifier beginning with a dollar sign cannot contain any additional dollar sign characters. Otherwise, the leading dollar sign is permitted but triggers a deprecation warning.

The dollar sign can still be used as the leading character of such an identifier without producing the warning, when it is quoted according to the rules given later in this section.

The identifier quote character is the backtick (`):

```
mysql> SELECT * FROM `select` WHERE `select`.id > 100;
```

If the `ANSI_QUOTES` SQL mode is enabled, it is also permissible to quote identifiers within double quotation marks:

```
mysql> CREATE TABLE "test" (col INT);
ERROR 1064: You have an error in your SQL syntax...
mysql> SET sql_mode='ANSI_QUOTES';
mysql> CREATE TABLE "test" (col INT);
Query OK, 0 rows affected (0.00 sec)
```

The `ANSI_QUOTES` mode causes the server to interpret double-quoted strings as identifiers. Consequently, when this mode is enabled, string literals must be enclosed within single quotation marks. They cannot be enclosed within double quotation marks. The server SQL mode is controlled as described in [Section 7.1.11, “Server SQL Modes”](#).

Identifier quote characters can be included within an identifier if you quote the identifier. If the character to be included within the identifier is the same as that used to quote the identifier itself, then you need to double the character. The following statement creates a table named `a`b` that contains a column named `c"d`:

```
mysql> CREATE TABLE `a``b` (`c"d` INT);
```

In the select list of a query, a quoted column alias can be specified using identifier or string quoting characters:

```
mysql> SELECT 1 AS `one`, 2 AS 'two';
+-----+-----+
| one | two |
```

```
+-----+-----+
| 1 | 2 |
+-----+-----+
```

Elsewhere in the statement, quoted references to the alias must use identifier quoting or the reference is treated as a string literal.

It is recommended that you do not use names that begin with *Me* or *MeN*, where *M* and *N* are integers. For example, avoid using *1e* as an identifier, because an expression such as *1e+3* is ambiguous. Depending on context, it might be interpreted as the expression *1e + 3* or as the number *1e+3*.

Be careful when using *MD5( )* to produce table names because it can produce names in illegal or ambiguous formats such as those just described.

It is also recommended that you do not use column names that begin with *!hidden!* to ensure that new names do not collide with names used by existing hidden columns for functional indexes.

A user variable cannot be used directly in an SQL statement as an identifier or as part of an identifier. See [Section 11.4, “User-Defined Variables”](#), for more information and examples of workarounds.

Special characters in database and table names are encoded in the corresponding file system names as described in [Section 11.2.4, “Mapping of Identifiers to File Names”](#).

## 11.2.1 Identifier Length Limits

The following table describes the maximum length for each type of identifier.

Identifier Type	Maximum Length (characters)
Database	64
Table	64
Column	64
Index	64
Constraint	64
Stored Program	64
View	64
Tablespace	64
Server	64
Log File Group	64
Alias	256 (see exception following table)
Compound Statement Label	16
User-Defined Variable	64
Resource Group	64

Aliases for column names in *CREATE VIEW* statements are checked against the maximum column length of 64 characters (not the maximum alias length of 256 characters).

For constraint definitions that include no constraint name, the server internally generates a name derived from the associated table name. For example, internally generated foreign key and *CHECK* constraint names consist of the table name plus *\_ibfk\_* or *\_chk\_* and a number. If the table name is close to the length limit for constraint names, the additional characters required for the constraint name may cause that name to exceed the limit, resulting in an error.

Identifiers are stored using Unicode (UTF-8). This applies to identifiers in table definitions and to identifiers stored in the grant tables in the `mysql` database. The sizes of the identifier string columns in the grant tables are measured in characters. You can use multibyte characters without reducing the number of characters permitted for values stored in these columns.

Values such as user name and host names in MySQL account names are strings rather than identifiers. For information about the maximum length of such values as stored in grant tables, see [Grant Table Scope Column Properties](#).

## 11.2.2 Identifier Qualifiers

Object names may be unqualified or qualified. An unqualified name is permitted in contexts where interpretation of the name is unambiguous. A qualified name includes at least one qualifier to clarify the interpretive context by overriding a default context or providing missing context.

For example, this statement creates a table using the unqualified name `t1`:

```
CREATE TABLE t1 (i INT);
```

Because `t1` includes no qualifier to specify a database, the statement creates the table in the default database. If there is no default database, an error occurs.

This statement creates a table using the qualified name `db1.t1`:

```
CREATE TABLE db1.t1 (i INT);
```

Because `db1.t1` includes a database qualifier `db1`, the statement creates `t1` in the database named `db1`, regardless of the default database. The qualifier *must* be specified if there is no default database. The qualifier *may* be specified if there is a default database, to specify a database different from the default, or to make the database explicit if the default is the same as the one specified.

Qualifiers have these characteristics:

- An unqualified name consists of a single identifier. A qualified name consists of multiple identifiers.
- The components of a multiple-part name must be separated by period (.) characters. The initial parts of a multiple-part name act as qualifiers that affect the context within which to interpret the final identifier.
- The qualifier character is a separate token and need not be contiguous with the associated identifiers. For example, `tbl_name.col_name` and `tbl_name . col_name` are equivalent.
- If any components of a multiple-part name require quoting, quote them individually rather than quoting the name as a whole. For example, write ``my-table`.`my-column``, not ``my-table.my-column``.
- A reserved word that follows a period in a qualified name must be an identifier, so in that context it need not be quoted.

The permitted qualifiers for object names depend on the object type:

- A database name is fully qualified and takes no qualifier:

```
CREATE DATABASE db1;
```

- A table, view, or stored program name may be given a database-name qualifier. Examples of unqualified and qualified names in `CREATE` statements:

```
CREATE TABLE mytable ...;
CREATE VIEW myview ...;
CREATE PROCEDURE myproc ...;
```

```
CREATE FUNCTION myfunc ...;
CREATE EVENT myevent ...;

CREATE TABLE mydb.mytable ...;
CREATE VIEW mydb.myview ...;
CREATE PROCEDURE mydb.myproc ...;
CREATE FUNCTION mydb.myfunc ...;
CREATE EVENT mydb.myevent ...;
```

- A trigger is associated with a table, so any qualifier applies to the table name:

```
CREATE TRIGGER mytrigger ... ON mytable ...;

CREATE TRIGGER mytrigger ... ON mydb.mytable ...;
```

- A column name may be given multiple qualifiers to indicate context in statements that reference it, as shown in the following table.

Column Reference	Meaning
<i>col_name</i>	Column <i>col_name</i> from whichever table used in the statement contains a column of that name
<i>tbl_name.col_name</i>	Column <i>col_name</i> from table <i>tbl_name</i> of the default database
<i>db_name.tbl_name.col_name</i>	Column <i>col_name</i> from table <i>tbl_name</i> of the database <i>db_name</i>

In other words, a column name may be given a table-name qualifier, which itself may be given a database-name qualifier. Examples of unqualified and qualified column references in [SELECT](#) statements:

```
SELECT c1 FROM mytable
WHERE c2 > 100;

SELECT mytable.c1 FROM mytable
WHERE mytable.c2 > 100;

SELECT mydb.mytable.c1 FROM mydb.mytable
WHERE mydb.mytable.c2 > 100;
```

You need not specify a qualifier for an object reference in a statement unless the unqualified reference is ambiguous. Suppose that column *c1* occurs only in table *t1*, *c2* only in *t2*, and *c* in both *t1* and *t2*. Any unqualified reference to *c* is ambiguous in a statement that refers to both tables and must be qualified as *t1.c* or *t2.c* to indicate which table you mean:

```
SELECT c1, c2, t1.c FROM t1 INNER JOIN t2
WHERE t2.c > 100;
```

Similarly, to retrieve from a table *t* in database *db1* and from a table *t* in database *db2* in the same statement, you must qualify the table references: For references to columns in those tables, qualifiers are required only for column names that appear in both tables. Suppose that column *c1* occurs only in table *db1.t*, *c2* only in *db2.t*, and *c* in both *db1.t* and *db2.t*. In this case, *c* is ambiguous and must be qualified but *c1* and *c2* need not be:

```
SELECT c1, c2, db1.t.c FROM db1.t INNER JOIN db2.t
WHERE db2.t.c > 100;
```

Table aliases enable qualified column references to be written more simply:

```
SELECT c1, c2, t1.c FROM db1.t AS t1 INNER JOIN db2.t AS t2
```

```
WHERE t2.c > 100;
```

### 11.2.3 Identifier Case Sensitivity

In MySQL, databases correspond to directories within the data directory. Each table within a database corresponds to at least one file within the database directory (and possibly more, depending on the storage engine). Triggers also correspond to files. Consequently, the case sensitivity of the underlying operating system plays a part in the case sensitivity of database, table, and trigger names. This means such names are not case-sensitive in Windows, but are case-sensitive in most varieties of Unix. One notable exception is macOS, which is Unix-based but uses a default file system type (HFS+) that is not case-sensitive. However, macOS also supports UFS volumes, which are case-sensitive just as on any Unix. See [Section 1.7.1, “MySQL Extensions to Standard SQL”](#). The `lower_case_table_names` system variable also affects how the server handles identifier case sensitivity, as described later in this section.

#### Note

Although database, table, and trigger names are not case-sensitive on some platforms, you should not refer to one of these using different cases within the same statement. The following statement would not work because it refers to a table both as `my_table` and as `MY_TABLE`:

```
mysql> SELECT * FROM my_table WHERE MY_TABLE.col=1;
```

Partition, subpartition, column, index, stored routine, event, and resource group names are not case-sensitive on any platform, nor are column aliases.

However, names of logfile groups are case-sensitive. This differs from standard SQL.

By default, table aliases are case-sensitive on Unix, but not so on Windows or macOS. The following statement would not work on Unix, because it refers to the alias both as `a` and as `A`:

```
mysql> SELECT col_name FROM tbl_name AS a
 WHERE a.col_name = 1 OR A.col_name = 2;
```

However, this same statement is permitted on Windows. To avoid problems caused by such differences, it is best to adopt a consistent convention, such as always creating and referring to databases and tables using lowercase names. This convention is recommended for maximum portability and ease of use.

How table and database names are stored on disk and used in MySQL is affected by the `lower_case_table_names` system variable. `lower_case_table_names` can take the values shown in the following table. This variable does *not* affect case sensitivity of trigger identifiers. On Unix, the default value of `lower_case_table_names` is 0. On Windows, the default value is 1. On macOS, the default value is 2.

`lower_case_table_names` can only be configured when initializing the server. Changing the `lower_case_table_names` setting after the server is initialized is prohibited.

Value	Meaning
0	Table and database names are stored on disk using the lettercase specified in the <code>CREATE TABLE</code> or <code>CREATE DATABASE</code> statement. Name comparisons are case-sensitive. You should <i>not</i> set this variable to 0 if you are running MySQL on a system that has case-insensitive file names (such as Windows or macOS). If you force this variable

Value	Meaning
	to 0 with <code>--lower-case-table-names=0</code> on a case-insensitive file system and access <code>MyISAM</code> table names using different lettercases, index corruption may result.
1	Table names are stored in lowercase on disk and name comparisons are not case-sensitive. MySQL converts all table names to lowercase on storage and lookup. This behavior also applies to database names and table aliases.
2	Table and database names are stored on disk using the lettercase specified in the <code>CREATE TABLE</code> or <code>CREATE DATABASE</code> statement, but MySQL converts them to lowercase on lookup. Name comparisons are not case-sensitive. This works <i>only</i> on file systems that are not case-sensitive! <code>InnoDB</code> table names and view names are stored in lowercase, as for <code>lower_case_table_names=1</code> .

If you are using MySQL on only one platform, you do not normally have to use a `lower_case_table_names` setting other than the default. However, you may encounter difficulties if you want to transfer tables between platforms that differ in file system case sensitivity. For example, on Unix, you can have two different tables named `my_table` and `MY_TABLE`, but on Windows these two names are considered identical. To avoid data transfer problems arising from lettercase of database or table names, you have two options:

- Use `lower_case_table_names=1` on all systems. The main disadvantage with this is that when you use `SHOW TABLES` or `SHOW DATABASES`, you do not see the names in their original lettercase.
- Use `lower_case_table_names=0` on Unix and `lower_case_table_names=2` on Windows. This preserves the lettercase of database and table names. The disadvantage of this is that you must ensure that your statements always refer to your database and table names with the correct lettercase on Windows. If you transfer your statements to Unix, where lettercase is significant, they do not work if the lettercase is incorrect.

**Exception:** If you are using `InnoDB` tables and you are trying to avoid these data transfer problems, you should use `lower_case_table_names=1` on all platforms to force names to be converted to lowercase.

Object names may be considered duplicates if their uppercase forms are equal according to a binary collation. That is true for names of cursors, conditions, procedures, functions, savepoints, stored routine parameters, stored program local variables, and plugins. It is not true for names of columns, constraints, databases, partitions, statements prepared with `PREPARE`, tables, triggers, users, and user-defined variables.

File system case sensitivity can affect searches in string columns of `INFORMATION_SCHEMA` tables. For more information, see [Section 12.8.7, “Using Collation in INFORMATION\\_SCHEMA Searches”](#).

## 11.2.4 Mapping of Identifiers to File Names

There is a correspondence between database and table identifiers and names in the file system. For the basic structure, MySQL represents each database as a directory in the data directory, and depending upon the storage engine, each table may be represented by one or more files in the appropriate database directory.

For the data and index files, the exact representation on disk is storage engine specific. These files may be stored in the database directory, or the information may be stored in a separate file. **InnoDB** data is stored in the InnoDB data files. If you are using tablespaces with **InnoDB**, then the specific tablespace files you create are used instead.

Any character is legal in database or table identifiers except ASCII NUL (`x'00'`). MySQL encodes any characters that are problematic in the corresponding file system objects when it creates database directories or table files:

- Basic Latin letters (`a..zA..Z`), digits (`0..9`) and underscore (`_`) are encoded as is. Consequently, their case sensitivity directly depends on file system features.
- All other national letters from alphabets that have uppercase/lowercase mapping are encoded as shown in the following table. Values in the Code Range column are UCS-2 values.

Code Range	Pattern	Number	Used	Unused	Blocks
00C0..017F	[@][0..4][g..z]	5*20= 100	97	3	Latin-1 Supplement + Latin Extended-A
0370..03FF	[@][5..9][g..z]	5*20= 100	88	12	Greek and Coptic
0400..052F	[@][g..z][0..6]	20*7= 140	137	3	Cyrillic + Cyrillic Supplement
0530..058F	[@][g..z][7..8]	20*2= 40	38	2	Armenian
2160..217F	[@][g..z][9]	20*1= 20	16	4	Number Forms
0180..02AF	[@][g..z][a..k]	20*11=220	203	17	Latin Extended-B + IPA Extensions
1E00..1EFF	[@][g..z][l..r]	20*7= 140	136	4	Latin Extended Additional
1F00..1FFF	[@][g..z][s..z]	20*8= 160	144	16	Greek Extended
.... ..	[@][a..f][g..z]	6*20= 120	0	120	RESERVED
24B6..24E9	[@][@][a..z]	26	26	0	Enclosed Alphanumerics
FF21..FF5A	[@][a..z][@]	26	26	0	Halfwidth and Fullwidth forms

One of the bytes in the sequence encodes lettercase. For example: **LATIN CAPITAL LETTER A WITH GRAVE** is encoded as `@0G`, whereas **LATIN SMALL LETTER A WITH GRAVE** is encoded as `@0g`. Here the third byte (`G` or `g`) indicates lettercase. (On a case-insensitive file system, both letters are treated as the same.)

For some blocks, such as Cyrillic, the second byte determines lettercase. For other blocks, such as Latin1 Supplement, the third byte determines lettercase. If two bytes in the sequence are letters (as in Greek Extended), the leftmost letter character stands for lettercase. All other letter bytes must be in lowercase.

- All nonletter characters except underscore (`_`), as well as letters from alphabets that do not have uppercase/lowercase mapping (such as Hebrew) are encoded using hexadecimal representation using lowercase letters for hexadecimal digits `a..f`:

```
0x003F -> @003f
0xFFFF -> @ffff
```

The hexadecimal values correspond to character values in the `ucs2` double-byte character set.

On Windows, some names such as `nul`, `prn`, and `aux` are encoded by appending `@@@` to the name when the server creates the corresponding file or directory. This occurs on all platforms for portability of the corresponding database object between platforms.

The following names are reserved and appended with `@@@` if used in schema or table names:

- CON
- PRN
- AUX
- NUL
- COM1 through COM9
- LPT1 through LPT9

CLOCK\$ is also a member of this group of reserved names, but is not appended with `@@@`, but `@0024` instead. That is, if CLOCK\$ is used as a schema or table name, it is written to the file system as `CLOCK@0024`. The same is true for any use of \$ (dollar sign) in a schema or table name; it is replaced with `@0024` on the filesystem.

**Note**

These names are also written to `INNODB TABLES` in their appended forms, but are written to `TABLES` in their unappended form, as entered by the user.

## 11.2.5 Function Name Parsing and Resolution

MySQL supports built-in (native) functions, loadable functions, and stored functions. This section describes how the server recognizes whether the name of a built-in function is used as a function call or as an identifier, and how the server determines which function to use in cases when functions of different types exist with a given name.

- [Built-In Function Name Parsing](#)
- [Function Name Resolution](#)

### Built-In Function Name Parsing

The parser uses default rules for parsing names of built-in functions. These rules can be changed by enabling the `IGNORE_SPACE` SQL mode.

When the parser encounters a word that is the name of a built-in function, it must determine whether the name signifies a function call or is instead a nonexpression reference to an identifier such as a table or column name. For example, in the following statements, the first reference to `count` is a function call, whereas the second reference is a table name:

```
SELECT COUNT(*) FROM mytable;
CREATE TABLE count (i INT);
```

The parser should recognize the name of a built-in function as indicating a function call only when parsing what is expected to be an expression. That is, in nonexpression context, function names are permitted as identifiers.

However, some built-in functions have special parsing or implementation considerations, so the parser uses the following rules by default to distinguish whether their names are being used as function calls or as identifiers in nonexpression context:

- To use the name as a function call in an expression, there must be no whitespace between the name and the following ( parenthesis character.
- Conversely, to use the function name as an identifier, it must not be followed immediately by a parenthesis.

The requirement that function calls be written with no whitespace between the name and the parenthesis applies only to the built-in functions that have special considerations. `COUNT` is one such name. The `sql/lex.h` source file lists the names of these special functions for which following whitespace determines their interpretation: names defined by the `SYM_FN( )` macro in the `symbols[ ]` array.

The following list names the functions in MySQL 9.1 that are affected by the `IGNORE_SPACE` setting and listed as special in the `sql/lex.h` source file. You may find it easiest to treat the no-whitespace requirement as applying to all function calls.

- `ADDDATE`
- `BIT_AND`
- `BIT_OR`
- `BIT_XOR`
- `CAST`
- `COUNT`
- `CURDATE`
- `CURTIME`
- `DATE_ADD`
- `DATE_SUB`
- `EXTRACT`
- `GROUP_CONCAT`
- `MAX`
- `MID`
- `MIN`
- `NOW`
- `POSITION`
- `SESSION_USER`
- `STD`

- `STDDEV`
- `STDDEV_POP`
- `STDDEV_SAMP`
- `SUBDATE`
- `SUBSTR`
- `SUBSTRING`
- `SUM`
- `SYSDATE`
- `SYSTEM_USER`
- `TRIM`
- `VARIANCE`
- `VAR_POP`
- `VAR_SAMP`

For functions not listed as special in `sql/lex.h`, whitespace does not matter. They are interpreted as function calls only when used in expression context and may be used freely as identifiers otherwise. `ASCII` is one such name. However, for these unaffected function names, interpretation may vary in expression context: `func_name ()` is interpreted as a built-in function if there is one with the given name; if not, `func_name ()` is interpreted as a loadable function or stored function if one exists with that name.

The `IGNORE_SPACE` SQL mode can be used to modify how the parser treats function names that are whitespace-sensitive:

- With `IGNORE_SPACE` disabled, the parser interprets the name as a function call when there is no whitespace between the name and the following parenthesis. This occurs even when the function name is used in nonexpression context:

```
mysql> CREATE TABLE count(i INT);
ERROR 1064 (42000): You have an error in your SQL syntax ...
near 'count(i INT)'
```

To eliminate the error and cause the name to be treated as an identifier, either use whitespace following the name or write it as a quoted identifier (or both):

```
CREATE TABLE count (i INT);
CREATE TABLE `count`(i INT);
CREATE TABLE `count` (i INT);
```

- With `IGNORE_SPACE` enabled, the parser loosens the requirement that there be no whitespace between the function name and the following parenthesis. This provides more flexibility in writing function calls. For example, either of the following function calls are legal:

```
SELECT COUNT(*) FROM mytable;
SELECT COUNT (*) FROM mytable;
```

However, enabling `IGNORE_SPACE` also has the side effect that the parser treats the affected function names as reserved words (see [Section 11.3, “Keywords and Reserved Words”](#)). This means that a space following the name no longer signifies its use as an identifier. The name can be used in function

calls with or without following whitespace, but causes a syntax error in nonexpression context unless it is quoted. For example, with `IGNORE_SPACE` enabled, both of the following statements fail with a syntax error because the parser interprets `count` as a reserved word:

```
CREATE TABLE count(i INT);
CREATE TABLE count (i INT);
```

To use the function name in nonexpression context, write it as a quoted identifier:

```
CREATE TABLE `count`(i INT);
CREATE TABLE `count` (i INT);
```

To enable the `IGNORE_SPACE` SQL mode, use this statement:

```
SET sql_mode = 'IGNORE_SPACE';
```

`IGNORE_SPACE` is also enabled by certain other composite modes such as `ANSI` that include it in their value:

```
SET sql_mode = 'ANSI';
```

Check [Section 7.1.11, “Server SQL Modes”](#), to see which composite modes enable `IGNORE_SPACE`.

To minimize the dependency of SQL code on the `IGNORE_SPACE` setting, use these guidelines:

- Avoid creating loadable functions or stored functions that have the same name as a built-in function.
- Avoid using function names in nonexpression context. For example, these statements use `count` (one of the affected function names affected by `IGNORE_SPACE`), so they fail with or without whitespace following the name if `IGNORE_SPACE` is enabled:

```
CREATE TABLE count(i INT);
CREATE TABLE count (i INT);
```

If you must use a function name in nonexpression context, write it as a quoted identifier:

```
CREATE TABLE `count`(i INT);
CREATE TABLE `count` (i INT);
```

## Function Name Resolution

The following rules describe how the server resolves references to function names for function creation and invocation:

- Built-in functions and loadable functions

An error occurs if you try to create a loadable function with the same name as a built-in function.

`IF NOT EXISTS` has no effect in such cases. See [Section 15.7.4.1, “CREATE FUNCTION Statement for Loadable Functions”](#), for more information.

- Built-in functions and stored functions

It is possible to create a stored function with the same name as a built-in function, but to invoke the stored function it is necessary to qualify it with a schema name. For example, if you create a stored function named `PI` in the `test` schema, invoke it as `test.PI()` because the server resolves `PI()` without a qualifier as a reference to the built-in function. The server generates a warning if the stored function name collides with a built-in function name. The warning can be displayed with `SHOW WARNINGS`.

`IF NOT EXISTS` has no effect in such cases; see [Section 15.1.17, “CREATE PROCEDURE and CREATE FUNCTION Statements”](#).

- Loadable functions and stored functions

It is possible to create a stored function with the same name as an existing loadable function, or the other way around. The server generates a warning if a proposed stored function name collides with an existing loadable function name, or if a proposed loadable function name would be the same as that of an existing stored function. In either case, once both functions exist, it is necessary thereafter to qualify the stored function with a schema name when invoking it; the server assumes in such cases that the unqualified name refers to the loadable function.

MySQL 9.1 supports `IF NOT EXISTS` with `CREATE FUNCTION` statements, but it has no effect in such cases.

The preceding function name resolution rules have implications for upgrading to versions of MySQL that implement new built-in functions:

- If you have already created a loadable function with a given name and upgrade MySQL to a version that implements a new built-in function with the same name, the loadable function becomes inaccessible. To correct this, use `DROP FUNCTION` to drop the loadable function and `CREATE FUNCTION` to re-create the loadable function with a different nonconflicting name. Then modify any affected code to use the new name.
- If a new version of MySQL implements a built-in function or loadable function with the same name as an existing stored function, you have two choices: Rename the stored function to use a nonconflicting name, or change any calls to the function that do not do so already to use a schema qualifier (`schema_name.func_name()` syntax). In either case, modify any affected code accordingly.

## 11.3 Keywords and Reserved Words

Keywords are words that have significance in SQL. Certain keywords, such as `SELECT`, `DELETE`, or `BIGINT`, are reserved and require special treatment for use as identifiers such as table and column names. This may also be true for the names of built-in functions.

Most nonreserved keywords are permitted as identifiers without quoting. Some keywords which are otherwise considered nonreserved are restricted from use as unquoted identifiers for roles, stored program labels, or, in some cases, both. See [MySQL 9.1 Restricted Keywords](#), for listings of these keywords.

Reserved words are permitted as identifiers if you quote them as described in [Section 11.2, “Schema Object Names”](#):

```
mysql> CREATE TABLE interval (begin INT, end INT);
ERROR 1064 (42000): You have an error in your SQL syntax ...
near 'interval (begin INT, end INT)'
```

`BEGIN` and `END` are keywords but not reserved, so their use as identifiers does not require quoting. `INTERVAL` is a reserved keyword and must be quoted to be used as an identifier:

```
mysql> CREATE TABLE `interval` (begin INT, end INT);
Query OK, 0 rows affected (0.01 sec)
```

Exception: A word that follows a period in a qualified name must be an identifier, so it need not be quoted even if it is reserved:

```
mysql> CREATE TABLE mydb.interval (begin INT, end INT);
Query OK, 0 rows affected (0.01 sec)
```

Names of built-in functions are permitted as identifiers but may require care to be used as such. For example, `COUNT` is acceptable as a column name. However, by default, no whitespace is permitted in function invocations between the function name and the following `(` character. This requirement enables the parser to distinguish whether the name is used in a function call or in nonfunction context. For further details on recognition of function names, see [Section 11.2.5, “Function Name Parsing and Resolution”](#).

The `INFORMATION_SCHEMA.KEYWORDS` table lists the words considered keywords by MySQL and indicates whether they are reserved. See [Section 28.3.17, “The INFORMATION\\_SCHEMA KEYWORDS Table”](#).

- [MySQL 9.1 Keywords and Reserved Words](#)
- [MySQL 9.1 New Keywords and Reserved Words](#)
- [MySQL 9.1 Removed Keywords and Reserved Words](#)
- [MySQL 9.1 Restricted Keywords](#)

## MySQL 9.1 Keywords and Reserved Words

The following list shows the keywords and reserved words in MySQL 9.1, along with changes to individual words from version to version. Reserved keywords are marked with (R). In addition, `_FILENAME` is reserved.

At some point, you might upgrade to a higher version, so it is a good idea to have a look at future reserved words, too. You can find these in the manuals that cover higher versions of MySQL. Most of the reserved words in the list are forbidden by standard SQL as column or table names (for example, `GROUP`). A few are reserved because MySQL needs them and uses a `yacc` parser.

A | B | C | D | E | F | G | H | I | J | K | L | M | N | O | P | Q | R | S | T | U | V | W | X | Y | Z

## MySQL 9.1 New Keywords and Reserved Words

The following list shows the keywords and reserved words that are added in MySQL 9.1, compared to MySQL 8.4. Reserved keywords are marked with (R).

- [VECTOR](#)

## MySQL 9.1 Removed Keywords and Reserved Words

The following list shows the keywords and reserved words that are removed in MySQL 9.1, compared to MySQL 8.4. Reserved keywords are marked with (R).

There are no keywords removed between MySQL 8.4-9.1.

## MySQL 9.1 Restricted Keywords

Some MySQL keywords are not reserved but even so must be quoted in certain circumstances. This section provides listings of these keywords.

- [Keywords which must be quoted when used as labels](#)
- [Keywords which must be quoted when used as role names](#)
- [Keywords which must be quoted when used as labels or role names](#)

## Keywords which must be quoted when used as labels

The keywords listed here must be quoted when used as labels in MySQL stored programs:

A | B | C | D | E | F | H | I | L | N | P | R | S | T | U | X

### A

- ASCII

### B

- BEGIN
- BYTE

### C

- CACHE
- CHARSET
- CHECKSUM
- CLONE
- COMMENT
- COMMIT
- CONTAINS

### D

- DEALLOCATE
- DO

### E

- END

### F

- FLUSH
- FOLLOWS

### H

- HANDLER
- HELP

### I

- IMPORT
- INSTALL

## L

- `LANGUAGE`

## N

- `NO`

## P

- `PRECEDES`
- `PREPARE`

## R

- `REPAIR`
- `RESET`
- `ROLLBACK`

## S

- `SAVEPOINT`
- `SIGNED`
- `SLAVE`
- `START`
- `STOP`

## T

## U

- `UNICODE`
- `UNINSTALL`

## X

- `XA`

## Keywords which must be quoted when used as role names

The keywords listed here must be quoted when used as names of roles:

- `EVENT`
- `FILE`
- `NONE`
- `PROCESS`
- `PROXY`

- `RELOAD`
- `REPLICATION`
- `RESOURCE`
- `SUPER`

### Keywords which must be quoted when used as labels or role names

The keywords listed here must be quoted when used as labels in stored programs, or as names of roles:

- `EXECUTE`
- `RESTART`
- `SHUTDOWN`

## 11.4 User-Defined Variables

You can store a value in a user-defined variable in one statement and refer to it later in another statement. This enables you to pass values from one statement to another.

User variables are written as `@var_name`, where the variable name `var_name` consists of alphanumeric characters, `.`, `_`, and `$`. A user variable name can contain other characters if you quote it as a string or identifier (for example, `@'my-var'`, `@"my-var"`, or `@`my-var``).

User-defined variables are session specific. A user variable defined by one client cannot be seen or used by other clients. (Exception: A user with access to the Performance Schema `user_variables_by_thread` table can see all user variables for all sessions.) All variables for a given client session are automatically freed when that client exits.

User variable names are not case-sensitive. Names have a maximum length of 64 characters.

One way to set a user-defined variable is by issuing a `SET` statement:

```
SET @var_name = expr [, @var_name = expr] ...
```

For `SET`, either `=` or `:=` can be used as the assignment operator.

User variables can be assigned a value from a limited set of data types: integer, decimal, floating-point, binary or nonbinary string, or `NULL` value. Assignment of decimal and real values does not preserve the precision or scale of the value. A value of a type other than one of the permissible types is converted to a permissible type. For example, a value having a temporal or spatial data type is converted to a binary string. A value having the `JSON` data type is converted to a string with a character set of `utf8mb4` and a collation of `utf8mb4_bin`.

If a user variable is assigned a nonbinary (character) string value, it has the same character set and collation as the string. The coercibility of user variables is implicit. (This is the same coercibility as for table column values.)

Hexadecimal or bit values assigned to user variables are treated as binary strings. To assign a hexadecimal or bit value as a number to a user variable, use it in numeric context. For example, add 0 or use `CAST(... AS UNSIGNED)`:

```
mysql> SET @v1 = X'41';
mysql> SET @v2 = X'41'+0;
```

```
mysql> SET @v3 = CAST(X'41' AS UNSIGNED);
mysql> SELECT @v1, @v2, @v3;
+-----+-----+-----+
| @v1 | @v2 | @v3 |
+-----+-----+-----+
| A | 65 | 65 |
+-----+-----+-----+
mysql> SET @v1 = b'1000001';
mysql> SET @v2 = b'1000001'+0;
mysql> SET @v3 = CAST(b'1000001' AS UNSIGNED);
mysql> SELECT @v1, @v2, @v3;
+-----+-----+-----+
| @v1 | @v2 | @v3 |
+-----+-----+-----+
| A | 65 | 65 |
+-----+-----+-----+
```

If the value of a user variable is selected in a result set, it is returned to the client as a string.

If you refer to a variable that has not been initialized, it has a value of `NULL` and a type of string.

A reference to a user variable in a prepared statement has its type determined when the statement is first prepared, and retains this type each time the statement is executed thereafter. Similarly, the type of a user variable employed in a statement within a stored procedure is determined the first time the stored procedure is invoked, and retains this type with each subsequent invocation.

User variables may be used in most contexts where expressions are permitted. This does not currently include contexts that explicitly require a literal value, such as in the `LIMIT` clause of a `SELECT` statement, or the `IGNORE N LINES` clause of a `LOAD DATA` statement.

Previous releases of MySQL made it possible to assign a value to a user variable in statements other than `SET`. This functionality is supported in MySQL 9.1 for backward compatibility but is subject to removal in a future release of MySQL.

When making an assignment in this way, you must use `:=` as the assignment operator; `=` is treated as the comparison operator in statements other than `SET`.

The order of evaluation for expressions involving user variables is undefined. For example, there is no guarantee that `SELECT @a, @a:=@a+1` evaluates `@a` first and then performs the assignment.

In addition, the default result type of a variable is based on its type at the beginning of the statement. This may have unintended effects if a variable holds a value of one type at the beginning of a statement in which it is also assigned a new value of a different type.

To avoid problems with this behavior, either do not assign a value to and read the value of the same variable within a single statement, or else set the variable to `0`, `0.0`, or `' '` to define its type before you use it.

`HAVING`, `GROUP BY`, and `ORDER BY`, when referring to a variable that is assigned a value in the select expression list do not work as expected because the expression is evaluated on the client and thus can use stale column values from a previous row.

User variables are intended to provide data values. They cannot be used directly in an SQL statement as an identifier or as part of an identifier, such as in contexts where a table or database name is expected, or as a reserved word such as `SELECT`. This is true even if the variable is quoted, as shown in the following example:

```
mysql> SELECT c1 FROM t;
+----+
| c1 |
```

```
+-----+
| 0 |
+-----+
| 1 |
+-----+
2 rows in set (0.00 sec)

mysql> SET @col = "c1";
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @col FROM t;
+-----+
| @col |
+-----+
| c1 |
+-----+
1 row in set (0.00 sec)

mysql> SELECT `@col` FROM t;
ERROR 1054 (42S22): Unknown column '@col' in 'field list'

mysql> SET @col = "`c1`";
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @col FROM t;
+-----+
| @col |
+-----+
| `c1` |
+-----+
1 row in set (0.00 sec)
```

An exception to this principle that user variables cannot be used to provide identifiers, is when you are constructing a string for use as a prepared statement to execute later. In this case, user variables can be used to provide any part of the statement. The following example illustrates how this can be done:

```
mysql> SET @c = "c1";
Query OK, 0 rows affected (0.00 sec)

mysql> SET @s = CONCAT("SELECT ", @c, " FROM t");
Query OK, 0 rows affected (0.00 sec)

mysql> PREPARE stmt FROM @s;
Query OK, 0 rows affected (0.04 sec)
Statement prepared

mysql> EXECUTE stmt;
+-----+
| c1 |
+-----+
| 0 |
+-----+
| 1 |
+-----+
2 rows in set (0.00 sec)

mysql> DEALLOCATE PREPARE stmt;
Query OK, 0 rows affected (0.00 sec)
```

See [Section 15.5, “Prepared Statements”](#), for more information.

A similar technique can be used in application programs to construct SQL statements using program variables, as shown here using PHP 5:

```
<?php
$mysqli = new mysqli("localhost", "user", "pass", "test");
```

```

if(mysqli_connect_errno())
 die("Connection failed: %s\n", mysqli_connect_error());

$col = "c1";

$query = "SELECT $col FROM t";

$result = $mysqli->query($query);

while($row = $result->fetch_assoc())
{
 echo "<p>" . $row["$col"] . "</p>\n";
}

$result->close();

$mysqli->close();

?>

```

Assembling an SQL statement in this fashion is sometimes known as “Dynamic SQL”.

## 11.5 Expressions

This section lists the grammar rules that expressions must follow in MySQL and provides additional information about the types of terms that may appear in expressions.

- [Expression Syntax](#)
- [Expression Term Notes](#)
- [Temporal Intervals](#)

### Expression Syntax

The following grammar rules define expression syntax in MySQL. The grammar shown here is based on that given in the `sql/sql_yacc.yy` file of MySQL source distributions. For additional information about some of the expression terms, see [Expression Term Notes](#).

```

expr:
 expr OR expr
 | expr || expr
 | expr XOR expr
 | expr AND expr
 | expr && expr
 | NOT expr
 | ! expr
 | boolean_primary IS [NOT] {TRUE | FALSE | UNKNOWN}
 | boolean_primary

boolean_primary:
 boolean_primary IS [NOT] NULL
 | boolean_primary <=> predicate
 | boolean_primary comparison_operator predicate
 | boolean_primary comparison_operator {ALL | ANY} (subquery)
 | predicate

comparison_operator: = | >= | > | <= | < | <> | !=

predicate:
 bit_expr [NOT] IN (subquery)
 | bit_expr [NOT] IN (expr [, expr] ...)
 | bit_expr [NOT] BETWEEN bit_expr AND predicate

```

```

| bit_expr SOUNDS LIKE bit_expr
| bit_expr [NOT] LIKE simple_expr [ESCAPE simple_expr]
| bit_expr [NOT] REGEXP bit_expr
| bit_expr

bit_expr:
 bit_expr | bit_expr
| bit_expr & bit_expr
| bit_expr << bit_expr
| bit_expr >> bit_expr
| bit_expr + bit_expr
| bit_expr - bit_expr
| bit_expr * bit_expr
| bit_expr / bit_expr
| bit_expr DIV bit_expr
| bit_expr MOD bit_expr
| bit_expr % bit_expr
| bit_expr ^ bit_expr
| bit_expr + interval_expr
| bit_expr - interval_expr
| simple_expr

simple_expr:
 literal
| identifier
| function_call
| simple_expr COLLATE collation_name
| param_marker
| variable
| simple_expr || simple_expr
| + simple_expr
| - simple_expr
| ~ simple_expr
| ! simple_expr
| BINARY simple_expr
| (expr [, expr] ...)
| ROW (expr, expr [, expr] ...)
| (subquery)
| EXISTS (subquery)
| {identifier expr}
| match_expr
| case_expr
| interval_expr

```

For operator precedence, see [Section 14.4.1, “Operator Precedence”](#). The precedence and meaning of some operators depends on the SQL mode:

- By default, `||` is a logical `OR` operator. With `PIPES_AS_CONCAT` enabled, `||` is string concatenation, with a precedence between `^` and the unary operators.
- By default, `!` has a higher precedence than `NOT`. With `HIGH_NOT_PRECEDENCE` enabled, `!` and `NOT` have the same precedence.

See [Section 7.1.11, “Server SQL Modes”](#).

## Expression Term Notes

For literal value syntax, see [Section 11.1, “Literal Values”](#).

For identifier syntax, see [Section 11.2, “Schema Object Names”](#).

Variables can be user variables, system variables, or stored program local variables or parameters:

- User variables: [Section 11.4, “User-Defined Variables”](#)

- System variables: [Section 7.1.9, “Using System Variables”](#)
- Stored program local variables: [Section 15.6.4.1, “Local Variable DECLARE Statement”](#)
- Stored program parameters: [Section 15.1.17, “CREATE PROCEDURE and CREATE FUNCTION Statements”](#)

*param\_marker* is `?` as used in prepared statements for placeholders. See [Section 15.5.1, “PREPARE Statement”](#).

*(subquery)* indicates a subquery that returns a single value; that is, a scalar subquery. See [Section 15.2.15.1, “The Subquery as Scalar Operand”](#).

*{identifier expr}* is ODBC escape syntax and is accepted for ODBC compatibility. The value is *expr*. The `{` and `}` curly braces in the syntax should be written literally; they are not metasyntax as used elsewhere in syntax descriptions.

*match\_expr* indicates a `MATCH` expression. See [Section 14.9, “Full-Text Search Functions”](#).

*case\_expr* indicates a `CASE` expression. See [Section 14.5, “Flow Control Functions”](#).

*interval\_expr* represents a temporal interval. See [Temporal Intervals](#).

## Temporal Intervals

*interval\_expr* in expressions represents a temporal interval. Intervals have this syntax:

```
INTERVAL expr unit
```

*expr* represents a quantity. *unit* represents the unit for interpreting the quantity; it is a specifier such as `HOURL`, `DAY`, or `WEEK`. The `INTERVAL` keyword and the *unit* specifier are not case-sensitive.

The following table shows the expected form of the *expr* argument for each *unit* value.

**Table 11.2 Temporal Interval Expression and Unit Arguments**

<i>unit</i> Value	Expected <i>expr</i> Format
MICROSECOND	MICROSECONDS
SECOND	SECONDS
MINUTE	MINUTES
HOURL	HOURS
DAY	DAYS
WEEK	WEEKS
MONTH	MONTHS
QUARTER	QUARTERS
YEAR	YEARS
SECOND_MICROSECOND	' SECONDS . MICROSECONDS '
MINUTE_MICROSECOND	' MINUTES : SECONDS . MICROSECONDS '
MINUTE_SECOND	' MINUTES : SECONDS '
HOURL_MICROSECOND	' HOURS : MINUTES : SECONDS . MICROSECONDS '
HOURL_SECOND	' HOURS : MINUTES : SECONDS '

<i>unit</i> Value	Expected <i>expr</i> Format
HOUR_MINUTE	'HOURS:MINUTES'
DAY_MICROSECOND	'DAYS HOURS:MINUTES:SECONDS.MICROSECONDS'
DAY_SECOND	'DAYS HOURS:MINUTES:SECONDS'
DAY_MINUTE	'DAYS HOURS:MINUTES'
DAY_HOUR	'DAYS HOURS'
YEAR_MONTH	'YEARS-MONTHS'

MySQL permits any punctuation delimiter in the *expr* format. Those shown in the table are the suggested delimiters.

Temporal intervals are used for certain functions, such as `DATE_ADD()` and `DATE_SUB()`:

```
mysql> SELECT DATE_ADD('2018-05-01',INTERVAL 1 DAY);
-> '2018-05-02'
mysql> SELECT DATE_SUB('2018-05-01',INTERVAL 1 YEAR);
-> '2017-05-01'
mysql> SELECT DATE_ADD('2020-12-31 23:59:59',
-> INTERVAL 1 SECOND);
-> '2021-01-01 00:00:00'
mysql> SELECT DATE_ADD('2018-12-31 23:59:59',
-> INTERVAL 1 DAY);
-> '2019-01-01 23:59:59'
mysql> SELECT DATE_ADD('2100-12-31 23:59:59',
-> INTERVAL '1:1' MINUTE_SECOND);
-> '2101-01-01 00:01:00'
mysql> SELECT DATE_SUB('2025-01-01 00:00:00',
-> INTERVAL '1 1:1:1' DAY_SECOND);
-> '2024-12-30 22:58:59'
mysql> SELECT DATE_ADD('1900-01-01 00:00:00',
-> INTERVAL '-1 10' DAY_HOUR);
-> '1899-12-30 14:00:00'
mysql> SELECT DATE_SUB('1998-01-02', INTERVAL 31 DAY);
-> '1997-12-02'
mysql> SELECT DATE_ADD('1992-12-31 23:59:59.000002',
-> INTERVAL '1.999999' SECOND_MICROSECOND);
-> '1993-01-01 00:00:01.000001'
```

Temporal arithmetic also can be performed in expressions using `INTERVAL` together with the `+` or `-` operator:

```
date + INTERVAL expr unit
date - INTERVAL expr unit
```

`INTERVAL expr unit` is permitted on either side of the `+` operator if the expression on the other side is a date or datetime value. For the `-` operator, `INTERVAL expr unit` is permitted only on the right side, because it makes no sense to subtract a date or datetime value from an interval.

```
mysql> SELECT '2018-12-31 23:59:59' + INTERVAL 1 SECOND;
-> '2019-01-01 00:00:00'
mysql> SELECT INTERVAL 1 DAY + '2018-12-31';
-> '2019-01-01'
mysql> SELECT '2025-01-01' - INTERVAL 1 SECOND;
-> '2024-12-31 23:59:59'
```

The `EXTRACT()` function uses the same kinds of *unit* specifiers as `DATE_ADD()` or `DATE_SUB()`, but extracts parts from the date rather than performing date arithmetic:

```
mysql> SELECT EXTRACT(YEAR FROM '2019-07-02');
```

```

-> 2019
mysql> SELECT EXTRACT(YEAR_MONTH FROM '2019-07-02 01:02:03');
-> 201907

```

Temporal intervals can be used in `CREATE EVENT` statements:

```

CREATE EVENT myevent
 ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 1 HOUR
 DO
 UPDATE myschema.mytable SET mycol = mycol + 1;

```

If you specify an interval value that is too short (does not include all the interval parts that would be expected from the `unit` keyword), MySQL assumes that you have left out the leftmost parts of the interval value. For example, if you specify a `unit` of `DAY_SECOND`, the value of `expr` is expected to have days, hours, minutes, and seconds parts. If you specify a value like `'1:10'`, MySQL assumes that the days and hours parts are missing and the value represents minutes and seconds. In other words, `'1:10' DAY_SECOND` is interpreted in such a way that it is equivalent to `'1:10' MINUTE_SECOND`. This is analogous to the way that MySQL interprets `TIME` values as representing elapsed time rather than as a time of day.

`expr` is treated as a string, so be careful if you specify a nonstring value with `INTERVAL`. For example, with an interval specifier of `HOURL_MINUTE`, `'6/4'` is treated as 6 hours, four minutes, whereas `6/4` evaluates to `1.5000` and is treated as 1 hour, 5000 minutes:

```

mysql> SELECT '6/4', 6/4;
-> 1.5000
mysql> SELECT DATE_ADD('2019-01-01', INTERVAL '6/4' HOUR_MINUTE);
-> '2019-01-01 06:04:00'
mysql> SELECT DATE_ADD('2019-01-01', INTERVAL 6/4 HOUR_MINUTE);
-> '2019-01-04 12:20:00'

```

To ensure interpretation of the interval value as you expect, a `CAST()` operation may be used. To treat `6/4` as 1 hour, 5 minutes, cast it to a `DECIMAL` value with a single fractional digit:

```

mysql> SELECT CAST(6/4 AS DECIMAL(3,1));
-> 1.5
mysql> SELECT DATE_ADD('1970-01-01 12:00:00',
-> INTERVAL CAST(6/4 AS DECIMAL(3,1)) HOUR_MINUTE);
-> '1970-01-01 13:05:00'

```

If you add to or subtract from a date value something that contains a time part, the result is automatically converted to a datetime value:

```

mysql> SELECT DATE_ADD('2023-01-01', INTERVAL 1 DAY);
-> '2023-01-02'
mysql> SELECT DATE_ADD('2023-01-01', INTERVAL 1 HOUR);
-> '2023-01-01 01:00:00'

```

If you add `MONTH`, `YEAR_MONTH`, or `YEAR` and the resulting date has a day that is larger than the maximum day for the new month, the day is adjusted to the maximum days in the new month:

```

mysql> SELECT DATE_ADD('2019-01-30', INTERVAL 1 MONTH);
-> '2019-02-28'

```

Date arithmetic operations require complete dates and do not work with incomplete dates such as `'2016-07-00'` or badly malformed dates:

```

mysql> SELECT DATE_ADD('2016-07-00', INTERVAL 1 DAY);
-> NULL
mysql> SELECT '2005-03-32' + INTERVAL 1 MONTH;
-> NULL

```

## 11.6 Query Attributes

The most visible part of an SQL statement is the text of the statement. Clients can also define query attributes that apply to the next statement sent to the server for execution:

- Attributes are defined prior to sending the statement.
- Attributes exist until statement execution ends, at which point the attribute set is cleared.
- While attributes exist, they can be accessed on the server side.

Examples of the ways query attributes may be used:

- A web application produces pages that generate database queries, and for each query must track the URL of the page that generated it.
- An application passes extra processing information with each query, for use by a plugin such as an audit plugin or query rewrite plugin.

MySQL supports these capabilities without the use of workarounds such as specially formatted comments included in query strings. The remainder of this section describes how to use query attribute support, including the prerequisites that must be satisfied.

- [Defining and Accessing Query Attributes](#)
- [Prerequisites for Using Query Attributes](#)
- [Query Attribute Loadable Functions](#)

### Defining and Accessing Query Attributes

Applications that use the MySQL C API define query attributes by calling the `mysql_bind_param()` function. See [mysql\\_bind\\_param\(\)](#). Other MySQL connectors may also provide query-attribute support. See the documentation for individual connectors.

The `mysql` client has a `query_attributes` command that enables defining up to 32 pairs of attribute names and values. See [Section 6.5.1.2, “mysql Client Commands”](#).

Query attribute names are transmitted using the character set indicated by the `character_set_client` system variable.

To access query attributes within SQL statements for which attributes have been defined, install the `query_attributes` component as described in [Prerequisites for Using Query Attributes](#). The component implements a `mysql_query_attribute_string()` loadable function that takes an attribute name argument and returns the attribute value as a string, or `NULL` if the attribute does not exist. See [Query Attribute Loadable Functions](#).

The following examples use the `mysql` client `query_attributes` command to define attribute name/value pairs, and the `mysql_query_attribute_string()` function to access attribute values by name.

This example defines two attributes named `n1` and `n2`. The first `SELECT` shows how to retrieve those attributes, and also demonstrates that retrieving a nonexistent attribute (`n3`) returns `NULL`. The second `SELECT` shows that attributes do not persist across statements.

```
mysql> query_attributes n1 v1 n2 v2;
mysql> SELECT
 mysql_query_attribute_string('n1') AS 'attr 1',
 mysql_query_attribute_string('n2') AS 'attr 2',
 mysql_query_attribute_string('n3') AS 'attr 3';
```

```

mysql_query_attribute_string('n3') AS 'attr 3';
+-----+-----+-----+
| attr 1 | attr 2 | attr 3 |
+-----+-----+-----+
| v1 | v2 | NULL |
+-----+-----+-----+

mysql> SELECT
 mysql_query_attribute_string('n1') AS 'attr 1',
 mysql_query_attribute_string('n2') AS 'attr 2';
+-----+-----+
| attr 1 | attr 2 |
+-----+-----+
| NULL | NULL |
+-----+-----+

```

As shown by the second `SELECT` statement, attributes defined prior to a given statement are available only to that statement and are cleared after the statement executes. To use an attribute value across multiple statements, assign it to a variable. The following example shows how to do this, and illustrates that attribute values are available in subsequent statements by means of the variables, but not by calling `mysql_query_attribute_string()`:

```

mysql> query_attributes n1 v1 n2 v2;
mysql> SET
 @attr1 = mysql_query_attribute_string('n1'),
 @attr2 = mysql_query_attribute_string('n2');

mysql> SELECT
 @attr1, mysql_query_attribute_string('n1') AS 'attr 1',
 @attr2, mysql_query_attribute_string('n2') AS 'attr 2';
+-----+-----+-----+-----+
| @attr1 | attr 1 | @attr2 | attr 2 |
+-----+-----+-----+-----+
| v1 | NULL | v2 | NULL |
+-----+-----+-----+-----+

```

Attributes can also be saved for later use by storing them in a table:

```

mysql> CREATE TABLE t1 (c1 CHAR(20), c2 CHAR(20));

mysql> query_attributes n1 v1 n2 v2;
mysql> INSERT INTO t1 (c1, c2) VALUES(
 mysql_query_attribute_string('n1'),
 mysql_query_attribute_string('n2')
);

mysql> SELECT * FROM t1;
+-----+-----+
| c1 | c2 |
+-----+-----+
| v1 | v2 |
+-----+-----+

```

Query attributes are subject to these limitations and restrictions:

- If multiple attribute-definition operations occur prior to sending a statement to the server for execution, the most recent definition operation applies and replaces attributes defined in earlier operations.
- If multiple attributes are defined with the same name, attempts to retrieve the attribute value have an undefined result.
- An attribute defined with an empty name cannot be retrieved by name.
- Attributes are not available to statements prepared with `PREPARE`.

- The `mysql_query_attribute_string()` function cannot be used in DDL statements.
- Attributes are not replicated. Statements that invoke the `mysql_query_attribute_string()` function will not get the same value on all servers.

## Prerequisites for Using Query Attributes

To access query attributes within SQL statements for which attributes have been defined, the `query_attributes` component must be installed. Do so using this statement:

```
INSTALL COMPONENT "file://component_query_attributes";
```

Component installation is a one-time operation that need not be done per server startup. `INSTALL COMPONENT` loads the component, and also registers it in the `mysql.component` system table to cause it to be loaded during subsequent server startups.

The `query_attributes` component accesses query attributes to implement a `mysql_query_attribute_string()` function. See [Section 7.5.4, “Query Attribute Components”](#).

To uninstall the `query_attributes` component, use this statement:

```
UNINSTALL COMPONENT "file://component_query_attributes";
```

`UNINSTALL COMPONENT` unloads the component, and unregisters it from the `mysql.component` system table to cause it not to be loaded during subsequent server startups.

Because installing and uninstalling the `query_attributes` component installs and uninstalls the `mysql_query_attribute_string()` function that the component implements, it is not necessary to use `CREATE FUNCTION` or `DROP FUNCTION` to do so.

## Query Attribute Loadable Functions

- `mysql_query_attribute_string(name)`

Applications can define attributes that apply to the next query sent to the server. The `mysql_query_attribute_string()` function returns an attribute value as a string, given the attribute name. This function enables a query to access and incorporate values of the attributes that apply to it.

`mysql_query_attribute_string()` is installed by installing the `query_attributes` component. See [Section 11.6, “Query Attributes”](#), which also discusses the purpose and use of query attributes.

Arguments:

- `name`: The attribute name.

Return value:

Returns the attribute value as a string for success, or `NULL` if the attribute does not exist.

Example:

The following example uses the `mysql` client `query_attributes` command to define query attributes that can be retrieved by `mysql_query_attribute_string()`. The `SELECT` shows that retrieving a nonexistent attribute (`n3`) returns `NULL`.

```
mysql> query_attributes n1 v1 n2 v2;
mysql> SELECT
```

```

-> mysql_query_attribute_string('n1') AS 'attr 1',
-> mysql_query_attribute_string('n2') AS 'attr 2',
-> mysql_query_attribute_string('n3') AS 'attr 3';
+-----+-----+-----+
| attr 1 | attr 2 | attr 3 |
+-----+-----+-----+
| v1 | v2 | NULL |
+-----+-----+-----+

```

## 11.7 Comments

MySQL Server supports three comment styles:

- From a `#` character to the end of the line.
- From a `--` sequence to the end of the line. In MySQL, the `--` (double-dash) comment style requires the second dash to be followed by at least one whitespace or control character, such as a space or tab. This syntax differs slightly from standard SQL comment syntax, as discussed in [Section 1.7.2.4, “--' as the Start of a Comment”](#).
- From a `/*` sequence to the following `*/` sequence, as in the C programming language. This syntax enables a comment to extend over multiple lines because the beginning and closing sequences need not be on the same line.

The following example demonstrates all three comment styles:

```

mysql> SELECT 1+1; # This comment continues to the end of line
mysql> SELECT 1+1; -- This comment continues to the end of line
mysql> SELECT 1 /* this is an in-line comment */ + 1;
mysql> SELECT 1+
/*
this is a
multiple-line comment
*/
1;

```

Nested comments are not supported, and are deprecated; expect them to be removed in a future MySQL release. (Under some conditions, nested comments might be permitted, but usually are not, and users should avoid them.)

MySQL Server supports certain variants of C-style comments. These enable you to write code that includes MySQL extensions, but is still portable, by using comments of the following form:

```

/*! MySQL-specific code */

```

In this case, MySQL Server parses and executes the code within the comment as it would any other SQL statement, but other SQL servers should ignore the extensions. For example, MySQL Server recognizes the `STRAIGHT_JOIN` keyword in the following statement, but other servers should not:

```

SELECT /*! STRAIGHT_JOIN */ col1 FROM table1,table2 WHERE ...

```

If you add a version number after the `!` character, the syntax within the comment is executed only if the MySQL version is greater than or equal to the specified version number. The `KEY_BLOCK_SIZE` keyword in the following comment is executed only by servers from MySQL 5.1.10 or higher:

```

CREATE TABLE t1(a INT, KEY (a)) /*!50110 KEY_BLOCK_SIZE=1024 */;

```

The version number uses the format `Mmmrrr`, where `M` is a major version, `mm` is a two-digit minor version, and `rr` is a two-digit release number. For example: In a statement to be run only by a MySQL server version 9.1.0 or later, use `90100` in the comment.

In MySQL 9.1, the version number can also optionally be comprised of six digits in *MMmmrr* format, where *MM* is a two-digit major version, and *mm* and *rr* are the two-digit minor version and two-digit release numbers, respectively.

The version number should be followed by at least one whitespace character (or the end of the comment). If the comment begins with six digits followed by whitespace, this is interpreted as a six-digit version number. Otherwise, if it begins with at least five digits, these are interpreted as a five-digit version number (and any remaining characters ignored for this purpose); if it begins with fewer than five digits, the comment is handled as a normal MySQL comment.

The comment syntax just described applies to how the `mysqld` server parses SQL statements. The `mysql` client program also performs some parsing of statements before sending them to the server. (It does this to determine statement boundaries within a multiple-statement input line.) For information about differences between the server and `mysql` client parsers, see [Section 6.5.1.6, “mysql Client Tips”](#).

Comments in `/*!12345 ... */` format are not stored on the server. If this format is used to comment stored programs, the comments are not retained in the program body.

Another variant of C-style comment syntax is used to specify optimizer hints. Hint comments include a `+` character following the `/*` comment opening sequence. Example:

```
SELECT /*+ BKA(t1) */ FROM ... ;
```

For more information, see [Section 10.9.3, “Optimizer Hints”](#).

The use of short-form `mysql` commands such as `\C` within multiple-line `/* ... */` comments is not supported. Short-form commands do work within single-line `/*! ... */` version comments, as do `/*+ ... */` optimizer-hint comments, which are stored in object definitions. If there is a concern that optimizer-hint comments may be stored in object definitions so that dump files when reloaded with `mysql` would result in execution of such commands, either invoke `mysql` with the `--binary-mode` option or use a reload client other than `mysql`.

12.14.4 Adding a UCA Collation to a Unicode Character Set .....	2120
12.15 Character Set Configuration .....	2127
12.16 MySQL Server Locale Support .....	2128

MySQL includes character set support that enables you to store data using a variety of character sets and perform comparisons according to a variety of collations. The default MySQL server character set and collation are `utf8mb4` and `utf8mb4_0900_ai_ci`, but you can specify character sets at the server, database, table, column, and string literal levels. To maximize interoperability and future-proofing of your data and applications, we recommend that you use the `utf8mb4` character set whenever possible.

#### Note

`UTF8` is a deprecated synonym for `utf8mb3`, and you should expect it to be removed in a future version of MySQL. Specify `utfmb3` or (preferably) `utfmb4` instead.

This chapter discusses the following topics:

- What are character sets and collations?
- The multiple-level default system for character set assignment.
- Syntax for specifying character sets and collations.
- Affected functions and operations.
- Unicode support.
- The character sets and collations that are available, with notes.
- Selecting the language for error messages.
- Selecting the locale for day and month names.

Character set issues affect not only data storage, but also communication between client programs and the MySQL server. If you want the client program to communicate with the server using a character set different from the default, you need to indicate which one. For example, to use the `latin1` Unicode character set, issue this statement after connecting to the server:

```
SET NAMES 'latin1';
```

For more information about configuring character sets for application use and character set-related issues in client/server communication, see [Section 12.5, “Configuring Application Character Set and Collation”](#), and [Section 12.4, “Connection Character Sets and Collations”](#).

## 12.1 Character Sets and Collations in General

A *character set* is a set of symbols and encodings. A *collation* is a set of rules for comparing characters in a character set. Let's make the distinction clear with an example of an imaginary character set.

Suppose that we have an alphabet with four letters: **A**, **B**, **a**, **b**. We give each letter a number: **A** = 0, **B** = 1, **a** = 2, **b** = 3. The letter **A** is a symbol, the number 0 is the *encoding* for **A**, and the combination of all four letters and their encodings is a *character set*.

Suppose that we want to compare two string values, **A** and **B**. The simplest way to do this is to look at the encodings: 0 for **A** and 1 for **B**. Because 0 is less than 1, we say **A** is less than **B**. What we've just done is apply a collation to our character set. The collation is a set of rules (only one rule in this case): “compare the encodings.” We call this simplest of all possible collations a *binary* collation.

But what if we want to say that the lowercase and uppercase letters are equivalent? Then we would have at least two rules: (1) treat the lowercase letters **a** and **b** as equivalent to **A** and **B**; (2) then compare the encodings. We call this a *case-insensitive* collation. It is a little more complex than a binary collation.

In real life, most character sets have many characters: not just **A** and **B** but whole alphabets, sometimes multiple alphabets or eastern writing systems with thousands of characters, along with many special symbols and punctuation marks. Also in real life, most collations have many rules, not just for whether to distinguish lettercase, but also for whether to distinguish accents (an “accent” is a mark attached to a character as in German **Ö**), and for multiple-character mappings (such as the rule that **Ö** = **OE** in one of the two German collations).

MySQL can do these things for you:

- Store strings using a variety of character sets.
- Compare strings using a variety of collations.
- Mix strings with different character sets or collations in the same server, the same database, or even the same table.
- Enable specification of character set and collation at any level.

To use these features effectively, you must know what character sets and collations are available, how to change the defaults, and how they affect the behavior of string operators and functions.

## 12.2 Character Sets and Collations in MySQL

MySQL Server supports multiple character sets, including several Unicode character sets. To display the available character sets, use the `INFORMATION_SCHEMA.CHARACTER_SETS` table or the `SHOW CHARACTER SET` statement. A partial listing follows. For more complete information, see [Section 12.10, “Supported Character Sets and Collations”](#).

```
mysql> SHOW CHARACTER SET;
```

Charset	Description	Default collation	Maxlen
big5	Big5 Traditional Chinese	big5_chinese_ci	2
binary	Binary pseudo charset	binary	1
...			
latin1	cp1252 West European	latin1_swedish_ci	1
...			
ucs2	UCS-2 Unicode	ucs2_general_ci	2
...			
utf8mb3	UTF-8 Unicode	utf8mb3_general_ci	3
utf8mb4	UTF-8 Unicode	utf8mb4_0900_ai_ci	4
...			

By default, the `SHOW CHARACTER SET` statement displays all available character sets. It takes an optional `LIKE` or `WHERE` clause that indicates which character set names to match. The following example shows some of the Unicode character sets (those based on Unicode Transformation Format):

```
mysql> SHOW CHARACTER SET LIKE 'utf%';
```

Charset	Description	Default collation	Maxlen
utf16	UTF-16 Unicode	utf16_general_ci	4
utf16le	UTF-16LE Unicode	utf16le_general_ci	4
utf32	UTF-32 Unicode	utf32_general_ci	4
utf8mb3	UTF-8 Unicode	utf8mb3_general_ci	3
utf8mb4	UTF-8 Unicode	utf8mb4_0900_ai_ci	4

A given character set always has at least one collation, and most character sets have several. To list the display collations for a character set, use the [INFORMATION\\_SCHEMA COLLATIONS](#) table or the [SHOW COLLATION](#) statement.

By default, the [SHOW COLLATION](#) statement displays all available collations. It takes an optional [LIKE](#) or [WHERE](#) clause that indicates which collation names to display. For example, to see the collations for the default character set, `utf8mb4`, use this statement:

```
mysql> SHOW COLLATION WHERE Charset = 'utf8mb4';
```

Collation	Charset	Id	Default	Compiled	Sortlen	Pad_attribute
utf8mb4_0900_ai_ci	utf8mb4	255	Yes	Yes	0	NO PAD
utf8mb4_0900_as_ci	utf8mb4	305		Yes	0	NO PAD
utf8mb4_0900_as_cs	utf8mb4	278		Yes	0	NO PAD
utf8mb4_0900_bin	utf8mb4	309		Yes	1	NO PAD
utf8mb4_bin	utf8mb4	46		Yes	1	PAD SPACE
utf8mb4_croatian_ci	utf8mb4	245		Yes	8	PAD SPACE
utf8mb4_cs_0900_ai_ci	utf8mb4	266		Yes	0	NO PAD
utf8mb4_cs_0900_as_cs	utf8mb4	289		Yes	0	NO PAD
utf8mb4_czech_ci	utf8mb4	234		Yes	8	PAD SPACE
utf8mb4_danish_ci	utf8mb4	235		Yes	8	PAD SPACE
utf8mb4_da_0900_ai_ci	utf8mb4	267		Yes	0	NO PAD
utf8mb4_da_0900_as_cs	utf8mb4	290		Yes	0	NO PAD
utf8mb4_de_pb_0900_ai_ci	utf8mb4	256		Yes	0	NO PAD
utf8mb4_de_pb_0900_as_cs	utf8mb4	279		Yes	0	NO PAD
utf8mb4_eo_0900_ai_ci	utf8mb4	273		Yes	0	NO PAD
utf8mb4_eo_0900_as_cs	utf8mb4	296		Yes	0	NO PAD
utf8mb4_esperanto_ci	utf8mb4	241		Yes	8	PAD SPACE
utf8mb4_estonian_ci	utf8mb4	230		Yes	8	PAD SPACE
utf8mb4_es_0900_ai_ci	utf8mb4	263		Yes	0	NO PAD
utf8mb4_es_0900_as_cs	utf8mb4	286		Yes	0	NO PAD
utf8mb4_es_trad_0900_ai_ci	utf8mb4	270		Yes	0	NO PAD
utf8mb4_es_trad_0900_as_cs	utf8mb4	293		Yes	0	NO PAD

utf8mb4_zh_0900_as_cs	utf8mb4	308	Yes	0	NO PAD

For more information about those collations, see [Section 12.10.1, “Unicode Character Sets”](#).

Collations have these general characteristics:

- Two different character sets cannot have the same collation.
- Each character set has a *default collation*. For example, the default collations for `utf8mb4` and `latin1` are `utf8mb4_0900_ai_ci` and `latin1_swedish_ci`, respectively. The `INFORMATION_SCHEMA.CHARACTER_SETS` table and the `SHOW CHARACTER SET` statement indicate the default collation for each character set. The `INFORMATION_SCHEMA.COLLATIONS` table and the `SHOW COLLATION` statement have a column that indicates for each collation whether it is the default for its character set (`Yes` if so, empty if not).
- Collation names start with the name of the character set with which they are associated, generally followed by one or more suffixes indicating other collation characteristics. For additional information about naming conventions, see [Section 12.3.1, “Collation Naming Conventions”](#).

When a character set has multiple collations, it might not be clear which collation is most suitable for a given application. To avoid choosing an inappropriate collation, perform some comparisons with representative data values to make sure that a given collation sorts values the way you expect.

## 12.2.1 Character Set Repertoire

The *repertoire* of a character set is the collection of characters in the set.

String expressions have a repertoire attribute, which can have two values:

- **ASCII:** The expression can contain only ASCII characters; that is, characters in the Unicode range `U+0000` to `U+007F`.

- **UNICODE**: The expression can contain characters in the Unicode range `U+0000` to `U+10FFFF`. This includes characters in the Basic Multilingual Plane (BMP) range (`U+0000` to `U+FFFF`) and supplementary characters outside the BMP range (`U+10000` to `U+10FFFF`).

The **ASCII** range is a subset of **UNICODE** range, so a string with **ASCII** repertoire can be converted safely without loss of information to the character set of any string with **UNICODE** repertoire. It can also be converted safely to any character set that is a superset of the **ascii** character set. (All MySQL character sets are supersets of **ascii** with the exception of **swe7**, which reuses some punctuation characters for Swedish accented characters.)

The use of repertoire enables character set conversion in expressions for many cases where MySQL would otherwise return an “illegal mix of collations” error when the rules for collation coercibility are insufficient to resolve ambiguities. (For information about coercibility, see [Section 12.8.4, “Collation Coercibility in Expressions”](#).)

The following discussion provides examples of expressions and their repertoires, and describes how the use of repertoire changes string expression evaluation:

- The repertoire for a string constant depends on string content and may differ from the repertoire of the string character set. Consider these statements:

```
SET NAMES utf8mb4; SELECT 'abc';
SELECT _utf8mb4'def';
```

Although the character set is **utf8mb4** in each of the preceding cases, the strings do not actually contain any characters outside the ASCII range, so their repertoire is **ASCII** rather than **UNICODE**.

- A column having the **ascii** character set has **ASCII** repertoire because of its character set. In the following table, **c1** has **ASCII** repertoire:

```
CREATE TABLE t1 (c1 CHAR(1) CHARACTER SET ascii);
```

The following example illustrates how repertoire enables a result to be determined in a case where an error occurs without repertoire:

```
CREATE TABLE t1 (
 c1 CHAR(1) CHARACTER SET latin1,
 c2 CHAR(1) CHARACTER SET ascii
);
INSERT INTO t1 VALUES ('a','b');
SELECT CONCAT(c1,c2) FROM t1;
```

Without repertoire, this error occurs:

```
ERROR 1267 (HY000): Illegal mix of collations (latin1_swedish_ci,IMPLICIT)
and (ascii_general_ci,IMPLICIT) for operation 'concat'
```

Using repertoire, subset to superset (**ascii** to **latin1**) conversion can occur and a result is returned:

```
+-----+
| CONCAT(c1,c2) |
+-----+
| ab |
+-----+
```

- Functions with one string argument inherit the repertoire of their argument. The result of `UPPER(_utf8mb4'abc')` has **ASCII** repertoire because its argument has **ASCII** repertoire. (Despite the **\_utf8mb4** introducer, the string **'abc'** contains no characters outside the ASCII range.)

- For functions that return a string but do not have string arguments and use `character_set_connection` as the result character set, the result repertoire is `ASCII` if `character_set_connection` is `ascii`, and `UNICODE` otherwise:

```
FORMAT(numeric_column, 4);
```

Use of repertoire changes how MySQL evaluates the following example:

```
SET NAMES ascii;
CREATE TABLE t1 (a INT, b VARCHAR(10) CHARACTER SET latin1);
INSERT INTO t1 VALUES (1, 'b');
SELECT CONCAT(FORMAT(a, 4), b) FROM t1;
```

Without repertoire, this error occurs:

```
ERROR 1267 (HY000): Illegal mix of collations (ascii_general_ci,COERCIBLE)
and (latin1_swedish_ci,IMPLICIT) for operation 'concat'
```

With repertoire, a result is returned:

```
+-----+
| CONCAT(FORMAT(a, 4), b) |
+-----+
| 1.0000b |
+-----+
```

- Functions with two or more string arguments use the “widest” argument repertoire for the result repertoire, where `UNICODE` is wider than `ASCII`. Consider the following `CONCAT( )` calls:

```
CONCAT(_ucs2 X'0041', _ucs2 X'0042')
CONCAT(_ucs2 X'0041', _ucs2 X'00C2')
```

For the first call, the repertoire is `ASCII` because both arguments are within the ASCII range. For the second call, the repertoire is `UNICODE` because the second argument is outside the ASCII range.

- The repertoire for function return values is determined based on the repertoire of only those arguments that affect the result's character set and collation.

```
IF(column1 < column2, 'smaller', 'greater')
```

The result repertoire is `ASCII` because the two string arguments (the second argument and the third argument) both have `ASCII` repertoire. The first argument does not matter for the result repertoire, even if the expression uses string values.

## 12.2.2 UTF-8 for Metadata

*Metadata* is “the data about the data.” Anything that *describes* the database—as opposed to being the *contents* of the database—is metadata. Thus column names, database names, user names, version names, and most of the string results from `SHOW` are metadata. This is also true of the contents of tables in `INFORMATION_SCHEMA` because those tables by definition contain information about database objects.

Representation of metadata must satisfy these requirements:

- All metadata must be in the same character set. Otherwise, neither the `SHOW` statements nor `SELECT` statements for tables in `INFORMATION_SCHEMA` would work properly because different rows in the same column of the results of these operations would be in different character sets.
- Metadata must include all characters in all languages. Otherwise, users would not be able to name columns and tables using their own languages.

To satisfy both requirements, MySQL stores metadata in a Unicode character set, namely UTF-8. This does not cause any disruption if you never use accented or non-Latin characters. But if you do, you should be aware that metadata is in UTF-8.

The metadata requirements mean that the return values of the `USER()`, `CURRENT_USER()`, `SESSION_USER()`, `SYSTEM_USER()`, `DATABASE()`, and `VERSION()` functions have the UTF-8 character set by default.

The server sets the `character_set_system` system variable to the name of the metadata character set:

```
mysql> SHOW VARIABLES LIKE 'character_set_system';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| character_set_system | utf8mb3 |
+-----+-----+
```

Storage of metadata using Unicode does *not* mean that the server returns headers of columns and the results of `DESCRIBE` functions in the `character_set_system` character set by default. When you use `SELECT column1 FROM t`, the name `column1` itself is returned from the server to the client in the character set determined by the value of the `character_set_results` system variable, which has a default value of `utf8mb4`. If you want the server to pass metadata results back in a different character set, use the `SET NAMES` statement to force the server to perform character set conversion. `SET NAMES` sets the `character_set_results` and other related system variables. (See [Section 12.4, “Connection Character Sets and Collations”](#).) Alternatively, a client program can perform the conversion after receiving the result from the server. It is more efficient for the client to perform the conversion, but this option is not always available for all clients.

If `character_set_results` is set to `NULL`, no conversion is performed and the server returns metadata using its original character set (the set indicated by `character_set_system`).

Error messages returned from the server to the client are converted to the client character set automatically, as with metadata.

If you are using (for example) the `USER()` function for comparison or assignment within a single statement, don't worry. MySQL performs some automatic conversion for you.

```
SELECT * FROM t1 WHERE USER() = latin1_column;
```

This works because the contents of `latin1_column` are automatically converted to UTF-8 before the comparison.

```
INSERT INTO t1 (latin1_column) SELECT USER();
```

This works because the contents of `USER()` are automatically converted to `latin1` before the assignment.

Although automatic conversion is not in the SQL standard, the standard does say that every character set is (in terms of supported characters) a “subset” of Unicode. Because it is a well-known principle that “what applies to a superset can apply to a subset,” we believe that a collation for Unicode can apply for comparisons with non-Unicode strings. For more information about coercion of strings, see [Section 12.8.4, “Collation Coercibility in Expressions”](#).

## 12.3 Specifying Character Sets and Collations

There are default settings for character sets and collations at four levels: server, database, table, and column. The description in the following sections may appear complex, but it has been found in practice that multiple-level defaulting leads to natural and obvious results.

`CHARACTER SET` is used in clauses that specify a character set. `CHARSET` can be used as a synonym for `CHARACTER SET`.

Character set issues affect not only data storage, but also communication between client programs and the MySQL server. If you want the client program to communicate with the server using a character set different from the default, you need to indicate which one. For example, to use the `latin1` Unicode character set, issue this statement after connecting to the server:

```
SET NAMES 'latin1';
```

For more information about character set-related issues in client/server communication, see [Section 12.4, “Connection Character Sets and Collations”](#).

## 12.3.1 Collation Naming Conventions

MySQL collation names follow these conventions:

- A collation name starts with the name of the character set with which it is associated, generally followed by one or more suffixes indicating other collation characteristics. For example, `utf8mb4_0900_ai_ci` and `latin1_swedish_ci` are collations for the `utf8mb4` and `latin1` character sets, respectively. The `binary` character set has a single collation, also named `binary`, with no suffixes.
- A language-specific collation includes a locale code or language name. For example, `utf8mb4_tr_0900_ai_ci` and `utf8mb4_hu_0900_ai_ci` sort characters for the `utf8mb4` character set using the rules of Turkish and Hungarian, respectively. `utf8mb4_turkish_ci` and `utf8mb4_hungarian_ci` are similar but based on a less recent version of the Unicode Collation Algorithm.
- Collation suffixes indicate whether a collation is case-sensitive, accent-sensitive, or kana-sensitive (or some combination thereof), or binary. The following table shows the suffixes used to indicate these characteristics.

**Table 12.1 Collation Suffix Meanings**

Suffix	Meaning
<code>_ai</code>	Accent-insensitive
<code>_as</code>	Accent-sensitive
<code>_ci</code>	Case-insensitive
<code>_cs</code>	Case-sensitive
<code>_ks</code>	Kana-sensitive
<code>_bin</code>	Binary

For nonbinary collation names that do not specify accent sensitivity, it is determined by case sensitivity. If a collation name does not contain `_ai` or `_as`, `_ci` in the name implies `_ai` and `_cs` in the name implies `_as`. For example, `latin1_general_ci` is explicitly case-insensitive and implicitly accent-insensitive, `latin1_general_cs` is explicitly case-sensitive and implicitly accent-sensitive, and `utf8mb4_0900_ai_ci` is explicitly case-insensitive and accent-insensitive.

For Japanese collations, the `_ks` suffix indicates that a collation is kana-sensitive; that is, it distinguishes Katakana characters from Hiragana characters. Japanese collations without the `_ks` suffix are not kana-sensitive and treat Katakana and Hiragana characters equal for sorting.

For the `binary` collation of the `binary` character set, comparisons are based on numeric byte values. For the `_bin` collation of a nonbinary character set, comparisons are based on numeric character code

values, which differ from byte values for multibyte characters. For information about the differences between the `binary` collation of the `binary` character set and the `_bin` collations of nonbinary character sets, see [Section 12.8.5, “The binary Collation Compared to \\_bin Collations”](#).

- Collation names for Unicode character sets may include a version number to indicate the version of the Unicode Collation Algorithm (UCA) on which the collation is based. UCA-based collations without a version number in the name use the version-4.0.0 UCA weight keys. For example:
  - `utf8mb4_0900_ai_ci` is based on UCA 9.0.0 weight keys (<http://www.unicode.org/Public/UCA/9.0.0/allkeys.txt>).
  - `utf8mb4_unicode_520_ci` is based on UCA 5.2.0 weight keys (<http://www.unicode.org/Public/UCA/5.2.0/allkeys.txt>).
  - `utf8mb4_unicode_ci` (with no version named) is based on UCA 4.0.0 weight keys (<http://www.unicode.org/Public/UCA/4.0.0/allkeys-4.0.0.txt>).
- For Unicode character sets, the `xxx_general_mysql500_ci` collations preserve the pre-5.1.24 ordering of the original `xxx_general_ci` collations and permit upgrades for tables created before MySQL 5.1.24 (Bug #27877).

## 12.3.2 Server Character Set and Collation

MySQL Server has a server character set and a server collation. By default, these are `utf8mb4` and `utf8mb4_0900_ai_ci`, but they can be set explicitly at server startup on the command line or in an option file and changed at runtime.

Initially, the server character set and collation depend on the options that you use when you start `mysqld`. You can use `--character-set-server` for the character set. Along with it, you can add `--collation-server` for the collation. If you don't specify a character set, that is the same as saying `--character-set-server=utf8mb4`. If you specify only a character set (for example, `utf8mb4`) but not a collation, that is the same as saying `--character-set-server=utf8mb4 --collation-server=utf8mb4_0900_ai_ci` because `utf8mb4_0900_ai_ci` is the default collation for `utf8mb4`. Therefore, the following three commands all have the same effect:

```
mysqld
mysqld --character-set-server=utf8mb4
mysqld --character-set-server=utf8mb4 \
 --collation-server=utf8mb4_0900_ai_ci
```

One way to change the settings is by recompiling. To change the default server character set and collation when building from sources, use the `DEFAULT_CHARSET` and `DEFAULT_COLLATION` options for `CMake`. For example:

```
cmake . -DDEFAULT_CHARSET=latin1
```

Or:

```
cmake . -DDEFAULT_CHARSET=latin1 \
 -DDEFAULT_COLLATION=latin1_german1_ci
```

Both `mysqld` and `CMake` verify that the character set/collation combination is valid. If not, each program displays an error message and terminates.

The server character set and collation are used as default values if the database character set and collation are not specified in `CREATE DATABASE` statements. They have no other purpose.

The current server character set and collation can be determined from the values of the `character_set_server` and `collation_server` system variables. These variables can be changed at runtime.

### 12.3.3 Database Character Set and Collation

Every database has a database character set and a database collation. The `CREATE DATABASE` and `ALTER DATABASE` statements have optional clauses for specifying the database character set and collation:

```
CREATE DATABASE db_name
 [[DEFAULT] CHARACTER SET charset_name]
 [[DEFAULT] COLLATE collation_name]

ALTER DATABASE db_name
 [[DEFAULT] CHARACTER SET charset_name]
 [[DEFAULT] COLLATE collation_name]
```

The keyword `SCHEMA` can be used instead of `DATABASE`.

The `CHARACTER SET` and `COLLATE` clauses make it possible to create databases with different character sets and collations on the same MySQL server.

Database options are stored in the data dictionary and can be examined by checking the Information Schema `SCHEMATA` table.

Example:

```
CREATE DATABASE db_name CHARACTER SET latin1 COLLATE latin1_swedish_ci;
```

MySQL chooses the database character set and database collation in the following manner:

- If both `CHARACTER SET charset_name` and `COLLATE collation_name` are specified, character set *charset\_name* and collation *collation\_name* are used.
- If `CHARACTER SET charset_name` is specified without `COLLATE`, character set *charset\_name* and its default collation are used. To see the default collation for each character set, use the `SHOW CHARACTER SET` statement or query the `INFORMATION_SCHEMA.CHARACTER_SETS` table.
- If `COLLATE collation_name` is specified without `CHARACTER SET`, the character set associated with *collation\_name* and collation *collation\_name* are used.
- Otherwise (neither `CHARACTER SET` nor `COLLATE` is specified), the server character set and server collation are used.

The character set and collation for the default database can be determined from the values of the `character_set_database` and `collation_database` system variables. The server sets these variables whenever the default database changes. If there is no default database, the variables have the same value as the corresponding server-level system variables, `character_set_server` and `collation_server`.

To see the default character set and collation for a given database, use these statements:

```
USE db_name;
SELECT @@character_set_database, @@collation_database;
```

Alternatively, to display the values without changing the default database:

```
SELECT DEFAULT_CHARACTER_SET_NAME, DEFAULT_COLLATION_NAME
FROM INFORMATION_SCHEMA.SCHEMATA WHERE SCHEMA_NAME = 'db_name';
```

The database character set and collation affect these aspects of server operation:

- For `CREATE TABLE` statements, the database character set and collation are used as default values for table definitions if the table character set and collation are not specified. To override this, provide explicit `CHARACTER SET` and `COLLATE` table options.
- For `LOAD DATA` statements that include no `CHARACTER SET` clause, the server uses the character set indicated by the `character_set_database` system variable to interpret the information in the file. To override this, provide an explicit `CHARACTER SET` clause.
- For stored routines (procedures and functions), the database character set and collation in effect at routine creation time are used as the character set and collation of character data parameters for which the declaration includes no `CHARACTER SET` or a `COLLATE` attribute. To override this, provide `CHARACTER SET` and `COLLATE` explicitly.

### 12.3.4 Table Character Set and Collation

Every table has a table character set and a table collation. The `CREATE TABLE` and `ALTER TABLE` statements have optional clauses for specifying the table character set and collation:

```
CREATE TABLE tbl_name (column_list)
 [[DEFAULT] CHARACTER SET charset_name]
 [COLLATE collation_name]]

ALTER TABLE tbl_name
 [[DEFAULT] CHARACTER SET charset_name]
 [COLLATE collation_name]
```

Example:

```
CREATE TABLE t1 (...)
CHARACTER SET latin1 COLLATE latin1_danish_ci;
```

MySQL chooses the table character set and collation in the following manner:

- If both `CHARACTER SET charset_name` and `COLLATE collation_name` are specified, character set *charset\_name* and collation *collation\_name* are used.
- If `CHARACTER SET charset_name` is specified without `COLLATE`, character set *charset\_name* and its default collation are used. To see the default collation for each character set, use the `SHOW CHARACTER SET` statement or query the `INFORMATION_SCHEMA.CHARACTER_SETS` table.
- If `COLLATE collation_name` is specified without `CHARACTER SET`, the character set associated with *collation\_name* and collation *collation\_name* are used.
- Otherwise (neither `CHARACTER SET` nor `COLLATE` is specified), the database character set and collation are used.

The table character set and collation are used as default values for column definitions if the column character set and collation are not specified in individual column definitions. The table character set and collation are MySQL extensions; there are no such things in standard SQL.

### 12.3.5 Column Character Set and Collation

Every “character” column (that is, a column of type `CHAR`, `VARCHAR`, a `TEXT` type, or any synonym) has a column character set and a column collation. Column definition syntax for `CREATE TABLE` and `ALTER TABLE` has optional clauses for specifying the column character set and collation:

```
col_name {CHAR | VARCHAR | TEXT} (col_length)
 [CHARACTER SET charset_name]
```

```
[COLLATE collation_name]
```

These clauses can also be used for [ENUM](#) and [SET](#) columns:

```
col_name {ENUM | SET} (val_list)
 [CHARACTER SET charset_name]
 [COLLATE collation_name]
```

Examples:

```
CREATE TABLE t1
(
 coll VARCHAR(5)
 CHARACTER SET latin1
 COLLATE latin1_german1_ci
);

ALTER TABLE t1 MODIFY
 coll VARCHAR(5)
 CHARACTER SET latin1
 COLLATE latin1_swedish_ci;
```

MySQL chooses the column character set and collation in the following manner:

- If both [CHARACTER SET \*charset\\_name\*](#) and [COLLATE \*collation\\_name\*](#) are specified, character set *charset\_name* and collation *collation\_name* are used.

```
CREATE TABLE t1
(
 coll CHAR(10) CHARACTER SET utf8mb4 COLLATE utf8mb4_unicode_ci
) CHARACTER SET latin1 COLLATE latin1_bin;
```

The character set and collation are specified for the column, so they are used. The column has character set *utf8mb4* and collation *utf8mb4\_unicode\_ci*.

- If [CHARACTER SET \*charset\\_name\*](#) is specified without [COLLATE](#), character set *charset\_name* and its default collation are used.

```
CREATE TABLE t1
(
 coll CHAR(10) CHARACTER SET utf8mb4
) CHARACTER SET latin1 COLLATE latin1_bin;
```

The character set is specified for the column, but the collation is not. The column has character set *utf8mb4* and the default collation for *utf8mb4*, which is *utf8mb4\_0900\_ai\_ci*. To see the default collation for each character set, use the [SHOW CHARACTER SET](#) statement or query the [INFORMATION\\_SCHEMA.CHARACTER\\_SETS](#) table.

- If [COLLATE \*collation\\_name\*](#) is specified without [CHARACTER SET](#), the character set associated with *collation\_name* and collation *collation\_name* are used.

```
CREATE TABLE t1
(
 coll CHAR(10) COLLATE utf8mb4_polish_ci
) CHARACTER SET latin1 COLLATE latin1_bin;
```

The collation is specified for the column, but the character set is not. The column has collation *utf8mb4\_polish\_ci* and the character set is the one associated with the collation, which is *utf8mb4*.

- Otherwise (neither [CHARACTER SET](#) nor [COLLATE](#) is specified), the table character set and collation are used.

```
CREATE TABLE t1
```

```
(
 coll CHAR(10)
) CHARACTER SET latin1 COLLATE latin1_bin;
```

Neither the character set nor collation is specified for the column, so the table defaults are used. The column has character set `latin1` and collation `latin1_bin`.

The `CHARACTER SET` and `COLLATE` clauses are standard SQL.

If you use `ALTER TABLE` to convert a column from one character set to another, MySQL attempts to map the data values, but if the character sets are incompatible, there may be data loss.

## 12.3.6 Character String Literal Character Set and Collation

Every character string literal has a character set and a collation.

For the simple statement `SELECT 'string'`, the string has the connection default character set and collation defined by the `character_set_connection` and `collation_connection` system variables.

A character string literal may have an optional character set introducer and `COLLATE` clause, to designate it as a string that uses a particular character set and collation:

```
[_charset_name]'string' [COLLATE collation_name]
```

The `_charset_name` expression is formally called an *introducer*. It tells the parser, “the string that follows uses character set `charset_name`.” An introducer does not change the string to the introducer character set like `CONVERT( )` would do. It does not change the string value, although padding may occur. The introducer is just a signal. See [Section 12.3.8, “Character Set Introducers”](#).

Examples:

```
SELECT 'abc';
SELECT _latin1'abc';
SELECT _binary'abc';
SELECT _utf8mb4'abc' COLLATE utf8mb4_danish_ci;
```

Character set introducers and the `COLLATE` clause are implemented according to standard SQL specifications.

MySQL determines the character set and collation of a character string literal in the following manner:

- If both `_charset_name` and `COLLATE collation_name` are specified, character set `charset_name` and collation `collation_name` are used. `collation_name` must be a permitted collation for `charset_name`.
- If `_charset_name` is specified but `COLLATE` is not specified, character set `charset_name` and its default collation are used. To see the default collation for each character set, use the `SHOW CHARACTER SET` statement or query the `INFORMATION_SCHEMA.CHARACTER_SETS` table.
- If `_charset_name` is not specified but `COLLATE collation_name` is specified, the connection default character set given by the `character_set_connection` system variable and collation `collation_name` are used. `collation_name` must be a permitted collation for the connection default character set.
- Otherwise (neither `_charset_name` nor `COLLATE collation_name` is specified), the connection default character set and collation given by the `character_set_connection` and `collation_connection` system variables are used.

Examples:

- A nonbinary string with `latin1` character set and `latin1_german1_ci` collation:

```
SELECT _latin1'Müller' COLLATE latin1_german1_ci;
```

- A nonbinary string with `utf8mb4` character set and its default collation (that is, `utf8mb4_0900_ai_ci`):

```
SELECT _utf8mb4'Müller';
```

- A binary string with `binary` character set and its default collation (that is, `binary`):

```
SELECT _binary'Müller';
```

- A nonbinary string with the connection default character set and `utf8mb4_0900_ai_ci` collation (fails if the connection character set is not `utf8mb4`):

```
SELECT 'Müller' COLLATE utf8mb4_0900_ai_ci;
```

- A string with the connection default character set and collation:

```
SELECT 'Müller';
```

An introducer indicates the character set for the following string, but does not change how the parser performs escape processing within the string. Escapes are always interpreted by the parser according to the character set given by `character_set_connection`.

The following examples show that escape processing occurs using `character_set_connection` even in the presence of an introducer. The examples use `SET NAMES` (which changes `character_set_connection`, as discussed in [Section 12.4, “Connection Character Sets and Collations”](#)), and display the resulting strings using the `HEX()` function so that the exact string contents can be seen.

Example 1:

```
mysql> SET NAMES latin1;
mysql> SELECT HEX('à\n'), HEX(_sjis'à\n');
+-----+-----+
| HEX('à\n') | HEX(_sjis'à\n') |
+-----+-----+
| E00A | E00A |
+-----+-----+
```

Here, `à` (hexadecimal value `E0`) is followed by `\n`, the escape sequence for newline. The escape sequence is interpreted using the `character_set_connection` value of `latin1` to produce a literal newline (hexadecimal value `0A`). This happens even for the second string. That is, the `_sjis` introducer does not affect the parser's escape processing.

Example 2:

```
mysql> SET NAMES sjis;
mysql> SELECT HEX('à\n'), HEX(_latin1'à\n');
+-----+-----+
| HEX('à\n') | HEX(_latin1'à\n') |
+-----+-----+
| E05C6E | E05C6E |
+-----+-----+
```

Here, `character_set_connection` is `sjis`, a character set in which the sequence of `à` followed by `\` (hexadecimal values `05` and `5C`) is a valid multibyte character. Hence, the first two bytes of the string are interpreted as a single `sjis` character, and the `\` is not interpreted as an escape character. The following `n` (hexadecimal value `6E`) is not interpreted as part of an escape sequence. This is true even for the second string; the `_latin1` introducer does not affect escape processing.

## 12.3.7 The National Character Set

Standard SQL defines `NCHAR` or `NATIONAL CHAR` as a way to indicate that a `CHAR` column should use some predefined character set. MySQL uses `utf8` as this predefined character set. For example, these data type declarations are equivalent:

```
CHAR(10) CHARACTER SET utf8
NATIONAL CHARACTER(10)
NCHAR(10)
```

As are these:

```
VARCHAR(10) CHARACTER SET utf8
NATIONAL VARCHAR(10)
NVARCHAR(10)
NCHAR VARCHAR(10)
NATIONAL CHARACTER VARYING(10)
NATIONAL CHAR VARYING(10)
```

You can use `N'literal'` (or `n'literal'`) to create a string in the national character set. These statements are equivalent:

```
SELECT N'some text';
SELECT n'some text';
SELECT _utf8'some text';
```

MySQL 9.1 interprets the national character set as `utf8mb3`, which is now deprecated. Thus, using `NATIONAL CHARACTER` or one of its synonyms to define the character set for a database, table, or column raises a warning similar to this one:

```
NATIONAL/NCHAR/NVARCHAR implies the character set UTF8MB3, which will be
replaced by UTF8MB4 in a future release. Please consider using CHAR(x) CHARACTER
SET UTF8MB4 in order to be unambiguous.
```

## 12.3.8 Character Set Introducers

A character string literal, hexadecimal literal, or bit-value literal may have an optional character set introducer and `COLLATE` clause, to designate it as a string that uses a particular character set and collation:

```
[_charset_name] literal [COLLATE collation_name]
```

The `_charset_name` expression is formally called an *introducer*. It tells the parser, “the string that follows uses character set `charset_name`.” An introducer does not change the string to the introducer character set like `CONVERT( )` would do. It does not change the string value, although padding may occur. The introducer is just a signal.

For character string literals, space between the introducer and the string is permitted but optional.

For character set literals, an introducer indicates the character set for the following string, but does not change how the parser performs escape processing within the string. Escapes are always interpreted by the parser according to the character set given by `character_set_connection`. For additional discussion and examples, see [Section 12.3.6, “Character String Literal Character Set and Collation”](#).

Examples:

```
SELECT 'abc';
SELECT _latin1'abc';
SELECT _binary'abc';
SELECT _utf8mb4'abc' COLLATE utf8mb4_danish_ci;
```

```

SELECT _latin1 X'4D7953514C';
SELECT _utf8mb4 0x4D7953514C COLLATE utf8mb4_danish_ci;

SELECT _latin1 b'1000001';
SELECT _utf8mb4 0b1000001 COLLATE utf8mb4_danish_ci;

```

Character set introducers and the `COLLATE` clause are implemented according to standard SQL specifications.

Character string literals can be designated as binary strings by using the `_binary` introducer. Hexadecimal literals and bit-value literals are binary strings by default, so `_binary` is permitted, but normally unnecessary. `_binary` may be useful to preserve a hexadecimal or bit literal as a binary string in contexts for which the literal is otherwise treated as a number. For example, bit operations permit numeric or binary string arguments in MySQL 9.1 and higher, but treat hexadecimal and bit literals as numbers by default. To explicitly specify binary string context for such literals, use a `_binary` introducer for at least one of the arguments:

```

mysql> SET @v1 = X'000D' | X'0BC0';
mysql> SET @v2 = _binary X'000D' | X'0BC0';
mysql> SELECT HEX(@v1), HEX(@v2);
+-----+-----+
| HEX(@v1) | HEX(@v2) |
+-----+-----+
| BCD | 0BCD |
+-----+-----+

```

The displayed result appears similar for both bit operations, but the result without `_binary` is a `BIGINT` value, whereas the result with `_binary` is a binary string. Due to the difference in result types, the displayed values differ: High-order 0 digits are not displayed for the numeric result.

MySQL determines the character set and collation of a character string literal, hexadecimal literal, or bit-value literal in the following manner:

- If both `_charset_name` and `COLLATE collation_name` are specified, character set `charset_name` and collation `collation_name` are used. `collation_name` must be a permitted collation for `charset_name`.
- If `_charset_name` is specified but `COLLATE` is not specified, character set `charset_name` and its default collation are used. To see the default collation for each character set, use the `SHOW CHARACTER SET` statement or query the `INFORMATION_SCHEMA.CHARACTER_SETS` table.
- If `_charset_name` is not specified but `COLLATE collation_name` is specified:
  - For a character string literal, the connection default character set given by the `character_set_connection` system variable and collation `collation_name` are used. `collation_name` must be a permitted collation for the connection default character set.
  - For a hexadecimal literal or bit-value literal, the only permitted collation is `binary` because these types of literals are binary strings by default.
- Otherwise (neither `_charset_name` nor `COLLATE collation_name` is specified):
  - For a character string literal, the connection default character set and collation given by the `character_set_connection` and `collation_connection` system variables are used.
  - For a hexadecimal literal or bit-value literal, the character set and collation are `binary`.

Examples:

- Nonbinary strings with `latin1` character set and `latin1_german1_ci` collation:

```
SELECT _latin1'Müller' COLLATE latin1_german1_ci;
SELECT _latin1 X'0A0D' COLLATE latin1_german1_ci;
SELECT _latin1 b'0110' COLLATE latin1_german1_ci;
```

- Nonbinary strings with `utf8mb4` character set and its default collation (that is, `utf8mb4_0900_ai_ci`):

```
SELECT _utf8mb4'Müller';
SELECT _utf8mb4 X'0A0D';
SELECT _utf8mb4 b'0110';
```

- Binary strings with `binary` character set and its default collation (that is, `binary`):

```
SELECT _binary'Müller';
SELECT X'0A0D';
SELECT b'0110';
```

The hexadecimal literal and bit-value literal need no introducer because they are binary strings by default.

- A nonbinary string with the connection default character set and `utf8mb4_0900_ai_ci` collation (fails if the connection character set is not `utf8mb4`):

```
SELECT 'Müller' COLLATE utf8mb4_0900_ai_ci;
```

This construction (`COLLATE` only) does not work for hexadecimal literals or bit literals because their character set is `binary` no matter the connection character set, and `binary` is not compatible with the `utf8mb4_0900_ai_ci` collation. The only permitted `COLLATE` clause in the absence of an introducer is `COLLATE binary`.

- A string with the connection default character set and collation:

```
SELECT 'Müller';
```

## 12.3.9 Examples of Character Set and Collation Assignment

The following examples show how MySQL determines default character set and collation values.

### Example 1: Table and Column Definition

```
CREATE TABLE t1
(
 c1 CHAR(10) CHARACTER SET latin1 COLLATE latin1_german1_ci
) DEFAULT CHARACTER SET latin2 COLLATE latin2_bin;
```

Here we have a column with a `latin1` character set and a `latin1_german1_ci` collation. The definition is explicit, so that is straightforward. Notice that there is no problem with storing a `latin1` column in a `latin2` table.

### Example 2: Table and Column Definition

```
CREATE TABLE t1
(
 c1 CHAR(10) CHARACTER SET latin1
) DEFAULT CHARACTER SET latin1 COLLATE latin1_danish_ci;
```

This time we have a column with a `latin1` character set and a default collation. Although it might seem natural, the default collation is not taken from the table level. Instead, because the default collation for `latin1` is always `latin1_swedish_ci`, column `c1` has a collation of `latin1_swedish_ci` (not `latin1_danish_ci`).

**Example 3: Table and Column Definition**

```
CREATE TABLE t1
(
 c1 CHAR(10)
) DEFAULT CHARACTER SET latin1 COLLATE latin1_danish_ci;
```

We have a column with a default character set and a default collation. In this circumstance, MySQL checks the table level to determine the column character set and collation. Consequently, the character set for column `c1` is `latin1` and its collation is `latin1_danish_ci`.

**Example 4: Database, Table, and Column Definition**

```
CREATE DATABASE d1
 DEFAULT CHARACTER SET latin2 COLLATE latin2_czech_cs;
USE d1;
CREATE TABLE t1
(
 c1 CHAR(10)
);
```

We create a column without specifying its character set and collation. We're also not specifying a character set and a collation at the table level. In this circumstance, MySQL checks the database level to determine the table settings, which thereafter become the column settings.) Consequently, the character set for column `c1` is `latin2` and its collation is `latin2_czech_cs`.

## 12.3.10 Compatibility with Other DBMSs

For MaxDB compatibility these two statements are the same:

```
CREATE TABLE t1 (f1 CHAR(N) UNICODE);
CREATE TABLE t1 (f1 CHAR(N) CHARACTER SET ucs2);
```

Both the `UNICODE` attribute and the `ucs2` character set are deprecated; you should expect them to be removed in a future version of MySQL.

## 12.4 Connection Character Sets and Collations

A “connection” is what a client program makes when it connects to the server, to begin a session within which it interacts with the server. The client sends SQL statements, such as queries, over the session connection. The server sends responses, such as result sets or error messages, over the connection back to the client.

- [Connection Character Set and Collation System Variables](#)
- [Impermissible Client Character Sets](#)
- [Client Program Connection Character Set Configuration](#)
- [SQL Statements for Connection Character Set Configuration](#)
- [Connection Character Set Error Handling](#)

### Connection Character Set and Collation System Variables

Several character set and collation system variables relate to a client's interaction with the server. Some of these have been mentioned in earlier sections:

- The `character_set_server` and `collation_server` system variables indicate the server character set and collation. See [Section 12.3.2, “Server Character Set and Collation”](#).

- The `character_set_database` and `collation_database` system variables indicate the character set and collation of the default database. See [Section 12.3.3, “Database Character Set and Collation”](#).

Additional character set and collation system variables are involved in handling traffic for the connection between a client and the server. Every client has session-specific connection-related character set and collation system variables. These session system variable values are initialized at connect time, but can be changed within the session.

Several questions about character set and collation handling for client connections can be answered in terms of system variables:

- What character set are statements in when they leave the client?

The server takes the `character_set_client` system variable to be the character set in which statements are sent by the client.

#### Note

Some character sets cannot be used as the client character set. See [Impermissible Client Character Sets](#).

- What character set should the server translate statements to after receiving them?

To determine this, the server uses the `character_set_connection` and `collation_connection` system variables:

- The server converts statements sent by the client from `character_set_client` to `character_set_connection`. Exception: For string literals that have an introducer such as `_utf8mb4` or `_latin2`, the introducer determines the character set. See [Section 12.3.8, “Character Set Introducers”](#).
- `collation_connection` is important for comparisons of literal strings. For comparisons of strings with column values, `collation_connection` does not matter because columns have their own collation, which has a higher collation precedence (see [Section 12.8.4, “Collation Coercibility in Expressions”](#)).
- What character set should the server translate query results to before shipping them back to the client?

The `character_set_results` system variable indicates the character set in which the server returns query results to the client. This includes result data such as column values, result metadata such as column names, and error messages.

To tell the server to perform no conversion of result sets or error messages, set `character_set_results` to `NULL` or `binary`:

```
SET character_set_results = NULL;
SET character_set_results = binary;
```

For more information about character sets and error messages, see [Section 12.6, “Error Message Character Set”](#).

To see the values of the character set and collation system variables that apply to the current session, use this statement:

```
SELECT * FROM performance_schema.session_variables
WHERE VARIABLE_NAME IN (
 'character_set_client', 'character_set_connection',
 'character_set_results', 'collation_connection'
) ORDER BY VARIABLE_NAME;
```

The following simpler statements also display the connection variables, but include other related variables as well. They can be useful to see *all* character set and collation system variables:

```
SHOW SESSION VARIABLES LIKE 'character_set_%\';
SHOW SESSION VARIABLES LIKE 'collation_%\';
```

Clients can fine-tune the settings for these variables, or depend on the defaults (in which case, you can skip the rest of this section). If you do not use the defaults, you must change the character settings *for each connection to the server*.

## Impermissible Client Character Sets

The `character_set_client` system variable cannot be set to certain character sets:

```
ucs2
utf16
utf16le
utf32
```

Attempting to use any of those character sets as the client character set produces an error:

```
mysql> SET character_set_client = 'ucs2';
ERROR 1231 (42000): Variable 'character_set_client'
can't be set to the value of 'ucs2'
```

The same error occurs if any of those character sets are used in the following contexts, all of which result in an attempt to set `character_set_client` to the named character set:

- The `--default-character-set=charset_name` command option used by MySQL client programs such as `mysql` and `mysqladmin`.
- The `SET NAMES 'charset_name'` statement.
- The `SET CHARACTER SET 'charset_name'` statement.

## Client Program Connection Character Set Configuration

When a client connects to the server, it indicates which character set it wants to use for communication with the server. (Actually, the client indicates the default collation for that character set, from which the server can determine the character set.) The server uses this information to set the `character_set_client`, `character_set_results`, `character_set_connection` system variables to the character set, and `collation_connection` to the character set default collation. In effect, the server performs the equivalent of a `SET NAMES` operation.

If the server does not support the requested character set or collation, it falls back to using the server character set and collation to configure the connection. For additional detail about this fallback behavior, see [Connection Character Set Error Handling](#).

The `mysql`, `mysqladmin`, `mysqlcheck`, `mysqlimport`, and `mysqlshow` client programs determine the default character set to use as follows:

- In the absence of other information, each client uses the compiled-in default character set, usually `utf8mb4`.
- Each client can autodetect which character set to use based on the operating system setting, such as the value of the `LANG` or `LC_ALL` locale environment variable on Unix systems or the code page setting on Windows systems. For systems on which the locale is available from the OS, the client uses it to set the default character set rather than using the compiled-in default. For example, setting `LANG` to `ru_RU.KOI8-R` causes the `koi8r` character set to be used. Thus, users can configure the locale in their environment for use by MySQL clients.

The OS character set is mapped to the closest MySQL character set if there is no exact match. If the client does not support the matching character set, it uses the compiled-in default. For example, `utf8` and `utf-8` map to `utf8mb4`, and `ucs2` is not supported as a connection character set, so it maps to the compiled-in default.

C applications can use character set autodetection based on the OS setting by invoking `mysql_options()` as follows before connecting to the server:

```
mysql_options(mysql,
 MYSQL_SET_CHARSET_NAME,
 MYSQL_AUTODETECT_CHARSET_NAME);
```

- Each client supports a `--default-character-set` option, which enables users to specify the character set explicitly to override whatever default the client otherwise determines.

#### Note

Some character sets cannot be used as the client character set. Attempting to use them with `--default-character-set` produces an error. See [Impermissible Client Character Sets](#).

With the `mysql` client, to use a character set different from the default, you could explicitly execute a `SET NAMES` statement every time you connect to the server (see [Client Program Connection Character Set Configuration](#)). To accomplish the same result more easily, specify the character set in your option file. For example, the following option file setting changes the three connection-related character set system variables set to `koi8r` each time you invoke `mysql`:

```
[mysql]
default-character-set=koi8r
```

If you are using the `mysql` client with auto-reconnect enabled (which is not recommended), it is preferable to use the `charset` command rather than `SET NAMES`. For example:

```
mysql> charset koi8r
Charset changed
```

The `charset` command issues a `SET NAMES` statement, and also changes the default character set that `mysql` uses when it reconnects after the connection has dropped.

When configuring client programs, you must also consider the environment within which they execute. See [Section 12.5, “Configuring Application Character Set and Collation”](#).

## SQL Statements for Connection Character Set Configuration

After a connection has been established, clients can change the character set and collation system variables for the current session. These variables can be changed individually using `SET` statements, but two more convenient statements affect the connection-related character set system variables as a group:

- `SET NAMES 'charset_name' [COLLATE 'collation_name']`

`SET NAMES` indicates what character set the client uses to send SQL statements to the server. Thus, `SET NAMES 'cp1251'` tells the server, “future incoming messages from this client are in character set `cp1251`.” It also specifies the character set that the server should use for sending results back to the client. (For example, it indicates what character set to use for column values if you use a `SELECT` statement that produces a result set.)

A `SET NAMES 'charset_name'` statement is equivalent to these three statements:

```
SET character_set_client = charset_name;
SET character_set_results = charset_name;
SET character_set_connection = charset_name;
```

Setting `character_set_connection` to `charset_name` also implicitly sets `collation_connection` to the default collation for `charset_name`. It is unnecessary to set that collation explicitly. To specify a particular collation to use for `collation_connection`, add a `COLLATE` clause:

```
SET NAMES 'charset_name' COLLATE 'collation_name'
```

- `SET CHARACTER SET 'charset_name'`

`SET CHARACTER SET` is similar to `SET NAMES` but sets `character_set_connection` and `collation_connection` to `character_set_database` and `collation_database` (which, as mentioned previously, indicate the character set and collation of the default database).

A `SET CHARACTER SET charset_name` statement is equivalent to these three statements:

```
SET character_set_client = charset_name;
SET character_set_results = charset_name;
SET collation_connection = @@collation_database;
```

Setting `collation_connection` also implicitly sets `character_set_connection` to the character set associated with the collation (equivalent to executing `SET character_set_connection = @@character_set_database`). It is unnecessary to set `character_set_connection` explicitly.

#### Note

Some character sets cannot be used as the client character set. Attempting to use them with `SET NAMES` or `SET CHARACTER SET` produces an error. See [Impermissible Client Character Sets](#).

Example: Suppose that `column1` is defined as `CHAR(5) CHARACTER SET latin2`. If you do not say `SET NAMES` or `SET CHARACTER SET`, then for `SELECT column1 FROM t`, the server sends back all the values for `column1` using the character set that the client specified when it connected. On the other hand, if you say `SET NAMES 'latin1'` or `SET CHARACTER SET 'latin1'` before issuing the `SELECT` statement, the server converts the `latin2` values to `latin1` just before sending results back. Conversion may be lossy for characters that are not in both character sets.

## Connection Character Set Error Handling

Attempts to use an inappropriate connection character set or collation can produce an error, or cause the server to fall back to its default character set and collation for a given connection. This section describes problems that can occur when configuring the connection character set. These problems can occur when establishing a connection or when changing the character set within an established connection.

- [Connect-Time Error Handling](#)
- [Runtime Error Handling](#)

### Connect-Time Error Handling

Some character sets cannot be used as the client character set; see [Impermissible Client Character Sets](#). If you specify a character set that is valid but not permitted as a client character set, the server returns an error:

```
$> mysql --default-character-set=ucs2
```

```
ERROR 1231 (42000): Variable 'character_set_client' can't be set to
the value of 'ucs2'
```

If you specify a character set that the client does not recognize, it produces an error:

```
$> mysql --default-character-set=bogus
mysql: Character set 'bogus' is not a compiled character set and is
not specified in the '/usr/local/mysql/share/charsets/Index.xml' file
ERROR 2019 (HY000): Can't initialize character set bogus
(path: /usr/local/mysql/share/charsets/)
```

If you specify a character set that the client recognizes but the server does not, the server falls back to its default character set and collation. Suppose that the server is configured to use `latin1` and `latin1_swedish_ci` as its defaults, and that it does not recognize `gb18030` as a valid character set. A client that specifies `--default-character-set=gb18030` is able to connect to the server, but the resulting character set is not what the client wants:

```
mysql> SHOW SESSION VARIABLES LIKE 'character_set_%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| character_set_client | latin1 |
| character_set_connection | latin1 |
...
| character_set_results | latin1 |
...
+-----+-----+
mysql> SHOW SESSION VARIABLES LIKE 'collation_connection';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| collation_connection | latin1_swedish_ci |
+-----+-----+
```

You can see that the connection system variables have been set to reflect a character set and collation of `latin1` and `latin1_swedish_ci`. This occurs because the server cannot satisfy the client character set request and falls back to its defaults.

In this case, the client cannot use the character set that it wants because the server does not support it. The client must either be willing to use a different character set, or connect to a different server that supports the desired character set.

The same problem occurs when the client tells the server to use a character set that the server recognizes, but the default collation for that character set on the client side is not known on the server side.

## Runtime Error Handling

Within an established connection, the client can request a change of connection character set and collation with `SET NAMES` or `SET CHARACTER SET`.

Some character sets cannot be used as the client character set; see [Impermissible Client Character Sets](#). If you specify a character set that is valid but not permitted as a client character set, the server returns an error:

```
mysql> SET NAMES 'ucs2';
ERROR 1231 (42000): Variable 'character_set_client' can't be set to
the value of 'ucs2'
```

If the server does not recognize the character set (or the collation), it produces an error:

```
mysql> SET NAMES 'bogus';
ERROR 1115 (42000): Unknown character set: 'bogus'
```

```
mysql> SET NAMES 'utf8mb4' COLLATE 'bogus';
ERROR 1273 (HY000): Unknown collation: 'bogus'
```

**Tip**

A client that wants to verify whether its requested character set was honored by the server can execute the following statement after connecting and checking that the result is the expected character set:

```
SELECT @@character_set_client;
```

## 12.5 Configuring Application Character Set and Collation

For applications that store data using the default MySQL character set and collation ([utf8mb4](#), [utf8mb4\\_0900\\_ai\\_ci](#)), no special configuration should be needed. If applications require data storage using a different character set or collation, you can configure character set information several ways:

- Specify character settings per database. For example, applications that use one database might use the default of [utf8mb4](#), whereas applications that use another database might use [sjis](#).
- Specify character settings at server startup. This causes the server to use the given settings for all applications that do not make other arrangements.
- Specify character settings at configuration time, if you build MySQL from source. This causes the server to use the given settings as the defaults for all applications, without having to specify them at server startup.

When different applications require different character settings, the per-database technique provides a good deal of flexibility. If most or all applications use the same character set, specifying character settings at server startup or configuration time may be most convenient.

For the per-database or server-startup techniques, the settings control the character set for data storage. Applications must also tell the server which character set to use for client/server communications, as described in the following instructions.

The examples shown here assume use of the [latin1](#) character set and [latin1\\_swedish\\_ci](#) collation in particular contexts as an alternative to the defaults of [utf8mb4](#) and [utf8mb4\\_0900\\_ai\\_ci](#).

- **Specify character settings per database.** To create a database such that its tables use a given default character set and collation for data storage, use a [CREATE DATABASE](#) statement like this:

```
CREATE DATABASE mydb
 CHARACTER SET latin1
 COLLATE latin1_swedish_ci;
```

Tables created in the database use [latin1](#) and [latin1\\_swedish\\_ci](#) by default for any character columns.

Applications that use the database should also configure their connection to the server each time they connect. This can be done by executing a [SET NAMES 'latin1'](#) statement after connecting. The statement can be used regardless of connection method (the [mysql](#) client, PHP scripts, and so forth).

In some cases, it may be possible to configure the connection to use the desired character set some other way. For example, to connect using [mysql](#), you can specify the [--default-character-set=latin1](#) command-line option to achieve the same effect as [SET NAMES 'latin1'](#).

For more information about configuring client connections, see [Section 12.4, “Connection Character Sets and Collations”](#).

**Note**

If you use `ALTER DATABASE` to change the database default character set or collation, existing stored routines in the database that use those defaults must be dropped and recreated so that they use the new defaults. (In a stored routine, variables with character data types use the database defaults if the character set or collation are not specified explicitly. See [Section 15.1.17, “CREATE PROCEDURE and CREATE FUNCTION Statements”](#).)

- **Specify character settings at server startup.** To select a character set and collation at server startup, use the `--character-set-server` and `--collation-server` options. For example, to specify the options in an option file, include these lines:

```
[mysqld]
character-set-server=latin1
collation-server=latin1_swedish_ci
```

These settings apply server-wide and apply as the defaults for databases created by any application, and for tables created in those databases.

It is still necessary for applications to configure their connection using `SET NAMES` or equivalent after they connect, as described previously. You might be tempted to start the server with the `--init_connect="SET NAMES 'latin1'"` option to cause `SET NAMES` to be executed automatically for each client that connects. However, this may yield inconsistent results because the `init_connect` value is not executed for users who have the `CONNECTION_ADMIN` privilege (or the deprecated `SUPER` privilege).

- **Specify character settings at MySQL configuration time.** To select a character set and collation if you configure and build MySQL from source, use the `DEFAULT_CHARSET` and `DEFAULT_COLLATION` CMake options:

```
cmake . -DDEFAULT_CHARSET=latin1 \
-DDEFAULT_COLLATION=latin1_swedish_ci
```

The resulting server uses `latin1` and `latin1_swedish_ci` as the default for databases and tables and for client connections. It is unnecessary to use `--character-set-server` and `--collation-server` to specify those defaults at server startup. It is also unnecessary for applications to configure their connection using `SET NAMES` or equivalent after they connect to the server.

Regardless of how you configure the MySQL character set for application use, you must also consider the environment within which those applications execute. For example, if you intend to send statements using UTF-8 text taken from a file that you create in an editor, you should edit the file with the locale of your environment set to UTF-8 so that the file encoding is correct and so that the operating system handles it correctly. If you use the `mysql` client from within a terminal window, the window must be configured to use UTF-8 or characters may not display properly. For a script that executes in a Web environment, the script must handle character encoding properly for its interaction with the MySQL server, and it must generate pages that correctly indicate the encoding so that browsers know how to display the content of the pages. For example, you can include this `<meta>` tag within your `<head>` element:

```
<meta http-equiv="Content-Type" content="text/html; charset=utf-8" />
```

## 12.6 Error Message Character Set

This section describes how the MySQL server uses character sets for constructing error messages. For information about the language of error messages (rather than the character set), see [Section 12.12](#),

[“Setting the Error Message Language”](#). For general information about configuring error logging, see [Section 7.4.2, “The Error Log”](#).

- [Character Set for Error Message Construction](#)
- [Character Set for Error Message Disposition](#)

## Character Set for Error Message Construction

The server constructs error messages as follows:

- The message template uses UTF-8 (`utf8mb3`).
- Parameters in the message template are replaced with values that apply to a specific error occurrence:
  - Identifiers such as table or column names use UTF-8 internally so they are copied as is.
  - Character (nonbinary) string values are converted from their character set to UTF-8.
  - Binary string values are copied as is for bytes in the range `0x20` to `0x7E`, and using `\x` hexadecimal encoding for bytes outside that range. For example, if a duplicate-key error occurs for an attempt to insert `0x41CF9F` into a `VARBINARY` unique column, the resulting error message uses UTF-8 with some bytes hexadecimal encoded:

```
Duplicate entry 'A\xCF\x9F' for key 1
```

## Character Set for Error Message Disposition

An error message, once constructed, can be written by the server to the error log or sent to clients:

- If the server writes the error message to the error log, it writes it in UTF-8, as constructed, without conversion to another character set.
- If the server sends the error message to a client program, the server converts it from UTF-8 to the character set specified by the `character_set_results` system variable. If `character_set_results` has a value of `NULL` or `binary`, no conversion occurs. No conversion occurs if the variable value is `utf8mb3` or `utf8mb4`, either, because those character sets have a repertoire that includes all UTF-8 characters used in message construction.

If characters cannot be represented in `character_set_results`, some encoding may occur during the conversion. The encoding uses Unicode code point values:

- Characters in the Basic Multilingual Plane (BMP) range (`0x0000` to `0xFFFF`) are written using `\nnnn` notation.
- Characters outside the BMP range (`0x10000` to `0x10FFFF`) are written using `\+nnnnnnn` notation.

Clients can set `character_set_results` to control the character set in which they receive error messages. The variable can be set directly, or indirectly by means such as `SET NAMES`. For more information about `character_set_results`, see [Section 12.4, “Connection Character Sets and Collations”](#).

## 12.7 Column Character Set Conversion

To convert a binary or nonbinary string column to use a particular character set, use `ALTER TABLE`. For successful conversion to occur, one of the following conditions must apply:

- If the column has a binary data type ([BINARY](#), [VARBINARY](#), [BLOB](#)), all the values that it contains must be encoded using a single character set (the character set you're converting the column to). If you use a binary column to store information in multiple character sets, MySQL has no way to know which values use which character set and cannot convert the data properly.
- If the column has a nonbinary data type ([CHAR](#), [VARCHAR](#), [TEXT](#)), its contents should be encoded in the column character set, not some other character set. If the contents are encoded in a different character set, you can convert the column to use a binary data type first, and then to a nonbinary column with the desired character set.

Suppose that a table `t` has a binary column named `col1` defined as [VARBINARY\(50\)](#). Assuming that the information in the column is encoded using a single character set, you can convert it to a nonbinary column that has that character set. For example, if `col1` contains binary data representing characters in the [greek](#) character set, you can convert it as follows:

```
ALTER TABLE t MODIFY col1 VARCHAR(50) CHARACTER SET greek;
```

If your original column has a type of [BINARY\(50\)](#), you could convert it to [CHAR\(50\)](#), but the resulting values are padded with `0x00` bytes at the end, which may be undesirable. To remove these bytes, use the [TRIM\(\)](#) function:

```
UPDATE t SET col1 = TRIM(TRAILING 0x00 FROM col1);
```

Suppose that table `t` has a nonbinary column named `col1` defined as [CHAR\(50\) CHARACTER SET latin1](#) but you want to convert it to use [utf8mb4](#) so that you can store values from many languages. The following statement accomplishes this:

```
ALTER TABLE t MODIFY col1 CHAR(50) CHARACTER SET utf8mb4;
```

Conversion may be lossy if the column contains characters that are not in both character sets.

A special case occurs if you have old tables from before MySQL 4.1 where a nonbinary column contains values that actually are encoded in a character set different from the server's default character set. For example, an application might have stored [sjis](#) values in a column, even though MySQL's default character set was different. It is possible to convert the column to use the proper character set but an additional step is required. Suppose that the server's default character set was [latin1](#) and `col1` is defined as [CHAR\(50\)](#) but its contents are [sjis](#) values. The first step is to convert the column to a binary data type, which removes the existing character set information without performing any character conversion:

```
ALTER TABLE t MODIFY col1 BLOB;
```

The next step is to convert the column to a nonbinary data type with the proper character set:

```
ALTER TABLE t MODIFY col1 CHAR(50) CHARACTER SET sjis;
```

This procedure requires that the table not have been modified already with statements such as [INSERT](#) or [UPDATE](#) after an upgrade to MySQL 4.1 or higher. In that case, MySQL would store new values in the column using [latin1](#), and the column would contain a mix of [sjis](#) and [latin1](#) values and cannot be converted properly.

If you specified attributes when creating a column initially, you should also specify them when altering the table with [ALTER TABLE](#). For example, if you specified [NOT NULL](#) and an explicit [DEFAULT](#) value, you should also provide them in the [ALTER TABLE](#) statement. Otherwise, the resulting column definition does not include those attributes.

To convert all character columns in a table, the [ALTER TABLE ... CONVERT TO CHARACTER SET charset](#) statement may be useful. See [Section 15.1.9, "ALTER TABLE Statement"](#).

**Note**

`ALTER TABLE` statements which make changes in table or column character sets or collations must be performed using `ALGORITHM=COPY`. For more information, see [Section 17.12.1, “Online DDL Operations”](#).

## 12.8 Collation Issues

The following sections discuss various aspects of character set collations.

### 12.8.1 Using COLLATE in SQL Statements

With the `COLLATE` clause, you can override whatever the default collation is for a comparison. `COLLATE` may be used in various parts of SQL statements. Here are some examples:

- With `ORDER BY`:

```
SELECT k
FROM t1
ORDER BY k COLLATE latin1_german2_ci;
```

- With `AS`:

```
SELECT k COLLATE latin1_german2_ci AS k1
FROM t1
ORDER BY k1;
```

- With `GROUP BY`:

```
SELECT k
FROM t1
GROUP BY k COLLATE latin1_german2_ci;
```

- With aggregate functions:

```
SELECT MAX(k COLLATE latin1_german2_ci)
FROM t1;
```

- With `DISTINCT`:

```
SELECT DISTINCT k COLLATE latin1_german2_ci
FROM t1;
```

- With `WHERE`:

```
SELECT *
FROM t1
WHERE _latin1 'Müller' COLLATE latin1_german2_ci = k;
```

```
SELECT *
FROM t1
WHERE k LIKE _latin1 'Müller' COLLATE latin1_german2_ci;
```

- With `HAVING`:

```
SELECT k
FROM t1
GROUP BY k
HAVING k = _latin1 'Müller' COLLATE latin1_german2_ci;
```

## 12.8.2 COLLATE Clause Precedence

The `COLLATE` clause has high precedence (higher than `| |`), so the following two expressions are equivalent:

```
x | | y COLLATE z
x | | (y COLLATE z)
```

## 12.8.3 Character Set and Collation Compatibility

Each character set has one or more collations, but each collation is associated with one and only one character set. Therefore, the following statement causes an error message because the `latin2_bin` collation is not legal with the `latin1` character set:

```
mysql> SELECT _latin1 'x' COLLATE latin2_bin;
ERROR 1253 (42000): COLLATION 'latin2_bin' is not valid
for CHARACTER SET 'latin1'
```

## 12.8.4 Collation Coercibility in Expressions

In the great majority of statements, it is obvious what collation MySQL uses to resolve a comparison operation. For example, in the following cases, it should be clear that the collation is the collation of column `x`:

```
SELECT x FROM T ORDER BY x;
SELECT x FROM T WHERE x = x;
SELECT DISTINCT x FROM T;
```

However, with multiple operands, there can be ambiguity. For example, this statement performs a comparison between the column `x` and the string literal `'Y'`:

```
SELECT x FROM T WHERE x = 'Y';
```

If `x` and `'Y'` have the same collation, there is no ambiguity about the collation to use for the comparison. But if they have different collations, should the comparison use the collation of `x`, or of `'Y'`? Both `x` and `'Y'` have collations, so which collation takes precedence?

A mix of collations may also occur in contexts other than comparison. For example, a multiple-argument concatenation operation such as `CONCAT(x, 'Y')` combines its arguments to produce a single string. What collation should the result have?

To resolve questions like these, MySQL checks whether the collation of one item can be coerced to the collation of the other. MySQL assigns coercibility values as follows:

- An explicit `COLLATE` clause has a coercibility of 0 (not coercible at all).
- The concatenation of two strings with different collations has a coercibility of 1.
- The collation of a column or a stored routine parameter or local variable has a coercibility of 2.
- A “system constant” (the string returned by functions such as `USER()` or `VERSION()`) has a coercibility of 3.
- The collation of a literal has a coercibility of 4.
- The collation of a numeric or temporal value has a coercibility of 5.
- `NULL` or an expression that is derived from `NULL` has a coercibility of 6.

MySQL uses coercibility values with the following rules to resolve ambiguities:

- Use the collation with the lowest coercibility value.
- If both sides have the same coercibility, then:
  - If both sides are Unicode, or both sides are not Unicode, it is an error.
  - If one of the sides has a Unicode character set, and another side has a non-Unicode character set, the side with Unicode character set wins, and automatic character set conversion is applied to the non-Unicode side. For example, the following statement does not return an error:

```
SELECT CONCAT(utf8mb4_column, latin1_column) FROM t1;
```

It returns a result that has a character set of `utf8mb4` and the same collation as `utf8mb4_column`. Values of `latin1_column` are automatically converted to `utf8mb4` before concatenating.

- For an operation with operands from the same character set but that mix a `_bin` collation and a `_ci` or `_cs` collation, the `_bin` collation is used. This is similar to how operations that mix nonbinary and binary strings evaluate the operands as binary strings, applied to collations rather than data types.

Although automatic conversion is not in the SQL standard, the standard does say that every character set is (in terms of supported characters) a “subset” of Unicode. Because it is a well-known principle that “what applies to a superset can apply to a subset,” we believe that a collation for Unicode can apply for comparisons with non-Unicode strings. More generally, MySQL uses the concept of character set repertoire, which can sometimes be used to determine subset relationships among character sets and enable conversion of operands in operations that would otherwise produce an error. See [Section 12.2.1, “Character Set Repertoire”](#).

The following table illustrates some applications of the preceding rules.

Comparison	Collation Used
<code>column1 = 'A'</code>	Use collation of <code>column1</code>
<code>column1 = 'A' COLLATE x</code>	Use collation of <code>'A' COLLATE x</code>
<code>column1 COLLATE x = 'A' COLLATE y</code>	Error

To determine the coercibility of a string expression, use the `COERCIBILITY()` function (see [Section 14.15, “Information Functions”](#)):

```
mysql> SELECT COERCIBILITY(_utf8mb4'A' COLLATE utf8mb4_bin);
-> 0
mysql> SELECT COERCIBILITY(VERSION());
-> 3
mysql> SELECT COERCIBILITY('A');
-> 4
mysql> SELECT COERCIBILITY(1000);
-> 5
mysql> SELECT COERCIBILITY(NULL);
-> 6
```

For implicit conversion of a numeric or temporal value to a string, such as occurs for the argument `1` in the expression `CONCAT(1, 'abc')`, the result is a character (nonbinary) string that has a character set and collation determined by the `character_set_connection` and `collation_connection` system variables. See [Section 14.3, “Type Conversion in Expression Evaluation”](#).

## 12.8.5 The binary Collation Compared to \_bin Collations

This section describes how the `binary` collation for binary strings compares to `_bin` collations for nonbinary strings.

Binary strings (as stored using the `BINARY`, `VARBINARY`, and `BLOB` data types) have a character set and collation named `binary`. Binary strings are sequences of bytes and the numeric values of those bytes determine comparison and sort order. See [Section 12.10.8, “The Binary Character Set”](#).

Nonbinary strings (as stored using the `CHAR`, `VARCHAR`, and `TEXT` data types) have a character set and collation other than `binary`. A given nonbinary character set can have several collations, each of which defines a particular comparison and sort order for the characters in the set. For most character sets, one of these is the binary collation, indicated by a `_bin` suffix in the collation name. For example, the binary collations for `latin1` and `big5` are named `latin1_bin` and `big5_bin`, respectively. `utf8mb4` is an exception that has two binary collations, `utf8mb4_bin` and `utf8mb4_0900_bin`; see [Section 12.10.1, “Unicode Character Sets”](#).

The `binary` collation differs from `_bin` collations in several respects, discussed in the following sections:

- [The Unit for Comparison and Sorting](#)
- [Character Set Conversion](#)
- [Lettercase Conversion](#)
- [Trailing Space Handling in Comparisons](#)
- [Trailing Space Handling for Inserts and Retrievals](#)

## The Unit for Comparison and Sorting

Binary strings are sequences of bytes. For the `binary` collation, comparison and sorting are based on numeric byte values. Nonbinary strings are sequences of characters, which might be multibyte. Collations for nonbinary strings define an ordering of the character values for comparison and sorting. For `_bin` collations, this ordering is based on numeric character code values, which is similar to ordering for binary strings except that character code values might be multibyte.

## Character Set Conversion

A nonbinary string has a character set and is automatically converted to another character set in many cases, even when the string has a `_bin` collation:

- When assigning column values to another column that has a different character set:

```
UPDATE t1 SET utf8mb4_bin_column=latin1_column;
INSERT INTO t1 (latin1_column) SELECT utf8mb4_bin_column FROM t2;
```

- When assigning column values for `INSERT` or `UPDATE` using a string literal:

```
SET NAMES latin1;
INSERT INTO t1 (utf8mb4_bin_column) VALUES ('string-in-latin1');
```

- When sending results from the server to a client:

```
SET NAMES latin1;
SELECT utf8mb4_bin_column FROM t2;
```

For binary string columns, no conversion occurs. For cases similar to those preceding, the string value is copied byte-wise.

## Lettercase Conversion

Collations for nonbinary character sets provide information about lettercase of characters, so characters in a nonbinary string can be converted from one lettercase to another, even for `_bin` collations that ignore lettercase for ordering:

```
mysql> SET NAMES utf8mb4 COLLATE utf8mb4_bin;
mysql> SELECT LOWER('aA'), UPPER('zZ');
+-----+-----+
| LOWER('aA') | UPPER('zZ') |
+-----+-----+
| aa | ZZ |
+-----+-----+
```

The concept of lettercase does not apply to bytes in a binary string. To perform lettercase conversion, the string must first be converted to a nonbinary string using a character set appropriate for the data stored in the string:

```
mysql> SET NAMES binary;
mysql> SELECT LOWER('aA'), LOWER(CONVERT('aA' USING utf8mb4));
+-----+-----+
| LOWER('aA') | LOWER(CONVERT('aA' USING utf8mb4)) |
+-----+-----+
| aA | aa |
+-----+-----+
```

## Trailing Space Handling in Comparisons

MySQL collations have a pad attribute, which has a value of `PAD SPACE` or `NO PAD`:

- Most MySQL collations have a pad attribute of `PAD SPACE`.
- The Unicode collations based on UCA 9.0.0 and higher have a pad attribute of `NO PAD`; see [Section 12.10.1, “Unicode Character Sets”](#).

For nonbinary strings (`CHAR`, `VARCHAR`, and `TEXT` values), the string collation pad attribute determines treatment in comparisons of trailing spaces at the end of strings:

- For `PAD SPACE` collations, trailing spaces are insignificant in comparisons; strings are compared without regard to trailing spaces.
- `NO PAD` collations treat trailing spaces as significant in comparisons, like any other character.

The differing behaviors can be demonstrated using the two `utf8mb4` binary collations, one of which is `PAD SPACE`, the other of which is `NO PAD`. The example also shows how to use the `INFORMATION_SCHEMA.COLLATIONS` table to determine the pad attribute for collations.

```
mysql> SELECT COLLATION_NAME, PAD_ATTRIBUTE
FROM INFORMATION_SCHEMA.COLLATIONS
WHERE COLLATION_NAME LIKE 'utf8mb4%bin';
+-----+-----+
| COLLATION_NAME | PAD_ATTRIBUTE |
+-----+-----+
| utf8mb4_bin | PAD SPACE |
| utf8mb4_0900_bin | NO PAD |
+-----+-----+
mysql> SET NAMES utf8mb4 COLLATE utf8mb4_bin;
mysql> SELECT 'a ' = 'a';
+-----+
| 'a ' = 'a' |
+-----+
```

```

| 1 |
+-----+
mysql> SET NAMES utf8mb4 COLLATE utf8mb4_0900_bin;
mysql> SELECT 'a ' = 'a';
+-----+
| 'a ' = 'a' |
+-----+
| 0 |
+-----+

```

**Note**

“Comparison” in this context does not include the [LIKE](#) pattern-matching operator, for which trailing spaces are significant, regardless of collation.

For binary strings ([BINARY](#), [VARBINARY](#), and [BLOB](#) values), all bytes are significant in comparisons, including trailing spaces:

```

mysql> SET NAMES binary;
mysql> SELECT 'a ' = 'a';
+-----+
| 'a ' = 'a' |
+-----+
| 0 |
+-----+

```

## Trailing Space Handling for Inserts and Retrievals

[CHAR\(N\)](#) columns store nonbinary strings *N* characters long. For inserts, values shorter than *N* characters are extended with spaces. For retrievals, trailing spaces are removed.

[BINARY\(N\)](#) columns store binary strings *N* bytes long. For inserts, values shorter than *N* bytes are extended with `0x00` bytes. For retrievals, nothing is removed; a value of the declared length is always returned.

```

mysql> CREATE TABLE t1 (
 a CHAR(10) CHARACTER SET utf8mb4 COLLATE utf8mb4_bin,
 b BINARY(10)
);
mysql> INSERT INTO t1 VALUES ('x','x');
mysql> INSERT INTO t1 VALUES ('x ','x ');
mysql> SELECT a, b, HEX(a), HEX(b) FROM t1;
+-----+-----+-----+-----+
| a | b | HEX(a) | HEX(b) |
+-----+-----+-----+-----+
| x | 0x78000000000000000000 | 78 | 78000000000000000000 |
| x | 0x78200000000000000000 | 78 | 78200000000000000000 |
+-----+-----+-----+-----+

```

## 12.8.6 Examples of the Effect of Collation

### Example 1: Sorting German Umlauts

Suppose that column *x* in table *T* has these [latin1](#) column values:

```

Muffler
Müller
MX Systems
MySQL

```

Suppose also that the column values are retrieved using the following statement:

```
SELECT X FROM T ORDER BY X COLLATE collation_name;
```

The following table shows the resulting order of the values if we use `ORDER BY` with different collations.

<code>latin1_swedish_ci</code>	<code>latin1_german1_ci</code>	<code>latin1_german2_ci</code>
Muffler	Muffler	Müller
MX Systems	Müller	Muffler
Müller	MX Systems	MX Systems
MySQL	MySQL	MySQL

The character that causes the different sort orders in this example is `ü` (German “U-umlaut”).

- The first column shows the result of the `SELECT` using the Swedish/Finnish collating rule, which says that U-umlaut sorts with Y.
- The second column shows the result of the `SELECT` using the German DIN-1 rule, which says that U-umlaut sorts with U.
- The third column shows the result of the `SELECT` using the German DIN-2 rule, which says that U-umlaut sorts with UE.

### Example 2: Searching for German Umlauts

Suppose that you have three tables that differ only by the character set and collation used:

```
mysql> SET NAMES utf8mb4;
mysql> CREATE TABLE german1 (
 c CHAR(10)
) CHARACTER SET latin1 COLLATE latin1_german1_ci;
mysql> CREATE TABLE german2 (
 c CHAR(10)
) CHARACTER SET latin1 COLLATE latin1_german2_ci;
mysql> CREATE TABLE germanutf8 (
 c CHAR(10)
) CHARACTER SET utf8mb4 COLLATE utf8mb4_unicode_ci;
```

Each table contains two records:

```
mysql> INSERT INTO german1 VALUES ('Bar'), ('Bär');
mysql> INSERT INTO german2 VALUES ('Bar'), ('Bär');
mysql> INSERT INTO germanutf8 VALUES ('Bar'), ('Bär');
```

Two of the above collations have an `A = Ä` equality, and one has no such equality (`latin1_german2_ci`). For that reason, comparisons yield the results shown here:

```
mysql> SELECT * FROM german1 WHERE c = 'Bär';
+-----+
| c |
+-----+
| Bar |
| Bär |
+-----+
mysql> SELECT * FROM german2 WHERE c = 'Bär';
+-----+
| c |
+-----+
| Bär |
+-----+
```

```
mysql> SELECT * FROM germanutf8 WHERE c = 'Bär';
```

c
Bar
Bär

This is not a bug but rather a consequence of the sorting properties of `latin1_german1_ci` and `utf8mb4_unicode_ci` (the sorting shown is done according to the German DIN 5007 standard).

## 12.8.7 Using Collation in INFORMATION\_SCHEMA Searches

String columns in `INFORMATION_SCHEMA` tables have a collation of `utf8mb3_general_ci`, which is case-insensitive. However, for values that correspond to objects that are represented in the file system, such as databases and tables, searches in `INFORMATION_SCHEMA` string columns can be case-sensitive or case-insensitive, depending on the characteristics of the underlying file system and the `lower_case_table_names` system variable setting. For example, searches may be case-sensitive if the file system is case-sensitive. This section describes this behavior and how to modify it if necessary.

Suppose that a query searches the `SCHEMATA.SCHEMA_NAME` column for the `test` database. On Linux, file systems are case-sensitive, so comparisons of `SCHEMATA.SCHEMA_NAME` with `'test'` match, but comparisons with `'TEST'` do not:

```
mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
 WHERE SCHEMA_NAME = 'test';
```

SCHEMA_NAME
test

```
mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
 WHERE SCHEMA_NAME = 'TEST';
```

Empty set (0.00 sec)

These results occur with the `lower_case_table_names` system variable set to 0. A `lower_case_table_names` setting of 1 or 2 causes the second query to return the same (nonempty) result as the first query.

### Note

It is prohibited to start the server with a `lower_case_table_names` setting that is different from the setting used when the server was initialized.

On Windows or macOS, file systems are not case-sensitive, so comparisons match both `'test'` and `'TEST'`:

```
mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
 WHERE SCHEMA_NAME = 'test';
```

SCHEMA_NAME
test

```
mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
 WHERE SCHEMA_NAME = 'TEST';
```

SCHEMA_NAME
test

```
| TEST |
+-----+
```

The value of `lower_case_table_names` makes no difference in this context.

The preceding behavior occurs because the `utf8mb3_general_ci` collation is not used for `INFORMATION_SCHEMA` queries when searching for values that correspond to objects represented in the file system.

If the result of a string operation on an `INFORMATION_SCHEMA` column differs from expectations, a workaround is to use an explicit `COLLATE` clause to force a suitable collation (see [Section 12.8.1, “Using COLLATE in SQL Statements”](#)). For example, to perform a case-insensitive search, use `COLLATE` with the `INFORMATION_SCHEMA` column name:

```
mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
 WHERE SCHEMA_NAME COLLATE utf8mb3_general_ci = 'test';
+-----+
| SCHEMA_NAME |
+-----+
| test |
+-----+

mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
 WHERE SCHEMA_NAME COLLATE utf8mb3_general_ci = 'TEST';
+-----+
| SCHEMA_NAME |
+-----+
| test |
+-----+
```

You can also use the `UPPER()` or `LOWER()` function:

```
WHERE UPPER(SCHEMA_NAME) = 'TEST'
WHERE LOWER(SCHEMA_NAME) = 'test'
```

Although a case-insensitive comparison can be performed even on platforms with case-sensitive file systems, as just shown, it is not necessarily always the right thing to do. On such platforms, it is possible to have multiple objects with names that differ only in lettercase. For example, tables named `city`, `CITY`, and `City` can all exist simultaneously. Consider whether a search should match all such names or just one and write queries accordingly. The first of the following comparisons (with `utf8mb3_bin`) is case-sensitive; the others are not:

```
WHERE TABLE_NAME COLLATE utf8mb3_bin = 'City'
WHERE TABLE_NAME COLLATE utf8mb3_general_ci = 'city'
WHERE UPPER(TABLE_NAME) = 'CITY'
WHERE LOWER(TABLE_NAME) = 'city'
```

Searches in `INFORMATION_SCHEMA` string columns for values that refer to `INFORMATION_SCHEMA` itself do use the `utf8mb3_general_ci` collation because `INFORMATION_SCHEMA` is a “virtual” database not represented in the file system. For example, comparisons with `SCHEMATA.SCHEMA_NAME` match `'information_schema'` or `'INFORMATION_SCHEMA'` regardless of platform:

```
mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
 WHERE SCHEMA_NAME = 'information_schema';
+-----+
| SCHEMA_NAME |
+-----+
| information_schema |
+-----+

mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
```

```
WHERE SCHEMA_NAME = 'INFORMATION_SCHEMA';
```

SCHEMA_NAME
information_schema

## 12.9 Unicode Support

The Unicode Standard includes characters from the Basic Multilingual Plane (BMP) and supplementary characters that lie outside the BMP. This section describes support for Unicode in MySQL. For information about the Unicode Standard itself, visit the [Unicode Consortium website](#).

BMP characters have these characteristics:

- Their code point values are between 0 and 65535 (or `U+0000` and `U+FFFF`).
- They can be encoded in a variable-length encoding using 8, 16, or 24 bits (1 to 3 bytes).
- They can be encoded in a fixed-length encoding using 16 bits (2 bytes).
- They are sufficient for almost all characters in major languages.

Supplementary characters lie outside the BMP:

- Their code point values are between `U+10000` and `U+10FFFF`.
- Unicode support for supplementary characters requires character sets that have a range outside BMP characters and therefore take more space than BMP characters (up to 4 bytes per character).

The UTF-8 (Unicode Transformation Format with 8-bit units) method for encoding Unicode data is implemented according to RFC 3629, which describes encoding sequences that take from one to four bytes. The idea of UTF-8 is that various Unicode characters are encoded using byte sequences of different lengths:

- Basic Latin letters, digits, and punctuation signs use one byte.
- Most European and Middle East script letters fit into a 2-byte sequence: extended Latin letters (with tilde, macron, acute, grave and other accents), Cyrillic, Greek, Armenian, Hebrew, Arabic, Syriac, and others.
- Korean, Chinese, and Japanese ideographs use 3-byte or 4-byte sequences.

MySQL supports these Unicode character sets:

- `utf8mb4`: A UTF-8 encoding of the Unicode character set using one to four bytes per character.
- `utf8mb3`: A UTF-8 encoding of the Unicode character set using one to three bytes per character. This character set is deprecated and subject to removal in a future release; use `utf8mb4` instead.
- `utf8`: A deprecated alias for `utf8mb3`; use `utf8mb4` instead.

### Note

`utf8` is expected in a future version of MySQL to become an alias for `utf8mb4`.

- `ucs2`: The UCS-2 encoding of the Unicode character set using two bytes per character. Deprecated; expect support for this character set to be removed in a future release.

- `utf16`: The UTF-16 encoding for the Unicode character set using two or four bytes per character. Like `ucs2` but with an extension for supplementary characters.
- `utf16le`: The UTF-16LE encoding for the Unicode character set. Like `utf16` but little-endian rather than big-endian.
- `utf32`: The UTF-32 encoding for the Unicode character set using four bytes per character.

**Note**

The `utf8mb3` character set is deprecated and you should expect it to be removed in a future MySQL release. Please use `utf8mb4` instead. `utf8` is currently an alias for `utf8mb3`, but it is now deprecated as such, and `utf8` is expected subsequently to become a reference to `utf8mb4`. MySQL 9.1 also displays `utf8mb3` in place of `utf8` in the columns of Information Schema tables, and in the output of SQL `SHOW` statements.

In addition, you should be aware that collations using the `utf8_` prefix in older releases of MySQL have since been renamed using the prefix `utf8mb3_`, instead.

To avoid ambiguity about the meaning of `utf8`, consider specifying `utf8mb4` explicitly for character set references.

Table 12.2, “Unicode Character Set General Characteristics”, summarizes the general characteristics of Unicode character sets supported by MySQL.

**Table 12.2 Unicode Character Set General Characteristics**

Character Set	Supported Characters	Required Storage Per Character
<code>utf8mb3</code> , <code>utf8</code> (deprecated)	BMP only	1, 2, or 3 bytes
<code>ucs2</code>	BMP only	2 bytes
<code>utf8mb4</code>	BMP and supplementary	1, 2, 3, or 4 bytes
<code>utf16</code>	BMP and supplementary	2 or 4 bytes
<code>utf16le</code>	BMP and supplementary	2 or 4 bytes
<code>utf32</code>	BMP and supplementary	4 bytes

Characters outside the BMP compare as `REPLACEMENT CHARACTER` and convert to `'?'` when converted to a Unicode character set that supports only BMP characters (`utf8mb3` or `ucs2`).

If you use character sets that support supplementary characters and thus are “wider” than the BMP-only `utf8mb3` and `ucs2` character sets, there are potential incompatibility issues for your applications; see Section 12.9.8, “Converting Between 3-Byte and 4-Byte Unicode Character Sets”. That section also describes how to convert tables from the (3-byte) `utf8mb3` to the (4-byte) `utf8mb4`, and what constraints may apply in doing so.

A similar set of collations is available for most Unicode character sets. For example, each has a Danish collation, the names of which are `utf8mb4_danish_ci`, `utf8mb3_danish_ci` (deprecated), `utf8_danish_ci` (deprecated), `ucs2_danish_ci`, `utf16_danish_ci`, and `utf32_danish_ci`. The exception is `utf16le`, which has only two collations. For information about Unicode collations and their differentiating properties, including collation properties for supplementary characters, see Section 12.10.1, “Unicode Character Sets”.

The MySQL implementation of UCS-2, UTF-16, and UTF-32 stores characters in big-endian byte order and does not use a byte order mark (BOM) at the beginning of values. Other database systems might use little-

endian byte order or a BOM. In such cases, conversion of values needs to be performed when transferring data between those systems and MySQL. The implementation of UTF-16LE is little-endian.

MySQL uses no BOM for UTF-8 values.

Client applications that communicate with the server using Unicode should set the client character set accordingly (for example, by issuing a `SET NAMES 'utf8mb4'` statement). Some character sets cannot be used as the client character set. Attempting to use them with `SET NAMES` or `SET CHARACTER SET` produces an error. See [Impermissible Client Character Sets](#).

The following sections provide additional detail on the Unicode character sets in MySQL.

## 12.9.1 The utf8mb4 Character Set (4-Byte UTF-8 Unicode Encoding)

The `utf8mb4` character set has these characteristics:

- Supports BMP and supplementary characters.
- Requires a maximum of four bytes per multibyte character.

`utf8mb4` contrasts with the `utf8mb3` character set, which supports only BMP characters and uses a maximum of three bytes per character:

- For a BMP character, `utf8mb4` and `utf8mb3` have identical storage characteristics: same code values, same encoding, same length.
- For a supplementary character, `utf8mb4` requires four bytes to store it, whereas `utf8mb3` cannot store the character at all. When converting `utf8mb3` columns to `utf8mb4`, you need not worry about converting supplementary characters because there are none.

`utf8mb4` is a superset of `utf8mb3`, so for an operation such as the following concatenation, the result has character set `utf8mb4` and the collation of `utf8mb4_col`:

```
SELECT CONCAT(utf8mb3_col, utf8mb4_col);
```

Similarly, the following comparison in the `WHERE` clause works according to the collation of `utf8mb4_col`:

```
SELECT * FROM utf8mb3_tbl, utf8mb4_tbl
WHERE utf8mb3_tbl.utf8mb3_col = utf8mb4_tbl.utf8mb4_col;
```

For information about data type storage as it relates to multibyte character sets, see [String Type Storage Requirements](#).

## 12.9.2 The utf8mb3 Character Set (3-Byte UTF-8 Unicode Encoding)

The `utf8mb3` character set has these characteristics:

- Supports BMP characters only (no support for supplementary characters)
- Requires a maximum of three bytes per multibyte character.

Applications that use UTF-8 data but require supplementary character support should use `utf8mb4` rather than `utf8mb3` (see [Section 12.9.1, “The utf8mb4 Character Set \(4-Byte UTF-8 Unicode Encoding\)”](#)).

Exactly the same set of characters is available in `utf8mb3` and `ucs2`. That is, they have the same [repertoire](#).

**Note**

The recommended character set for MySQL is [utf8mb4](#). All new applications should use [utf8mb4](#).

The [utf8mb3](#) character set is deprecated. [utf8mb3](#) remains supported for the lifetimes of the MySQL 8.0.x and MySQL 8.4.x LTS release series.

Expect [utf8mb3](#) to be removed in a future major release of MySQL.

Since changing character sets can be a complex and time-consuming task, you should begin to prepare for this change now by using [utf8mb4](#) for new applications. For guidance in converting existing applications which use [utfmb3](#), see [Section 12.9.8, “Converting Between 3-Byte and 4-Byte Unicode Character Sets”](#).

[utf8mb3](#) can be used in [CHARACTER SET](#) clauses, and [utf8mb3\\_collation\\_substring](#) in [COLLATE](#) clauses, where *collation\_substring* is [bin](#), [czech\\_ci](#), [danish\\_ci](#), [esperanto\\_ci](#), [estonian\\_ci](#), and so forth. For example:

```
CREATE TABLE t (s1 CHAR(1)) CHARACTER SET utf8mb3;
SELECT * FROM t WHERE s1 COLLATE utf8mb3_general_ci = 'x';
DECLARE x VARCHAR(5) CHARACTER SET utf8mb3 COLLATE utf8mb3_danish_ci;
SELECT CAST('a' AS CHAR CHARACTER SET utf8mb4) COLLATE utf8mb4_czech_ci;
```

In statements such as [SHOW CREATE TABLE](#) or [SELECT CHARACTER\\_SET\\_NAME FROM INFORMATION\\_SCHEMA.COLUMNS](#) or [SELECT COLLATION\\_NAME FROM INFORMATION\\_SCHEMA.COLUMNS](#), character sets or collation names prefixed with [utf8](#) or [utf8\\_](#) are displayed using [utf8mb3](#) or [utf8mb3\\_](#), respectively.

[utf8mb3](#) is also valid (but deprecated) in contexts other than [CHARACTER SET](#) clauses. For example:

```
mysqld --character-set-server=utf8mb3
```

```
SET NAMES 'utf8mb3'; /* and other SET statements that have similar effect */
SELECT _utf8mb3 'a';
```

For information about data type storage as it relates to multibyte character sets, see [String Type Storage Requirements](#).

## 12.9.3 The utf8 Character Set (Deprecated alias for utf8mb3)

[utf8](#) has been used by MySQL in the past as an alias for the [utf8mb3](#) character set, but this usage is now deprecated; in MySQL 9.1, [SHOW](#) statements and columns of [INFORMATION\\_SCHEMA](#) tables display [utf8mb3](#) instead. For more information, see [Section 12.9.2, “The utf8mb3 Character Set \(3-Byte UTF-8 Unicode Encoding\)”](#).

**Note**

The recommended character set for MySQL is [utf8mb4](#). All new applications should use [utf8mb4](#).

The [utf8mb3](#) character set is deprecated. [utf8mb3](#) remains supported for the lifetimes of the MySQL 8.0.x and MySQL 8.4.x LTS release series.

Expect [utf8mb3](#) to be removed in a future major release of MySQL.

Since changing character sets can be a complex and time-consuming task, you should begin to prepare for this change now by using [utf8mb4](#) for new

applications. For guidance in converting existing applications which use utfmb3, see [Section 12.9.8, “Converting Between 3-Byte and 4-Byte Unicode Character Sets”](#).

## 12.9.4 The ucs2 Character Set (UCS-2 Unicode Encoding)

### Note

The `ucs2` character set is deprecated; expect it to be removed in a future MySQL release. You should use `utf8mb4` instead.

In UCS-2, every character is represented by a 2-byte Unicode code with the most significant byte first. For example: `LATIN CAPITAL LETTER A` has the code `0x0041` and it is stored as a 2-byte sequence: `0x00 0x41`. `CYRILLIC SMALL LETTER YERU` (Unicode `0x044B`) is stored as a 2-byte sequence: `0x04 0x4B`. For Unicode characters and their codes, please refer to the [Unicode Consortium website](#).

The `ucs2` character set has these characteristics:

- Supports BMP characters only (no support for supplementary characters)
- Uses a fixed-length 16-bit encoding and requires two bytes per character.

## 12.9.5 The utf16 Character Set (UTF-16 Unicode Encoding)

The `utf16` character set is the `ucs2` character set with an extension that enables encoding of supplementary characters:

- For a BMP character, `utf16` and `ucs2` have identical storage characteristics: same code values, same encoding, same length.
- For a supplementary character, `utf16` has a special sequence for representing the character using 32 bits. This is called the “surrogate” mechanism: For a number greater than `0xffff`, take 10 bits and add them to `0xd800` and put them in the first 16-bit word, take 10 more bits and add them to `0xdc00` and put them in the next 16-bit word. Consequently, all supplementary characters require 32 bits, where the first 16 bits are a number between `0xd800` and `0xdbff`, and the last 16 bits are a number between `0xdc00` and `0xdfff`. Examples are in [Section 15.5 Surrogates Area](#) of the Unicode 4.0 document.

Because `utf16` supports surrogates and `ucs2` does not, there is a validity check that applies only in `utf16`: You cannot insert a top surrogate without a bottom surrogate, or vice versa. For example:

```
INSERT INTO t (ucs2_column) VALUES (0xd800); /* legal */
INSERT INTO t (utf16_column)VALUES (0xd800); /* illegal */
```

There is no validity check for characters that are technically valid but are not true Unicode (that is, characters that Unicode considers to be “unassigned code points” or “private use” characters or even “illegals” like `0xffff`). For example, since `U+F8FF` is the Apple Logo, this is legal:

```
INSERT INTO t (utf16_column)VALUES (0xf8ff); /* legal */
```

Such characters cannot be expected to mean the same thing to everyone.

Because MySQL must allow for the worst case (that one character requires four bytes) the maximum length of a `utf16` column or index is only half of the maximum length for a `ucs2` column or index. For example, the maximum length of a `MEMORY` table index key is 3072 bytes, so these statements create tables with the longest permitted indexes for `ucs2` and `utf16` columns:

```
CREATE TABLE tf (s1 VARCHAR(1536) CHARACTER SET ucs2) ENGINE=MEMORY;
CREATE INDEX i ON tf (s1);
```

```
CREATE TABLE tg (s1 VARCHAR(768) CHARACTER SET utf16) ENGINE=MEMORY;
CREATE INDEX i ON tg (s1);
```

## 12.9.6 The utf16le Character Set (UTF-16LE Unicode Encoding)

This is the same as `utf16` but is little-endian rather than big-endian.

## 12.9.7 The utf32 Character Set (UTF-32 Unicode Encoding)

The `utf32` character set is fixed length (like `ucs2` and unlike `utf16`). `utf32` uses 32 bits for every character, unlike `ucs2` (which uses 16 bits for every character), and unlike `utf16` (which uses 16 bits for some characters and 32 bits for others).

`utf32` takes twice as much space as `ucs2` and more space than `utf16`, but `utf32` has the same advantage as `ucs2` that it is predictable for storage: The required number of bytes for `utf32` equals the number of characters times 4. Also, unlike `utf16`, there are no tricks for encoding in `utf32`, so the stored value equals the code value.

To demonstrate how the latter advantage is useful, here is an example that shows how to determine a `utf8mb4` value given the `utf32` code value:

```
/* Assume code value = 100cc LINEAR B WHEELED CHARIOT */
CREATE TABLE tmp (utf32_col CHAR(1) CHARACTER SET utf32,
 utf8mb4_col CHAR(1) CHARACTER SET utf8mb4);
INSERT INTO tmp VALUES (0x000100cc,NULL);
UPDATE tmp SET utf8mb4_col = utf32_col;
SELECT HEX(utf32_col),HEX(utf8mb4_col) FROM tmp;
```

MySQL is very forgiving about additions of unassigned Unicode characters or private-use-area characters. There is in fact only one validity check for `utf32`: No code value may be greater than `0x10ffff`. For example, this is illegal:

```
INSERT INTO t (utf32_column) VALUES (0x110000); /* illegal */
```

## 12.9.8 Converting Between 3-Byte and 4-Byte Unicode Character Sets

This section describes issues that you may face when converting character data between the `utf8mb3` and `utf8mb4` character sets.

### Note

This discussion focuses primarily on converting between `utf8mb3` and `utf8mb4`, but similar principles apply to converting between the `ucs2` character set and character sets such as `utf16` or `utf32`.

The `utf8mb3` and `utf8mb4` character sets differ as follows:

- `utf8mb3` supports only characters in the Basic Multilingual Plane (BMP). `utf8mb4` additionally supports supplementary characters that lie outside the BMP.
- `utf8mb3` uses a maximum of three bytes per character. `utf8mb4` uses a maximum of four bytes per character.

### Note

This discussion refers to the `utf8mb3` and `utf8mb4` character set names to be explicit about referring to 3-byte and 4-byte UTF-8 character set data.

One advantage of converting from `utf8mb3` to `utf8mb4` is that this enables applications to use supplementary characters. One tradeoff is that this may increase data storage space requirements.

In terms of table content, conversion from `utf8mb3` to `utf8mb4` presents no problems:

- For a BMP character, `utf8mb4` and `utf8mb3` have identical storage characteristics: same code values, same encoding, same length.
- For a supplementary character, `utf8mb4` requires four bytes to store it, whereas `utf8mb3` cannot store the character at all. When converting `utf8mb3` columns to `utf8mb4`, you need not worry about converting supplementary characters because there are none.

In terms of table structure, these are the primary potential incompatibilities:

- For the variable-length character data types (`VARCHAR` and the `TEXT` types), the maximum permitted length in characters is less for `utf8mb4` columns than for `utf8mb3` columns.
- For all character data types (`CHAR`, `VARCHAR`, and the `TEXT` types), the maximum number of characters that can be indexed is less for `utf8mb4` columns than for `utf8mb3` columns.

Consequently, to convert tables from `utf8mb3` to `utf8mb4`, it may be necessary to change some column or index definitions.

Tables can be converted from `utf8mb3` to `utf8mb4` by using `ALTER TABLE`. Suppose that a table has this definition:

```
CREATE TABLE t1 (
 col1 CHAR(10) CHARACTER SET utf8mb3 COLLATE utf8mb3_unicode_ci NOT NULL,
 col2 CHAR(10) CHARACTER SET utf8mb3 COLLATE utf8mb3_bin NOT NULL
) CHARACTER SET utf8mb3;
```

The following statement converts `t1` to use `utf8mb4`:

```
ALTER TABLE t1
 DEFAULT CHARACTER SET utf8mb4,
 MODIFY col1 CHAR(10)
 CHARACTER SET utf8mb4 COLLATE utf8mb4_unicode_ci NOT NULL,
 MODIFY col2 CHAR(10)
 CHARACTER SET utf8mb4 COLLATE utf8mb4_bin NOT NULL;
```

The catch when converting from `utf8mb3` to `utf8mb4` is that the maximum length of a column or index key is unchanged in terms of *bytes*. Therefore, it is smaller in terms of *characters* because the maximum length of a character is four bytes instead of three. For the `CHAR`, `VARCHAR`, and `TEXT` data types, watch for these issues when converting your MySQL tables:

- Check all definitions of `utf8mb3` columns and make sure they do not exceed the maximum length for the storage engine.
- Check all indexes on `utf8mb3` columns and make sure they do not exceed the maximum length for the storage engine. Sometimes the maximum can change due to storage engine enhancements.

If the preceding conditions apply, you must either reduce the defined length of columns or indexes, or continue to use `utf8mb3` rather than `utf8mb4`.

Here are some examples where structural changes may be needed:

- A `TINYTEXT` column can hold up to 255 bytes, so it can hold up to 85 3-byte or 63 4-byte characters. Suppose that you have a `TINYTEXT` column that uses `utf8mb3` but must be able to contain more than

63 characters. You cannot convert it to `utf8mb4` unless you also change the data type to a longer type such as `TEXT`.

Similarly, a very long `VARCHAR` column may need to be changed to one of the longer `TEXT` types if you want to convert it from `utf8mb3` to `utf8mb4`.

- `InnoDB` has a maximum index length of 767 bytes for tables that use `COMPACT` or `REDUNDANT` row format, so for `utf8mb3` or `utf8mb4` columns, you can index a maximum of 255 or 191 characters, respectively. If you currently have `utf8mb3` columns with indexes longer than 191 characters, you must index a smaller number of characters.

In an `InnoDB` table that uses `COMPACT` or `REDUNDANT` row format, these column and index definitions are legal:

```
coll VARCHAR(500) CHARACTER SET utf8mb3, INDEX (coll(255))
```

To use `utf8mb4` instead, the index must be smaller:

```
coll VARCHAR(500) CHARACTER SET utf8mb4, INDEX (coll(191))
```

#### Note

For `InnoDB` tables that use `COMPRESSED` or `DYNAMIC` row format, [index key prefixes](#) longer than 767 bytes (up to 3072 bytes) are permitted. Tables created with these row formats enable you to index a maximum of 1024 or 768 characters for `utf8mb3` or `utf8mb4` columns, respectively. For related information, see [Section 17.21, “InnoDB Limits”](#), and [DYNAMIC Row Format](#).

The preceding types of changes are most likely to be required only if you have very long columns or indexes. Otherwise, you should be able to convert your tables from `utf8mb3` to `utf8mb4` without problems, using `ALTER TABLE` as described previously.

The following items summarize other potential incompatibilities:

- `SET NAMES 'utf8mb4'` causes use of the 4-byte character set for connection character sets. As long as no 4-byte characters are sent from the server, there should be no problems. Otherwise, applications that expect to receive a maximum of three bytes per character may have problems. Conversely, applications that expect to send 4-byte characters must ensure that the server understands them.
- For replication, if character sets that support supplementary characters are to be used on the source, all replicas must understand them as well.

Also, keep in mind the general principle that if a table has different definitions on the source and replica, this can lead to unexpected results. For example, the differences in maximum index key length make it risky to use `utf8mb3` on the source and `utf8mb4` on the replica.

If you have converted to `utf8mb4`, `utf16`, `utf16le`, or `utf32`, and then decide to convert back to `utf8mb3` or `ucs2` (for example, to downgrade to an older version of MySQL), these considerations apply:

- `utf8mb3` and `ucs2` data should present no problems.
- The server must be recent enough to recognize definitions referring to the character set from which you are converting.
- For object definitions that refer to the `utf8mb4` character set, you can dump them with `mysqldump` prior to downgrading, edit the dump file to change instances of `utf8mb4` to `utf8`, and reload the file in the older server, as long as there are no 4-byte characters in the data. The older server sees `utf8` in the dump file object definitions and create new objects that use the (3-byte) `utf8` character set.

## 12.10 Supported Character Sets and Collations

This section indicates which character sets MySQL supports. There is one subsection for each group of related character sets. For each character set, the permissible collations are listed.

To list the available character sets and their default collations, use the `SHOW CHARACTER SET` statement or query the `INFORMATION_SCHEMA.CHARACTER_SETS` table. For example:

```
mysql> SHOW CHARACTER SET;
```

Charset	Description	Default collation	Maxlen
armscii8	ARMSCII-8 Armenian	armscii8_general_ci	1
ascii	US ASCII	ascii_general_ci	1
big5	Big5 Traditional Chinese	big5_chinese_ci	2
binary	Binary pseudo charset	binary	1
cp1250	Windows Central European	cp1250_general_ci	1
cp1251	Windows Cyrillic	cp1251_general_ci	1
cp1256	Windows Arabic	cp1256_general_ci	1
cp1257	Windows Baltic	cp1257_general_ci	1
cp850	DOS West European	cp850_general_ci	1
cp852	DOS Central European	cp852_general_ci	1
cp866	DOS Russian	cp866_general_ci	1
cp932	SJIS for Windows Japanese	cp932_japanese_ci	2
dec8	DEC West European	dec8_swedish_ci	1
eucjpms	UJIS for Windows Japanese	eucjpms_japanese_ci	3
euckr	EUC-KR Korean	euckr_korean_ci	2
gb18030	China National Standard GB18030	gb18030_chinese_ci	4
gb2312	GB2312 Simplified Chinese	gb2312_chinese_ci	2
gbk	GBK Simplified Chinese	gbk_chinese_ci	2
geostd8	GEOSTD8 Georgian	geostd8_general_ci	1
greek	ISO 8859-7 Greek	greek_general_ci	1
hebrew	ISO 8859-8 Hebrew	hebrew_general_ci	1
hp8	HP West European	hp8_english_ci	1
keybcs2	DOS Kamenicky Czech-Slovak	keybcs2_general_ci	1
koi8r	KOI8-R Relcom Russian	koi8r_general_ci	1
koi8u	KOI8-U Ukrainian	koi8u_general_ci	1
latin1	cp1252 West European	latin1_swedish_ci	1
latin2	ISO 8859-2 Central European	latin2_general_ci	1
latin5	ISO 8859-9 Turkish	latin5_turkish_ci	1
latin7	ISO 8859-13 Baltic	latin7_general_ci	1
macce	Mac Central European	macce_general_ci	1
macroman	Mac West European	macroman_general_ci	1
sjis	Shift-JIS Japanese	sjis_japanese_ci	2
swe7	7bit Swedish	swe7_swedish_ci	1
tis620	TIS620 Thai	tis620_thai_ci	1
ucs2	UCS-2 Unicode	ucs2_general_ci	2
ujis	EUC-JP Japanese	ujis_japanese_ci	3
utf16	UTF-16 Unicode	utf16_general_ci	4
utf16le	UTF-16LE Unicode	utf16le_general_ci	4
utf32	UTF-32 Unicode	utf32_general_ci	4
utf8mb3	UTF-8 Unicode	utf8mb3_general_ci	3
utf8mb4	UTF-8 Unicode	utf8mb4_0900_ai_ci	4

In cases where a character set has multiple collations, it might not be clear which collation is most suitable for a given application. To avoid choosing the wrong collation, it can be helpful to perform some comparisons with representative data values to make sure that a given collation sorts values the way you expect.

### 12.10.1 Unicode Character Sets

This section describes the collations available for Unicode character sets and their differentiating properties. For general information about Unicode, see [Section 12.9, “Unicode Support”](#).

MySQL supports multiple Unicode character sets:

- [utf8mb4](#): A UTF-8 encoding of the Unicode character set using one to four bytes per character.
- [utf8mb3](#): A UTF-8 encoding of the Unicode character set using one to three bytes per character. This character set is deprecated; please use [utf8mb4](#) instead.
- [utf8](#): A deprecated alias for [utf8mb3](#). Use [utf8mb4](#) instead.

**Note**

[utf8](#) is expected in a future release to become an alias for [utf8mb4](#).

- [ucs2](#): The UCS-2 encoding of the Unicode character set using two bytes per character. Deprecated; expect support for this character set to be removed in a future version of MySQL.
- [utf16](#): The UTF-16 encoding for the Unicode character set using two or four bytes per character. Like [ucs2](#) but with an extension for supplementary characters.
- [utf16le](#): The UTF-16LE encoding for the Unicode character set. Like [utf16](#) but little-endian rather than big-endian.
- [utf32](#): The UTF-32 encoding for the Unicode character set using four bytes per character.

**Note**

The [utf8mb3](#) character set is deprecated and you should expect it to be removed in a future MySQL release. Please use [utf8mb4](#) instead. [utf8](#) is currently an alias for [utf8mb3](#), but it is now deprecated as such, and [utf8](#) is expected subsequently to become a reference to [utf8mb4](#). [utf8mb3](#) is also displayed in place of [utf8](#) in columns of Information Schema tables, and in the output of SQL [SHOW](#) statements.

To avoid ambiguity about the meaning of [utf8](#), consider specifying [utf8mb4](#) explicitly for character set references.

[utf8mb4](#), [utf16](#), [utf16le](#), and [utf32](#) support Basic Multilingual Plane (BMP) characters and supplementary characters that lie outside the BMP. [utf8mb3](#) and [ucs2](#) support only BMP characters.

Most Unicode character sets have a general collation (indicated by [\\_general](#) in the name or by the absence of a language specifier), a binary collation (indicated by [\\_bin](#) in the name), and several language-specific collations (indicated by language specifiers). For example, for [utf8mb4](#), [utf8mb4\\_general\\_ci](#) and [utf8mb4\\_bin](#) are its general and binary collations, and [utf8mb4\\_danish\\_ci](#) is one of its language-specific collations.

Most character sets have a single binary collation. [utf8mb4](#) is an exception that has two: [utf8mb4\\_bin](#) and [utf8mb4\\_0900\\_bin](#). These two binary collations have the same sort order but are distinguished by their pad attribute and collating weight characteristics. See [Collation Pad Attributes](#), and [Character Collating Weights](#).

Collation support for [utf16le](#) is limited. The only collations available are [utf16le\\_general\\_ci](#) and [utf16le\\_bin](#). These are similar to [utf16\\_general\\_ci](#) and [utf16\\_bin](#).

- [Unicode Collation Algorithm \(UCA\) Versions](#)

- [Language-Specific Collations](#)
- [\\_general\\_ci Versus \\_unicode\\_ci Collations](#)

- [Character Collating Weights](#)
- [Miscellaneous Information](#)

## Unicode Collation Algorithm (UCA) Versions

MySQL implements the `xxx_unicode_ci` collations according to the Unicode Collation Algorithm (UCA) described at <http://www.unicode.org/reports/tr10/>. The collation uses the version-4.0.0 UCA weight keys: <http://www.unicode.org/Public/UCA/4.0.0/allkeys-4.0.0.txt>. The `xxx_unicode_ci` collations have only partial support for the Unicode Collation Algorithm. Some characters are not supported, and combining marks are not fully supported. This affects languages such as Vietnamese, Yoruba, and Navajo. A combined character is considered different from the same character written with a single unicode character in string comparisons, and the two characters are considered to have a different length (for example, as returned by the `CHAR_LENGTH()` function or in result set metadata).

Unicode collations based on UCA versions higher than 4.0.0 include the version in the collation name. Examples:

- `utf8mb4_unicode_520_ci` is based on UCA 5.2.0 weight keys (<http://www.unicode.org/Public/UCA/5.2.0/allkeys.txt>),
- `utf8mb4_0900_ai_ci` is based on UCA 9.0.0 weight keys (<http://www.unicode.org/Public/UCA/9.0.0/allkeys.txt>).

The `LOWER()` and `UPPER()` functions perform case folding according to the collation of their argument. A character that has uppercase and lowercase versions only in a Unicode version higher than 4.0.0 is converted by these functions only if the argument collation uses a high enough UCA version.

## Collation Pad Attributes

Collations based on UCA 9.0.0 and higher are faster than collations based on UCA versions prior to 9.0.0. They also have a pad attribute of `NO PAD`, in contrast to `PAD SPACE` as used in collations based on UCA versions prior to 9.0.0. For comparison of nonbinary strings, `NO PAD` collations treat spaces at the end of strings like any other character (see [Trailing Space Handling in Comparisons](#)).

To determine the pad attribute for a collation, use the `INFORMATION_SCHEMA.COLLATIONS` table, which has a `PAD_ATTRIBUTE` column. For example:

```
mysql> SELECT COLLATION_NAME, PAD_ATTRIBUTE
FROM INFORMATION_SCHEMA.COLLATIONS
WHERE CHARACTER_SET_NAME = 'utf8mb4';
```

COLLATION_NAME	PAD_ATTRIBUTE
utf8mb4_general_ci	PAD SPACE
utf8mb4_bin	PAD SPACE
utf8mb4_unicode_ci	PAD SPACE
utf8mb4_icelandic_ci	PAD SPACE
...	
utf8mb4_0900_ai_ci	NO PAD
utf8mb4_de_pb_0900_ai_ci	NO PAD
utf8mb4_is_0900_ai_ci	NO PAD
...	
utf8mb4_ja_0900_as_cs	NO PAD
utf8mb4_ja_0900_as_cs_ks	NO PAD
utf8mb4_0900_as_ci	NO PAD
utf8mb4_ru_0900_ai_ci	NO PAD
utf8mb4_ru_0900_as_cs	NO PAD
utf8mb4_zh_0900_as_cs	NO PAD
utf8mb4_0900_bin	NO PAD

Comparison of nonbinary string values (`CHAR`, `VARCHAR`, and `TEXT`) that have a `NO PAD` collation differ from other collations with respect to trailing spaces. For example, `'a'` and `'a '` compare as different strings, not the same string. This can be seen using the binary collations for `utf8mb4`. The `pad` attribute for `utf8mb4_bin` is `PAD SPACE`, whereas for `utf8mb4_0900_bin` it is `NO PAD`. Consequently, operations involving `utf8mb4_0900_bin` do not add trailing spaces, and comparisons involving strings with trailing spaces may differ for the two collations:

```
mysql> CREATE TABLE t1 (c CHAR(10) COLLATE utf8mb4_bin);
Query OK, 0 rows affected (0.03 sec)

mysql> INSERT INTO t1 VALUES('a');
Query OK, 1 row affected (0.01 sec)

mysql> SELECT * FROM t1 WHERE c = 'a ';
+-----+
| c |
+-----+
| a |
+-----+
1 row in set (0.00 sec)

mysql> ALTER TABLE t1 MODIFY c CHAR(10) COLLATE utf8mb4_0900_bin;
Query OK, 0 rows affected (0.02 sec)
Records: 0 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM t1 WHERE c = 'a ';
Empty set (0.00 sec)
```

## Language-Specific Collations

MySQL implements language-specific Unicode collations if the ordering based only on the Unicode Collation Algorithm (UCA) does not work well for a language. Language-specific collations are UCA-based, with additional language tailoring rules. Examples of such rules appear later in this section. For questions about particular language orderings, <http://unicode.org> provides Common Locale Data Repository (CLDR) collation charts at <http://www.unicode.org/cldr/charts/30/collation/index.html>.

For example, the nonlanguage-specific `utf8mb4_0900_ai_ci` and language-specific `utf8mb4_LOCALE_0900_ai_ci` Unicode collations each have these characteristics:

- The collation is based on UCA 9.0.0 and CLDR v30, is accent-insensitive and case-insensitive. These characteristics are indicated by `_0900`, `_ai`, and `_ci` in the collation name. Exception: `utf8mb4_la_0900_ai_ci` is not based on CLDR because Classical Latin is not defined in CLDR.
- The collation works for all characters in the range [U+0, U+10FFFF].
- If the collation is not language specific, it sorts all characters, including supplementary characters, in default order (described following). If the collation is language specific, it sorts characters of the language correctly according to language-specific rules, and characters not in the language in default order.
- By default, the collation sorts characters having a code point listed in the DUCET table (Default Unicode Collation Element Table) according to the weight value assigned in the table. The collation sorts characters not having a code point listed in the DUCET table using their implicit weight value, which is constructed according to the UCA.
- For non-language-specific collations, characters in contraction sequences are treated as separate characters. For language-specific collations, contractions might change character sorting order.

A collation name that includes a locale code or language name shown in the following table is a language-specific collation. Unicode character sets may include collations for one or more of these languages.

**Table 12.3 Unicode Collation Language Specifiers**

Language	Language Specifier
Bosnian	<code>bs</code>
Bulgarian	<code>bg</code>
Chinese	<code>zh</code>
Classical Latin	<code>la</code> or <code>roman</code>
Croatian	<code>hr</code> or <code>croatian</code>
Czech	<code>cs</code> or <code>czech</code>
Danish	<code>da</code> or <code>danish</code>
Esperanto	<code>eo</code> or <code>esperanto</code>
Estonian	<code>et</code> or <code>estonian</code>
Galician	<code>gl</code>
German phone book order	<code>de_pb</code> or <code>german2</code>
Hungarian	<code>hu</code> or <code>hungarian</code>
Icelandic	<code>is</code> or <code>icelandic</code>
Japanese	<code>ja</code>
Latvian	<code>lv</code> or <code>latvian</code>
Lithuanian	<code>lt</code> or <code>lithuanian</code>
Mongolian	<code>mn</code>
Norwegian / Bokmål	<code>nb</code>
Norwegian / Nynorsk	<code>nn</code>
Persian	<code>persian</code>
Polish	<code>pl</code> or <code>polish</code>
Romanian	<code>ro</code> or <code>romanian</code>
Russian	<code>ru</code>
Serbian	<code>sr</code>
Sinhala	<code>sinhala</code>
Slovak	<code>sk</code> or <code>slovak</code>
Slovenian	<code>sl</code> or <code>slovenian</code>
Modern Spanish	<code>es</code> or <code>spanish</code>
Traditional Spanish	<code>es_trad</code> or <code>spanish2</code>
Swedish	<code>sv</code> or <code>swedish</code>
Turkish	<code>tr</code> or <code>turkish</code>
Vietnamese	<code>vi</code> or <code>vietnamese</code>

MySQL provides the Bulgarian collations `utf8mb4_bg_0900_ai_ci` and `utf8mb4_bg_0900_as_cs`.

Croatian collations are tailored for these Croatian letters: Č, Ć, Dž, Đ, Lj, Nj, Š, Ž.

MySQL provides the `utf8mb4_sr_latn_0900_ai_ci` and `utf8mb4_sr_latn_0900_as_cs` collations for Serbian and the `utf8mb4_bs_0900_ai_ci` and `utf8mb4_bs_0900_as_cs` collations for Bosnian, when these languages are written with the Latin alphabet.

MySQL provides collations for both major varieties of Norwegian: for Bokmål, you can use `utf8mb4_nb_0900_ai_ci` and `utf8mb4_nb_0900_as_cs`; for Nynorsk, MySQL now provides `utf8mb4_nn_0900_ai_ci` and `utf8mb4_nn_0900_as_cs`.

For Japanese, the `utf8mb4` character set includes `utf8mb4_ja_0900_as_cs` and `utf8mb4_ja_0900_as_cs_ks` collations. Both collations are accent-sensitive and case-sensitive. `utf8mb4_ja_0900_as_cs_ks` is also kana-sensitive and distinguishes Katakana characters from Hiragana characters, whereas `utf8mb4_ja_0900_as_cs` treats Katakana and Hiragana characters as equal for sorting. Applications that require a Japanese collation but not kana sensitivity may use `utf8mb4_ja_0900_as_cs` for better sort performance. `utf8mb4_ja_0900_as_cs` uses three weight levels for sorting; `utf8mb4_ja_0900_as_cs_ks` uses four.

For Classical Latin collations that are accent-insensitive, `İ` and `Ț` compare as equal, and `Ů` and `Ț` compare as equal. `İ` and `Ț`, and `Ů` and `Ț` compare as equal on the base letter level. In other words, `Ț` is regarded as an accented `İ`, and `Ů` is regarded as an accented `Ț`.

MySQL provides collations for the Mongolian language when written with Cyrillic characters, `utf8mb4_mn_cyrl_0900_ai_ci` and `utf8mb4_mn_cyrl_0900_as_cs`.

Spanish collations are available for modern and traditional Spanish. For both, `ñ` (n-tilde) is a separate letter between `n` and `o`. In addition, for traditional Spanish, `ch` is a separate letter between `c` and `d`, and `ll` is a separate letter between `l` and `m`.

Traditional Spanish collations may also be used for Asturian and Galician. MySQL also provides `utf8mb4_gl_0900_ai_ci` and `utf8mb4_gl_0900_as_cs` collations for Galician. (These are the same collations as `utf8mb4_es_0900_ai_ci` and `utf8mb4_es_0900_as_cs`, respectively.)

Swedish collations include Swedish rules. For example, in Swedish, the following relationship holds, which is not something expected by a German or French speaker:

```
Ü = Y < Ö
```

## `_general_ci` Versus `_unicode_ci` Collations

For any Unicode character set, operations performed using the `xxx_general_ci` collation are faster than those for the `xxx_unicode_ci` collation. For example, comparisons for the `utf8mb4_general_ci` collation are faster, but slightly less correct, than comparisons for `utf8mb4_unicode_ci`. The reason is that `utf8mb4_unicode_ci` supports mappings such as expansions; that is, when one character compares as equal to combinations of other characters. For example, `ß` is equal to `ss` in German and some other languages. `utf8mb4_unicode_ci` also supports contractions and ignorable characters. `utf8mb4_general_ci` is a legacy collation that does not support expansions, contractions, or ignorable characters. It can make only one-to-one comparisons between characters.

To further illustrate, the following equalities hold in both `utf8mb4_general_ci` and `utf8mb4_unicode_ci` (for the effect of this in comparisons or searches, see [Section 12.8.6, “Examples of the Effect of Collation”](#)):

```
Ä = A
Ö = O
Ü = U
```

A difference between the collations is that this is true for `utf8mb4_general_ci`:

```
ß = s
```

Whereas this is true for `utf8mb4_unicode_ci`, which supports the German DIN-1 ordering (also known as dictionary order):

```
ß = ss
```

MySQL implements language-specific Unicode collations if the ordering with `utf8mb4_unicode_ci` does not work well for a language. For example, `utf8mb4_unicode_ci` works fine for German dictionary order and French, so there is no need to create special `utf8mb4` collations.

`utf8mb4_general_ci` also is satisfactory for both German and French, except that `ß` is equal to `s`, and not to `ss`. If this is acceptable for your application, you should use `utf8mb4_general_ci` because it is faster. If this is not acceptable (for example, if you require German dictionary order), use `utf8mb4_unicode_ci` because it is more accurate.

If you require German DIN-2 (phone book) ordering, use the `utf8mb4_german2_ci` collation, which compares the following sets of characters equal:

```
Ä = Æ = AE
Ö = Œ = OE
Ü = UE
ß = ss
```

`utf8mb4_german2_ci` is similar to `latin1_german2_ci`, but the latter does not compare `Æ` equal to `AE` or `Œ` equal to `OE`. There is no `utf8mb4_german_ci` corresponding to `latin1_german_ci` for German dictionary order because `utf8mb4_general_ci` suffices.

## Character Collating Weights

A character's collating weight is determined as follows:

- For all Unicode collations except the `_bin` (binary) collations, MySQL performs a table lookup to find a character's collating weight.
- For `_bin` collations except `utf8mb4_0900_bin`, the weight is based on the code point, possibly with leading zero bytes added.
- For `utf8mb4_0900_bin`, the weight is the `utf8mb4` encoding bytes. The sort order is the same as for `utf8mb4_bin`, but much faster.

Collating weights can be displayed using the `WEIGHT_STRING()` function. (See [Section 14.8, “String Functions and Operators”](#).) If a collation uses a weight lookup table, but a character is not in the table (for example, because it is a “new” character), collating weight determination becomes more complex:

- For BMP characters in general collations (`xxx_general_ci`), the weight is the code point.
- For BMP characters in UCA collations (for example, `xxx_unicode_ci` and language-specific collations), the following algorithm applies:

```
if (code >= 0x3400 && code <= 0x4DB5)
 base= 0xFB80; /* CJK Ideograph Extension */
else if (code >= 0x4E00 && code <= 0x9FA5)
 base= 0xFB40; /* CJK Ideograph */
else
 base= 0xFBC0; /* All other characters */
aaaa= base + (code >> 15);
bbbb= (code & 0x7FFF) | 0x8000;
```

The result is a sequence of two collating elements, `aaaa` followed by `bbbb`. For example:

```
mysql> SELECT HEX(WEIGHT_STRING(_ucs2 0x04CF COLLATE ucs2_unicode_ci));
+-----+
| HEX(WEIGHT_STRING(_ucs2 0x04CF COLLATE ucs2_unicode_ci)) |
+-----+
| FBC084CF |
```

Thus, U+04cf CYRILLIC SMALL LETTER PALOCHKA (#) is, with all UCA 4.0.0 collations, greater than U+04c0 CYRILLIC LETTER PALOCHKA (l). With UCA 5.2.0 collations, all palochkas sort together.

- For supplementary characters in general collations, the weight is the weight for 0xffff REPLACEMENT CHARACTER. For supplementary characters in UCA 4.0.0 collations, their collating weight is 0xffff. That is, to MySQL, all supplementary characters are equal to each other, and greater than almost all BMP characters.

An example with Deseret characters and COUNT(DISTINCT):

```
CREATE TABLE t (s1 VARCHAR(5) CHARACTER SET utf32 COLLATE utf32_unicode_ci);
INSERT INTO t VALUES (0xffff); /* REPLACEMENT CHARACTER */
INSERT INTO t VALUES (0x010412); /* DESERET CAPITAL LETTER BEE */
INSERT INTO t VALUES (0x010413); /* DESERET CAPITAL LETTER TEE */
SELECT COUNT(DISTINCT s1) FROM t;
```

The result is 2 because in the MySQL `xxx_unicode_ci` collations, the replacement character has a weight of 0x0dc6, whereas Deseret Bee and Deseret Tee both have a weight of 0xffff. (Were the `utf32_general_ci` collation used instead, the result is 1 because all three characters have a weight of 0xffff in that collation.)

An example with cuneiform characters and WEIGHT\_STRING():

```
/*
The four characters in the INSERT string are
00000041 # LATIN CAPITAL LETTER A
0001218F # CUNEIFORM SIGN KAB
000121A7 # CUNEIFORM SIGN KISH
00000042 # LATIN CAPITAL LETTER B
*/
CREATE TABLE t (s1 CHAR(4) CHARACTER SET utf32 COLLATE utf32_unicode_ci);
INSERT INTO t VALUES (0x000000410001218f000121a700000042);
SELECT HEX(WEIGHT_STRING(s1)) FROM t;
```

The result is:

```
0E33 FFFD FFFD 0E4A
```

0E33 and 0E4A are primary weights as in UCA 4.0.0. FFFD is the weight for KAB and also for KISH.

The rule that all supplementary characters are equal to each other is nonoptimal but is not expected to cause trouble. These characters are very rare, so it is very rare that a multi-character string consists entirely of supplementary characters. In Japan, since the supplementary characters are obscure Kanji ideographs, the typical user does not care what order they are in, anyway. If you really want rows sorted by the MySQL rule and secondarily by code point value, it is easy:

```
ORDER BY s1 COLLATE utf32_unicode_ci, s1 COLLATE utf32_bin
```

- For supplementary characters based on UCA versions higher than 4.0.0 (for example, `xxx_unicode_520_ci`), supplementary characters do not necessarily all have the same collating weight. Some have explicit weights from the UCA `allkeys.txt` file. Others have weights calculated from this algorithm:

```
aaaa= base + (code >> 15);
bbbb= (code & 0x7FFF) | 0x8000;
```

There is a difference between “ordering by the character's code value” and “ordering by the character's binary representation,” a difference that appears only with `utf16_bin`, because of surrogates.

Suppose that `utf16_bin` (the binary collation for `utf16`) was a binary comparison “byte by byte” rather than “character by character.” If that were so, the order of characters in `utf16_bin` would differ from the order in `utf8mb4_bin`. For example, the following chart shows two rare characters. The first character is in the range `E000-FFFF`, so it is greater than a surrogate but less than a supplementary. The second character is a supplementary.

Code point	Character	utf8mb4	utf16
-----	-----	-----	-----
0FF9D	HALFWIDTH KATAKANA LETTER N	EF BE 9D	FF 9D
10384	UGARITIC LETTER DELTA	F0 90 8E 84	D8 00 DF 84

The two characters in the chart are in order by code point value because `0xff9d < 0x10384`. And they are in order by `utf8mb4` value because `0xef < 0xf0`. But they are not in order by `utf16` value, if we use byte-by-byte comparison, because `0xff > 0xd8`.

So MySQL's `utf16_bin` collation is not “byte by byte.” It is “by code point.” When MySQL sees a supplementary-character encoding in `utf16`, it converts to the character's code-point value, and then compares. Therefore, `utf8mb4_bin` and `utf16_bin` are the same ordering. This is consistent with the SQL:2008 standard requirement for a UCS\_BASIC collation: “UCS\_BASIC is a collation in which the ordering is determined entirely by the Unicode scalar values of the characters in the strings being sorted. It is applicable to the UCS character repertoire. Since every character repertoire is a subset of the UCS repertoire, the UCS\_BASIC collation is potentially applicable to every character set. NOTE 11: The Unicode scalar value of a character is its code point treated as an unsigned integer.”

If the character set is `ucs2`, comparison is byte-by-byte, but `ucs2` strings should not contain surrogates, anyway.

## Miscellaneous Information

The `xxx_general_mysql500_ci` collations preserve the pre-5.1.24 ordering of the original `xxx_general_ci` collations and permit upgrades for tables created before MySQL 5.1.24 (Bug #27877).

## 12.10.2 West European Character Sets

Western European character sets cover most West European languages, such as French, Spanish, Catalan, Basque, Portuguese, Italian, Albanian, Dutch, German, Danish, Swedish, Norwegian, Finnish, Faroese, Icelandic, Irish, Scottish, and English.

- `ascii` (US ASCII) collations:
  - `ascii_bin`
  - `ascii_general_ci` (default)
- `cp850` (DOS West European) collations:
  - `cp850_bin`
  - `cp850_general_ci` (default)
- `dec8` (DEC Western European) collations:
  - `dec8_bin`
  - `dec8_swedish_ci` (default)

The `dec` character set is deprecated; expect support for it to be removed in a subsequent MySQL release.

- `hp8` (HP Western European) collations:

- `hp8_bin`
- `hp8_english_ci` (default)

The `hp8` character set is deprecated; expect support for it to be removed in a subsequent MySQL release.

- `latin1` (cp1252 West European) collations:

- `latin1_bin`
- `latin1_danish_ci`
- `latin1_general_ci`
- `latin1_general_cs`
- `latin1_german1_ci`
- `latin1_german2_ci`
- `latin1_spanish_ci`
- `latin1_swedish_ci` (default)

MySQL's `latin1` is the same as the Windows `cp1252` character set. This means it is the same as the official [ISO 8859-1](#) or IANA (Internet Assigned Numbers Authority) `latin1`, except that IANA `latin1` treats the code points between `0x80` and `0x9f` as “undefined,” whereas `cp1252`, and therefore MySQL's `latin1`, assign characters for those positions. For example, `0x80` is the Euro sign. For the “undefined” entries in `cp1252`, MySQL translates `0x81` to Unicode `0x0081`, `0x8d` to `0x008d`, `0x8f` to `0x008f`, `0x90` to `0x0090`, and `0x9d` to `0x009d`.

The `latin1_swedish_ci` collation is the default that probably is used by the majority of MySQL customers. Although it is frequently said that it is based on the Swedish/Finnish collation rules, there are Swedes and Finns who disagree with this statement.

The `latin1_german1_ci` and `latin1_german2_ci` collations are based on the DIN-1 and DIN-2 standards, where DIN stands for *Deutsches Institut für Normung* (the German equivalent of ANSI). DIN-1 is called the “dictionary collation” and DIN-2 is called the “phone book collation.” For an example of the effect this has in comparisons or when doing searches, see [Section 12.8.6, “Examples of the Effect of Collation”](#).

- `latin1_german1_ci` (dictionary) rules:

```
Ä = A
Ö = O
Ü = U
ß = s
```

- `latin1_german2_ci` (phone-book) rules:

```
Ä = AE
Ö = OE
Ü = UE
ß = ss
```

In the `latin1_spanish_ci` collation, ñ (n-tilde) is a separate letter between `n` and `o`.

- `macroman` (Mac West European) collations:

- `macroman_bin`
- `macroman_general_ci` (default)

`macroroman` is deprecated; expect support for it to be removed in a subsequent MySQL release.

- `swe7` (7bit Swedish) collations:

- `swe7_bin`
- `swe7_swedish_ci` (default)

### 12.10.3 Central European Character Sets

MySQL provides some support for character sets used in the Czech Republic, Slovakia, Hungary, Romania, Slovenia, Croatia, Poland, and Serbia (Latin).

- `cp1250` (Windows Central European) collations:

- `cp1250_bin`
- `cp1250_croatian_ci`
- `cp1250_czech_cs`
- `cp1250_general_ci` (default)
- `cp1250_polish_ci`

- `cp852` (DOS Central European) collations:

- `cp852_bin`
- `cp852_general_ci` (default)

- `keybcs2` (DOS Kamenicky Czech-Slovak) collations:

- `keybcs2_bin`
- `keybcs2_general_ci` (default)

- `latin2` (ISO 8859-2 Central European) collations:

- `latin2_bin`
- `latin2_croatian_ci`
- `latin2_czech_cs`
- `latin2_general_ci` (default)
- `latin2_hungarian_ci`

- `macce` (Mac Central European) collations:

- `macce_bin`

- `macce_general_ci` (default)

`macce` is deprecated; expect support for it to be removed in a subsequent MySQL release.

## 12.10.4 South European and Middle East Character Sets

South European and Middle Eastern character sets supported by MySQL include Armenian, Arabic, Georgian, Greek, Hebrew, and Turkish.

- `armscii8` (ARMScii8 Armenian) collations:

- `armscii8_bin`
- `armscii8_general_ci` (default)

- `cp1256` (Windows Arabic) collations:

- `cp1256_bin`
- `cp1256_general_ci` (default)

- `geostd8` (GEOSTD8 Georgian) collations:

- `geostd8_bin`
- `geostd8_general_ci` (default)

- `greek` (ISO 8859-7 Greek) collations:

- `greek_bin`
- `greek_general_ci` (default)

- `hebrew` (ISO 8859-8 Hebrew) collations:

- `hebrew_bin`
- `hebrew_general_ci` (default)

- `latin5` (ISO 8859-9 Turkish) collations:

- `latin5_bin`
- `latin5_turkish_ci` (default)

## 12.10.5 Baltic Character Sets

The Baltic character sets cover Estonian, Latvian, and Lithuanian languages.

- `cp1257` (Windows Baltic) collations:

- `cp1257_bin`
- `cp1257_general_ci` (default)
- `cp1257_lithuanian_ci`

- `latin7` (ISO 8859-13 Baltic) collations:

- `latin7_bin`
- `latin7_estonian_cs`
- `latin7_general_ci` (default)
- `latin7_general_cs`

## 12.10.6 Cyrillic Character Sets

The Cyrillic character sets and collations are for use with Belarusian, Bulgarian, Russian, Ukrainian, and Serbian (Cyrillic) languages.

- `cp1251` (Windows Cyrillic) collations:
  - `cp1251_bin`
  - `cp1251_bulgarian_ci`
  - `cp1251_general_ci` (default)
  - `cp1251_general_cs`
  - `cp1251_ukrainian_ci`
- `cp866` (DOS Russian) collations:
  - `cp866_bin`
  - `cp866_general_ci` (default)
- `koi8r` (KOI8-R Relcom Russian) collations:
  - `koi8r_bin`
  - `koi8r_general_ci` (default)
- `koi8u` (KOI8-U Ukrainian) collations:
  - `koi8u_bin`
  - `koi8u_general_ci` (default)

## 12.10.7 Asian Character Sets

The Asian character sets that we support include Chinese, Japanese, Korean, and Thai. These can be complicated. For example, the Chinese sets must allow for thousands of different characters. See [Section 12.10.7.1, “The cp932 Character Set”](#), for additional information about the `cp932` and `sjis` character sets. See [Section 12.10.7.2, “The gb18030 Character Set”](#), for additional information about character set support for the Chinese National Standard GB 18030.

For answers to some common questions and problems relating support for Asian character sets in MySQL, see [Section A.11, “MySQL 9.1 FAQ: MySQL Chinese, Japanese, and Korean Character Sets”](#).

- `big5` (Big5 Traditional Chinese) collations:
  - `big5_bin`

- `big5_chinese_ci` (default)
- `cp932` (SJIS for Windows Japanese) collations:
  - `cp932_bin`
  - `cp932_japanese_ci` (default)
- `ucjpm` (UJIS for Windows Japanese) collations:
  - `ucjpm_bin`
  - `ucjpm_japanese_ci` (default)
- `euckr` (EUC-KR Korean) collations:
  - `euckr_bin`
  - `euckr_korean_ci` (default)
- `gb2312` (GB2312 Simplified Chinese) collations:
  - `gb2312_bin`
  - `gb2312_chinese_ci` (default)
- `gbk` (GBK Simplified Chinese) collations:
  - `gbk_bin`
  - `gbk_chinese_ci` (default)
- `gb18030` (China National Standard GB18030) collations:
  - `gb18030_bin`
  - `gb18030_chinese_ci` (default)
  - `gb18030_unicode_520_ci`
- `sjis` (Shift-JIS Japanese) collations:
  - `sjis_bin`
  - `sjis_japanese_ci` (default)
- `tis620` (TIS620 Thai) collations:
  - `tis620_bin`
  - `tis620_thai_ci` (default)
- `ujis` (EUC-JP Japanese) collations:
  - `ujis_bin`
  - `ujis_japanese_ci` (default)

The `big5_chinese_ci` collation sorts on number of strokes.

### 12.10.7.1 The cp932 Character Set

#### Why is cp932 needed?

In MySQL, the `sjis` character set corresponds to the `Shift_JIS` character set defined by IANA, which supports JIS X0201 and JIS X0208 characters. (See <http://www.iana.org/assignments/character-sets>.)

However, the meaning of “SHIFT JIS” as a descriptive term has become very vague and it often includes the extensions to `Shift_JIS` that are defined by various vendors.

For example, “SHIFT JIS” used in Japanese Windows environments is a Microsoft extension of `Shift_JIS` and its exact name is `Microsoft Windows Codepage : 932` or `cp932`. In addition to the characters supported by `Shift_JIS`, `cp932` supports extension characters such as NEC special characters, NEC selected—IBM extended characters, and IBM selected characters.

Many Japanese users have experienced problems using these extension characters. These problems stem from the following factors:

- MySQL automatically converts character sets.
- Character sets are converted using Unicode (`ucs2`).
- The `sjis` character set does not support the conversion of these extension characters.
- There are several conversion rules from so-called “SHIFT JIS” to Unicode, and some characters are converted to Unicode differently depending on the conversion rule. MySQL supports only one of these rules (described later).

The MySQL `cp932` character set is designed to solve these problems.

Because MySQL supports character set conversion, it is important to separate IANA `Shift_JIS` and `cp932` into two different character sets because they provide different conversion rules.

#### How does cp932 differ from sjis?

The `cp932` character set differs from `sjis` in the following ways:

- `cp932` supports NEC special characters, NEC selected—IBM extended characters, and IBM selected characters.
- Some `cp932` characters have two different code points, both of which convert to the same Unicode code point. When converting from Unicode back to `cp932`, one of the code points must be selected. For this “round trip conversion,” the rule recommended by Microsoft is used. (See <http://support.microsoft.com/kb/170559/EN-US/>.)

The conversion rule works like this:

- If the character is in both JIS X 0208 and NEC special characters, use the code point of JIS X 0208.
- If the character is in both NEC special characters and IBM selected characters, use the code point of NEC special characters.
- If the character is in both IBM selected characters and NEC selected—IBM extended characters, use the code point of IBM extended characters.

The table shown at <https://msdn.microsoft.com/en-us/global/cc305152.aspx> provides information about the Unicode values of `cp932` characters. For `cp932` table entries with characters under which a four-digit number appears, the number represents the corresponding Unicode (`ucs2`) encoding. For table entries with an underlined two-digit value appears, there is a range of `cp932` character values that

begin with those two digits. Clicking such a table entry takes you to a page that displays the Unicode value for each of the `cp932` characters that begin with those digits.

The following links are of special interest. They correspond to the encodings for the following sets of characters:

- NEC special characters (lead byte `0x87`):

<https://msdn.microsoft.com/en-us/goglobal/gg674964>

- NEC selected—IBM extended characters (lead byte `0xED` and `0xEE`):

<https://msdn.microsoft.com/en-us/goglobal/gg671837>  
<https://msdn.microsoft.com/en-us/goglobal/gg671838>

- IBM selected characters (lead byte `0xFA`, `0xFB`, `0xFC`):

<https://msdn.microsoft.com/en-us/goglobal/gg671839>  
<https://msdn.microsoft.com/en-us/goglobal/gg671840>  
<https://msdn.microsoft.com/en-us/goglobal/gg671841>

- `cp932` supports conversion of user-defined characters in combination with `eucjpm`s, and solves the problems with `sjis/ujis` conversion. For details, please refer to <http://www.sjfaq.org/afaq/encodings.html>.

For some characters, conversion to and from `ucs2` is different for `sjis` and `cp932`. The following tables illustrate these differences.

Conversion to `ucs2`:

<code>sjis/cp932</code> Value	<code>sjis</code> -> <code>ucs2</code> Conversion	<code>cp932</code> -> <code>ucs2</code> Conversion
5C	005C	005C
7E	007E	007E
815C	2015	2015
815F	005C	FF3C
8160	301C	FF5E
8161	2016	2225
817C	2212	FF0D
8191	00A2	FFE0
8192	00A3	FFE1
81CA	00AC	FFE2

Conversion from `ucs2`:

<code>ucs2</code> value	<code>ucs2</code> -> <code>sjis</code> Conversion	<code>ucs2</code> -> <code>cp932</code> Conversion
005C	815F	5C
007E	7E	7E
00A2	8191	3F
00A3	8192	3F
00AC	81CA	3F

FFE1	3F	8192
FFE2	3F	81CA

### 12.10.7.2 The gb18030 Character Set

In MySQL, the [gb18030](#) character set corresponds to the *Chinese National Standard GB 18030-2005: Information technology—Chinese coded character set*, which is the official character set of the People's Republic of China (PRC).

#### Characteristics of the MySQL gb18030 Character Set

- Supports all code points defined by the GB 18030-2005 standard. Unassigned code points in the ranges (GB+8431A439, GB+90308130) and (GB+E3329A36, GB+EF39EF39) are treated as '?' (0x3F). Conversion of unassigned code points returns '?'.
- Supports UPPER and LOWER conversion for all GB18030 code points. Case folding defined by Unicode is also supported (based on [CaseFolding-6.3.0.txt](#)).
- Supports Conversion of data to and from other character sets.
- Supports SQL statements such as [SET NAMES](#).
- Supports comparison between [gb18030](#) strings, and between [gb18030](#) strings and strings of other character sets. There is a conversion if strings have different character sets. Comparisons that include or ignore trailing spaces are also supported.
- The private use area (U+E000, U+F8FF) in Unicode is mapped to [gb18030](#).
- There is no mapping between (U+D800, U+DFFF) and GB18030. Attempted conversion of code points in this range returns '?'.
- If an incoming sequence is illegal, an error or warning is returned. If an illegal sequence is used in [CONVERT\( \)](#), an error is returned. Otherwise, a warning is returned.
- For consistency with [utf8mb3](#) and [utf8mb4](#), UPPER is not supported for ligatures.
- Searches for ligatures also match uppercase ligatures when using the [gb18030\\_unicode\\_520\\_ci](#) collation.
- If a character has more than one uppercase character, the chosen uppercase character is the one whose lowercase is the character itself.
- The minimum multibyte length is 1 and the maximum is 4. The character set determines the length of a sequence using the first 1 or 2 bytes.

## Supported Collations

- `gb18030_bin`: A binary collation.
- `gb18030_chinese_ci`: The default collation, which supports Pinyin. Sorting of non-Chinese characters is based on the order of the original sort key. The original sort key is `GB(UPPER(ch))` if `UPPER(ch)` exists. Otherwise, the original sort key is `GB(ch)`. Chinese characters are sorted according to the Pinyin collation defined in the Unicode Common Locale Data Repository (CLDR 24). Non-Chinese characters are sorted before Chinese characters with the exception of `GB+FE39FE39`, which is the code point maximum.
- `gb18030_unicode_520_ci`: A Unicode collation. Use this collation if you need to ensure that ligatures are sorted correctly.

### 12.10.8 The Binary Character Set

The `binary` character set is the character set for binary strings, which are sequences of bytes. The `binary` character set has one collation, also named `binary`. Comparison and sorting are based on numeric byte values, rather than on numeric character code values (which for multibyte characters differ from numeric byte values). For information about the differences between the `binary` collation of the `binary` character set and the `_bin` collations of nonbinary character sets, see [Section 12.8.5, “The binary Collation Compared to \\_bin Collations”](#).

For the `binary` character set, the concepts of lettercase and accent equivalence do not apply:

- For single-byte characters stored as binary strings, character and byte boundaries are the same, so lettercase and accent differences are significant in comparisons. That is, the `binary` collation is case-sensitive and accent-sensitive.

```
mysql> SET NAMES 'binary';
mysql> SELECT CHARSET('abc'), COLLATION('abc');
+-----+-----+
| CHARSET('abc') | COLLATION('abc') |
+-----+-----+
| binary | binary |
+-----+-----+
mysql> SELECT 'abc' = 'ABC', 'a' = 'ä';
+-----+-----+
| 'abc' = 'ABC' | 'a' = 'ä' |
+-----+-----+
| 0 | 0 |
+-----+-----+
```

- For multibyte characters stored as binary strings, character and byte boundaries differ. Character boundaries are lost, so comparisons that depend on them are not meaningful.

To perform lettercase conversion of a binary string, first convert it to a nonbinary string using a character set appropriate for the data stored in the string:

```
mysql> SET @str = BINARY 'New York';
mysql> SELECT LOWER(@str), LOWER(CONVERT(@str USING utf8mb4));
+-----+-----+
| LOWER(@str) | LOWER(CONVERT(@str USING utf8mb4)) |
+-----+-----+
| New York | new york |
+-----+-----+
```

To convert a string expression to a binary string, these constructs are equivalent:

```
BINARY expr
CAST(expr AS BINARY)
```

```
CONVERT(expr USING BINARY)
```

If a value is a character string literal, the `_binary` introducer may be used to designate it as a binary string. For example:

```
_binary 'a'
```

The `_binary` introducer is permitted for hexadecimal literals and bit-value literals as well, but unnecessary; such literals are binary strings by default.

For more information about introducers, see [Section 12.3.8, “Character Set Introducers”](#).

#### Note

Within the `mysql` client, binary strings display using hexadecimal notation, depending on the value of the `--binary-as-hex`. For more information about that option, see [Section 6.5.1, “mysql — The MySQL Command-Line Client”](#).

## 12.11 Restrictions on Character Sets

- Identifiers are stored in `mysql` database tables (`user`, `db`, and so forth) using `utf8mb3`, but identifiers can contain only characters in the Basic Multilingual Plane (BMP). Supplementary characters are not permitted in identifiers.
- The `ucs2`, `utf16`, `utf16le`, and `utf32` character sets have the following restrictions:
  - None of them can be used as the client character set. See [Impermissible Client Character Sets](#).
  - It is currently not possible to use `LOAD DATA` to load data files that use these character sets.
  - `FULLTEXT` indexes cannot be created on a column that uses any of these character sets. However, you can perform `IN BOOLEAN MODE` searches on the column without an index.
- The `REGEXP` and `RLIKE` operators work in byte-wise fashion, so they are not multibyte safe and may produce unexpected results with multibyte character sets. In addition, these operators compare characters by their byte values and accented characters may not compare as equal even if a given collation treats them as equal.

## 12.12 Setting the Error Message Language

By default, `mysqld` produces error messages in English, but they can be displayed instead in any of several other languages: Czech, Danish, Dutch, Estonian, French, German, Greek, Hungarian, Italian, Japanese, Korean, Norwegian, Norwegian-ny, Polish, Portuguese, Romanian, Russian, Slovak, Spanish, or Swedish. This applies to messages the server writes to the error log and sends to clients.

To select the language in which the server writes error messages, follow the instructions in this section. For information about changing the character set for error messages (rather than the language), see [Section 12.6, “Error Message Character Set”](#). For general information about configuring error logging, see [Section 7.4.2, “The Error Log”](#).

The server searches for the error message file using these rules:

- It looks for the file in a directory constructed from two system variable values, `lc_messages_dir` and `lc_messages`, with the latter converted to a language name. Suppose that you start the server using this command:

```
mysqld --lc_messages_dir=/usr/share/mysql --lc_messages=fr_FR
```

In this case, `mysqld` maps the locale `fr_FR` to the language `french` and looks for the error file in the `/usr/share/mysql/french` directory.

By default, the language files are located in the `share/mysql/LANGUAGE` directory under the MySQL base directory.

- If the message file cannot be found in the directory constructed as just described, the server ignores the `lc_messages` value and uses only the `lc_messages_dir` value as the location in which to look.
- If the server cannot find the configured message file, it writes a message to the error log to indicate the problem and defaults to built-in English messages.

The `lc_messages_dir` system variable can be set only at server startup and has only a global read-only value at runtime. `lc_messages` can be set at server startup and has global and session values that can be modified at runtime. Thus, the error message language can be changed while the server is running, and each client can have its own error message language by setting its session `lc_messages` value to the desired locale name. For example, if the server is using the `fr_FR` locale for error messages, a client can execute this statement to receive error messages in English:

```
SET lc_messages = 'en_US';
```

## 12.13 Adding a Character Set

This section discusses the procedure for adding a character set to MySQL. The proper procedure depends on whether the character set is simple or complex:

- If the character set does not need special string collating routines for sorting and does not need multibyte character support, it is simple.
- If the character set needs either of those features, it is complex.

For example, `greek` and `swe7` are simple character sets, whereas `big5` and `czech` are complex character sets.

To use the following instructions, you must have a MySQL source distribution. In the instructions, *MYSET* represents the name of the character set that you want to add.

1. Add a `<charset>` element for *MYSET* to the `sql/share/charsets/Index.xml` file. Use the existing contents in the file as a guide to adding new contents. A partial listing for the `latin1` `<charset>` element follows:

```
<charset name="latin1">
 <family>Western</family>
 <description>cp1252 West European</description>
 ...
 <collation name="latin1_swedish_ci" id="8" order="Finnish, Swedish">
 <flag>primary</flag>
 <flag>compiled</flag>
 </collation>
 <collation name="latin1_danish_ci" id="15" order="Danish"/>
 ...
 <collation name="latin1_bin" id="47" order="Binary">
 <flag>binary</flag>
 <flag>compiled</flag>
 </collation>
 ...
</charset>
```

The `<charset>` element must list all the collations for the character set. These must include at least a binary collation and a default (primary) collation. The default collation is often named using a suffix of

`general_ci` (general, case-insensitive). It is possible for the binary collation to be the default collation, but usually they are different. The default collation should have a `primary` flag. The binary collation should have a `binary` flag.

You must assign a unique ID number to each collation. The range of IDs from 1024 to 2047 is reserved for user-defined collations. To find the maximum of the currently used collation IDs, use this query:

```
SELECT MAX(ID) FROM INFORMATION_SCHEMA.COLLATIONS;
```

2. This step depends on whether you are adding a simple or complex character set. A simple character set requires only a configuration file, whereas a complex character set requires C source file that defines collation functions, multibyte functions, or both.

For a simple character set, create a configuration file, `MYSET.xml`, that describes the character set properties. Create this file in the `sql/share/charsets` directory. You can use a copy of `latin1.xml` as the basis for this file. The syntax for the file is very simple:

- Comments are written as ordinary XML comments (`<!-- text -->`).
- Words within `<map>` array elements are separated by arbitrary amounts of whitespace.
- Each word within `<map>` array elements must be a number in hexadecimal format.
- The `<map>` array element for the `<ctype>` element has 257 words. The other `<map>` array elements after that have 256 words. See [Section 12.13.1, “Character Definition Arrays”](#).
- For each collation listed in the `<charset>` element for the character set in `Index.xml`, `MYSET.xml` must contain a `<collation>` element that defines the character ordering.

For a complex character set, create a C source file that describes the character set properties and defines the support routines necessary to properly perform operations on the character set:

- Create the file `ctype-MYSET.c` in the `strings` directory. Look at one of the existing `ctype-*.c` files (such as `ctype-big5.c`) to see what needs to be defined. The arrays in your file must have names like `ctype_MYSET`, `to_lower_MYSET`, and so on. These correspond to the arrays for a simple character set. See [Section 12.13.1, “Character Definition Arrays”](#).
  - For each `<collation>` element listed in the `<charset>` element for the character set in `Index.xml`, the `ctype-MYSET.c` file must provide an implementation of the collation.
  - If the character set requires string collating functions, see [Section 12.13.2, “String Collating Support for Complex Character Sets”](#).
  - If the character set requires multibyte character support, see [Section 12.13.3, “Multi-Byte Character Support for Complex Character Sets”](#).
3. Modify the configuration information. Use the existing configuration information as a guide to adding information for `MYSYS`. The example here assumes that the character set has default and binary collations, but more lines are needed if `MYSET` has additional collations.
    - a. Edit `mysys/charset-def.c`, and “register” the collations for the new character set.

Add these lines to the “declaration” section:

```
#ifdef HAVE_CHARSET_MYSET
extern CHARSET_INFO my_charset_MYSET_general_ci;
extern CHARSET_INFO my_charset_MYSET_bin;
#endif
```

Add these lines to the “registration” section:

```
#ifdef HAVE_CHARSET_MYSET
 add_compiled_collation(&my_charset_MYSET_general_ci);
 add_compiled_collation(&my_charset_MYSET_bin);
#endif
```

- b. If the character set uses `ctype-MYSET.c`, edit `strings/CMakeLists.txt` and add `ctype-MYSET.c` to the definition of the `STRINGS_SOURCES` variable.
- c. Edit `cmake/character_sets.cmake`:
  - i. Add `MYSET` to the value of with `CHARSETS_AVAILABLE` in alphabetic order.
  - ii. Add `MYSET` to the value of `CHARSETS_COMPLEX` in alphabetic order. This is needed even for simple character sets, so that `CMake` can recognize `-DDEFAULT_CHARSET=MYSET`.

4. Reconfigure, recompile, and test.

## 12.13.1 Character Definition Arrays

Each simple character set has a configuration file located in the `sql/share/charsets` directory. For a character set named `MYSYS`, the file is named `MYSET.xml`. It uses `<map>` array elements to list character set properties. `<map>` elements appear within these elements:

- `<ctype>` defines attributes for each character.
- `<lower>` and `<upper>` list the lowercase and uppercase characters.
- `<unicode>` maps 8-bit character values to Unicode values.
- `<collation>` elements indicate character ordering for comparison and sorting, one element per collation. Binary collations need no `<map>` element because the character codes themselves provide the ordering.

For a complex character set as implemented in a `ctype-MYSET.c` file in the `strings` directory, there are corresponding arrays: `ctype_MYSET[]`, `to_lower_MYSET[]`, and so forth. Not every complex character set has all of the arrays. See also the existing `ctype-*.c` files for examples. See the `CHARSET_INFO.txt` file in the `strings` directory for additional information.

Most of the arrays are indexed by character value and have 256 elements. The `<ctype>` array is indexed by character value + 1 and has 257 elements. This is a legacy convention for handling `EOF`.

`<ctype>` array elements are bit values. Each element describes the attributes of a single character in the character set. Each attribute is associated with a bitmask, as defined in `include/m_ctype.h`:

```
#define _MY_U 01 /* Upper case */
#define _MY_L 02 /* Lower case */
#define _MY_NMR 04 /* Numeral (digit) */
#define _MY_SPC 010 /* Spacing character */
#define _MY_PNT 020 /* Punctuation */
#define _MY_CTR 040 /* Control character */
#define _MY_B 0100 /* Blank */
#define _MY_X 0200 /* hexadecimal digit */
```

The `<ctype>` value for a given character should be the union of the applicable bitmask values that describe the character. For example, `'A'` is an uppercase character (`_MY_U`) as well as a hexadecimal digit (`_MY_X`), so its `ctype` value should be defined like this:

```
ctype['A'+1] = _MY_U | _MY_X = 01 | 0200 = 0201
```

The bitmask values in `m_ctype.h` are octal values, but the elements of the `<ctype>` array in `MYSET.xml` should be written as hexadecimal values.

The `<lower>` and `<upper>` arrays hold the lowercase and uppercase characters corresponding to each member of the character set. For example:

```
lower['A'] should contain 'a'
upper['a'] should contain 'A'
```

Each `<collation>` array indicates how characters should be ordered for comparison and sorting purposes. MySQL sorts characters based on the values of this information. In some cases, this is the same as the `<upper>` array, which means that sorting is case-insensitive. For more complicated sorting rules (for complex character sets), see the discussion of string collating in [Section 12.13.2, “String Collating Support for Complex Character Sets”](#).

## 12.13.2 String Collating Support for Complex Character Sets

For a simple character set named `MYSET`, sorting rules are specified in the `MYSET.xml` configuration file using `<map>` array elements within `<collation>` elements. If the sorting rules for your language are too complex to be handled with simple arrays, you must define string collating functions in the `ctype-MYSET.c` source file in the `strings` directory.

The existing character sets provide the best documentation and examples to show how these functions are implemented. Look at the `ctype-*.c` files in the `strings` directory, such as the files for the `big5`, `czech`, `gbk`, `sjis`, and `tis160` character sets. Take a look at the `MY_COLLATION_HANDLER` structures to see how they are used. See also the `CHARSET_INFO.txt` file in the `strings` directory for additional information.

## 12.13.3 Multi-Byte Character Support for Complex Character Sets

If you want to add support for a new character set named `MYSET` that includes multibyte characters, you must use multibyte character functions in the `ctype-MYSET.c` source file in the `strings` directory.

The existing character sets provide the best documentation and examples to show how these functions are implemented. Look at the `ctype-*.c` files in the `strings` directory, such as the files for the `euc_kr`, `gb2312`, `gbk`, `sjis`, and `ujis` character sets. Take a look at the `MY_CHARSET_HANDLER` structures to see how they are used. See also the `CHARSET_INFO.txt` file in the `strings` directory for additional information.

## 12.14 Adding a Collation to a Character Set

### Warning

User-defined collations are deprecated; you should expect support for them to be removed in a future version of MySQL. The MySQL 9.1 server issues a warning for any use of `COLLATE user_defined_collation` in an SQL statement; a warning is also issued when the server is started with `--collation-server` set equal to the name of a user-defined collation.

A collation is a set of rules that defines how to compare and sort character strings. Each collation in MySQL belongs to a single character set. Every character set has at least one collation, and most have two or more collations.

A collation orders characters based on weights. Each character in a character set maps to a weight. Characters with equal weights compare as equal, and characters with unequal weights compare according to the relative magnitude of their weights.

The `WEIGHT_STRING()` function can be used to see the weights for the characters in a string. The value that it returns to indicate weights is a binary string, so it is convenient to use `HEX(WEIGHT_STRING(str))` to display the weights in printable form. The following example shows that weights do not differ for lettercase for the letters in 'AaBb' if it is a nonbinary case-insensitive string, but do differ if it is a binary string:

```
mysql> SELECT HEX(WEIGHT_STRING('AaBb' COLLATE latin1_swedish_ci));
+-----+
| HEX(WEIGHT_STRING('AaBb' COLLATE latin1_swedish_ci)) |
+-----+
| 41414242 |
+-----+
mysql> SELECT HEX(WEIGHT_STRING(BINARY 'AaBb'));
+-----+
| HEX(WEIGHT_STRING(BINARY 'AaBb')) |
+-----+
| 41614262 |
+-----+
```

MySQL supports several collation implementations, as discussed in [Section 12.14.1, “Collation Implementation Types”](#). Some of these can be added to MySQL without recompiling:

- Simple collations for 8-bit character sets.
- UCA-based collations for Unicode character sets.
- Binary (`xxx_bin`) collations.

The following sections describe how to add user-defined collations of the first two types to existing character sets. All existing character sets already have a binary collation, so there is no need here to describe how to add one.

### Warning

Redefining built-in collations is not supported and may result in unexpected server behavior.

Summary of the procedure for adding a new user-defined collation:

1. Choose a collation ID.
2. Add configuration information that names the collation and describes the character-ordering rules.
3. Restart the server.
4. Verify that the server recognizes the collation.

The instructions here cover only user-defined collations that can be added without recompiling MySQL. To add a collation that does require recompiling (as implemented by means of functions in a C source file), use the instructions in [Section 12.13, “Adding a Character Set”](#). However, instead of adding all the information required for a complete character set, just modify the appropriate files for an existing character set. That is, based on what is already present for the character set's current collations, add data structures, functions, and configuration information for the new collation.

### Note

If you modify an existing user-defined collation, that may affect the ordering of rows for indexes on columns that use the collation. In this case, rebuild any such indexes

to avoid problems such as incorrect query results. See [Section 3.14, “Rebuilding or Repairing Tables or Indexes”](#).

## Additional Resources

- Example showing how to add a collation for full-text searches: [Section 14.9.7, “Adding a User-Defined Collation for Full-Text Indexing”](#)
- The Unicode Collation Algorithm (UCA) specification: <http://www.unicode.org/reports/tr10/>
- The Locale Data Markup Language (LDML) specification: <http://www.unicode.org/reports/tr35/>

### 12.14.1 Collation Implementation Types

MySQL implements several types of collations:

#### Simple collations for 8-bit character sets

This kind of collation is implemented using an array of 256 weights that defines a one-to-one mapping from character codes to weights. `latin1_swedish_ci` is an example. It is a case-insensitive collation, so the uppercase and lowercase versions of a character have the same weights and they compare as equal.

```
mysql> SET NAMES 'latin1' COLLATE 'latin1_swedish_ci';
Query OK, 0 rows affected (0.01 sec)

mysql> SELECT HEX(WEIGHT_STRING('a')), HEX(WEIGHT_STRING('A'));
+-----+-----+
| HEX(WEIGHT_STRING('a')) | HEX(WEIGHT_STRING('A')) |
+-----+-----+
| 41 | 41 |
+-----+-----+
1 row in set (0.01 sec)

mysql> SELECT 'a' = 'A';
+-----+
| 'a' = 'A' |
+-----+
| 1 |
+-----+
1 row in set (0.12 sec)
```

For implementation instructions, see [Section 12.14.3, “Adding a Simple Collation to an 8-Bit Character Set”](#).

#### Complex collations for 8-bit character sets

This kind of collation is implemented using functions in a C source file that define how to order characters, as described in [Section 12.13, “Adding a Character Set”](#).

#### Collations for non-Unicode multibyte character sets

For this type of collation, 8-bit (single-byte) and multibyte characters are handled differently. For 8-bit characters, character codes map to weights in case-insensitive fashion. (For example, the single-byte characters `'a'` and `'A'` both have a weight of `0x41`.) For multibyte characters, there are two types of relationship between character codes and weights:

- Weights equal character codes. `sjis_japanese_ci` is an example of this kind of collation. The multibyte character `'ㇿ'` has a character code of `0x82C0`, and the weight is also `0x82C0`.

```
mysql> CREATE TABLE t1
```

```

 (c1 VARCHAR(2) CHARACTER SET sjis COLLATE sjis_japanese_ci);
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO t1 VALUES ('a'),('A'),(0x82C0);
Query OK, 3 rows affected (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 0

mysql> SELECT c1, HEX(c1), HEX(WEIGHT_STRING(c1)) FROM t1;
+-----+-----+-----+
| c1 | HEX(c1) | HEX(WEIGHT_STRING(c1)) |
+-----+-----+-----+
| a | 61 | 41 |
| A | 41 | 41 |
| 𐤀 | 82C0 | 82C0 |
+-----+-----+-----+
3 rows in set (0.00 sec)

```

- Character codes map one-to-one to weights, but a code is not necessarily equal to the weight. `gbk_chinese_ci` is an example of this kind of collation. The multibyte character '腦' has a character code of `0x81B0` but a weight of `0xC286`.

```

mysql> CREATE TABLE t1
 (c1 VARCHAR(2) CHARACTER SET gbk COLLATE gbk_chinese_ci);
Query OK, 0 rows affected (0.33 sec)

mysql> INSERT INTO t1 VALUES ('a'),('A'),(0x81B0);
Query OK, 3 rows affected (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 0

mysql> SELECT c1, HEX(c1), HEX(WEIGHT_STRING(c1)) FROM t1;
+-----+-----+-----+
| c1 | HEX(c1) | HEX(WEIGHT_STRING(c1)) |
+-----+-----+-----+
| a | 61 | 41 |
| A | 41 | 41 |
| 腦 | 81B0 | C286 |
+-----+-----+-----+
3 rows in set (0.00 sec)

```

For implementation instructions, see [Section 12.13](#), “Adding a Character Set”.

### Collations for Unicode multibyte character sets

Some of these collations are based on the Unicode Collation Algorithm (UCA), others are not.

Non-UCA collations have a one-to-one mapping from character code to weight. In MySQL, such collations are case-insensitive and accent-insensitive. `utf8mb4_general_ci` is an example: 'a', 'A', 'À', and 'á' each have different character codes but all have a weight of `0x0041` and compare as equal.

```

mysql> SET NAMES 'utf8mb4' COLLATE 'utf8mb4_general_ci';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t1
 (c1 CHAR(1) CHARACTER SET UTF8MB4 COLLATE utf8mb4_general_ci);
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO t1 VALUES ('a'),('A'),('À'),('á');
Query OK, 4 rows affected (0.00 sec)
Records: 4 Duplicates: 0 Warnings: 0

mysql> SELECT c1, HEX(c1), HEX(WEIGHT_STRING(c1)) FROM t1;
+-----+-----+-----+
| c1 | HEX(c1) | HEX(WEIGHT_STRING(c1)) |
+-----+-----+-----+
| a | 61 | 0041 |
+-----+-----+-----+

```

A	41	0041
À	C380	0041
á	C3A1	0041

4 rows in set (0.00 sec)

UCA-based collations in MySQL have these properties:

- If a character has weights, each weight uses 2 bytes (16 bits).
- A character may have zero weights (or an empty weight). In this case, the character is ignorable. Example: "U+0000 NULL" does not have a weight and is ignorable.
- A character may have one weight. Example: 'a' has a weight of 0x0E33.

```
mysql> SET NAMES 'utf8mb4' COLLATE 'utf8mb4_unicode_ci';
Query OK, 0 rows affected (0.05 sec)
```

```
mysql> SELECT HEX('a'), HEX(WEIGHT_STRING('a'));
+-----+-----+
| HEX('a') | HEX(WEIGHT_STRING('a')) |
+-----+-----+
| 61 | 0E33 |
+-----+-----+
1 row in set (0.02 sec)
```

- A character may have many weights. This is an expansion. Example: The German letter 'ß' (SZ ligature, or SHARP S) has a weight of 0x0FEA0FEA.

```
mysql> SET NAMES 'utf8mb4' COLLATE 'utf8mb4_unicode_ci';
Query OK, 0 rows affected (0.11 sec)
```

```
mysql> SELECT HEX('ß'), HEX(WEIGHT_STRING('ß'));
+-----+-----+
| HEX('ß') | HEX(WEIGHT_STRING('ß')) |
+-----+-----+
| C39F | 0FEA0FEA |
+-----+-----+
1 row in set (0.00 sec)
```

- Many characters may have one weight. This is a contraction. Example: 'ch' is a single letter in Czech and has a weight of 0x0EE2.

```
mysql> SET NAMES 'utf8mb4' COLLATE 'utf8mb4_czech_ci';
Query OK, 0 rows affected (0.09 sec)
```

```
mysql> SELECT HEX('ch'), HEX(WEIGHT_STRING('ch'));
+-----+-----+
| HEX('ch') | HEX(WEIGHT_STRING('ch')) |
+-----+-----+
| 6368 | 0EE2 |
+-----+-----+
1 row in set (0.00 sec)
```

A many-characters-to-many-weights mapping is also possible (this is contraction with expansion), but is not supported by MySQL.

For implementation instructions, for a non-UCA collation, see [Section 12.13, “Adding a Character Set”](#). For a UCA collation, see [Section 12.14.4, “Adding a UCA Collation to a Unicode Character Set”](#).

### Miscellaneous collations

There are also a few collations that do not fall into any of the previous categories.

## 12.14.2 Choosing a Collation ID

Each collation must have a unique ID. To add a collation, you must choose an ID value that is not currently used. MySQL supports two-byte collation IDs. The range of IDs from 1024 to 2047 is reserved for user-defined collations.

The collation ID that you choose appears in these contexts:

- The `ID` column of the Information Schema `COLLATIONS` table.
- The `Id` column of `SHOW COLLATION` output.
- The `charsetnr` member of the `MYSQL_FIELD` C API data structure.
- The `number` member of the `MY_CHARSET_INFO` data structure returned by the `mysql_get_character_set_info()` C API function.

To determine the largest currently used ID, issue the following statement:

```
mysql> SELECT MAX(ID) FROM INFORMATION_SCHEMA.COLLATIONS;
+-----+
| MAX(ID) |
+-----+
| 247 |
+-----+
```

To display a list of all currently used IDs, issue this statement:

```
mysql> SELECT ID FROM INFORMATION_SCHEMA.COLLATIONS ORDER BY ID;
+-----+
| ID |
+-----+
| 1 |
| 2 |
| ... |
| 52 |
| 53 |
| 57 |
| 58 |
| ... |
| 98 |
| 99 |
| 128 |
| 129 |
| ... |
| 247 |
+-----+
```

### Warning

Before upgrading, you should save the configuration files that you change. If you upgrade in place, the process replaces the modified files.

## 12.14.3 Adding a Simple Collation to an 8-Bit Character Set

This section describes how to add a simple collation for an 8-bit character set by writing the `<collation>` elements associated with a `<charset>` character set description in the MySQL `Index.xml` file. The procedure described here does not require recompiling MySQL. The example adds a collation named `latin1_test_ci` to the `latin1` character set.

1. Choose a collation ID, as shown in [Section 12.14.2, “Choosing a Collation ID”](#). The following steps use an ID of 1024.

2. Modify the `Index.xml` and `latin1.xml` configuration files. These files are located in the directory named by the `character_sets_dir` system variable. You can check the variable value as follows, although the path name might be different on your system:

```
mysql> SHOW VARIABLES LIKE 'character_sets_dir';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| character_sets_dir | /user/local/mysql/share/mysqlCharsets/ |
+-----+-----+
```

3. Choose a name for the collation and list it in the `Index.xml` file. Find the `<charset>` element for the character set to which the collation is being added, and add a `<collation>` element that indicates the collation name and ID, to associate the name with the ID. For example:

```
<charset name="latin1">
...
 <collation name="latin1_test_ci" id="1024"/>
...
</charset>
```

4. In the `latin1.xml` configuration file, add a `<collation>` element that names the collation and that contains a `<map>` element that defines a character code-to-weight mapping table for character codes 0 to 255. Each value within the `<map>` element must be a number in hexadecimal format.

```
<collation name="latin1_test_ci">
<map>
00 01 02 03 04 05 06 07 08 09 0A 0B 0C 0D 0E 0F
10 11 12 13 14 15 16 17 18 19 1A 1B 1C 1D 1E 1F
20 21 22 23 24 25 26 27 28 29 2A 2B 2C 2D 2E 2F
30 31 32 33 34 35 36 37 38 39 3A 3B 3C 3D 3E 3F
40 41 42 43 44 45 46 47 48 49 4A 4B 4C 4D 4E 4F
50 51 52 53 54 55 56 57 58 59 5A 5B 5C 5D 5E 5F
60 41 42 43 44 45 46 47 48 49 4A 4B 4C 4D 4E 4F
50 51 52 53 54 55 56 57 58 59 5A 7B 7C 7D 7E 7F
80 81 82 83 84 85 86 87 88 89 8A 8B 8C 8D 8E 8F
90 91 92 93 94 95 96 97 98 99 9A 9B 9C 9D 9E 9F
A0 A1 A2 A3 A4 A5 A6 A7 A8 A9 AA AB AC AD AE AF
B0 B1 B2 B3 B4 B5 B6 B7 B8 B9 BA BB BC BD BE BF
41 41 41 41 5B 5D 5B 43 45 45 45 45 49 49 49 49
44 4E 4F 4F 4F 4F 5C D7 5C 55 55 55 59 59 DE DF
41 41 41 41 5B 5D 5B 43 45 45 45 45 49 49 49 49
44 4E 4F 4F 4F 4F 5C F7 5C 55 55 55 59 59 DE FF
</map>
</collation>
```

5. Restart the server and use this statement to verify that the collation is present:

```
mysql> SHOW COLLATION WHERE Collation = 'latin1_test_ci';
+-----+-----+-----+-----+-----+-----+
| Collation | Charset | Id | Default | Compiled | Sortlen |
+-----+-----+-----+-----+-----+-----+
| latin1_test_ci | latin1 | 1024 | | | 1 |
+-----+-----+-----+-----+-----+-----+
```

## 12.14.4 Adding a UCA Collation to a Unicode Character Set

This section describes how to add a UCA collation for a Unicode character set by writing the `<collation>` element within a `<charset>` character set description in the MySQL `Index.xml` file. The procedure described here does not require recompiling MySQL. It uses a subset of the Locale Data Markup Language (LDML) specification, which is available at <http://www.unicode.org/reports/tr35/>. With this method, you need not define the entire collation. Instead, you begin with an existing “base” collation and describe the new collation in terms of how it differs from the base collation. The following table lists the

base collations of the Unicode character sets for which UCA collations can be defined. It is not possible to create user-defined UCA collations for `utf16le`; there is no `utf16le_unicode_ci` collation that would serve as the basis for such collations.

**Table 12.4 MySQL Character Sets Available for User-Defined UCA Collations**

Character Set	Base Collation
<code>utf8mb4</code>	<code>utf8mb4_unicode_ci</code>
<code>ucs2</code>	<code>ucs2_unicode_ci</code>
<code>utf16</code>	<code>utf16_unicode_ci</code>
<code>utf32</code>	<code>utf32_unicode_ci</code>

The following sections show how to add a collation that is defined using LDML syntax, and provide a summary of LDML rules supported in MySQL.

### 12.14.4.1 Defining a UCA Collation Using LDML Syntax

To add a UCA collation for a Unicode character set without recompiling MySQL, use the following procedure. If you are unfamiliar with the LDML rules used to describe the collation's sort characteristics, see [Section 12.14.4.2, “LDML Syntax Supported in MySQL”](#).

The example adds a collation named `utf8mb4_phone_ci` to the `utf8mb4` character set. The collation is designed for a scenario involving a Web application for which users post their names and phone numbers. Phone numbers can be given in very different formats:

```
+7-12345-67
+7-12-345-67
+7 12 345 67
+7 (12) 345 67
+71234567
```

The problem raised by dealing with these kinds of values is that the varying permissible formats make searching for a specific phone number very difficult. The solution is to define a new collation that reorders punctuation characters, making them ignorable.

1. Choose a collation ID, as shown in [Section 12.14.2, “Choosing a Collation ID”](#). The following steps use an ID of 1029.
2. To modify the `Index.xml` configuration file. This file is located in the directory named by the `character_sets_dir` system variable. You can check the variable value as follows, although the path name might be different on your system:

```
mysql> SHOW VARIABLES LIKE 'character_sets_dir';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| character_sets_dir | /user/local/mysql/share/mysql/charsets/ |
+-----+-----+
```

3. Choose a name for the collation and list it in the `Index.xml` file. In addition, you must provide the collation ordering rules. Find the `<charset>` element for the character set to which the collation is being added, and add a `<collation>` element that indicates the collation name and ID, to associate the name with the ID. Within the `<collation>` element, provide a `<rules>` element containing the ordering rules:

```
<charset name="utf8mb4">
...
 <collation name="utf8mb4_phone_ci" id="1029">
```

```

<rules>
 <reset>\u0000</reset>
 <i>\u0020</i> <!-- space -->
 <i>\u0028</i> <!-- left parenthesis -->
 <i>\u0029</i> <!-- right parenthesis -->
 <i>\u002B</i> <!-- plus -->
 <i>\u002D</i> <!-- hyphen -->
</rules>
</collation>
...
</charset>

```

- If you want a similar collation for other Unicode character sets, add other `<collation>` elements. For example, to define `ucs2_phone_ci`, add a `<collation>` element to the `<charset name="ucs2">` element. Remember that each collation must have its own unique ID.
- Restart the server and use this statement to verify that the collation is present:

```

mysql> SHOW COLLATION WHERE Collation = 'utf8mb4_phone_ci';
+-----+-----+-----+-----+-----+-----+
| Collation | Charset | Id | Default | Compiled | Sortlen |
+-----+-----+-----+-----+-----+-----+
| utf8mb4_phone_ci | utf8mb4 | 1029 | | | 8 |
+-----+-----+-----+-----+-----+-----+

```

Now test the collation to make sure that it has the desired properties.

Create a table containing some sample phone numbers using the new collation:

```

mysql> CREATE TABLE phonebook (
 name VARCHAR(64),
 phone VARCHAR(64) CHARACTER SET utf8mb4 COLLATE utf8mb4_phone_ci
);
Query OK, 0 rows affected (0.09 sec)

mysql> INSERT INTO phonebook VALUES ('Svoj','+7 912 800 80 02');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO phonebook VALUES ('Hf','+7 (912) 800 80 04');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO phonebook VALUES ('Bar','+7-912-800-80-01');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO phonebook VALUES ('Ramil','(7912) 800 80 03');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO phonebook VALUES ('Sanja','+380 (912) 8008005');
Query OK, 1 row affected (0.00 sec)

```

Run some queries to see whether the ignored punctuation characters are in fact ignored for comparison and sorting:

```

mysql> SELECT * FROM phonebook ORDER BY phone;
+-----+-----+
| name | phone |
+-----+-----+
| Sanja | +380 (912) 8008005 |
| Bar | +7-912-800-80-01 |
| Svoj | +7 912 800 80 02 |
| Ramil | (7912) 800 80 03 |
| Hf | +7 (912) 800 80 04 |
+-----+-----+
5 rows in set (0.00 sec)

```

```
mysql> SELECT * FROM phonebook WHERE phone='+7(912)800-80-01';
+-----+-----+
| name | phone |
+-----+-----+
| Bar | +7-912-800-80-01 |
+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT * FROM phonebook WHERE phone='79128008001';
+-----+-----+
| name | phone |
+-----+-----+
| Bar | +7-912-800-80-01 |
+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT * FROM phonebook WHERE phone='7 9 1 2 8 0 0 8 0 0 1';
+-----+-----+
| name | phone |
+-----+-----+
| Bar | +7-912-800-80-01 |
+-----+-----+
1 row in set (0.00 sec)
```

### 12.14.4.2 LDML Syntax Supported in MySQL

This section describes the LDML syntax that MySQL recognizes. This is a subset of the syntax described in the LDML specification available at <http://www.unicode.org/reports/tr35/>, which should be consulted for further information. MySQL recognizes a large enough subset of the syntax that, in many cases, it is possible to download a collation definition from the Unicode Common Locale Data Repository and paste the relevant part (that is, the part between the `<rules>` and `</rules>` tags) into the MySQL `Index.xml` file. The rules described here are all supported except that character sorting occurs only at the primary level. Rules that specify differences at secondary or higher sort levels are recognized (and thus can be included in collation definitions) but are treated as equality at the primary level.

The MySQL server generates diagnostics when it finds problems while parsing the `Index.xml` file. See [Section 12.14.4.3, “Diagnostics During Index.xml Parsing”](#).

#### Character Representation

Characters named in LDML rules can be written literally or in `\unnnn` format, where `nnnn` is the hexadecimal Unicode code point value. For example, `A` and `á` can be written literally or as `\u0041` and `\u00E1`. Within hexadecimal values, the digits `A` through `F` are not case-sensitive; `\u00E1` and `\u00e1` are equivalent. For UCA 4.0.0 collations, hexadecimal notation can be used only for characters in the Basic Multilingual Plane, not for characters outside the BMP range of `0000` to `FFFF`. For UCA 5.2.0 collations, hexadecimal notation can be used for any character.

The `Index.xml` file itself should be written using UTF-8 encoding.

#### Syntax Rules

LDML has reset rules and shift rules to specify character ordering. Orderings are given as a set of rules that begin with a reset rule that establishes an anchor point, followed by shift rules that indicate how characters sort relative to the anchor point.

- A `<reset>` rule does not specify any ordering in and of itself. Instead, it “resets” the ordering for subsequent shift rules to cause them to be taken in relation to a given character. Either of the following rules resets subsequent shift rules to be taken in relation to the letter `'A'`:

```
<reset>A</reset>
```

```
<reset>\u0041</reset>
```

- The `<p>`, `<s>`, and `<t>` shift rules define primary, secondary, and tertiary differences of a character from another character:
  - Use primary differences to distinguish separate letters.
  - Use secondary differences to distinguish accent variations.
  - Use tertiary differences to distinguish lettercase variations.

Either of these rules specifies a primary shift rule for the 'G' character:

```
<p>G</p>
<p>\u0047</p>
```

- The `<i>` shift rule indicates that one character sorts identically to another. The following rules cause 'b' to sort the same as 'a':

```
<reset>a</reset>
<i>b</i>
```

- Abbreviated shift syntax specifies multiple shift rules using a single pair of tags. The following table shows the correspondence between abbreviated syntax rules and the equivalent nonabbreviated rules.

**Table 12.5 Abbreviated Shift Syntax**

Abbreviated Syntax	Nonabbreviated Syntax
<code>&lt;pc&gt;xyz&lt;/pc&gt;</code>	<code>&lt;p&gt;x&lt;/p&gt;&lt;p&gt;y&lt;/p&gt;&lt;p&gt;z&lt;/p&gt;</code>
<code>&lt;sc&gt;xyz&lt;/sc&gt;</code>	<code>&lt;s&gt;x&lt;/s&gt;&lt;s&gt;y&lt;/s&gt;&lt;s&gt;z&lt;/s&gt;</code>
<code>&lt;tc&gt;xyz&lt;/tc&gt;</code>	<code>&lt;t&gt;x&lt;/t&gt;&lt;t&gt;y&lt;/t&gt;&lt;t&gt;z&lt;/t&gt;</code>
<code>&lt;ic&gt;xyz&lt;/ic&gt;</code>	<code>&lt;i&gt;x&lt;/i&gt;&lt;i&gt;y&lt;/i&gt;&lt;i&gt;z&lt;/i&gt;</code>

- An expansion is a reset rule that establishes an anchor point for a multiple-character sequence. MySQL supports expansions 2 to 6 characters long. The following rules put 'z' greater at the primary level than the sequence of three characters 'abc':

```
<reset>abc</reset>
<p>z</p>
```

- A contraction is a shift rule that sorts a multiple-character sequence. MySQL supports contractions 2 to 6 characters long. The following rules put the sequence of three characters 'xyz' greater at the primary level than 'a':

```
<reset>a</reset>
<p>xyz</p>
```

- Long expansions and long contractions can be used together. These rules put the sequence of three characters 'xyz' greater at the primary level than the sequence of three characters 'abc':

```
<reset>abc</reset>
<p>xyz</p>
```

- Normal expansion syntax uses `<x>` plus `<extend>` elements to specify an expansion. The following rules put the character 'k' greater at the secondary level than the sequence 'ch'. That is, 'k' behaves as if it expands to a character after 'c' followed by 'h':

```
<reset>c</reset>
<x><s>k</s><extend>h</extend></x>
```

This syntax permits long sequences. These rules sort the sequence 'ccs' greater at the tertiary level than the sequence 'cscs':

```
<reset>cs</reset>
<x><t>ccs</t><extend>cs</extend></x>
```

The LDML specification describes normal expansion syntax as “tricky.” See that specification for details.

- Previous context syntax uses `<x>` plus `<context>` elements to specify that the context before a character affects how it sorts. The following rules put '-' greater at the secondary level than 'a', but only when '-' occurs after 'b':

```
<reset>a</reset>
<x><context>b</context><s>-</s></x>
```

- Previous context syntax can include the `<extend>` element. These rules put 'def' greater at the primary level than 'aghi', but only when 'def' comes after 'abc':

```
<reset>a</reset>
<x><context>abc</context><p>def</p><extend>ghi</extend></x>
```

- Reset rules permit a `before` attribute. Normally, shift rules after a reset rule indicate characters that sort after the reset character. Shift rules after a reset rule that has the `before` attribute indicate characters that sort before the reset character. The following rules put the character 'b' immediately before 'a' at the primary level:

```
<reset before="primary">a</reset>
<p>b</p>
```

Permissible `before` attribute values specify the sort level by name or the equivalent numeric value:

```
<reset before="primary">
<reset before="1">

<reset before="secondary">
<reset before="2">

<reset before="tertiary">
<reset before="3">
```

- A reset rule can name a logical reset position rather than a literal character:

```
<first_tertiary_ignorable/>
<last_tertiary_ignorable/>
<first_secondary_ignorable/>
<last_secondary_ignorable/>
<first_primary_ignorable/>
<last_primary_ignorable/>
<first_variable/>
<last_variable/>
<first_non_ignorable/>
<last_non_ignorable/>
<first_trailing/>
<last_trailing/>
```

These rules put 'z' greater at the primary level than nonignorable characters that have a Default Unicode Collation Element Table (DUCET) entry and that are not CJK:

```
<reset><last_non_ignorable/></reset>
```

```
<p>z</p>
```

Logical positions have the code points shown in the following table.

**Table 12.6 Logical Reset Position Code Points**

Logical Position	Unicode 4.0.0 Code Point	Unicode 5.2.0 Code Point
<code>&lt;first_non_ignorable/&gt;</code>	U+02D0	U+02D0
<code>&lt;last_non_ignorable/&gt;</code>	U+A48C	U+1342E
<code>&lt;first_primary_ignorable/&gt;</code>	U+0332	U+0332
<code>&lt;last_primary_ignorable/&gt;</code>	U+20EA	U+101FD
<code>&lt;first_secondary_ignorable/&gt;</code>	U+0000	U+0000
<code>&lt;last_secondary_ignorable/&gt;</code>	U+FE73	U+FE73
<code>&lt;first_tertiary_ignorable/&gt;</code>	U+0000	U+0000
<code>&lt;last_tertiary_ignorable/&gt;</code>	U+FE73	U+FE73
<code>&lt;first_trailing/&gt;</code>	U+0000	U+0000
<code>&lt;last_trailing/&gt;</code>	U+0000	U+0000
<code>&lt;first_variable/&gt;</code>	U+0009	U+0009
<code>&lt;last_variable/&gt;</code>	U+2183	U+1D371

- The `<collation>` element permits a `shift-after-method` attribute that affects character weight calculation for shift rules. The attribute has these permitted values:
  - `simple`: Calculate character weights as for reset rules that do not have a `before` attribute. This is the default if the attribute is not given.
  - `expand`: Use expansions for shifts after reset rules.

Suppose that '0' and '1' have weights of 0E29 and 0E2A and we want to put all basic Latin letters between '0' and '1':

```
<reset>0</reset>
<pc>abcdefghijklmnopqrstuvwxyz</pc>
```

For simple shift mode, weights are calculated as follows:

```
'a' has weight 0E29+1
'b' has weight 0E29+2
'c' has weight 0E29+3
...
```

However, there are not enough vacant positions to put 26 characters between '0' and '1'. The result is that digits and letters are intermixed.

To solve this, use `shift-after-method="expand"`. Then weights are calculated like this:

```
'a' has weight [0E29][233D+1]
'b' has weight [0E29][233D+2]
```

```
'c' has weight [0E29][233D+3]
...
```

233D is the UCA 4.0.0 weight for character 0xA48C, which is the last nonignorable character (a sort of the greatest character in the collation, excluding CJK). UCA 5.2.0 is similar but uses 3ACA, for character 0x1342E.

### MySQL-Specific LDML Extensions

An extension to LDML rules permits the `<collation>` element to include an optional `version` attribute in `<collation>` tags to indicate the UCA version on which the collation is based. If the `version` attribute is omitted, its default value is 4.0.0. For example, this specification indicates a collation that is based on UCA 5.2.0:

```
<collation id="nnn" name="utf8mb4_xxx_ci" version="5.2.0">
...
</collation>
```

#### 12.14.4.3 Diagnostics During Index.xml Parsing

The MySQL server generates diagnostics when it finds problems while parsing the `Index.xml` file:

- Unknown tags are written to the error log. For example, the following message results if a collation definition contains a `<aaa>` tag:

```
[Warning] Buffered warning: Unknown LDML tag:
'charsets/charset/collation/rules/aaa'
```

- If collation initialization is not possible, the server reports an “Unknown collation” error, and also generates warnings explaining the problems, such as in the previous example. In other cases, when a collation description is generally correct but contains some unknown tags, the collation is initialized and is available for use. The unknown parts are ignored, but a warning is generated in the error log.
- Problems with collations generate warnings that clients can display with `SHOW WARNINGS`. Suppose that a reset rule contains an expansion longer than the maximum supported length of 6 characters:

```
<reset>abcdefghi</reset>
<i>x</i>
```

An attempt to use the collation produces warnings:

```
mysql> SELECT _utf8mb4'test' COLLATE utf8mb4_test_ci;
ERROR 1273 (HY000): Unknown collation: 'utf8mb4_test_ci'
mysql> SHOW WARNINGS;
```

Level	Code	Message
Error	1273	Unknown collation: 'utf8mb4_test_ci'
Warning	1273	Expansion is too long at 'abcdefghi=x'

## 12.15 Character Set Configuration

The MySQL server has a compiled-in default character set and collation. To change these defaults, use the `--character-set-server` and `--collation-server` options when you start the server. See [Section 7.1.7, “Server Command Options”](#). The collation must be a legal collation for the default character set. To determine which collations are available for each character set, use the `SHOW COLLATION` statement or query the `INFORMATION_SCHEMA.COLLATIONS` table.

If you try to use a character set that is not compiled into your binary, you might run into the following problems:

- If your program uses an incorrect path to determine where the character sets are stored (which is typically the `share/mysql/charsets` or `share/charsets` directory under the MySQL installation directory), this can be fixed by using the `--character-sets-dir` option when you run the program. For example, to specify a directory to be used by MySQL client programs, list it in the `[client]` group of your option file. The examples given here show what the setting might look like for Unix or Windows, respectively:

```
[client]
character-sets-dir=/usr/local/mysql/share/mysql/charsets

[client]
character-sets-dir="C:/Program Files/MySQL/MySQL Server 9.1/share/charsets"
```

- If the character set is a complex character set that cannot be loaded dynamically, you must recompile the program with support for the character set.

For Unicode character sets, you can define collations without recompiling by using LDML notation. See [Section 12.14.4, “Adding a UCA Collation to a Unicode Character Set”](#).

- If the character set is a dynamic character set, but you do not have a configuration file for it, you should install the configuration file for the character set from a new MySQL distribution.
- If your character set index file (`Index.xml`) does not contain the name for the character set, your program displays an error message:

```
Character set 'charset_name' is not a compiled character set and is not
specified in the '/usr/share/mysql/charsets/Index.xml' file
```

To solve this problem, you should either get a new index file or manually add the name of any missing character sets to the current file.

You can force client programs to use specific character set as follows:

```
[client]
default-character-set=charset_name
```

This is normally unnecessary. However, when `character_set_system` differs from `character_set_server` or `character_set_client`, and you input characters manually (as database object identifiers, column values, or both), these may be displayed incorrectly in output from the client or the output itself may be formatted incorrectly. In such cases, starting the mysql client with `--default-character-set=system_character_set`—that is, setting the client character set to match the system character set—should fix the problem.

## 12.16 MySQL Server Locale Support

The locale indicated by the `lc_time_names` system variable controls the language used to display day and month names and abbreviations. This variable affects the output from the `DATE_FORMAT()`, `DAYNAME()`, and `MONTHNAME()` functions.

`lc_time_names` does not affect the `STR_TO_DATE()` or `GET_FORMAT()` function.

The `lc_time_names` value does not affect the result from `FORMAT()`, but this function takes an optional third parameter that enables a locale to be specified to be used for the result number's decimal point, thousands separator, and grouping between separators. Permissible locale values are the same as the legal values for the `lc_time_names` system variable.

Locale names have language and region subtags listed by IANA (<http://www.iana.org/assignments/language-subtag-registry>) such as `'ja_JP'` or `'pt_BR'`. The default value is `'en_US'` regardless of your

system's locale setting, but you can set the value at server startup, or set the `GLOBAL` value at runtime if you have privileges sufficient to set global system variables; see [Section 7.1.9.1, “System Variable Privileges”](#). Any client can examine the value of `lc_time_names` or set its `SESSION` value to affect the locale for its own connection.

(The first `SET NAMES` statement in the following example may not be necessary if no settings relating to character set and collation have been changed from their defaults; we include it for completeness.)

```
mysql> SET NAMES 'utf8mb4';
Query OK, 0 rows affected (0.09 sec)

mysql> SELECT @@lc_time_names;
+-----+
| @@lc_time_names |
+-----+
| en_US |
+-----+
1 row in set (0.00 sec)

mysql> SELECT DAYNAME('2020-01-01'), MONTHNAME('2020-01-01');
+-----+-----+
| DAYNAME('2020-01-01') | MONTHNAME('2020-01-01') |
+-----+-----+
| Wednesday | January |
+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT DATE_FORMAT('2020-01-01','%W %a %M %b');
+-----+
| DATE_FORMAT('2020-01-01','%W %a %M %b') |
+-----+
| Wednesday Wed January Jan |
+-----+
1 row in set (0.00 sec)

mysql> SET lc_time_names = 'es_MX';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @@lc_time_names;
+-----+
| @@lc_time_names |
+-----+
| es_MX |
+-----+
1 row in set (0.00 sec)

mysql> SELECT DAYNAME('2020-01-01'), MONTHNAME('2020-01-01');
+-----+-----+
| DAYNAME('2020-01-01') | MONTHNAME('2020-01-01') |
+-----+-----+
| miércoles | enero |
+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT DATE_FORMAT('2020-01-01','%W %a %M %b');
+-----+
| DATE_FORMAT('2020-01-01','%W %a %M %b') |
+-----+
| miércoles mié enero ene |
+-----+
1 row in set (0.00 sec)
```

The day or month name for each of the affected functions is converted from `utf8mb4` to the character set indicated by the `character_set_connection` system variable.

`lc_time_names` may be set to any of the following locale values. The set of locales supported by MySQL may differ from those supported by your operating system.

Locale Value	Meaning
<code>ar_AE</code>	Arabic - United Arab Emirates
<code>ar_BH</code>	Arabic - Bahrain
<code>ar_DZ</code>	Arabic - Algeria
<code>ar_EG</code>	Arabic - Egypt
<code>ar_IN</code>	Arabic - India
<code>ar_IQ</code>	Arabic - Iraq
<code>ar_JO</code>	Arabic - Jordan
<code>ar_KW</code>	Arabic - Kuwait
<code>ar_LB</code>	Arabic - Lebanon
<code>ar_LY</code>	Arabic - Libya
<code>ar_MA</code>	Arabic - Morocco
<code>ar_OM</code>	Arabic - Oman
<code>ar_QA</code>	Arabic - Qatar
<code>ar_SA</code>	Arabic - Saudi Arabia
<code>ar_SD</code>	Arabic - Sudan
<code>ar_SY</code>	Arabic - Syria
<code>ar_TN</code>	Arabic - Tunisia
<code>ar_YE</code>	Arabic - Yemen
<code>be_BY</code>	Belarusian - Belarus
<code>bg_BG</code>	Bulgarian - Bulgaria
<code>ca_ES</code>	Catalan - Spain
<code>cs_CZ</code>	Czech - Czech Republic
<code>da_DK</code>	Danish - Denmark
<code>de_AT</code>	German - Austria
<code>de_BE</code>	German - Belgium
<code>de_CH</code>	German - Switzerland
<code>de_DE</code>	German - Germany
<code>de_LU</code>	German - Luxembourg
<code>el_GR</code>	Greek - Greece
<code>en_AU</code>	English - Australia
<code>en_CA</code>	English - Canada
<code>en_GB</code>	English - United Kingdom
<code>en_IN</code>	English - India
<code>en_NZ</code>	English - New Zealand
<code>en_PH</code>	English - Philippines
<code>en_US</code>	English - United States

Locale Value	Meaning
en_ZA	English - South Africa
en_ZW	English - Zimbabwe
es_AR	Spanish - Argentina
es_BO	Spanish - Bolivia
es_CL	Spanish - Chile
es_CO	Spanish - Colombia
es_CR	Spanish - Costa Rica
es_DO	Spanish - Dominican Republic
es_EC	Spanish - Ecuador
es_ES	Spanish - Spain
es_GT	Spanish - Guatemala
es_HN	Spanish - Honduras
es_MX	Spanish - Mexico
es_NI	Spanish - Nicaragua
es_PA	Spanish - Panama
es_PE	Spanish - Peru
es_PR	Spanish - Puerto Rico
es_PY	Spanish - Paraguay
es_SV	Spanish - El Salvador
es_US	Spanish - United States
es_UY	Spanish - Uruguay
es_VE	Spanish - Venezuela
et_EE	Estonian - Estonia
eu_ES	Basque - Spain
fi_FI	Finnish - Finland
fo_FO	Faroese - Faroe Islands
fr_BE	French - Belgium
fr_CA	French - Canada
fr_CH	French - Switzerland
fr_FR	French - France
fr_LU	French - Luxembourg
gl_ES	Galician - Spain
gu_IN	Gujarati - India
he_IL	Hebrew - Israel
hi_IN	Hindi - India
hr_HR	Croatian - Croatia
hu_HU	Hungarian - Hungary
id_ID	Indonesian - Indonesia

Locale Value	Meaning
is_IS	Icelandic - Iceland
it_CH	Italian - Switzerland
it_IT	Italian - Italy
ja_JP	Japanese - Japan
ko_KR	Korean - Republic of Korea
lt_LT	Lithuanian - Lithuania
lv_LV	Latvian - Latvia
mk_MK	Macedonian - North Macedonia
mn_MN	Mongolia - Mongolian
ms_MY	Malay - Malaysia
nb_NO	Norwegian(Bokmål) - Norway
nl_BE	Dutch - Belgium
nl_NL	Dutch - The Netherlands
no_NO	Norwegian - Norway
pl_PL	Polish - Poland
pt_BR	Portugese - Brazil
pt_PT	Portugese - Portugal
rm_CH	Romansh - Switzerland
ro_RO	Romanian - Romania
ru_RU	Russian - Russia
ru_UA	Russian - Ukraine
sk_SK	Slovak - Slovakia
sl_SI	Slovenian - Slovenia
sq_AL	Albanian - Albania
sr_RS	Serbian - Serbia
sv_FI	Swedish - Finland
sv_SE	Swedish - Sweden
ta_IN	Tamil - India
te_IN	Telugu - India
th_TH	Thai - Thailand
tr_TR	Turkish - Turkey
uk_UA	Ukrainian - Ukraine
ur_PK	Urdu - Pakistan
vi_VN	Vietnamese - Vietnam
zh_CN	Chinese - China
zh_HK	Chinese - Hong Kong
zh_TW	Chinese - Taiwan

# Chapter 13 Data Types

## Table of Contents

13.1	Numeric Data Types .....	2134
13.1.1	Numeric Data Type Syntax .....	2134
13.1.2	Integer Types (Exact Value) - INTEGER, INT, SMALLINT, TINYINT, MEDIUMINT, BIGINT .....	2138
13.1.3	Fixed-Point Types (Exact Value) - DECIMAL, NUMERIC .....	2139
13.1.4	Floating-Point Types (Approximate Value) - FLOAT, DOUBLE .....	2139
13.1.5	Bit-Value Type - BIT .....	2140
13.1.6	Numeric Type Attributes .....	2140
13.1.7	Out-of-Range and Overflow Handling .....	2141
13.2	Date and Time Data Types .....	2143
13.2.1	Date and Time Data Type Syntax .....	2144
13.2.2	The DATE, DATETIME, and TIMESTAMP Types .....	2146
13.2.3	The TIME Type .....	2148
13.2.4	The YEAR Type .....	2148
13.2.5	Automatic Initialization and Updating for TIMESTAMP and DATETIME .....	2149
13.2.6	Fractional Seconds in Time Values .....	2152
13.2.7	What Calendar Is Used By MySQL? .....	2153
13.2.8	Conversion Between Date and Time Types .....	2154
13.2.9	2-Digit Years in Dates .....	2155
13.3	String Data Types .....	2155
13.3.1	String Data Type Syntax .....	2156
13.3.2	The CHAR and VARCHAR Types .....	2159
13.3.3	The BINARY and VARBINARY Types .....	2161
13.3.4	The BLOB and TEXT Types .....	2162
13.3.5	The VECTOR Type .....	2164
13.3.6	The ENUM Type .....	2165
13.3.7	The SET Type .....	2168
13.4	Spatial Data Types .....	2170
13.4.1	Spatial Data Types .....	2172
13.4.2	The OpenGIS Geometry Model .....	2173
13.4.3	Supported Spatial Data Formats .....	2179
13.4.4	Geometry Well-Formedness and Validity .....	2182
13.4.5	Spatial Reference System Support .....	2183
13.4.6	Creating Spatial Columns .....	2184
13.4.7	Populating Spatial Columns .....	2185
13.4.8	Fetching Spatial Data .....	2186
13.4.9	Optimizing Spatial Analysis .....	2186
13.4.10	Creating Spatial Indexes .....	2186
13.4.11	Using Spatial Indexes .....	2187
13.5	The JSON Data Type .....	2189
13.6	Data Type Default Values .....	2205
13.7	Data Type Storage Requirements .....	2208
13.8	Choosing the Right Type for a Column .....	2213
13.9	Using Data Types from Other Database Engines .....	2213

MySQL supports [SQL](#) data types in several categories: numeric types, date and time types, string (character and byte) types, spatial types, and the [JSON](#) data type. This chapter provides an overview and more detailed description of the properties of the types in each category, and a summary of the data type

storage requirements. The initial overviews are intentionally brief. Consult the more detailed descriptions for additional information about particular data types, such as the permissible formats in which you can specify values.

Data type descriptions use these conventions:

- For integer types, *M* indicates the maximum display width. For floating-point and fixed-point types, *M* is the total number of digits that can be stored (the precision). For string types, *M* is the maximum length. The maximum permissible value of *M* depends on the data type.
- *D* applies to floating-point and fixed-point types and indicates the number of digits following the decimal point (the scale). The maximum possible value is 30, but should be no greater than *M*−2.
- *fsp* applies to the `TIME`, `DATETIME`, and `TIMESTAMP` types and represents fractional seconds precision; that is, the number of digits following the decimal point for fractional parts of seconds. The *fsp* value, if given, must be in the range 0 to 6. A value of 0 signifies that there is no fractional part. If omitted, the default precision is 0. (This differs from the standard SQL default of 6, for compatibility with previous MySQL versions.)
- Square brackets (`[` and `]`) indicate optional parts of type definitions.

## 13.1 Numeric Data Types

MySQL supports all standard SQL numeric data types. These types include the exact numeric data types (`INTEGER`, `SMALLINT`, `DECIMAL`, and `NUMERIC`), as well as the approximate numeric data types (`FLOAT`, `REAL`, and `DOUBLE PRECISION`). The keyword `INT` is a synonym for `INTEGER`, and the keywords `DEC` and `FIXED` are synonyms for `DECIMAL`. MySQL treats `DOUBLE` as a synonym for `DOUBLE PRECISION` (a nonstandard extension). MySQL also treats `REAL` as a synonym for `DOUBLE PRECISION` (a nonstandard variation), unless the `REAL_AS_FLOAT` SQL mode is enabled.

The `BIT` data type stores bit values and is supported for `MyISAM`, `MEMORY`, `InnoDB`, and `NDB` tables.

For information about how MySQL handles assignment of out-of-range values to columns and overflow during expression evaluation, see [Section 13.1.7, “Out-of-Range and Overflow Handling”](#).

For information about storage requirements of the numeric data types, see [Section 13.7, “Data Type Storage Requirements”](#).

For descriptions of functions that operate on numeric values, see [Section 14.6, “Numeric Functions and Operators”](#). The data type used for the result of a calculation on numeric operands depends on the types of the operands and the operations performed on them. For more information, see [Section 14.6.1, “Arithmetic Operators”](#).

### 13.1.1 Numeric Data Type Syntax

For integer data types, *M* indicates the minimum display width. The maximum display width is 255. Display width is unrelated to the range of values a type can store, as described in [Section 13.1.6, “Numeric Type Attributes”](#).

For floating-point and fixed-point data types, *M* is the total number of digits that can be stored.

The display width attribute is deprecated for integer data types; you should expect support for it to be removed in a future version of MySQL.

If you specify `ZEROFILL` for a numeric column, MySQL automatically adds the `UNSIGNED` attribute to the column.

The `ZEROFILL` attribute is deprecated for numeric data types; you should expect support for it to be removed in a future version of MySQL. Consider using an alternative means of producing the effect of this attribute. For example, applications could use the `LPAD()` function to zero-pad numbers up to the desired width, or they could store the formatted numbers in `CHAR` columns.

Numeric data types that permit the `UNSIGNED` attribute also permit `SIGNED`. However, these data types are signed by default, so the `SIGNED` attribute has no effect.

The `UNSIGNED` attribute is deprecated for columns of type `FLOAT`, `DOUBLE`, and `DECIMAL` (and any synonyms); you should expect support for it to be removed in a future version of MySQL. Consider using a simple `CHECK` constraint instead for such columns.

`SERIAL` is an alias for `BIGINT UNSIGNED NOT NULL AUTO_INCREMENT UNIQUE`.

`SERIAL DEFAULT VALUE` in the definition of an integer column is an alias for `NOT NULL AUTO_INCREMENT UNIQUE`.

### Warning

When you use subtraction between integer values where one is of type `UNSIGNED`, the result is unsigned unless the `NO_UNSIGNED_SUBTRACTION` SQL mode is enabled. See [Section 14.10, “Cast Functions and Operators”](#).

- `BIT[(M)]`

A bit-value type. *M* indicates the number of bits per value, from 1 to 64. The default is 1 if *M* is omitted.

- `TINYINT[(M)] [UNSIGNED] [ZEROFILL]`

A very small integer. The signed range is `-128` to `127`. The unsigned range is `0` to `255`.

- `BOOL`, `BOOLEAN`

These types are synonyms for `TINYINT(1)`. A value of zero is considered false. Nonzero values are considered true:

```
mysql> SELECT IF(0, 'true', 'false');
+-----+
| IF(0, 'true', 'false') |
+-----+
| false |
+-----+

mysql> SELECT IF(1, 'true', 'false');
+-----+
| IF(1, 'true', 'false') |
+-----+
| true |
+-----+

mysql> SELECT IF(2, 'true', 'false');
+-----+
| IF(2, 'true', 'false') |
+-----+
| true |
+-----+
```

However, the values `TRUE` and `FALSE` are merely aliases for `1` and `0`, respectively, as shown here:

```
mysql> SELECT IF(0 = FALSE, 'true', 'false');
+-----+
| IF(0 = FALSE, 'true', 'false') |
+-----+
```

```
+-----+
| true |
+-----+

mysql> SELECT IF(1 = TRUE, 'true', 'false');
+-----+
| IF(1 = TRUE, 'true', 'false') |
+-----+
| true |
+-----+

mysql> SELECT IF(2 = TRUE, 'true', 'false');
+-----+
| IF(2 = TRUE, 'true', 'false') |
+-----+
| false |
+-----+

mysql> SELECT IF(2 = FALSE, 'true', 'false');
+-----+
| IF(2 = FALSE, 'true', 'false') |
+-----+
| false |
+-----+
```

The last two statements display the results shown because 2 is equal to neither 1 nor 0.

- `SMALLINT[(M)] [UNSIGNED] [ZEROFILL]`

A small integer. The signed range is -32768 to 32767. The unsigned range is 0 to 65535.

- `MEDIUMINT[(M)] [UNSIGNED] [ZEROFILL]`

A medium-sized integer. The signed range is -8388608 to 8388607. The unsigned range is 0 to 16777215.

- `INT[(M)] [UNSIGNED] [ZEROFILL]`

A normal-size integer. The signed range is -2147483648 to 2147483647. The unsigned range is 0 to 4294967295.

- `INTEGER[(M)] [UNSIGNED] [ZEROFILL]`

This type is a synonym for `INT`.

- `BIGINT[(M)] [UNSIGNED] [ZEROFILL]`

A large integer. The signed range is -9223372036854775808 to 9223372036854775807. The unsigned range is 0 to 18446744073709551615.

`SERIAL` is an alias for `BIGINT UNSIGNED NOT NULL AUTO_INCREMENT UNIQUE`.

Some things you should be aware of with respect to `BIGINT` columns:

- All arithmetic is done using signed `BIGINT` or `DOUBLE` values, so you should not use unsigned big integers larger than 9223372036854775807 (63 bits) except with bit functions! If you do that, some of the last digits in the result may be wrong because of rounding errors when converting a `BIGINT` value to a `DOUBLE`.

MySQL can handle `BIGINT` in the following cases:

- When using integers to store large unsigned values in a `BIGINT` column.

- In `MIN(col_name)` or `MAX(col_name)`, where `col_name` refers to a `BIGINT` column.
- When using operators (+, -, \*, and so on) where both operands are integers.
- You can always store an exact integer value in a `BIGINT` column by storing it using a string. In this case, MySQL performs a string-to-number conversion that involves no intermediate double-precision representation.
- The -, +, and \* operators use `BIGINT` arithmetic when both operands are integer values. This means that if you multiply two big integers (or results from functions that return integers), you may get unexpected results when the result is larger than 9223372036854775807.
- `DECIMAL[(M[,D])] [UNSIGNED] [ZEROFILL]`

A packed “exact” fixed-point number. *M* is the total number of digits (the precision) and *D* is the number of digits after the decimal point (the scale). The decimal point and (for negative numbers) the - sign are not counted in *M*. If *D* is 0, values have no decimal point or fractional part. The maximum number of digits (*M*) for `DECIMAL` is 65. The maximum number of supported decimals (*D*) is 30. If *D* is omitted, the default is 0. If *M* is omitted, the default is 10. (There is also a limit on how long the text of `DECIMAL` literals can be; see [Section 14.25.3, “Expression Handling”](#).)

`UNSIGNED`, if specified, disallows negative values. The `UNSIGNED` attribute is deprecated for columns of type `DECIMAL` (and any synonyms); you should expect support for it to be removed in a future version of MySQL. Consider using a simple `CHECK` constraint instead for such columns.

All basic calculations (+, -, \*, /) with `DECIMAL` columns are done with a precision of 65 digits.

- `DEC[(M[,D])] [UNSIGNED] [ZEROFILL], NUMERIC[(M[,D])] [UNSIGNED] [ZEROFILL], FIXED[(M[,D])] [UNSIGNED] [ZEROFILL]`

These types are synonyms for `DECIMAL`. The `FIXED` synonym is available for compatibility with other database systems.

- `FLOAT(M,D) [UNSIGNED] [ZEROFILL]`

A small (single-precision) floating-point number. Permissible values are -3.402823466E+38 to -1.175494351E-38, 0, and 1.175494351E-38 to 3.402823466E+38. These are the theoretical limits, based on the IEEE standard. The actual range might be slightly smaller depending on your hardware or operating system.

*M* is the total number of digits and *D* is the number of digits following the decimal point. If *M* and *D* are omitted, values are stored to the limits permitted by the hardware. A single-precision floating-point number is accurate to approximately 7 decimal places.

`FLOAT(M,D)` is a nonstandard MySQL extension. This syntax is deprecated, and you should expect support for it to be removed in a future version of MySQL.

`UNSIGNED`, if specified, disallows negative values. The `UNSIGNED` attribute is deprecated for columns of type `FLOAT` (and any synonyms) and you should expect support for it to be removed in a future version of MySQL. Consider using a simple `CHECK` constraint instead for such columns.

Using `FLOAT` might give you some unexpected problems because all calculations in MySQL are done with double precision. See [Section B.3.4.7, “Solving Problems with No Matching Rows”](#).

- `FLOAT(p) [UNSIGNED] [ZEROFILL]`

A floating-point number. *p* represents the precision in bits, but MySQL uses this value only to determine whether to use `FLOAT` or `DOUBLE` for the resulting data type. If *p* is from 0 to 24, the data type becomes `FLOAT` with no *M* or *D* values. If *p* is from 25 to 53, the data type becomes `DOUBLE` with no *M* or *D* values. The range of the resulting column is the same as for the single-precision `FLOAT` or double-precision `DOUBLE` data types described earlier in this section.

`UNSIGNED`, if specified, disallows negative values. The `UNSIGNED` attribute is deprecated for columns of type `FLOAT` (and any synonyms) and you should expect support for it to be removed in a future version of MySQL. Consider using a simple `CHECK` constraint instead for such columns.

`FLOAT(p)` syntax is provided for ODBC compatibility.

- `DOUBLE[(M,D)] [UNSIGNED] [ZEROFILL]`

A normal-size (double-precision) floating-point number. Permissible values are `-1.7976931348623157E+308` to `-2.2250738585072014E-308`, `0`, and `2.2250738585072014E-308` to `1.7976931348623157E+308`. These are the theoretical limits, based on the IEEE standard. The actual range might be slightly smaller depending on your hardware or operating system.

*M* is the total number of digits and *D* is the number of digits following the decimal point. If *M* and *D* are omitted, values are stored to the limits permitted by the hardware. A double-precision floating-point number is accurate to approximately 15 decimal places.

`DOUBLE(M,D)` is a nonstandard MySQL extension; and is deprecated. You should expect support for this syntax to be removed in a future version of MySQL.

`UNSIGNED`, if specified, disallows negative values. The `UNSIGNED` attribute is deprecated for columns of type `DOUBLE` (and any synonyms) and you should expect support for it to be removed in a future version of MySQL. Consider using a simple `CHECK` constraint instead for such columns.

- `DOUBLE PRECISION[(M,D)] [UNSIGNED] [ZEROFILL]`, `REAL[(M,D)] [UNSIGNED] [ZEROFILL]`

These types are synonyms for `DOUBLE`. Exception: If the `REAL_AS_FLOAT` SQL mode is enabled, `REAL` is a synonym for `FLOAT` rather than `DOUBLE`.

### 13.1.2 Integer Types (Exact Value) - INTEGER, INT, SMALLINT, TINYINT, MEDIUMINT, BIGINT

MySQL supports the SQL standard integer types `INTEGER` (or `INT`) and `SMALLINT`. As an extension to the standard, MySQL also supports the integer types `TINYINT`, `MEDIUMINT`, and `BIGINT`. The following table shows the required storage and range for each integer type.

**Table 13.1 Required Storage and Range for Integer Types Supported by MySQL**

Type	Storage (Bytes)	Minimum Value Signed	Minimum Value Unsigned	Maximum Value Signed	Maximum Value Unsigned
<code>TINYINT</code>	1	-128	0	127	255
<code>SMALLINT</code>	2	-32768	0	32767	65535
<code>MEDIUMINT</code>	3	-8388608	0	8388607	16777215

Type	Storage (Bytes)	Minimum Value Signed	Minimum Value Unsigned	Maximum Value Signed	Maximum Value Unsigned
INT	4	-2147483648	0	2147483647	4294967295
BIGINT	8	$-2^{63}$	0	$2^{63}-1$	$2^{64}-1$

### 13.1.3 Fixed-Point Types (Exact Value) - DECIMAL, NUMERIC

The `DECIMAL` and `NUMERIC` types store exact numeric data values. These types are used when it is important to preserve exact precision, for example with monetary data. In MySQL, `NUMERIC` is implemented as `DECIMAL`, so the following remarks about `DECIMAL` apply equally to `NUMERIC`.

MySQL stores `DECIMAL` values in binary format. See [Section 14.25, “Precision Math”](#).

In a `DECIMAL` column declaration, the precision and scale can be (and usually is) specified. For example:

```
salary DECIMAL(5,2)
```

In this example, `5` is the precision and `2` is the scale. The precision represents the number of significant digits that are stored for values, and the scale represents the number of digits that can be stored following the decimal point.

Standard SQL requires that `DECIMAL(5,2)` be able to store any value with five digits and two decimals, so values that can be stored in the `salary` column range from `-999.99` to `999.99`.

In standard SQL, the syntax `DECIMAL(M)` is equivalent to `DECIMAL(M,0)`. Similarly, the syntax `DECIMAL` is equivalent to `DECIMAL(M,0)`, where the implementation is permitted to decide the value of `M`. MySQL supports both of these variant forms of `DECIMAL` syntax. The default value of `M` is 10.

If the scale is 0, `DECIMAL` values contain no decimal point or fractional part.

The maximum number of digits for `DECIMAL` is 65, but the actual range for a given `DECIMAL` column can be constrained by the precision or scale for a given column. When such a column is assigned a value with more digits following the decimal point than are permitted by the specified scale, the value is converted to that scale. (The precise behavior is operating system-specific, but generally the effect is truncation to the permissible number of digits.)

### 13.1.4 Floating-Point Types (Approximate Value) - FLOAT, DOUBLE

The `FLOAT` and `DOUBLE` types represent approximate numeric data values. MySQL uses four bytes for single-precision values and eight bytes for double-precision values.

For `FLOAT`, the SQL standard permits an optional specification of the precision (but not the range of the exponent) in bits following the keyword `FLOAT` in parentheses, that is, `FLOAT(p)`. MySQL also supports this optional precision specification, but the precision value in `FLOAT(p)` is used only to determine storage size. A precision from 0 to 23 results in a 4-byte single-precision `FLOAT` column. A precision from 24 to 53 results in an 8-byte double-precision `DOUBLE` column.

MySQL permits a nonstandard syntax: `FLOAT(M,D)` or `REAL(M,D)` or `DOUBLE PRECISION(M,D)`. Here, `(M,D)` means that values can be stored with up to `M` digits in total, of which `D` digits may be after the decimal point. For example, a column defined as `FLOAT(7,4)` is displayed as `-999.9999`. MySQL performs rounding when storing values, so if you insert `999.00009` into a `FLOAT(7,4)` column, the approximate result is `999.0001`.

`FLOAT(M,D)` and `DOUBLE(M,D)` are nonstandard MySQL extensions; and are deprecated. You should expect support for these variants to be removed in a future version of MySQL.

Because floating-point values are approximate and not stored as exact values, attempts to treat them as exact in comparisons may lead to problems. They are also subject to platform or implementation dependencies. For more information, see [Section B.3.4.8, “Problems with Floating-Point Values”](#).

For maximum portability, code requiring storage of approximate numeric data values should use `FLOAT` or `DOUBLE PRECISION` with no specification of precision or number of digits.

### 13.1.5 Bit-Value Type - BIT

The `BIT` data type is used to store bit values. A type of `BIT(M)` enables storage of *M*-bit values. *M* can range from 1 to 64.

To specify bit values, `b'value'` notation can be used. *value* is a binary value written using zeros and ones. For example, `b'111'` and `b'10000000'` represent 7 and 128, respectively. See [Section 11.1.5, “Bit-Value Literals”](#).

If you assign a value to a `BIT(M)` column that is less than *M* bits long, the value is padded on the left with zeros. For example, assigning a value of `b'101'` to a `BIT(6)` column is, in effect, the same as assigning `b'000101'`.

**NDB Cluster.** The maximum combined size of all `BIT` columns used in a given `NDB` table must not exceed 4096 bits.

### 13.1.6 Numeric Type Attributes

MySQL supports an extension for optionally specifying the display width of integer data types in parentheses following the base keyword for the type. For example, `INT(4)` specifies an `INT` with a display width of four digits. This optional display width may be used by applications to display integer values having a width less than the width specified for the column by left-padding them with spaces. (That is, this width is present in the metadata returned with result sets. Whether it is used is up to the application.)

The display width does *not* constrain the range of values that can be stored in the column. Nor does it prevent values wider than the column display width from being displayed correctly. For example, a column specified as `SMALLINT(3)` has the usual `SMALLINT` range of `-32768` to `32767`, and values outside the range permitted by three digits are displayed in full using more than three digits.

When used in conjunction with the optional (nonstandard) `ZEROFILL` attribute, the default padding of spaces is replaced with zeros. For example, for a column declared as `INT(4) ZEROFILL`, a value of 5 is retrieved as `0005`.

#### Note

The `ZEROFILL` attribute is ignored for columns involved in expressions or `UNION` queries.

If you store values larger than the display width in an integer column that has the `ZEROFILL` attribute, you may experience problems when MySQL generates temporary tables for some complicated joins. In these cases, MySQL assumes that the data values fit within the column display width.

The `ZEROFILL` attribute is deprecated for numeric data types, as is the display width attribute for integer data types. You should expect support for `ZEROFILL` and display widths for integer data types to be removed in a future version of MySQL. Consider using an alternative means of producing the effect of these attributes. For example, applications can use the `LPAD()` function to zero-pad numbers up to the desired width, or they can store the formatted numbers in `CHAR` columns.

All integer types can have an optional (nonstandard) `UNSIGNED` attribute. An unsigned type can be used to permit only nonnegative numbers in a column or when you need a larger upper numeric range for the column. For example, if an `INT` column is `UNSIGNED`, the size of the column's range is the same but its endpoints shift up, from `-2147483648` and `2147483647` to `0` and `4294967295`.

Floating-point and fixed-point types also can be `UNSIGNED`. As with integer types, this attribute prevents negative values from being stored in the column. Unlike the integer types, the upper range of column values remains the same. `UNSIGNED` is deprecated for columns of type `FLOAT`, `DOUBLE`, and `DECIMAL` (and any synonyms) and you should expect support for it to be removed in a future version of MySQL. Consider using a simple `CHECK` constraint instead for such columns.

If you specify `ZEROFILL` for a numeric column, MySQL automatically adds the `UNSIGNED` attribute.

Integer or floating-point data types can have the `AUTO_INCREMENT` attribute. When you insert a value of `NULL` into an indexed `AUTO_INCREMENT` column, the column is set to the next sequence value. Typically this is `value+1`, where `value` is the largest value for the column currently in the table. (`AUTO_INCREMENT` sequences begin with `1`.)

Storing `0` into an `AUTO_INCREMENT` column has the same effect as storing `NULL`, unless the `NO_AUTO_VALUE_ON_ZERO` SQL mode is enabled.

Inserting `NULL` to generate `AUTO_INCREMENT` values requires that the column be declared `NOT NULL`. If the column is declared `NULL`, inserting `NULL` stores a `NULL`. When you insert any other value into an `AUTO_INCREMENT` column, the column is set to that value and the sequence is reset so that the next automatically generated value follows sequentially from the inserted value.

Negative values for `AUTO_INCREMENT` columns are not supported.

`CHECK` constraints cannot refer to columns that have the `AUTO_INCREMENT` attribute, nor can the `AUTO_INCREMENT` attribute be added to existing columns that are used in `CHECK` constraints.

`AUTO_INCREMENT` for `FLOAT` and `DOUBLE` columns is not supported, as of MySQL 8.4.0. To upgrade an earlier version to MySQL 8.4.0, or higher, you must remove the `AUTO_INCREMENT` attribute from such columns to avoid compatibility issues, or convert them to an integer type.

### 13.1.7 Out-of-Range and Overflow Handling

When MySQL stores a value in a numeric column that is outside the permissible range of the column data type, the result depends on the SQL mode in effect at the time:

- If strict SQL mode is enabled, MySQL rejects the out-of-range value with an error, and the insert fails, in accordance with the SQL standard.
- If no restrictive modes are enabled, MySQL clips the value to the appropriate endpoint of the column data type range and stores the resulting value instead.

When an out-of-range value is assigned to an integer column, MySQL stores the value representing the corresponding endpoint of the column data type range.

When a floating-point or fixed-point column is assigned a value that exceeds the range implied by the specified (or default) precision and scale, MySQL stores the value representing the corresponding endpoint of that range.

Suppose that a table `t1` has this definition:

```
CREATE TABLE t1 (i1 TINYINT, i2 TINYINT UNSIGNED);
```

With strict SQL mode enabled, an out of range error occurs:

```
mysql> SET sql_mode = 'TRADITIONAL';
mysql> INSERT INTO t1 (i1, i2) VALUES(256, 256);
ERROR 1264 (22003): Out of range value for column 'i1' at row 1
mysql> SELECT * FROM t1;
Empty set (0.00 sec)
```

With strict SQL mode not enabled, clipping with warnings occurs:

```
mysql> SET sql_mode = '';
mysql> INSERT INTO t1 (i1, i2) VALUES(256, 256);
mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Warning | 1264 | Out of range value for column 'i1' at row 1 |
| Warning | 1264 | Out of range value for column 'i2' at row 1 |
+-----+-----+-----+
mysql> SELECT * FROM t1;
+-----+-----+
| i1 | i2 |
+-----+-----+
| 127 | 255 |
+-----+-----+
```

When strict SQL mode is not enabled, column-assignment conversions that occur due to clipping are reported as warnings for `ALTER TABLE`, `LOAD DATA`, `UPDATE`, and multiple-row `INSERT` statements. In strict mode, these statements fail, and some or all the values are not inserted or changed, depending on whether the table is a transactional table and other factors. For details, see [Section 7.1.11, “Server SQL Modes”](#).

Overflow during numeric expression evaluation results in an error. For example, the largest signed `BIGINT` value is 9223372036854775807, so the following expression produces an error:

```
mysql> SELECT 9223372036854775807 + 1;
ERROR 1690 (22003): BIGINT value is out of range in '(9223372036854775807 + 1)'
```

To enable the operation to succeed in this case, convert the value to unsigned;

```
mysql> SELECT CAST(9223372036854775807 AS UNSIGNED) + 1;
+-----+
| CAST(9223372036854775807 AS UNSIGNED) + 1 |
+-----+
| 9223372036854775808 |
+-----+
```

Whether overflow occurs depends on the range of the operands, so another way to handle the preceding expression is to use exact-value arithmetic because `DECIMAL` values have a larger range than integers:

```
mysql> SELECT 9223372036854775807.0 + 1;
+-----+
| 9223372036854775807.0 + 1 |
+-----+
| 9223372036854775808.0 |
+-----+
```

Subtraction between integer values, where one is of type `UNSIGNED`, produces an unsigned result by default. If the result would otherwise have been negative, an error results:

```
mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> SELECT CAST(0 AS UNSIGNED) - 1;
ERROR 1690 (22003): BIGINT UNSIGNED value is out of range in '(cast(0 as unsigned) - 1)'
```

If the `NO_UNSIGNED_SUBTRACTION` SQL mode is enabled, the result is negative:

```
mysql> SET sql_mode = 'NO_UNSIGNED_SUBTRACTION';
mysql> SELECT CAST(0 AS UNSIGNED) - 1;
+-----+
| CAST(0 AS UNSIGNED) - 1 |
+-----+
| -1 |
+-----+
```

If the result of such an operation is used to update an `UNSIGNED` integer column, the result is clipped to the maximum value for the column type, or clipped to 0 if `NO_UNSIGNED_SUBTRACTION` is enabled. If strict SQL mode is enabled, an error occurs and the column remains unchanged.

## 13.2 Date and Time Data Types

The date and time data types for representing temporal values are `DATE`, `TIME`, `DATETIME`, `TIMESTAMP`, and `YEAR`. Each temporal type has a range of valid values, as well as a “zero” value that may be used when you specify an invalid value that MySQL cannot represent. The `TIMESTAMP` and `DATETIME` types have special automatic updating behavior, described in [Section 13.2.5, “Automatic Initialization and Updating for TIMESTAMP and DATETIME”](#).

For information about storage requirements of the temporal data types, see [Section 13.7, “Data Type Storage Requirements”](#).

For descriptions of functions that operate on temporal values, see [Section 14.7, “Date and Time Functions”](#).

Keep in mind these general considerations when working with date and time types:

- MySQL retrieves values for a given date or time type in a standard output format, but it attempts to interpret a variety of formats for input values that you supply (for example, when you specify a value to be assigned to or compared to a date or time type). For a description of the permitted formats for date and time types, see [Section 11.1.3, “Date and Time Literals”](#). It is expected that you supply valid values. Unpredictable results may occur if you use values in other formats.
- Although MySQL tries to interpret values in several formats, date parts must always be given in year-month-day order (for example, `'98-09-04'`), rather than in the month-day-year or day-month-year orders commonly used elsewhere (for example, `'09-04-98'`, `'04-09-98'`). To convert strings in other orders to year-month-day order, the `STR_TO_DATE()` function may be useful.
- Dates containing 2-digit year values are ambiguous because the century is unknown. MySQL interprets 2-digit year values using these rules:
  - Year values in the range `70-99` become `1970-1999`.
  - Year values in the range `00-69` become `2000-2069`.

See also [Section 13.2.9, “2-Digit Years in Dates”](#).

- Conversion of values from one temporal type to another occurs according to the rules in [Section 13.2.8, “Conversion Between Date and Time Types”](#).
- MySQL automatically converts a date or time value to a number if the value is used in numeric context and vice versa.

- By default, when MySQL encounters a value for a date or time type that is out of range or otherwise invalid for the type, it converts the value to the “zero” value for that type. The exception is that out-of-range `TIME` values are clipped to the appropriate endpoint of the `TIME` range.
- By setting the SQL mode to the appropriate value, you can specify more exactly what kind of dates you want MySQL to support. (See [Section 7.1.11, “Server SQL Modes”](#).) You can get MySQL to accept certain dates, such as `'2009-11-31'`, by enabling the `ALLOW_INVALID_DATES` SQL mode. This is useful when you want to store a “possibly wrong” value which the user has specified (for example, in a web form) in the database for future processing. Under this mode, MySQL verifies only that the month is in the range from 1 to 12 and that the day is in the range from 1 to 31.
- MySQL permits you to store dates where the day or month and day are zero in a `DATE` or `DATETIME` column. This is useful for applications that need to store birthdates for which you may not know the exact date. In this case, you simply store the date as `'2009-00-00'` or `'2009-01-00'`. However, with dates such as these, you should not expect to get correct results for functions such as `DATE_SUB()` or `DATE_ADD()` that require complete dates. To disallow zero month or day parts in dates, enable the `NO_ZERO_IN_DATE` mode.
- MySQL permits you to store a “zero” value of `'0000-00-00'` as a “dummy date.” In some cases, this is more convenient than using `NULL` values, and uses less data and index space. To disallow `'0000-00-00'`, enable the `NO_ZERO_DATE` mode.
- “Zero” date or time values used through Connector/ODBC are converted automatically to `NULL` because ODBC cannot handle such values.

The following table shows the format of the “zero” value for each type. The “zero” values are special, but you can store or refer to them explicitly using the values shown in the table. You can also do this using the values `'0'` or `0`, which are easier to write. For temporal types that include a date part (`DATE`, `DATETIME`, and `TIMESTAMP`), use of these values may produce warning or errors. The precise behavior depends on which, if any, of the strict and `NO_ZERO_DATE` SQL modes are enabled; see [Section 7.1.11, “Server SQL Modes”](#).

Data Type	“Zero” Value
<code>DATE</code>	<code>'0000-00-00'</code>
<code>TIME</code>	<code>'00:00:00'</code>
<code>DATETIME</code>	<code>'0000-00-00 00:00:00'</code>
<code>TIMESTAMP</code>	<code>'0000-00-00 00:00:00'</code>
<code>YEAR</code>	<code>0000</code>

## 13.2.1 Date and Time Data Type Syntax

The date and time data types for representing temporal values are `DATE`, `TIME`, `DATETIME`, `TIMESTAMP`, and `YEAR`.

For the `DATE` and `DATETIME` range descriptions, “supported” means that although earlier values might work, there is no guarantee.

MySQL permits fractional seconds for `TIME`, `DATETIME`, and `TIMESTAMP` values, with up to microseconds (6 digits) precision. To define a column that includes a fractional seconds part, use the syntax `type_name(fsp)`, where `type_name` is `TIME`, `DATETIME`, or `TIMESTAMP`, and `fsp` is the fractional seconds precision. For example:

```
CREATE TABLE t1 (t TIME(3), dt DATETIME(6), ts TIMESTAMP(0));
```

The *fsp* value, if given, must be in the range 0 to 6. A value of 0 signifies that there is no fractional part. If omitted, the default precision is 0. (This differs from the standard SQL default of 6, for compatibility with previous MySQL versions.)

Any `TIMESTAMP` or `DATETIME` column in a table can have automatic initialization and updating properties; see [Section 13.2.5, “Automatic Initialization and Updating for TIMESTAMP and DATETIME”](#).

- `DATE`

A date. The supported range is '1000-01-01' to '9999-12-31'. MySQL displays `DATE` values in 'YYYY-MM-DD' format, but permits assignment of values to `DATE` columns using either strings or numbers.

- `DATETIME[(fsp)]`

A date and time combination. The supported range is '1000-01-01 00:00:00.000000' to '9999-12-31 23:59:59.499999'. MySQL displays `DATETIME` values in 'YYYY-MM-DD hh:mm:ss[.fraction]' format, but permits assignment of values to `DATETIME` columns using either strings or numbers.

An optional *fsp* value in the range from 0 to 6 may be given to specify fractional seconds precision. A value of 0 signifies that there is no fractional part. If omitted, the default precision is 0.

Automatic initialization and updating to the current date and time for `DATETIME` columns can be specified using `DEFAULT` and `ON UPDATE` column definition clauses, as described in [Section 13.2.5, “Automatic Initialization and Updating for TIMESTAMP and DATETIME”](#).

- `TIMESTAMP[(fsp)]`

A timestamp. The range is '1970-01-01 00:00:01.000000' UTC to '2038-01-19 03:14:07.499999' UTC. `TIMESTAMP` values are stored as the number of seconds since the epoch ('1970-01-01 00:00:00' UTC). A `TIMESTAMP` cannot represent the value '1970-01-01 00:00:00' because that is equivalent to 0 seconds from the epoch and the value 0 is reserved for representing '0000-00-00 00:00:00', the “zero” `TIMESTAMP` value.

An optional *fsp* value in the range from 0 to 6 may be given to specify fractional seconds precision. A value of 0 signifies that there is no fractional part. If omitted, the default precision is 0.

The way the server handles `TIMESTAMP` definitions depends on the value of the `explicit_defaults_for_timestamp` system variable (see [Section 7.1.8, “Server System Variables”](#)).

If `explicit_defaults_for_timestamp` is enabled, there is no automatic assignment of the `DEFAULT CURRENT_TIMESTAMP` or `ON UPDATE CURRENT_TIMESTAMP` attributes to any `TIMESTAMP` column. They must be included explicitly in the column definition. Also, any `TIMESTAMP` not explicitly declared as `NOT NULL` permits `NULL` values.

If `explicit_defaults_for_timestamp` is disabled, the server handles `TIMESTAMP` as follows:

Unless specified otherwise, the first `TIMESTAMP` column in a table is defined to be automatically set to the date and time of the most recent modification if not explicitly assigned a value. This makes `TIMESTAMP` useful for recording the timestamp of an `INSERT` or `UPDATE` operation. You can also set any `TIMESTAMP` column to the current date and time by assigning it a `NULL` value, unless it has been defined with the `NULL` attribute to permit `NULL` values.

Automatic initialization and updating to the current date and time can be specified using `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP` column definition clauses. By default,

the first `TIMESTAMP` column has these properties, as previously noted. However, any `TIMESTAMP` column in a table can be defined to have these properties.

- `TIME[(fsp)]`

A time. The range is `'-838:59:59.000000'` to `'838:59:59.000000'`. MySQL displays `TIME` values in `'hh:mm:ss[.fraction]'` format, but permits assignment of values to `TIME` columns using either strings or numbers.

An optional `fsp` value in the range from 0 to 6 may be given to specify fractional seconds precision. A value of 0 signifies that there is no fractional part. If omitted, the default precision is 0.

- `YEAR[(4)]`

A year in 4-digit format. MySQL displays `YEAR` values in `YYYY` format, but permits assignment of values to `YEAR` columns using either strings or numbers. Values display as `1901` to `2155`, or `0000`.

For additional information about `YEAR` display format and interpretation of input values, see [Section 13.2.4, “The YEAR Type”](#).

#### Note

The `YEAR(4)` data type with an explicit display width is deprecated; you should expect support for it to be removed in a future version of MySQL. Instead, use `YEAR` without a display width, which has the same meaning.

The `SUM()` and `AVG()` aggregate functions do not work with temporal values. (They convert the values to numbers, losing everything after the first nonnumeric character.) To work around this problem, convert to numeric units, perform the aggregate operation, and convert back to a temporal value. Examples:

```
SELECT SEC_TO_TIME(SUM(TIME_TO_SEC(time_col))) FROM tbl_name;
SELECT FROM_DAYS(SUM(TO_DAYS(date_col))) FROM tbl_name;
```

## 13.2.2 The DATE, DATETIME, and TIMESTAMP Types

The `DATE`, `DATETIME`, and `TIMESTAMP` types are related. This section describes their characteristics, how they are similar, and how they differ. MySQL recognizes `DATE`, `DATETIME`, and `TIMESTAMP` values in several formats, described in [Section 11.1.3, “Date and Time Literals”](#). For the `DATE` and `DATETIME` range descriptions, “supported” means that although earlier values might work, there is no guarantee.

The `DATE` type is used for values with a date part but no time part. MySQL retrieves and displays `DATE` values in `'YYYY-MM-DD'` format. The supported range is `'1000-01-01'` to `'9999-12-31'`.

The `DATETIME` type is used for values that contain both date and time parts. MySQL retrieves and displays `DATETIME` values in `'YYYY-MM-DD hh:mm:ss'` format. The supported range is `'1000-01-01 00:00:00'` to `'9999-12-31 23:59:59'`.

The `TIMESTAMP` data type is used for values that contain both date and time parts. `TIMESTAMP` has a range of `'1970-01-01 00:00:01'` UTC to `'2038-01-19 03:14:07'` UTC.

A `DATETIME` or `TIMESTAMP` value can include a trailing fractional seconds part in up to microseconds (6 digits) precision. In particular, any fractional part in a value inserted into a `DATETIME` or `TIMESTAMP` column is stored rather than discarded. With the fractional part included, the format for these values is `'YYYY-MM-DD hh:mm:ss[.fraction]'`, the range for `DATETIME` values is `'1000-01-01 00:00:00.000000'` to `'9999-12-31 23:59:59.499999'`, and the range for `TIMESTAMP` values is `'1970-01-01 00:00:01.000000'` to `'2038-01-19 03:14:07.499999'`. The fractional part should always be separated from the rest of the time by a decimal point; no other fractional seconds delimiter is

recognized. For information about fractional seconds support in MySQL, see [Section 13.2.6, “Fractional Seconds in Time Values”](#).

The `TIMESTAMP` and `DATETIME` data types offer automatic initialization and updating to the current date and time. For more information, see [Section 13.2.5, “Automatic Initialization and Updating for TIMESTAMP and DATETIME”](#).

MySQL converts `TIMESTAMP` values from the current time zone to UTC for storage, and back from UTC to the current time zone for retrieval. (This does not occur for other types such as `DATETIME`.) By default, the current time zone for each connection is the server's time. The time zone can be set on a per-connection basis. As long as the time zone setting remains constant, you get back the same value you store. If you store a `TIMESTAMP` value, and then change the time zone and retrieve the value, the retrieved value is different from the value you stored. This occurs because the same time zone was not used for conversion in both directions. The current time zone is available as the value of the `time_zone` system variable. For more information, see [Section 7.1.15, “MySQL Server Time Zone Support”](#).

You can specify a time zone offset when inserting a `TIMESTAMP` or `DATETIME` value into a table. See [Section 11.1.3, “Date and Time Literals”](#), for more information and examples.

Invalid `DATE`, `DATETIME`, or `TIMESTAMP` values are converted to the “zero” value of the appropriate type ('0000-00-00' or '0000-00-00 00:00:00'), if the SQL mode permits this conversion. The precise behavior depends on which if any of strict SQL mode and the `NO_ZERO_DATE` SQL mode are enabled; see [Section 7.1.11, “Server SQL Modes”](#).

You can convert `TIMESTAMP` values to UTC `DATETIME` values when retrieving them using `CAST()` with the `AT TIME ZONE` operator, as shown here:

```
mysql> SELECT col,
> CAST(col AT TIME ZONE INTERVAL '+00:00' AS DATETIME) AS ut
> FROM ts ORDER BY id;
```

col	ut
2020-01-01 10:10:10	2020-01-01 15:10:10
2019-12-31 23:40:10	2020-01-01 04:40:10
2020-01-01 13:10:10	2020-01-01 18:10:10
2020-01-01 10:10:10	2020-01-01 15:10:10
2020-01-01 04:40:10	2020-01-01 09:40:10
2020-01-01 18:10:10	2020-01-01 23:10:10

For complete information regarding syntax and additional examples, see the description of the `CAST()` function.

Be aware of certain properties of date value interpretation in MySQL:

- MySQL permits a “relaxed” format for values specified as strings, in which any punctuation character may be used as the delimiter between date parts or time parts. In some cases, this syntax can be deceiving. For example, a value such as '10:11:12' might look like a time value because of the :, but is interpreted as the year '2010-11-12' if used in date context. The value '10:45:15' is converted to '0000-00-00' because '45' is not a valid month.

The only delimiter recognized between a date and time part and a fractional seconds part is the decimal point.

- The server requires that month and day values be valid, and not merely in the range 1 to 12 and 1 to 31, respectively. With strict mode disabled, invalid dates such as '2004-04-31' are converted to '0000-00-00' and a warning is generated. With strict mode enabled, invalid dates generate an error. To permit such dates, enable `ALLOW_INVALID_DATES`. See [Section 7.1.11, “Server SQL Modes”](#), for more information.

- MySQL does not accept `TIME` values that include a zero in the day or month column or values that are not a valid date. The sole exception to this rule is the special “zero” value `'0000-00-00 00:00:00'`, if the SQL mode permits this value. The precise behavior depends on which if any of strict SQL mode and the `NO_ZERO_DATE` SQL mode are enabled; see [Section 7.1.11, “Server SQL Modes”](#).
- Dates containing 2-digit year values are ambiguous because the century is unknown. MySQL interprets 2-digit year values using these rules:
  - Year values in the range `00-69` become `2000-2069`.
  - Year values in the range `70-99` become `1970-1999`.

See also [Section 13.2.9, “2-Digit Years in Dates”](#).

### 13.2.3 The TIME Type

MySQL retrieves and displays `TIME` values in `'hh:mm:ss'` format (or `'hhh:mm:ss'` format for large hours values). `TIME` values may range from `'-838:59:59'` to `'838:59:59'`. The hours part may be so large because the `TIME` type can be used not only to represent a time of day (which must be less than 24 hours), but also elapsed time or a time interval between two events (which may be much greater than 24 hours, or even negative).

MySQL recognizes `TIME` values in several formats, some of which can include a trailing fractional seconds part in up to microseconds (6 digits) precision. See [Section 11.1.3, “Date and Time Literals”](#). For information about fractional seconds support in MySQL, see [Section 13.2.6, “Fractional Seconds in Time Values”](#). In particular, any fractional part in a value inserted into a `TIME` column is stored rather than discarded. With the fractional part included, the range for `TIME` values is `'-838:59:59.000000'` to `'838:59:59.000000'`.

Be careful about assigning abbreviated values to a `TIME` column. MySQL interprets abbreviated `TIME` values with colons as time of the day. That is, `'11:12'` means `'11:12:00'`, not `'00:11:12'`. MySQL interprets abbreviated values without colons using the assumption that the two rightmost digits represent seconds (that is, as elapsed time rather than as time of day). For example, you might think of `'1112'` and `1112` as meaning `'11:12:00'` (12 minutes after 11 o'clock), but MySQL interprets them as `'00:11:12'` (11 minutes, 12 seconds). Similarly, `'12'` and `12` are interpreted as `'00:00:12'`.

The only delimiter recognized between a time part and a fractional seconds part is the decimal point.

By default, values that lie outside the `TIME` range but are otherwise valid are clipped to the closest endpoint of the range. For example, `'-850:00:00'` and `'850:00:00'` are converted to `'-838:59:59'` and `'838:59:59'`. Invalid `TIME` values are converted to `'00:00:00'`. Note that because `'00:00:00'` is itself a valid `TIME` value, there is no way to tell, from a value of `'00:00:00'` stored in a table, whether the original value was specified as `'00:00:00'` or whether it was invalid.

For more restrictive treatment of invalid `TIME` values, enable strict SQL mode to cause errors to occur. See [Section 7.1.11, “Server SQL Modes”](#).

### 13.2.4 The YEAR Type

The `YEAR` type is a 1-byte type used to represent year values. It can be declared as `YEAR` with an implicit display width of 4 characters, or equivalently as `YEAR(4)` with an explicit display width.

#### Note

The `YEAR(4)` data type using an explicit display width is deprecated and you should expect support for it to be removed in a future version of MySQL. Instead, use `YEAR` without a display width, which has the same meaning.

MySQL displays `YEAR` values in `YYYY` format, with a range of 1901 to 2155, and 0000.

`YEAR` accepts input values in a variety of formats:

- As 4-digit strings in the range '1901' to '2155'.
- As 4-digit numbers in the range 1901 to 2155.
- As 1- or 2-digit strings in the range '0' to '99'. MySQL converts values in the ranges '0' to '69' and '70' to '99' to `YEAR` values in the ranges 2000 to 2069 and 1970 to 1999.
- As 1- or 2-digit numbers in the range 0 to 99. MySQL converts values in the ranges 1 to 69 and 70 to 99 to `YEAR` values in the ranges 2001 to 2069 and 1970 to 1999.

The result of inserting a numeric 0 has a display value of 0000 and an internal value of 0000. To insert zero and have it be interpreted as 2000, specify it as a string '0' or '00'.

- As the result of functions that return a value that is acceptable in `YEAR` context, such as `NOW()`.

If strict SQL mode is not enabled, MySQL converts invalid `YEAR` values to 0000. In strict SQL mode, attempting to insert an invalid `YEAR` value produces an error.

See also [Section 13.2.9, “2-Digit Years in Dates”](#).

## 13.2.5 Automatic Initialization and Updating for `TIMESTAMP` and `DATETIME`

`TIMESTAMP` and `DATETIME` columns can be automatically initialized and updated to the current date and time (that is, the current timestamp).

For any `TIMESTAMP` or `DATETIME` column in a table, you can assign the current timestamp as the default value, the auto-update value, or both:

- An auto-initialized column is set to the current timestamp for inserted rows that specify no value for the column.
- An auto-updated column is automatically updated to the current timestamp when the value of any other column in the row is changed from its current value. An auto-updated column remains unchanged if all other columns are set to their current values. To prevent an auto-updated column from updating when other columns change, explicitly set it to its current value. To update an auto-updated column even when other columns do not change, explicitly set it to the value it should have (for example, set it to `CURRENT_TIMESTAMP`).

In addition, if the `explicit_defaults_for_timestamp` system variable is disabled, you can initialize or update any `TIMESTAMP` (but not `DATETIME`) column to the current date and time by assigning it a `NULL` value, unless it has been defined with the `NULL` attribute to permit `NULL` values.

To specify automatic properties, use the `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP` clauses in column definitions. The order of the clauses does not matter. If both are present in a column definition, either can occur first. Any of the synonyms for `CURRENT_TIMESTAMP` have the same meaning as `CURRENT_TIMESTAMP`. These are `CURRENT_TIMESTAMP()`, `NOW()`, `LOCALTIME`, `LOCALTIME()`, `LOCALTIMESTAMP`, and `LOCALTIMESTAMP()`.

Use of `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP` is specific to `TIMESTAMP` and `DATETIME`. The `DEFAULT` clause also can be used to specify a constant (nonautomatic) default value (for example, `DEFAULT 0` or `DEFAULT '2000-01-01 00:00:00'`).

**Note**

The following examples use `DEFAULT 0`, a default that can produce warnings or errors depending on whether strict SQL mode or the `NO_ZERO_DATE` SQL mode is enabled. Be aware that the `TRADITIONAL` SQL mode includes strict mode and `NO_ZERO_DATE`. See [Section 7.1.11, “Server SQL Modes”](#).

`TIMESTAMP` or `DATETIME` column definitions can specify the current timestamp for both the default and auto-update values, for one but not the other, or for neither. Different columns can have different combinations of automatic properties. The following rules describe the possibilities:

- With both `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP`, the column has the current timestamp for its default value and is automatically updated to the current timestamp.

```
CREATE TABLE t1 (
 ts TIMESTAMP DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
 dt DATETIME DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP
);
```

- With a `DEFAULT` clause but no `ON UPDATE CURRENT_TIMESTAMP` clause, the column has the given default value and is not automatically updated to the current timestamp.

The default depends on whether the `DEFAULT` clause specifies `CURRENT_TIMESTAMP` or a constant value. With `CURRENT_TIMESTAMP`, the default is the current timestamp.

```
CREATE TABLE t1 (
 ts TIMESTAMP DEFAULT CURRENT_TIMESTAMP,
 dt DATETIME DEFAULT CURRENT_TIMESTAMP
);
```

With a constant, the default is the given value. In this case, the column has no automatic properties at all.

```
CREATE TABLE t1 (
 ts TIMESTAMP DEFAULT 0,
 dt DATETIME DEFAULT 0
);
```

- With an `ON UPDATE CURRENT_TIMESTAMP` clause and a constant `DEFAULT` clause, the column is automatically updated to the current timestamp and has the given constant default value.

```
CREATE TABLE t1 (
 ts TIMESTAMP DEFAULT 0 ON UPDATE CURRENT_TIMESTAMP,
 dt DATETIME DEFAULT 0 ON UPDATE CURRENT_TIMESTAMP
);
```

- With an `ON UPDATE CURRENT_TIMESTAMP` clause but no `DEFAULT` clause, the column is automatically updated to the current timestamp but does not have the current timestamp for its default value.

The default in this case is type dependent. `TIMESTAMP` has a default of 0 unless defined with the `NULL` attribute, in which case the default is `NULL`.

```
CREATE TABLE t1 (
 ts1 TIMESTAMP ON UPDATE CURRENT_TIMESTAMP, -- default 0
 ts2 TIMESTAMP NULL ON UPDATE CURRENT_TIMESTAMP -- default NULL
);
```

`DATETIME` has a default of `NULL` unless defined with the `NOT NULL` attribute, in which case the default is 0.

```
CREATE TABLE t1 (
```

```
dt1 DATETIME ON UPDATE CURRENT_TIMESTAMP, -- default NULL
dt2 DATETIME NOT NULL ON UPDATE CURRENT_TIMESTAMP -- default 0
);
```

`TIMESTAMP` and `DATETIME` columns have no automatic properties unless they are specified explicitly, with this exception: If the `explicit_defaults_for_timestamp` system variable is disabled, the *first* `TIMESTAMP` column has both `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP` if neither is specified explicitly. To suppress automatic properties for the first `TIMESTAMP` column, use one of these strategies:

- Enable the `explicit_defaults_for_timestamp` system variable. In this case, the `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP` clauses that specify automatic initialization and updating are available, but are not assigned to any `TIMESTAMP` column unless explicitly included in the column definition.
- Alternatively, if `explicit_defaults_for_timestamp` is disabled, do either of the following:
  - Define the column with a `DEFAULT` clause that specifies a constant default value.
  - Specify the `NULL` attribute. This also causes the column to permit `NULL` values, which means that you cannot assign the current timestamp by setting the column to `NULL`. Assigning `NULL` sets the column to `NULL`, not the current timestamp. To assign the current timestamp, set the column to `CURRENT_TIMESTAMP` or a synonym such as `NOW()`.

Consider these table definitions:

```
CREATE TABLE t1 (
 ts1 TIMESTAMP DEFAULT 0,
 ts2 TIMESTAMP DEFAULT CURRENT_TIMESTAMP
 ON UPDATE CURRENT_TIMESTAMP);
CREATE TABLE t2 (
 ts1 TIMESTAMP NULL,
 ts2 TIMESTAMP DEFAULT CURRENT_TIMESTAMP
 ON UPDATE CURRENT_TIMESTAMP);
CREATE TABLE t3 (
 ts1 TIMESTAMP NULL DEFAULT 0,
 ts2 TIMESTAMP DEFAULT CURRENT_TIMESTAMP
 ON UPDATE CURRENT_TIMESTAMP);
```

The tables have these properties:

- In each table definition, the first `TIMESTAMP` column has no automatic initialization or updating.
- The tables differ in how the `ts1` column handles `NULL` values. For `t1`, `ts1` is *NOT NULL* and assigning it a value of `NULL` sets it to the current timestamp. For `t2` and `t3`, `ts1` permits `NULL` and assigning it a value of `NULL` sets it to `NULL`.
- `t2` and `t3` differ in the default value for `ts1`. For `t2`, `ts1` is defined to permit `NULL`, so the default is also `NULL` in the absence of an explicit `DEFAULT` clause. For `t3`, `ts1` permits `NULL` but has an explicit default of 0.

If a `TIMESTAMP` or `DATETIME` column definition includes an explicit fractional seconds precision value anywhere, the same value must be used throughout the column definition. This is permitted:

```
CREATE TABLE t1 (
 ts TIMESTAMP(6) DEFAULT CURRENT_TIMESTAMP(6) ON UPDATE CURRENT_TIMESTAMP(6)
);
```

This is not permitted:

```
CREATE TABLE t1 (
```

```
ts TIMESTAMP(6) DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP(3)
);
```

## TIMESTAMP Initialization and the NULL Attribute

If the `explicit_defaults_for_timestamp` system variable is disabled, `TIMESTAMP` columns by default are `NOT NULL`, cannot contain `NULL` values, and assigning `NULL` assigns the current timestamp. To permit a `TIMESTAMP` column to contain `NULL`, explicitly declare it with the `NULL` attribute. In this case, the default value also becomes `NULL` unless overridden with a `DEFAULT` clause that specifies a different default value. `DEFAULT NULL` can be used to explicitly specify `NULL` as the default value. (For a `TIMESTAMP` column not declared with the `NULL` attribute, `DEFAULT NULL` is invalid.) If a `TIMESTAMP` column permits `NULL` values, assigning `NULL` sets it to `NULL`, not to the current timestamp.

The following table contains several `TIMESTAMP` columns that permit `NULL` values:

```
CREATE TABLE t
(
 ts1 TIMESTAMP NULL DEFAULT NULL,
 ts2 TIMESTAMP NULL DEFAULT 0,
 ts3 TIMESTAMP NULL DEFAULT CURRENT_TIMESTAMP
);
```

A `TIMESTAMP` column that permits `NULL` values does *not* take on the current timestamp at insert time except under one of the following conditions:

- Its default value is defined as `CURRENT_TIMESTAMP` and no value is specified for the column
- `CURRENT_TIMESTAMP` or any of its synonyms such as `NOW()` is explicitly inserted into the column

In other words, a `TIMESTAMP` column defined to permit `NULL` values auto-initializes only if its definition includes `DEFAULT CURRENT_TIMESTAMP`:

```
CREATE TABLE t (ts TIMESTAMP NULL DEFAULT CURRENT_TIMESTAMP);
```

If the `TIMESTAMP` column permits `NULL` values but its definition does not include `DEFAULT CURRENT_TIMESTAMP`, you must explicitly insert a value corresponding to the current date and time. Suppose that tables `t1` and `t2` have these definitions:

```
CREATE TABLE t1 (ts TIMESTAMP NULL DEFAULT '0000-00-00 00:00:00');
CREATE TABLE t2 (ts TIMESTAMP NULL DEFAULT NULL);
```

To set the `TIMESTAMP` column in either table to the current timestamp at insert time, explicitly assign it that value. For example:

```
INSERT INTO t2 VALUES (CURRENT_TIMESTAMP);
INSERT INTO t1 VALUES (NOW());
```

If the `explicit_defaults_for_timestamp` system variable is enabled, `TIMESTAMP` columns permit `NULL` values only if declared with the `NULL` attribute. Also, `TIMESTAMP` columns do not permit assigning `NULL` to assign the current timestamp, whether declared with the `NULL` or `NOT NULL` attribute. To assign the current timestamp, set the column to `CURRENT_TIMESTAMP` or a synonym such as `NOW()`.

## 13.2.6 Fractional Seconds in Time Values

MySQL has fractional seconds support for `TIME`, `DATETIME`, and `TIMESTAMP` values, with up to microseconds (6 digits) precision:

- To define a column that includes a fractional seconds part, use the syntax `type_name(fsp)`, where `type_name` is `TIME`, `DATETIME`, or `TIMESTAMP`, and `fsp` is the fractional seconds precision. For example:

```
CREATE TABLE t1 (t TIME(3), dt DATETIME(6));
```

The *fsp* value, if given, must be in the range 0 to 6. A value of 0 signifies that there is no fractional part. If omitted, the default precision is 0. (This differs from the standard SQL default of 6, for compatibility with previous MySQL versions.)

- Inserting a [TIME](#), [DATE](#), or [TIMESTAMP](#) value with a fractional seconds part into a column of the same type but having fewer fractional digits results in rounding. Consider a table created and populated as follows:

```
CREATE TABLE fractest(c1 TIME(2), c2 DATETIME(2), c3 TIMESTAMP(2));
INSERT INTO fractest VALUES
('17:51:04.777', '2018-09-08 17:51:04.777', '2018-09-08 17:51:04.777');
```

The temporal values are inserted into the table with rounding:

```
mysql> SELECT * FROM fractest;
+-----+-----+-----+
| c1 | c2 | c3 |
+-----+-----+-----+
| 17:51:04.78 | 2018-09-08 17:51:04.78 | 2018-09-08 17:51:04.78 |
+-----+-----+-----+
```

No warning or error is given when such rounding occurs. This behavior follows the SQL standard.

To insert the values with truncation instead, enable the [TIME\\_TRUNCATE\\_FRACTIONAL](#) SQL mode:

```
SET @@sql_mode = sys.list_add(@@sql_mode, 'TIME_TRUNCATE_FRACTIONAL');
```

With that SQL mode enabled, the temporal values are inserted with truncation:

```
mysql> SELECT * FROM fractest;
+-----+-----+-----+
| c1 | c2 | c3 |
+-----+-----+-----+
| 17:51:04.77 | 2018-09-08 17:51:04.77 | 2018-09-08 17:51:04.77 |
+-----+-----+-----+
```

- Functions that take temporal arguments accept values with fractional seconds. Return values from temporal functions include fractional seconds as appropriate. For example, [NOW\(\)](#) with no argument returns the current date and time with no fractional part, but takes an optional argument from 0 to 6 to specify that the return value includes a fractional seconds part of that many digits.
- Syntax for temporal literals produces temporal values: [DATE 'str'](#), [TIME 'str'](#), and [TIMESTAMP 'str'](#), and the ODBC-syntax equivalents. The resulting value includes a trailing fractional seconds part if specified. Previously, the temporal type keyword was ignored and these constructs produced the string value. See [Standard SQL and ODBC Date and Time Literals](#)

## 13.2.7 What Calendar Is Used By MySQL?

MySQL uses what is known as a *proleptic Gregorian calendar*.

Every country that has switched from the Julian to the Gregorian calendar has had to discard at least ten days during the switch. To see how this works, consider the month of October 1582, when the first Julian-to-Gregorian switch occurred.

Monday	Tuesday	Wednesday	Thursday	Friday	Saturday	Sunday
1	2	3	4	15	16	17

Monday	Tuesday	Wednesday	Thursday	Friday	Saturday	Sunday
18	19	20	21	22	23	24
25	26	27	28	29	30	31

There are no dates between October 4 and October 15. This discontinuity is called the *cutover*. Any dates before the cutover are Julian, and any dates following the cutover are Gregorian. Dates during a cutover are nonexistent.

A calendar applied to dates when it was not actually in use is called *proleptic*. Thus, if we assume there was never a cutover and Gregorian rules always rule, we have a proleptic Gregorian calendar. This is what is used by MySQL, as is required by standard SQL. For this reason, dates prior to the cutover stored as MySQL `DATE` or `DATETIME` values must be adjusted to compensate for the difference. It is important to realize that the cutover did not occur at the same time in all countries, and that the later it happened, the more days were lost. For example, in Great Britain, it took place in 1752, when Wednesday September 2 was followed by Thursday September 14. Russia remained on the Julian calendar until 1918, losing 13 days in the process, and what is popularly referred to as its “October Revolution” occurred in November according to the Gregorian calendar.

## 13.2.8 Conversion Between Date and Time Types

To some extent, you can convert a value from one temporal type to another. However, there may be some alteration of the value or loss of information. In all cases, conversion between temporal types is subject to the range of valid values for the resulting type. For example, although `DATE`, `DATETIME`, and `TIMESTAMP` values all can be specified using the same set of formats, the types do not all have the same range of values. `TIMESTAMP` values cannot be earlier than 1970 UTC or later than '2038-01-19 03:14:07' UTC. This means that a date such as '1968-01-01', while valid as a `DATE` or `DATETIME` value, is not valid as a `TIMESTAMP` value and is converted to 0.

Conversion of `DATE` values:

- Conversion to a `DATETIME` or `TIMESTAMP` value adds a time part of '00:00:00' because the `DATE` value contains no time information.
- Conversion to a `TIME` value is not useful; the result is '00:00:00'.

Conversion of `DATETIME` and `TIMESTAMP` values:

- Conversion to a `DATE` value takes fractional seconds into account and rounds the time part. For example, '1999-12-31 23:59:59.499' becomes '1999-12-31', whereas '1999-12-31 23:59:59.500' becomes '2000-01-01'.
- Conversion to a `TIME` value discards the date part because the `TIME` type contains no date information.

For conversion of `TIME` values to other temporal types, the value of `CURRENT_DATE()` is used for the date part. The `TIME` is interpreted as elapsed time (not time of day) and added to the date. This means that the date part of the result differs from the current date if the time value is outside the range from '00:00:00' to '23:59:59'.

Suppose that the current date is '2012-01-01'. `TIME` values of '12:00:00', '24:00:00', and '-12:00:00', when converted to `DATETIME` or `TIMESTAMP` values, result in '2012-01-01 12:00:00', '2012-01-02 00:00:00', and '2011-12-31 12:00:00', respectively.

Conversion of `TIME` to `DATE` is similar but discards the time part from the result: '2012-01-01', '2012-01-02', and '2011-12-31', respectively.

Explicit conversion can be used to override implicit conversion. For example, in comparison of `DATE` and `DATETIME` values, the `DATE` value is coerced to the `DATETIME` type by adding a time part of `'00:00:00'`. To perform the comparison by ignoring the time part of the `DATETIME` value instead, use the `CAST()` function in the following way:

```
date_col = CAST(datetime_col AS DATE)
```

Conversion of `TIME` and `DATETIME` values to numeric form (for example, by adding `+0`) depends on whether the value contains a fractional seconds part. `TIME(N)` or `DATETIME(N)` is converted to integer when `N` is 0 (or omitted) and to a `DECIMAL` value with `N` decimal digits when `N` is greater than 0:

```
mysql> SELECT CURTIME(), CURTIME()+0, CURTIME(3)+0;
+-----+-----+-----+
| CURTIME() | CURTIME()+0 | CURTIME(3)+0 |
+-----+-----+-----+
| 09:28:00 | 92800 | 92800.887 |
+-----+-----+-----+
mysql> SELECT NOW(), NOW()+0, NOW(3)+0;
+-----+-----+-----+
| NOW() | NOW()+0 | NOW(3)+0 |
+-----+-----+-----+
| 2012-08-15 09:28:00 | 20120815092800 | 20120815092800.889 |
+-----+-----+-----+
```

### 13.2.9 2-Digit Years in Dates

Date values with 2-digit years are ambiguous because the century is unknown. Such values must be interpreted into 4-digit form because MySQL stores years internally using 4 digits.

For `DATETIME`, `DATE`, and `TIMESTAMP` types, MySQL interprets dates specified with ambiguous year values using these rules:

- Year values in the range 00–69 become 2000–2069.
- Year values in the range 70–99 become 1970–1999.

For `YEAR`, the rules are the same, with this exception: A numeric 00 inserted into `YEAR` results in 0000 rather than 2000. To specify zero for `YEAR` and have it be interpreted as 2000, specify it as a string `'0'` or `'00'`.

Remember that these rules are only heuristics that provide reasonable guesses as to what your data values mean. If the rules used by MySQL do not produce the values you require, you must provide unambiguous input containing 4-digit year values.

`ORDER BY` properly sorts `YEAR` values that have 2-digit years.

Some functions like `MIN()` and `MAX()` convert a `YEAR` to a number. This means that a value with a 2-digit year does not work properly with these functions. The fix in this case is to convert the `YEAR` to 4-digit year format.

## 13.3 String Data Types

The string data types are `CHAR`, `VARCHAR`, `BINARY`, `VARBINARY`, `BLOB`, `TEXT`, `ENUM`, and `SET`.

For information about storage requirements of the string data types, see [Section 13.7, “Data Type Storage Requirements”](#).

For descriptions of functions that operate on string values, see [Section 14.8, “String Functions and Operators”](#).

### 13.3.1 String Data Type Syntax

The string data types are [CHAR](#), [VARCHAR](#), [BINARY](#), [VARBINARY](#), [BLOB](#), [TEXT](#), [ENUM](#), and [SET](#).

In some cases, MySQL may change a string column to a type different from that given in a [CREATE TABLE](#) or [ALTER TABLE](#) statement. See [Section 15.1.20.7, “Silent Column Specification Changes”](#).

For definitions of character string columns ([CHAR](#), [VARCHAR](#), and the [TEXT](#) types), MySQL interprets length specifications in character units. For definitions of binary string columns ([BINARY](#), [VARBINARY](#), and the [BLOB](#) types), MySQL interprets length specifications in byte units.

Column definitions for character string data types [CHAR](#), [VARCHAR](#), the [TEXT](#) types, [ENUM](#), [SET](#), and any synonyms) can specify the column character set and collation:

- [CHARACTER SET](#) specifies the character set. If desired, a collation for the character set can be specified with the [COLLATE](#) attribute, along with any other attributes. For example:

```
CREATE TABLE t
(
 c1 VARCHAR(20) CHARACTER SET utf8mb4,
 c2 TEXT CHARACTER SET latin1 COLLATE latin1_general_cs
);
```

This table definition creates a column named `c1` that has a character set of `utf8mb4` with the default collation for that character set, and a column named `c2` that has a character set of `latin1` and a case-sensitive (`_cs`) collation.

The rules for assigning the character set and collation when either or both of [CHARACTER SET](#) and the [COLLATE](#) attribute are missing are described in [Section 12.3.5, “Column Character Set and Collation”](#).

[CHARSET](#) is a synonym for [CHARACTER SET](#).

- Specifying the [CHARACTER SET binary](#) attribute for a character string data type causes the column to be created as the corresponding binary string data type: [CHAR](#) becomes [BINARY](#), [VARCHAR](#) becomes [VARBINARY](#), and [TEXT](#) becomes [BLOB](#). For the [ENUM](#) and [SET](#) data types, this does not occur; they are created as declared. Suppose that you specify a table using this definition:

```
CREATE TABLE t
(
 c1 VARCHAR(10) CHARACTER SET binary,
 c2 TEXT CHARACTER SET binary,
 c3 ENUM('a','b','c') CHARACTER SET binary
);
```

The resulting table has this definition:

```
CREATE TABLE t
(
 c1 VARBINARY(10),
 c2 BLOB,
 c3 ENUM('a','b','c') CHARACTER SET binary
);
```

- The [BINARY](#) attribute is a nonstandard MySQL extension that is shorthand for specifying the binary (`_bin`) collation of the column character set (or of the table default character set if no column character set is specified). In this case, comparison and sorting are based on numeric character code values. Suppose that you specify a table using this definition:

```
CREATE TABLE t
(
```

```
c1 VARCHAR(10) CHARACTER SET latin1 BINARY,
c2 TEXT BINARY
) CHARACTER SET utf8mb4;
```

The resulting table has this definition:

```
CREATE TABLE t (
 c1 VARCHAR(10) CHARACTER SET latin1 COLLATE latin1_bin,
 c2 TEXT CHARACTER SET utf8mb4 COLLATE utf8mb4_bin
) CHARACTER SET utf8mb4;
```

In MySQL 9.1, the `BINARY` attribute is deprecated and you should expect support for it to be removed in a future version of MySQL. Applications should be adjusted to use an explicit `_bin` collation instead.

The use of `BINARY` to specify a data type or character set remains unchanged.

- The `ASCII` attribute is shorthand for `CHARACTER SET latin1`. Supported in older MySQL releases, `ASCII` is deprecated; use `CHARACTER SET` instead.
- The `UNICODE` attribute is shorthand for `CHARACTER SET ucs2`. Supported in older MySQL releases, `UNICODE` is deprecated; use `CHARACTER SET` instead.

Character column comparison and sorting are based on the collation assigned to the column. For the `CHAR`, `VARCHAR`, `TEXT`, `ENUM`, and `SET` data types, you can declare a column with a binary (`_bin`) collation or the `BINARY` attribute to cause comparison and sorting to use the underlying character code values rather than a lexical ordering.

For additional information about use of character sets in MySQL, see [Chapter 12, Character Sets, Collations, Unicode](#).

- `[NATIONAL] CHAR[(M)] [CHARACTER SET charset_name] [COLLATE collation_name]`

A fixed-length string that is always right-padded with spaces to the specified length when stored. *M* represents the column length in characters. The range of *M* is 0 to 255. If *M* is omitted, the length is 1.

#### Note

Trailing spaces are removed when `CHAR` values are retrieved unless the `PAD_CHAR_TO_FULL_LENGTH` SQL mode is enabled.

`CHAR` is shorthand for `CHARACTER`. `NATIONAL CHAR` (or its equivalent short form, `NCHAR`) is the standard SQL way to define that a `CHAR` column should use some predefined character set. MySQL uses `utf8mb3` as this predefined character set. [Section 12.3.7, “The National Character Set”](#).

The `CHAR BYTE` data type is an alias for the `BINARY` data type. This is a compatibility feature.

MySQL permits you to create a column of type `CHAR(0)`. This is useful primarily when you must be compliant with old applications that depend on the existence of a column but that do not actually use its value. `CHAR(0)` is also quite nice when you need a column that can take only two values: A column that is defined as `CHAR(0) NULL` occupies only one bit and can take only the values `NULL` and `''` (the empty string).

- `[NATIONAL] VARCHAR(M) [CHARACTER SET charset_name] [COLLATE collation_name]`

A variable-length string. *M* represents the maximum column length in characters. The range of *M* is 0 to 65,535. The effective maximum length of a `VARCHAR` is subject to the maximum row size (65,535 bytes,

which is shared among all columns) and the character set used. For example, `utf8mb3` characters can require up to three bytes per character, so a `VARCHAR` column that uses the `utf8mb3` character set can be declared to be a maximum of 21,844 characters. See [Section 10.4.7, “Limits on Table Column Count and Row Size”](#).

MySQL stores `VARCHAR` values as a 1-byte or 2-byte length prefix plus data. The length prefix indicates the number of bytes in the value. A `VARCHAR` column uses one length byte if values require no more than 255 bytes, two length bytes if values may require more than 255 bytes.

**Note**

MySQL follows the standard SQL specification, and does *not* remove trailing spaces from `VARCHAR` values.

`VARCHAR` is shorthand for `CHARACTER VARYING`. `NATIONAL VARCHAR` is the standard SQL way to define that a `VARCHAR` column should use some predefined character set. MySQL uses `utf8mb3` as this predefined character set. [Section 12.3.7, “The National Character Set”](#). `NVARCHAR` is shorthand for `NATIONAL VARCHAR`.

- `BINARY[ (M) ]`

The `BINARY` type is similar to the `CHAR` type, but stores binary byte strings rather than nonbinary character strings. An optional length `M` represents the column length in bytes. If omitted, `M` defaults to 1.

- `VARBINARY(M)`

The `VARBINARY` type is similar to the `VARCHAR` type, but stores binary byte strings rather than nonbinary character strings. `M` represents the maximum column length in bytes.

- `TINYBLOB`

A `BLOB` column with a maximum length of 255 ( $2^8 - 1$ ) bytes. Each `TINYBLOB` value is stored using a 1-byte length prefix that indicates the number of bytes in the value.

- `TINYTEXT [CHARACTER SET charset_name] [COLLATE collation_name]`

A `TEXT` column with a maximum length of 255 ( $2^8 - 1$ ) characters. The effective maximum length is less if the value contains multibyte characters. Each `TINYTEXT` value is stored using a 1-byte length prefix that indicates the number of bytes in the value.

- `BLOB[ (M) ]`

A `BLOB` column with a maximum length of 65,535 ( $2^{16} - 1$ ) bytes. Each `BLOB` value is stored using a 2-byte length prefix that indicates the number of bytes in the value.

An optional length `M` can be given for this type. If this is done, MySQL creates the column as the smallest `BLOB` type large enough to hold values `M` bytes long.

- `TEXT[ (M) ] [CHARACTER SET charset_name] [COLLATE collation_name]`

A `TEXT` column with a maximum length of 65,535 ( $2^{16} - 1$ ) characters. The effective maximum length is less if the value contains multibyte characters. Each `TEXT` value is stored using a 2-byte length prefix that indicates the number of bytes in the value.

An optional length `M` can be given for this type. If this is done, MySQL creates the column as the smallest `TEXT` type large enough to hold values `M` characters long.

- `MEDIUMBLOB`

A **BLOB** column with a maximum length of 16,777,215 ( $2^{24} - 1$ ) bytes. Each **MEDIUMBLOB** value is stored using a 3-byte length prefix that indicates the number of bytes in the value.

- **MEDIUMTEXT** [**CHARACTER SET** *charset\_name*] [**COLLATE** *collation\_name*]

A **TEXT** column with a maximum length of 16,777,215 ( $2^{24} - 1$ ) characters. The effective maximum length is less if the value contains multibyte characters. Each **MEDIUMTEXT** value is stored using a 3-byte length prefix that indicates the number of bytes in the value.

- **LOB**

A **BLOB** column with a maximum length of 4,294,967,295 or 4GB ( $2^{32} - 1$ ) bytes. The effective maximum length of **LOB** columns depends on the configured maximum packet size in the client/server protocol and available memory. Each **LOB** value is stored using a 4-byte length prefix that indicates the number of bytes in the value.

- **LONGTEXT** [**CHARACTER SET** *charset\_name*] [**COLLATE** *collation\_name*]

A **TEXT** column with a maximum length of 4,294,967,295 or 4GB ( $2^{32} - 1$ ) characters. The effective maximum length is less if the value contains multibyte characters. The effective maximum length of **LONGTEXT** columns also depends on the configured maximum packet size in the client/server protocol and available memory. Each **LONGTEXT** value is stored using a 4-byte length prefix that indicates the number of bytes in the value.

- **ENUM**('value1', 'value2', ...) [**CHARACTER SET** *charset\_name*] [**COLLATE** *collation\_name*]

An enumeration. A string object that can have only one value, chosen from the list of values 'value1', 'value2', ..., **NULL** or the special '' error value. **ENUM** values are represented internally as integers.

An **ENUM** column can have a maximum of 65,535 distinct elements.

The maximum supported length of an individual **ENUM** element is  $M \leq 255$  and  $(M \times w) \leq 1020$ , where  $M$  is the element literal length and  $w$  is the number of bytes required for the maximum-length character in the character set.

- **SET**('value1', 'value2', ...) [**CHARACTER SET** *charset\_name*] [**COLLATE** *collation\_name*]

A set. A string object that can have zero or more values, each of which must be chosen from the list of values 'value1', 'value2', ... **SET** values are represented internally as integers.

A **SET** column can have a maximum of 64 distinct members.

The maximum supported length of an individual **SET** element is  $M \leq 255$  and  $(M \times w) \leq 1020$ , where  $M$  is the element literal length and  $w$  is the number of bytes required for the maximum-length character in the character set.

### 13.3.2 The CHAR and VARCHAR Types

The **CHAR** and **VARCHAR** types are similar, but differ in the way they are stored and retrieved. They also differ in maximum length and in whether trailing spaces are retained.

The **CHAR** and **VARCHAR** types are declared with a length that indicates the maximum number of characters you want to store. For example, **CHAR(30)** can hold up to 30 characters.

The length of a `CHAR` column is fixed to the length that you declare when you create the table. The length can be any value from 0 to 255. When `CHAR` values are stored, they are right-padded with spaces to the specified length. When `CHAR` values are retrieved, trailing spaces are removed unless the `PAD_CHAR_TO_FULL_LENGTH` SQL mode is enabled.

Values in `VARCHAR` columns are variable-length strings. The length can be specified as a value from 0 to 65,535. The effective maximum length of a `VARCHAR` is subject to the maximum row size (65,535 bytes, which is shared among all columns) and the character set used. See [Section 10.4.7, “Limits on Table Column Count and Row Size”](#).

In contrast to `CHAR`, `VARCHAR` values are stored as a 1-byte or 2-byte length prefix plus data. The length prefix indicates the number of bytes in the value. A column uses one length byte if values require no more than 255 bytes, two length bytes if values may require more than 255 bytes.

If strict SQL mode is not enabled and you assign a value to a `CHAR` or `VARCHAR` column that exceeds the column's maximum length, the value is truncated to fit and a warning is generated. For truncation of nonspace characters, you can cause an error to occur (rather than a warning) and suppress insertion of the value by using strict SQL mode. See [Section 7.1.11, “Server SQL Modes”](#).

For `VARCHAR` columns, trailing spaces in excess of the column length are truncated prior to insertion and a warning is generated, regardless of the SQL mode in use. For `CHAR` columns, truncation of excess trailing spaces from inserted values is performed silently regardless of the SQL mode.

`VARCHAR` values are not padded when they are stored. Trailing spaces are retained when values are stored and retrieved, in conformance with standard SQL.

The following table illustrates the differences between `CHAR` and `VARCHAR` by showing the result of storing various string values into `CHAR(4)` and `VARCHAR(4)` columns (assuming that the column uses a single-byte character set such as `latin1`).

Value	CHAR(4)	Storage Required	VARCHAR(4)	Storage Required
' '	' '	4 bytes	' '	1 byte
'ab'	'ab '	4 bytes	'ab'	3 bytes
'abcd'	'abcd'	4 bytes	'abcd'	5 bytes
'abcdefgh'	'abcd'	4 bytes	'abcd'	5 bytes

The values shown as stored in the last row of the table apply *only when not using strict SQL mode*; if strict mode is enabled, values that exceed the column length are *not stored*, and an error results.

InnoDB encodes fixed-length fields greater than or equal to 768 bytes in length as variable-length fields, which can be stored off-page. For example, a `CHAR(255)` column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with `utf8mb4`.

If a given value is stored into the `CHAR(4)` and `VARCHAR(4)` columns, the values retrieved from the columns are not always the same because trailing spaces are removed from `CHAR` columns upon retrieval. The following example illustrates this difference:

```
mysql> CREATE TABLE vc (v VARCHAR(4), c CHAR(4));
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO vc VALUES ('ab ', 'ab ');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT CONCAT('(', v, ')'), CONCAT('(', c, ')') FROM vc;
+-----+-----+
```

```

| CONCAT('(', v, ')') | CONCAT('(', c, ')') |
+-----+-----+
| (ab) | (ab) |
+-----+-----+
1 row in set (0.06 sec)

```

Values in [CHAR](#), [VARCHAR](#), and [TEXT](#) columns are sorted and compared according to the character set collation assigned to the column.

MySQL collations have a pad attribute of [PAD SPACE](#), other than Unicode collations based on UCA 9.0.0 and higher, which have a pad attribute of [NO PAD](#). (see [Section 12.10.1, “Unicode Character Sets”](#)).

To determine the pad attribute for a collation, use the [INFORMATION\\_SCHEMA COLLATIONS](#) table, which has a [PAD\\_ATTRIBUTE](#) column.

For nonbinary strings ([CHAR](#), [VARCHAR](#), and [TEXT](#) values), the string collation pad attribute determines treatment in comparisons of trailing spaces at the end of strings. [NO PAD](#) collations treat trailing spaces as significant in comparisons, like any other character. [PAD SPACE](#) collations treat trailing spaces as insignificant in comparisons; strings are compared without regard to trailing spaces. See [Trailing Space Handling in Comparisons](#). The server SQL mode has no effect on comparison behavior with respect to trailing spaces.

#### Note

For more information about MySQL character sets and collations, see [Chapter 12, Character Sets, Collations, Unicode](#). For additional information about storage requirements, see [Section 13.7, “Data Type Storage Requirements”](#).

For those cases where trailing pad characters are stripped or comparisons ignore them, if a column has an index that requires unique values, inserting into the column values that differ only in number of trailing pad characters results in a duplicate-key error. For example, if a table contains 'a', an attempt to store 'a ' causes a duplicate-key error.

### 13.3.3 The BINARY and VARBINARY Types

The [BINARY](#) and [VARBINARY](#) types are similar to [CHAR](#) and [VARCHAR](#), except that they store binary strings rather than nonbinary strings. That is, they store byte strings rather than character strings. This means they have the [binary](#) character set and collation, and comparison and sorting are based on the numeric values of the bytes in the values.

The permissible maximum length is the same for [BINARY](#) and [VARBINARY](#) as it is for [CHAR](#) and [VARCHAR](#), except that the length for [BINARY](#) and [VARBINARY](#) is measured in bytes rather than characters.

The [BINARY](#) and [VARBINARY](#) data types are distinct from the [CHAR BINARY](#) and [VARCHAR BINARY](#) data types. For the latter types, the [BINARY](#) attribute does not cause the column to be treated as a binary string column. Instead, it causes the binary ([\\_bin](#)) collation for the column character set (or the table default character set if no column character set is specified) to be used, and the column itself stores nonbinary character strings rather than binary byte strings. For example, if the default character set is [utf8mb4](#), [CHAR\(5\) BINARY](#) is treated as [CHAR\(5\) CHARACTER SET utf8mb4 COLLATE utf8mb4\\_bin](#). This differs from [BINARY\(5\)](#), which stores 5-byte binary strings that have the [binary](#) character set and collation. For information about the differences between the [binary](#) collation of the [binary](#) character set and the [\\_bin](#) collations of nonbinary character sets, see [Section 12.8.5, “The binary Collation Compared to \\_bin Collations”](#).

If strict SQL mode is not enabled and you assign a value to a [BINARY](#) or [VARBINARY](#) column that exceeds the column's maximum length, the value is truncated to fit and a warning is generated. For cases of

truncation, to cause an error to occur (rather than a warning) and suppress insertion of the value, use strict SQL mode. See [Section 7.1.11, “Server SQL Modes”](#).

When `BINARY` values are stored, they are right-padded with the pad value to the specified length. The pad value is `0x00` (the zero byte). Values are right-padded with `0x00` for inserts, and no trailing bytes are removed for retrievals. All bytes are significant in comparisons, including `ORDER BY` and `DISTINCT` operations. `0x00` and space differ in comparisons, with `0x00` sorting before space.

Example: For a `BINARY(3)` column, `'a '` becomes `'a \0'` when inserted. `'a\0'` becomes `'a\0\0'` when inserted. Both inserted values remain unchanged for retrievals.

For `VARBINARY`, there is no padding for inserts and no bytes are stripped for retrievals. All bytes are significant in comparisons, including `ORDER BY` and `DISTINCT` operations. `0x00` and space differ in comparisons, with `0x00` sorting before space.

For those cases where trailing pad bytes are stripped or comparisons ignore them, if a column has an index that requires unique values, inserting values into the column that differ only in number of trailing pad bytes results in a duplicate-key error. For example, if a table contains `'a '`, an attempt to store `'a\0'` causes a duplicate-key error.

You should consider the preceding padding and stripping characteristics carefully if you plan to use the `BINARY` data type for storing binary data and you require that the value retrieved be exactly the same as the value stored. The following example illustrates how `0x00`-padding of `BINARY` values affects column value comparisons:

```
mysql> CREATE TABLE t (c BINARY(3));
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO t SET c = 'a';
Query OK, 1 row affected (0.01 sec)

mysql> SELECT HEX(c), c = 'a', c = 'a\0\0' from t;
+-----+-----+-----+
| HEX(c) | c = 'a' | c = 'a\0\0' |
+-----+-----+-----+
| 610000 | 0 | 1 |
+-----+-----+-----+
1 row in set (0.09 sec)
```

If the value retrieved must be the same as the value specified for storage with no padding, it might be preferable to use `VARBINARY` or one of the `BLOB` data types instead.

#### Note

Within the `mysql` client, binary strings display using hexadecimal notation, depending on the value of the `--binary-as-hex`. For more information about that option, see [Section 6.5.1, “mysql — The MySQL Command-Line Client”](#).

### 13.3.4 The BLOB and TEXT Types

A `BLOB` is a binary large object that can hold a variable amount of data. The four `BLOB` types are `TINYBLOB`, `BLOB`, `MEDIUMBLOB`, and `LONGBLOB`. These differ only in the maximum length of the values they can hold. The four `TEXT` types are `TINYTEXT`, `TEXT`, `MEDIUMTEXT`, and `LONGTEXT`. These correspond to the four `BLOB` types and have the same maximum lengths and storage requirements. See [Section 13.7, “Data Type Storage Requirements”](#).

`BLOB` values are treated as binary strings (byte strings). They have the `binary` character set and collation, and comparison and sorting are based on the numeric values of the bytes in column values. `TEXT` values

are treated as nonbinary strings (character strings). They have a character set other than `binary`, and values are sorted and compared based on the collation of the character set.

If strict SQL mode is not enabled and you assign a value to a `BLOB` or `TEXT` column that exceeds the column's maximum length, the value is truncated to fit and a warning is generated. For truncation of nonspace characters, you can cause an error to occur (rather than a warning) and suppress insertion of the value by using strict SQL mode. See [Section 7.1.11, “Server SQL Modes”](#).

Truncation of excess trailing spaces from values to be inserted into `TEXT` columns always generates a warning, regardless of the SQL mode.

For `TEXT` and `BLOB` columns, there is no padding on insert and no bytes are stripped on select.

If a `TEXT` column is indexed, index entry comparisons are space-padded at the end. This means that, if the index requires unique values, duplicate-key errors occur for values that differ only in the number of trailing spaces. For example, if a table contains 'a', an attempt to store 'a ' causes a duplicate-key error. This is not true for `BLOB` columns.

In most respects, you can regard a `BLOB` column as a `VARBINARY` column that can be as large as you like. Similarly, you can regard a `TEXT` column as a `VARCHAR` column. `BLOB` and `TEXT` differ from `VARBINARY` and `VARCHAR` in the following ways:

- For indexes on `BLOB` and `TEXT` columns, you must specify an index prefix length. For `CHAR` and `VARCHAR`, a prefix length is optional. See [Section 10.3.5, “Column Indexes”](#).
- `BLOB` and `TEXT` columns cannot have `DEFAULT` values.

If you use the `BINARY` attribute with a `TEXT` data type, the column is assigned the binary (`_bin`) collation of the column character set.

`LONG` and `LONG VARCHAR` map to the `MEDIUMTEXT` data type. This is a compatibility feature.

MySQL Connector/ODBC defines `BLOB` values as `LONGVARBINARY` and `TEXT` values as `LONGVARCHAR`.

Because `BLOB` and `TEXT` values can be extremely long, you might encounter some constraints in using them:

- Only the first `max_sort_length` bytes of the column are used when sorting. The default value of `max_sort_length` is 1024. You can make more bytes significant in sorting or grouping by increasing the value of `max_sort_length` at server startup or runtime. Any client can change the value of its session `max_sort_length` variable:

```
mysql> SET max_sort_length = 2000;
mysql> SELECT id, comment FROM t
 -> ORDER BY comment;
```

- Instances of `BLOB` or `TEXT` columns in the result of a query that is processed using a temporary table causes the server to use a table on disk rather than in memory because the `MEMORY` storage engine does not support those data types (see [Section 10.4.4, “Internal Temporary Table Use in MySQL”](#)). Use of disk incurs a performance penalty, so include `BLOB` or `TEXT` columns in the query result only if they are really needed. For example, avoid using `SELECT *`, which selects all columns.
- The maximum size of a `BLOB` or `TEXT` object is determined by its type, but the largest value you actually can transmit between the client and server is determined by the amount of available memory and the size of the communications buffers. You can change the message buffer size by changing the value of the `max_allowed_packet` variable, but you must do so for both the server and your client program. For example, both `mysql` and `mysqldump` enable you to change the client-side `max_allowed_packet`

value. See [Section 7.1.1, “Configuring the Server”](#), [Section 6.5.1, “mysql — The MySQL Command-Line Client”](#), and [Section 6.5.4, “mysqldump — A Database Backup Program”](#). You may also want to compare the packet sizes and the size of the data objects you are storing with the storage requirements, see [Section 13.7, “Data Type Storage Requirements”](#)

Each [BLOB](#) or [TEXT](#) value is represented internally by a separately allocated object. This is in contrast to all other data types, for which storage is allocated once per column when the table is opened.

In some cases, it may be desirable to store binary data such as media files in [BLOB](#) or [TEXT](#) columns. You may find MySQL's string handling functions useful for working with such data. See [Section 14.8, “String Functions and Operators”](#). For security and other reasons, it is usually preferable to do so using application code rather than giving application users the [FILE](#) privilege. You can discuss specifics for various languages and platforms in the MySQL Forums (<http://forums.mysql.com/>).

#### Note

Within the `mysql` client, binary strings display using hexadecimal notation, depending on the value of the `--binary-as-hex`. For more information about that option, see [Section 6.5.1, “mysql — The MySQL Command-Line Client”](#).

## 13.3.5 The VECTOR Type

A [VECTOR](#) is a structure that can hold up to a specified number of entries *N*, defined as shown here:

```
VECTOR(N)
```

Each entry is a 4-byte (single-precision) floating-point value.

The default length is 2048; the maximum is 16383 entries. To declare a [VECTOR](#) column of the default length, define it as [VECTOR](#) with no parentheses following; trying to define a column as [VECTOR](#)( ) (with empty parentheses) raises a syntax error.

A [VECTOR](#) cannot be compared to any other type. It can be compared to another [VECTOR](#) for equality, but no other comparison is possible.

A [VECTOR](#) column cannot be used as any type of key. This includes all of the following types:

- Primary key
- Foreign key
- Unique key
- Partitioning key

A [VECTOR](#) column also cannot be used as a histogram source.

## VECTOR Supported and Unsupported Functions

[VECTOR](#) values can be used with the MySQL string functions [BIT\\_LENGTH](#)( ), [CHAR\\_LENGTH](#)( ), [HEX](#)( ), [LENGTH](#)( ), and [TO\\_BASE64](#)( ). Other string functions do not accept the [VECTOR](#) type as an argument.

[VECTOR](#) can be used as an argument to any of the encryption functions [AES\\_ENCRYPT](#)( ), [COMPRESS](#)( ), [MD5](#)( ), [SHA1](#)( ), and [SHA2](#)( ). [VECTOR](#) is not supported as an argument type by any other encryption functions.

[VECTOR](#) can be used as an argument to the [CASE](#) operator and related flow-control functions, including [COALESCE](#)( ), [IFNULL](#)( ), [NULLIF](#)( ), and [IF](#)( ).

`VECTOR` can be used as the argument to `CAST(expression AS BINARY)`; the result is a binary string with the same contents as the `VECTOR` argument. Casting to `VECTOR` with `CAST` is not supported; you can convert a suitable string to `VECTOR` using `STRING_TO_VECTOR()`.

`VECTOR` data types cannot be used as arguments to aggregate functions or window functions other than `COUNT [DISTINCT]`.

`VECTOR` cannot be used as an argument to any of the following types of functions and operators:

- Numeric functions and operators
- Temporal functions
- Fulltext search functions
- XML functions
- Bit functions such as bitwise `AND` and `OR`
- JSON functions

For more information, see [Section 14.21, “Vector Functions”](#).

`VECTOR` values are supported by JavaScript stored programs in MySQL 9.1 and later. See [Section 27.3.4, “JavaScript Stored Program Data Types and Argument Handling”](#), for more information.

**Note**

`VECTOR` is currently not supported by the `NDBCLUSTER` storage engine.

### 13.3.6 The ENUM Type

An `ENUM` is a string object with a value chosen from a list of permitted values that are enumerated explicitly in the column specification at table creation time.

See [Section 13.3.1, “String Data Type Syntax”](#) for `ENUM` type syntax and length limits.

The `ENUM` type has these advantages:

- Compact data storage in situations where a column has a limited set of possible values. The strings you specify as input values are automatically encoded as numbers. See [Section 13.7, “Data Type Storage Requirements”](#) for storage requirements for the `ENUM` type.
- Readable queries and output. The numbers are translated back to the corresponding strings in query results.

and these potential issues to consider:

- If you make enumeration values that look like numbers, it is easy to mix up the literal values with their internal index numbers, as explained in [Enumeration Limitations](#).
- Using `ENUM` columns in `ORDER BY` clauses requires extra care, as explained in [Enumeration Sorting](#).
- [Creating and Using ENUM Columns](#)
- [Index Values for Enumeration Literals](#)
- [Handling of Enumeration Literals](#)

- [Empty or NULL Enumeration Values](#)
- [Enumeration Sorting](#)
- [Enumeration Limitations](#)

## Creating and Using ENUM Columns

An enumeration value must be a quoted string literal. For example, you can create a table with an [ENUM](#) column like this:

```
CREATE TABLE shirts (
 name VARCHAR(40),
 size ENUM('x-small', 'small', 'medium', 'large', 'x-large')
);
INSERT INTO shirts (name, size) VALUES ('dress shirt','large'), ('t-shirt','medium'),
('polo shirt','small');
SELECT name, size FROM shirts WHERE size = 'medium';
+-----+-----+
| name | size |
+-----+-----+
| t-shirt | medium |
+-----+-----+
UPDATE shirts SET size = 'small' WHERE size = 'large';
COMMIT;
```

Inserting 1 million rows into this table with a value of `'medium'` would require 1 million bytes of storage, as opposed to 6 million bytes if you stored the actual string `'medium'` in a [VARCHAR](#) column.

## Index Values for Enumeration Literals

Each enumeration value has an index:

- The elements listed in the column specification are assigned index numbers, beginning with 1.
- The index value of the empty string error value is 0. This means that you can use the following [SELECT](#) statement to find rows into which invalid [ENUM](#) values were assigned:

```
mysql> SELECT * FROM tbl_name WHERE enum_col=0;
```

- The index of the [NULL](#) value is [NULL](#).
- The term “index” here refers to a position within the list of enumeration values. It has nothing to do with table indexes.

For example, a column specified as [ENUM](#)(`'Mercury'`, `'Venus'`, `'Earth'`) can have any of the values shown here. The index of each value is also shown.

Value	Index
<a href="#">NULL</a>	<a href="#">NULL</a>
<code>''</code>	0
<code>'Mercury'</code>	1
<code>'Venus'</code>	2
<code>'Earth'</code>	3

An [ENUM](#) column can have a maximum of 65,535 distinct elements.

If you retrieve an [ENUM](#) value in a numeric context, the column value's index is returned. For example, you can retrieve numeric values from an [ENUM](#) column like this:

```
mysql> SELECT enum_col+0 FROM tbl_name;
```

Functions such as `SUM()` or `AVG()` that expect a numeric argument cast the argument to a number if necessary. For `ENUM` values, the index number is used in the calculation.

## Handling of Enumeration Literals

Trailing spaces are automatically deleted from `ENUM` member values in the table definition when a table is created.

When retrieved, values stored into an `ENUM` column are displayed using the lettercase that was used in the column definition. Note that `ENUM` columns can be assigned a character set and collation. For binary or case-sensitive collations, lettercase is taken into account when assigning values to the column.

If you store a number into an `ENUM` column, the number is treated as the index into the possible values, and the value stored is the enumeration member with that index. (However, this does *not* work with `LOAD DATA`, which treats all input as strings.) If the numeric value is quoted, it is still interpreted as an index if there is no matching string in the list of enumeration values. For these reasons, it is not advisable to define an `ENUM` column with enumeration values that look like numbers, because this can easily become confusing. For example, the following column has enumeration members with string values of `'0'`, `'1'`, and `'2'`, but numeric index values of 1, 2, and 3:

```
numbers ENUM('0','1','2')
```

If you store 2, it is interpreted as an index value, and becomes `'1'` (the value with index 2). If you store `'2'`, it matches an enumeration value, so it is stored as `'2'`. If you store `'3'`, it does not match any enumeration value, so it is treated as an index and becomes `'2'` (the value with index 3).

```
mysql> INSERT INTO t (numbers) VALUES(2),('2'),('3');
mysql> SELECT * FROM t;
```

```
+-----+
| numbers |
+-----+
| 1 |
| 2 |
| 2 |
+-----+
```

To determine all possible values for an `ENUM` column, use `SHOW COLUMNS FROM tbl_name LIKE 'enum_col'` and parse the `ENUM` definition in the `Type` column of the output.

In the C API, `ENUM` values are returned as strings. For information about using result set metadata to distinguish them from other strings, see [C API Basic Data Structures](#).

## Empty or NULL Enumeration Values

An enumeration value can also be the empty string (`' '`) or `NULL` under certain circumstances:

- If you insert an invalid value into an `ENUM` (that is, a string not present in the list of permitted values), the empty string is inserted instead as a special error value. This string can be distinguished from a “normal” empty string by the fact that this string has the numeric value 0. See [Index Values for Enumeration Literals](#) for details about the numeric indexes for the enumeration values.

If strict SQL mode is enabled, attempts to insert invalid `ENUM` values result in an error.

- If an `ENUM` column is declared to permit `NULL`, the `NULL` value is a valid value for the column, and the default value is `NULL`. If an `ENUM` column is declared `NOT NULL`, its default value is the first element of the list of permitted values.

## Enumeration Sorting

`ENUM` values are sorted based on their index numbers, which depend on the order in which the enumeration members were listed in the column specification. For example, `'b'` sorts before `'a'` for `ENUM('b', 'a')`. The empty string sorts before nonempty strings, and `NULL` values sort before all other enumeration values.

To prevent unexpected results when using the `ORDER BY` clause on an `ENUM` column, use one of these techniques:

- Specify the `ENUM` list in alphabetic order.
- Make sure that the column is sorted lexically rather than by index number by coding `ORDER BY CAST(col AS CHAR)` or `ORDER BY CONCAT(col)`.

## Enumeration Limitations

An enumeration value cannot be an expression, even one that evaluates to a string value.

For example, this `CREATE TABLE` statement does *not* work because the `CONCAT` function cannot be used to construct an enumeration value:

```
CREATE TABLE sizes (
 size ENUM('small', CONCAT('med','ium'), 'large')
);
```

You also cannot employ a user variable as an enumeration value. This pair of statements do *not* work:

```
SET @mysize = 'medium';

CREATE TABLE sizes (
 size ENUM('small', @mysize, 'large')
);
```

We strongly recommend that you do *not* use numbers as enumeration values, because it does not save on storage over the appropriate `TINYINT` or `SMALLINT` type, and it is easy to mix up the strings and the underlying number values (which might not be the same) if you quote the `ENUM` values incorrectly. If you do use a number as an enumeration value, always enclose it in quotation marks. If the quotation marks are omitted, the number is regarded as an index. See [Handling of Enumeration Literals](#) to see how even a quoted number could be mistakenly used as a numeric index value.

Duplicate values in the definition cause a warning, or an error if strict SQL mode is enabled.

### 13.3.7 The SET Type

A `SET` is a string object that can have zero or more values, each of which must be chosen from a list of permitted values specified when the table is created. `SET` column values that consist of multiple set members are specified with members separated by commas (,). A consequence of this is that `SET` member values should not themselves contain commas.

For example, a column specified as `SET('one', 'two') NOT NULL` can have any of these values:

```
' '
'one'
'two'
'one,two'
```

A `SET` column can have a maximum of 64 distinct members.

Duplicate values in the definition cause a warning, or an error if strict SQL mode is enabled.

Trailing spaces are automatically deleted from **SET** member values in the table definition when a table is created.

See [String Type Storage Requirements](#) for storage requirements for the **SET** type.

See [Section 13.3.1, “String Data Type Syntax”](#) for **SET** type syntax and length limits.

When retrieved, values stored in a **SET** column are displayed using the lettercase that was used in the column definition. Note that **SET** columns can be assigned a character set and collation. For binary or case-sensitive collations, lettercase is taken into account when assigning values to the column.

MySQL stores **SET** values numerically, with the low-order bit of the stored value corresponding to the first set member. If you retrieve a **SET** value in a numeric context, the value retrieved has bits set corresponding to the set members that make up the column value. For example, you can retrieve numeric values from a **SET** column like this:

```
mysql> SELECT set_col+0 FROM tbl_name;
```

If a number is stored into a **SET** column, the bits that are set in the binary representation of the number determine the set members in the column value. For a column specified as **SET**( 'a' , 'b' , 'c' , 'd' ), the members have the following decimal and binary values.

SET Member	Decimal Value	Binary Value
'a'	1	0001
'b'	2	0010
'c'	4	0100
'd'	8	1000

If you assign a value of 9 to this column, that is 1001 in binary, so the first and fourth **SET** value members 'a' and 'd' are selected and the resulting value is 'a,d'.

For a value containing more than one **SET** element, it does not matter what order the elements are listed in when you insert the value. It also does not matter how many times a given element is listed in the value. When the value is retrieved later, each element in the value appears once, with elements listed according to the order in which they were specified at table creation time. Suppose that a column is specified as **SET**( 'a' , 'b' , 'c' , 'd' ):

```
mysql> CREATE TABLE myset (col SET('a', 'b', 'c', 'd'));
```

If you insert the values 'a,d', 'd,a', 'a,d,d', 'a,d,a', and 'd,a,d':

```
mysql> INSERT INTO myset (col) VALUES
-> ('a,d'), ('d,a'), ('a,d,a'), ('a,d,d'), ('d,a,d');
Query OK, 5 rows affected (0.01 sec)
Records: 5 Duplicates: 0 Warnings: 0
```

Then all these values appear as 'a,d' when retrieved:

```
mysql> SELECT col FROM myset;
+-----+
| col |
+-----+
| a,d |
| a,d |
| a,d |
| a,d |
| a,d |
+-----+
```

```
5 rows in set (0.04 sec)
```

If you set a [SET](#) column to an unsupported value, the value is ignored and a warning is issued:

```
mysql> INSERT INTO myset (col) VALUES ('a,d,d,s');
Query OK, 1 row affected, 1 warning (0.03 sec)

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Warning | 1265 | Data truncated for column 'col' at row 1 |
+-----+-----+-----+
1 row in set (0.04 sec)

mysql> SELECT col FROM myset;
+-----+
| col |
+-----+
| a,d |
| a,d |
| a,d |
| a,d |
| a,d |
| a,d |
+-----+
6 rows in set (0.01 sec)
```

If strict SQL mode is enabled, attempts to insert invalid [SET](#) values result in an error.

[SET](#) values are sorted numerically. [NULL](#) values sort before non-[NULL SET](#) values.

Functions such as [SUM\(\)](#) or [AVG\(\)](#) that expect a numeric argument cast the argument to a number if necessary. For [SET](#) values, the cast operation causes the numeric value to be used.

Normally, you search for [SET](#) values using the [FIND\\_IN\\_SET\(\)](#) function or the [LIKE](#) operator:

```
mysql> SELECT * FROM tbl_name WHERE FIND_IN_SET('value',set_col)>0;
mysql> SELECT * FROM tbl_name WHERE set_col LIKE '%value%';
```

The first statement finds rows where *set\_col* contains the *value* set member. The second is similar, but not the same: It finds rows where *set\_col* contains *value* anywhere, even as a substring of another set member.

The following statements also are permitted:

```
mysql> SELECT * FROM tbl_name WHERE set_col & 1;
mysql> SELECT * FROM tbl_name WHERE set_col = 'val1,val2';
```

The first of these statements looks for values containing the first set member. The second looks for an exact match. Be careful with comparisons of the second type. Comparing set values to '*val1,val2*' returns different results than comparing values to '*val2,val1*'. You should specify the values in the same order they are listed in the column definition.

To determine all possible values for a [SET](#) column, use [SHOW COLUMNS FROM tbl\\_name LIKE set\\_col](#) and parse the [SET](#) definition in the [Type](#) column of the output.

In the C API, [SET](#) values are returned as strings. For information about using result set metadata to distinguish them from other strings, see [C API Basic Data Structures](#).

## 13.4 Spatial Data Types

The [Open Geospatial Consortium](#) (OGC) is an international consortium of more than 250 companies, agencies, and universities participating in the development of publicly available conceptual solutions that can be useful with all kinds of applications that manage spatial data.

The Open Geospatial Consortium publishes the *OpenGIS® Implementation Standard for Geographic information - Simple feature access - Part 2: SQL option*, a document that proposes several conceptual ways for extending an SQL RDBMS to support spatial data. This specification is available from the OGC website at <http://www.opengeospatial.org/standards/sfs>.

Following the OGC specification, MySQL implements spatial extensions as a subset of the **SQL with Geometry Types** environment. This term refers to an SQL environment that has been extended with a set of geometry types. A geometry-valued SQL column is implemented as a column that has a geometry type. The specification describes a set of SQL geometry types, as well as functions on those types to create and analyze geometry values.

MySQL spatial extensions enable the generation, storage, and analysis of geographic features:

- Data types for representing spatial values
- Functions for manipulating spatial values
- Spatial indexing for improved access times to spatial columns

The spatial data types and functions are available for [MyISAM](#), [InnoDB](#), [NDB](#), and [ARCHIVE](#) tables. For indexing spatial columns, [MyISAM](#) and [InnoDB](#) support both [SPATIAL](#) and non-[SPATIAL](#) indexes. The other storage engines support non-[SPATIAL](#) indexes, as described in [Section 15.1.15, “CREATE INDEX Statement”](#).

A **geographic feature** is anything in the world that has a location. A feature can be:

- An entity. For example, a mountain, a pond, a city.
- A space. For example, town district, the tropics.
- A definable location. For example, a crossroad, as a particular place where two streets intersect.

Some documents use the term **geospatial feature** to refer to geographic features.

**Geometry** is another word that denotes a geographic feature. Originally the word **geometry** meant measurement of the earth. Another meaning comes from cartography, referring to the geometric features that cartographers use to map the world.

The discussion here considers these terms synonymous: **geographic feature**, **geospatial feature**, **feature**, or **geometry**. The term most commonly used is **geometry**, defined as *a point or an aggregate of points representing anything in the world that has a location*.

The following material covers these topics:

- The spatial data types implemented in MySQL model
- The basis of the spatial extensions in the OpenGIS geometry model
- Data formats for representing spatial data
- How to use spatial data in MySQL
- Use of indexing for spatial data

- MySQL differences from the OpenGIS specification

For information about functions that operate on spatial data, see [Section 14.16, “Spatial Analysis Functions”](#).

## Additional Resources

These standards are important for the MySQL implementation of spatial operations:

- SQL/MM Part 3: Spatial.
- The [Open Geospatial Consortium](#) publishes the *OpenGIS® Implementation Standard for Geographic information*, a document that proposes several conceptual ways for extending an SQL RDBMS to support spatial data. See in particular Simple Feature Access - Part 1: Common Architecture, and Simple Feature Access - Part 2: SQL Option. The Open Geospatial Consortium (OGC) maintains a website at <http://www.opengeospatial.org/>. The specification is available there at <http://www.opengeospatial.org/standards/sfs>. It contains additional information relevant to the material here.
- The grammar for [spatial reference system](#) (SRS) definitions is based on the grammar defined in *OpenGIS Implementation Specification: Coordinate Transformation Services*, Revision 1.00, OGC 01-009, January 12, 2001, Section 7.2. This specification is available at <http://www.opengeospatial.org/standards/ct>. For differences from that specification in SRS definitions as implemented in MySQL, see [Section 15.1.19, “CREATE SPATIAL REFERENCE SYSTEM Statement”](#).

If you have questions or concerns about the use of the spatial extensions to MySQL, you can discuss them in the GIS forum: <https://forums.mysql.com/list.php?23>.

### 13.4.1 Spatial Data Types

MySQL has spatial data types that correspond to OpenGIS classes. The basis for these types is described in [Section 13.4.2, “The OpenGIS Geometry Model”](#).

Some spatial data types hold single geometry values:

- [GEOMETRY](#)
- [POINT](#)
- [LINESTRING](#)
- [POLYGON](#)

[GEOMETRY](#) can store geometry values of any type. The other single-value types ([POINT](#), [LINESTRING](#), and [POLYGON](#)) restrict their values to a particular geometry type.

The other spatial data types hold collections of values:

- [MULTIPOINT](#)
- [MULTILINESTRING](#)
- [MULTIPOLYGON](#)
- [GEOMETRYCOLLECTION](#)

[GEOMETRYCOLLECTION](#) can store a collection of objects of any type. The other collection types ([MULTIPOINT](#), [MULTILINESTRING](#), and [MULTIPOLYGON](#)) restrict collection members to those having a particular geometry type.

Example: To create a table named `geom` that has a column named `g` that can store values of any geometry type, use this statement:

```
CREATE TABLE geom (g GEOMETRY);
```

Columns with a spatial data type can have an `SRID` attribute, to explicitly indicate the spatial reference system (SRS) for values stored in the column. For example:

```
CREATE TABLE geom (
 p POINT SRID 0,
 g GEOMETRY NOT NULL SRID 4326
);
```

`SPATIAL` indexes can be created on spatial columns if they are `NOT NULL` and have a specific SRID, so if you plan to index the column, declare it with the `NOT NULL` and `SRID` attributes:

```
CREATE TABLE geom (g GEOMETRY NOT NULL SRID 4326);
```

`InnoDB` tables permit `SRID` values for Cartesian and geographic SRSs. `MyISAM` tables permit `SRID` values for Cartesian SRSs.

The `SRID` attribute makes a spatial column SRID-restricted, which has these implications:

- The column can contain only values with the given SRID. Attempts to insert values with a different SRID produce an error.
- The optimizer can use `SPATIAL` indexes on the column. See [Section 10.3.3, “SPATIAL Index Optimization”](#).

Spatial columns with no `SRID` attribute are not SRID-restricted and accept values with any SRID. However, the optimizer cannot use `SPATIAL` indexes on them until the column definition is modified to include an `SRID` attribute, which may require that the column contents first be modified so that all values have the same SRID.

For other examples showing how to use spatial data types in MySQL, see [Section 13.4.6, “Creating Spatial Columns”](#). For information about spatial reference systems, see [Section 13.4.5, “Spatial Reference System Support”](#).

## 13.4.2 The OpenGIS Geometry Model

The set of geometry types proposed by OGC's **SQL with Geometry Types** environment is based on the **OpenGIS Geometry Model**. In this model, each geometric object has the following general properties:

- It is associated with a spatial reference system, which describes the coordinate space in which the object is defined.
- It belongs to some geometry class.

### 13.4.2.1 The Geometry Class Hierarchy

The geometry classes define a hierarchy as follows:

- `Geometry` (noninstantiable)
  - `Point` (instantiable)
  - `Curve` (noninstantiable)

- `LineString` (instantiable)
  - `Line`
  - `LinearRing`
- `Surface` (noninstantiable)
  - `Polygon` (instantiable)
- `GeometryCollection` (instantiable)
  - `MultiPoint` (instantiable)
  - `MultiCurve` (noninstantiable)
    - `MultiLineString` (instantiable)
  - `MultiSurface` (noninstantiable)
    - `MultiPolygon` (instantiable)

It is not possible to create objects in noninstantiable classes. It is possible to create objects in instantiable classes. All classes have properties, and instantiable classes may also have assertions (rules that define valid class instances).

`Geometry` is the base class. It is an abstract class. The instantiable subclasses of `Geometry` are restricted to zero-, one-, and two-dimensional geometric objects that exist in two-dimensional coordinate space. All instantiable geometry classes are defined so that valid instances of a geometry class are topologically closed (that is, all defined geometries include their boundary).

The base `Geometry` class has subclasses for `Point`, `Curve`, `Surface`, and `GeometryCollection`:

- `Point` represents zero-dimensional objects.
- `Curve` represents one-dimensional objects, and has subclass `LineString`, with sub-subclasses `Line` and `LinearRing`.
- `Surface` is designed for two-dimensional objects and has subclass `Polygon`.
- `GeometryCollection` has specialized zero-, one-, and two-dimensional collection classes named `MultiPoint`, `MultiLineString`, and `MultiPolygon` for modeling geometries corresponding to collections of `Points`, `LineStrings`, and `Polygons`, respectively. `MultiCurve` and `MultiSurface` are introduced as abstract superclasses that generalize the collection interfaces to handle `Curves` and `Surfaces`.

`Geometry`, `Curve`, `Surface`, `MultiCurve`, and `MultiSurface` are defined as noninstantiable classes. They define a common set of methods for their subclasses and are included for extensibility.

`Point`, `LineString`, `Polygon`, `GeometryCollection`, `MultiPoint`, `MultiLineString`, and `MultiPolygon` are instantiable classes.

### 13.4.2.2 Geometry Class

`Geometry` is the root class of the hierarchy. It is a noninstantiable class but has a number of properties, described in the following list, that are common to all geometry values created from any of the `Geometry` subclasses. Particular subclasses have their own specific properties, described later.

## Geometry Properties

A geometry value has the following properties:

- Its **type**. Each geometry belongs to one of the instantiable classes in the hierarchy.
- Its **SRID**, or spatial reference identifier. This value identifies the geometry's associated spatial reference system that describes the coordinate space in which the geometry object is defined.

In MySQL, the SRID value is an integer associated with the geometry value. The maximum usable SRID value is  $2^{32}-1$ . If a larger value is given, only the lower 32 bits are used.

SRID 0 represents an infinite flat Cartesian plane with no units assigned to its axes. To ensure SRID 0 behavior, create geometry values using SRID 0. SRID 0 is the default for new geometry values if no SRID is specified.

For computations on multiple geometry values, all values must have the same SRID or an error occurs.

- Its **coordinates** in its spatial reference system, represented as double-precision (8-byte) numbers. All nonempty geometries include at least one pair of (X,Y) coordinates. Empty geometries contain no coordinates.

Coordinates are related to the SRID. For example, in different coordinate systems, the distance between two objects may differ even when objects have the same coordinates, because the distance on the **planar** coordinate system and the distance on the **geodetic** system (coordinates on the Earth's surface) are different things.

- Its **interior**, **boundary**, and **exterior**.

Every geometry occupies some position in space. The exterior of a geometry is all space not occupied by the geometry. The interior is the space occupied by the geometry. The boundary is the interface between the geometry's interior and exterior.

- Its **MBR** (minimum bounding rectangle), or envelope. This is the bounding geometry, formed by the minimum and maximum (X,Y) coordinates:

```
((MINX MINY, MAXX MINY, MAXX MAXY, MINX MAXY, MINX MINY))
```

- Whether the value is **simple** or **nonsimple**. Geometry values of types ([LineString](#), [MultiPoint](#), [MultiLineString](#)) are either simple or nonsimple. Each type determines its own assertions for being simple or nonsimple.
- Whether the value is **closed** or **not closed**. Geometry values of types ([LineString](#), [MultiString](#)) are either closed or not closed. Each type determines its own assertions for being closed or not closed.
- Whether the value is **empty** or **nonempty**. A geometry is empty if it does not have any points. Exterior, interior, and boundary of an empty geometry are not defined (that is, they are represented by a [NULL](#) value). An empty geometry is defined to be always simple and has an area of 0.
- Its **dimension**. A geometry can have a dimension of -1, 0, 1, or 2:
  - -1 for an empty geometry.
  - 0 for a geometry with no length and no area.
  - 1 for a geometry with nonzero length and zero area.
  - 2 for a geometry with nonzero area.

`Point` objects have a dimension of zero. `LineString` objects have a dimension of 1. `Polygon` objects have a dimension of 2. The dimensions of `MultiPoint`, `MultiLineString`, and `MultiPolygon` objects are the same as the dimensions of the elements they consist of.

### 13.4.2.3 Point Class

A `Point` is a geometry that represents a single location in coordinate space.

#### `Point` Examples

- Imagine a large-scale map of the world with many cities. A `Point` object could represent each city.
- On a city map, a `Point` object could represent a bus stop.

#### `Point` Properties

- X-coordinate value.
- Y-coordinate value.
- `Point` is defined as a zero-dimensional geometry.
- The boundary of a `Point` is the empty set.

### 13.4.2.4 Curve Class

A `Curve` is a one-dimensional geometry, usually represented by a sequence of points. Particular subclasses of `Curve` define the type of interpolation between points. `Curve` is a noninstantiable class.

#### `Curve` Properties

- A `Curve` has the coordinates of its points.
- A `Curve` is defined as a one-dimensional geometry.
- A `Curve` is simple if it does not pass through the same point twice, with the exception that a curve can still be simple if the start and end points are the same.
- A `Curve` is closed if its start point is equal to its endpoint.
- The boundary of a closed `Curve` is empty.
- The boundary of a nonclosed `Curve` consists of its two endpoints.
- A `Curve` that is simple and closed is a `LinearRing`.

### 13.4.2.5 LineString Class

A `LineString` is a `Curve` with linear interpolation between points.

#### `LineString` Examples

- On a world map, `LineString` objects could represent rivers.
- In a city map, `LineString` objects could represent streets.

#### `LineString` Properties

- A [LineString](#) has coordinates of segments, defined by each consecutive pair of points.
- A [LineString](#) is a [Line](#) if it consists of exactly two points.
- A [LineString](#) is a [LinearRing](#) if it is both closed and simple.

### 13.4.2.6 Surface Class

A [Surface](#) is a two-dimensional geometry. It is a noninstantiable class. Its only instantiable subclass is [Polygon](#).

Simple surfaces in three-dimensional space are isomorphic to planar surfaces.

Polyhedral surfaces are formed by “stitching” together simple surfaces along their boundaries, polyhedral surfaces in three-dimensional space may not be planar as a whole.

#### [Surface](#) Properties

- A [Surface](#) is defined as a two-dimensional geometry.
- The OpenGIS specification defines a simple [Surface](#) as a geometry that consists of a single “patch” that is associated with a single exterior boundary and zero or more interior boundaries.
- The boundary of a simple [Surface](#) is the set of closed curves corresponding to its exterior and interior boundaries.

### 13.4.2.7 Polygon Class

A [Polygon](#) is a planar [Surface](#) representing a multisided geometry. It is defined by a single exterior boundary and zero or more interior boundaries, where each interior boundary defines a hole in the [Polygon](#).

#### [Polygon](#) Examples

- On a region map, [Polygon](#) objects could represent forests, districts, and so on.

#### [Polygon](#) Assertions

- The boundary of a [Polygon](#) consists of a set of [LinearRing](#) objects (that is, [LineString](#) objects that are both simple and closed) that make up its exterior and interior boundaries.
- A [Polygon](#) has no rings that cross. The rings in the boundary of a [Polygon](#) may intersect at a [Point](#), but only as a tangent.
- A [Polygon](#) has no lines, spikes, or punctures.
- A [Polygon](#) has an interior that is a connected point set.
- A [Polygon](#) may have holes. The exterior of a [Polygon](#) with holes is not connected. Each hole defines a connected component of the exterior.

The preceding assertions make a [Polygon](#) a simple geometry.

### 13.4.2.8 GeometryCollection Class

A [GeomCollection](#) is a geometry that is a collection of zero or more geometries of any class.

[GeomCollection](#) and [GeometryCollection](#) are synonymous, with [GeomCollection](#) the preferred type name.

All the elements in a geometry collection must be in the same spatial reference system (that is, in the same coordinate system). There are no other constraints on the elements of a geometry collection, although the subclasses of `GeomCollection` described in the following sections may restrict membership. Restrictions may be based on:

- Element type (for example, a `MultiPoint` may contain only `Point` elements)
- Dimension
- Constraints on the degree of spatial overlap between elements

#### 13.4.2.9 MultiPoint Class

A `MultiPoint` is a geometry collection composed of `Point` elements. The points are not connected or ordered in any way.

##### `MultiPoint` Examples

- On a world map, a `MultiPoint` could represent a chain of small islands.
- On a city map, a `MultiPoint` could represent the outlets for a ticket office.

##### `MultiPoint` Properties

- A `MultiPoint` is a zero-dimensional geometry.
- A `MultiPoint` is simple if no two of its `Point` values are equal (have identical coordinate values).
- The boundary of a `MultiPoint` is the empty set.

#### 13.4.2.10 MultiCurve Class

A `MultiCurve` is a geometry collection composed of `Curve` elements. `MultiCurve` is a noninstantiable class.

##### `MultiCurve` Properties

- A `MultiCurve` is a one-dimensional geometry.
- A `MultiCurve` is simple if and only if all of its elements are simple; the only intersections between any two elements occur at points that are on the boundaries of both elements.
- A `MultiCurve` boundary is obtained by applying the “mod 2 union rule” (also known as the “odd-even rule”): A point is in the boundary of a `MultiCurve` if it is in the boundaries of an odd number of `Curve` elements.
- A `MultiCurve` is closed if all of its elements are closed.
- The boundary of a closed `MultiCurve` is always empty.

#### 13.4.2.11 MultiLineString Class

A `MultiLineString` is a `MultiCurve` geometry collection composed of `LineString` elements.

##### `MultiLineString` Examples

- On a region map, a `MultiLineString` could represent a river system or a highway system.

### 13.4.2.12 MultiSurface Class

A [MultiSurface](#) is a geometry collection composed of surface elements. [MultiSurface](#) is a noninstantiable class. Its only instantiable subclass is [MultiPolygon](#).

#### [MultiSurface](#) Assertions

- Surfaces within a [MultiSurface](#) have no interiors that intersect.
- Surfaces within a [MultiSurface](#) have boundaries that intersect at most at a finite number of points.

### 13.4.2.13 MultiPolygon Class

A [MultiPolygon](#) is a [MultiSurface](#) object composed of [Polygon](#) elements.

#### [MultiPolygon](#) Examples

- On a region map, a [MultiPolygon](#) could represent a system of lakes.

#### [MultiPolygon](#) Assertions

- A [MultiPolygon](#) has no two [Polygon](#) elements with interiors that intersect.
- A [MultiPolygon](#) has no two [Polygon](#) elements that cross (crossing is also forbidden by the previous assertion), or that touch at an infinite number of points.
- A [MultiPolygon](#) may not have cut lines, spikes, or punctures. A [MultiPolygon](#) is a regular, closed point set.
- A [MultiPolygon](#) that has more than one [Polygon](#) has an interior that is not connected. The number of connected components of the interior of a [MultiPolygon](#) is equal to the number of [Polygon](#) values in the [MultiPolygon](#).

#### [MultiPolygon](#) Properties

- A [MultiPolygon](#) is a two-dimensional geometry.
- A [MultiPolygon](#) boundary is a set of closed curves ([LineString](#) values) corresponding to the boundaries of its [Polygon](#) elements.
- Each [Curve](#) in the boundary of the [MultiPolygon](#) is in the boundary of exactly one [Polygon](#) element.
- Every [Curve](#) in the boundary of an [Polygon](#) element is in the boundary of the [MultiPolygon](#).

## 13.4.3 Supported Spatial Data Formats

Two standard spatial data formats are used to represent geometry objects in queries:

- Well-Known Text (WKT) format
- Well-Known Binary (WKB) format

Internally, MySQL stores geometry values in a format that is not identical to either WKT or WKB format. (Internal format is like WKB but with an initial 4 bytes to indicate the SRID.)

There are functions available to convert between different data formats; see [Section 14.16.6, “Geometry Format Conversion Functions”](#).

The following sections describe the spatial data formats MySQL uses:

- [Well-Known Text \(WKT\) Format](#)
- [Well-Known Binary \(WKB\) Format](#)
- [Internal Geometry Storage Format](#)

## Well-Known Text (WKT) Format

The Well-Known Text (WKT) representation of geometry values is designed for exchanging geometry data in ASCII form. The OpenGIS specification provides a Backus-Naur grammar that specifies the formal production rules for writing WKT values (see [Section 13.4, “Spatial Data Types”](#)).

Examples of WKT representations of geometry objects:

- A [Point](#):

```
POINT(15 20)
```

The point coordinates are specified with no separating comma. This differs from the syntax for the SQL [Point\(\)](#) function, which requires a comma between the coordinates. Take care to use the syntax appropriate to the context of a given spatial operation. For example, the following statements both use [ST\\_X\(\)](#) to extract the X-coordinate from a [Point](#) object. The first produces the object directly using the [Point\(\)](#) function. The second uses a WKT representation converted to a [Point](#) with [ST\\_GeomFromText\(\)](#).

```
mysql> SELECT ST_X(Point(15, 20));
+-----+
| ST_X(Point(15, 20)) |
+-----+
| 15 |
+-----+

mysql> SELECT ST_X(ST_GeomFromText('POINT(15 20)'));
+-----+
| ST_X(ST_GeomFromText('POINT(15 20)')) |
+-----+
| 15 |
+-----+
```

- A [LineString](#) with four points:

```
LINESTRING(0 0, 10 10, 20 25, 50 60)
```

The point coordinate pairs are separated by commas.

- A [Polygon](#) with one exterior ring and one interior ring:

```
POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 7,5 5))
```

- A [MultiPoint](#) with three [Point](#) values:

```
MULTIPOINT(0 0, 20 20, 60 60)
```

Spatial functions such as [ST\\_MPointFromText\(\)](#) and [ST\\_GeomFromText\(\)](#) that accept WKT-format representations of [MultiPoint](#) values permit individual points within values to be surrounded by parentheses. For example, both of the following function calls are valid:

```
ST_MPointFromText('MULTIPOINT (1 1, 2 2, 3 3)')
ST_MPointFromText('MULTIPOINT ((1 1), (2 2), (3 3))')
```

- A [MultiLineString](#) with two [LineString](#) values:

```
MULTILINESTRING((10 10, 20 20), (15 15, 30 15))
```

- A [MultiPolygon](#) with two [Polygon](#) values:

```
MULTIPOLYGON(((0 0,10 0,10 10,0 10,0 0)),((5 5,7 5,7 7,5 7, 5 5)))
```

- A [GeometryCollection](#) consisting of two [Point](#) values and one [LineString](#):

```
GEOMETRYCOLLECTION(POINT(10 10), POINT(30 30), LINESTRING(15 15, 20 20))
```

## Well-Known Binary (WKB) Format

The Well-Known Binary (WKB) representation of geometric values is used for exchanging geometry data as binary streams represented by [BLOB](#) values containing geometric WKB information. This format is defined by the OpenGIS specification (see [Section 13.4, “Spatial Data Types”](#)). It is also defined in the ISO *SQL/MM Part 3: Spatial* standard.

WKB uses 1-byte unsigned integers, 4-byte unsigned integers, and 8-byte double-precision numbers (IEEE 754 format). A byte is eight bits.

For example, a WKB value that corresponds to [POINT\(1 -1\)](#) consists of this sequence of 21 bytes, each represented by two hexadecimal digits:

```
010100000000000000000000F03FF0000000000000F0BF
```

The sequence consists of the components shown in the following table.

**Table 13.2 WKB Components Example**

Component	Size	Value
Byte order	1 byte	01
WKB type	4 bytes	01000000
X coordinate	8 bytes	000000000000F03F
Y coordinate	8 bytes	000000000000F0BF

Component representation is as follows:

- The byte order indicator is either 1 or 0 to signify little-endian or big-endian storage. The little-endian and big-endian byte orders are also known as Network Data Representation (NDR) and External Data Representation (XDR), respectively.
- The WKB type is a code that indicates the geometry type. MySQL uses values from 1 through 7 to indicate [Point](#), [LineString](#), [Polygon](#), [MultiPoint](#), [MultiLineString](#), [MultiPolygon](#), and [GeometryCollection](#).
- A [Point](#) value has X and Y coordinates, each represented as a double-precision value.

WKB values for more complex geometry values have more complex data structures, as detailed in the OpenGIS specification.

## Internal Geometry Storage Format

MySQL stores geometry values using 4 bytes to indicate the SRID followed by the WKB representation of the value. For a description of WKB format, see [Well-Known Binary \(WKB\) Format](#).

For the WKB part, these MySQL-specific considerations apply:

- The byte-order indicator byte is 1 because MySQL stores geometries as little-endian values.
- MySQL supports geometry types of `Point`, `LineString`, `Polygon`, `MultiPoint`, `MultiLineString`, `MultiPolygon`, and `GeometryCollection`. Other geometry types are not supported.
- Only `GeometryCollection` can be empty. Such a value is stored with 0 elements.
- Polygon rings can be specified both clockwise and counterclockwise. MySQL flips the rings automatically when reading data.

Cartesian coordinates are stored in the length unit of the spatial reference system, with X values in the X coordinates and Y values in the Y coordinates. Axis directions are those specified by the spatial reference system.

Geographic coordinates are stored in the angle unit of the spatial reference system, with longitudes in the X coordinates and latitudes in the Y coordinates. Axis directions and the meridian are those specified by the spatial reference system.

The `LENGTH()` function returns the space in bytes required for value storage. Example:

```
mysql> SET @g = ST_GeomFromText('POINT(1 -1)');
mysql> SELECT LENGTH(@g);
+-----+
| LENGTH(@g) |
+-----+
| 25 |
+-----+
mysql> SELECT HEX(@g);
+-----+
| HEX(@g) |
+-----+
| 00000000010100000000000000000000F03F000000000000F0BF |
+-----+
```

The value length is 25 bytes, made up of these components (as can be seen from the hexadecimal value):

- 4 bytes for integer SRID (0)
- 1 byte for integer byte order (1 = little-endian)
- 4 bytes for integer type information (1 = `Point`)
- 8 bytes for double-precision X coordinate (1)
- 8 bytes for double-precision Y coordinate (-1)

## 13.4.4 Geometry Well-Formedness and Validity

For geometry values, MySQL distinguishes between the concepts of syntactically well-formed and geometrically valid.

A geometry is syntactically well-formed if it satisfies conditions such as those in this (nonexhaustive) list:

- Linestrings have at least two points
- Polygons have at least one ring
- Polygon rings are closed (first and last points the same)

- Polygon rings have at least 4 points (minimum polygon is a triangle with first and last points the same)
- Collections are not empty (except [GeometryCollection](#))

A geometry is geometrically valid if it is syntactically well-formed and satisfies conditions such as those in this (nonexhaustive) list:

- Polygons are not self-intersecting
- Polygon interior rings are inside the exterior ring
- Multipolygons do not have overlapping polygons

Spatial functions fail if a geometry is not syntactically well-formed. Spatial import functions that parse WKT or WKB values raise an error for attempts to create a geometry that is not syntactically well-formed. Syntactic well-formedness is also checked for attempts to store geometries into tables.

It is permitted to insert, select, and update geometrically invalid geometries, but they must be syntactically well-formed. Due to the computational expense, MySQL does not check explicitly for geometric validity. Spatial computations may detect some cases of invalid geometries and raise an error, but they may also return an undefined result without detecting the invalidity. Applications that require geometrically-valid geometries should check them using the [ST\\_IsValid\(\)](#) function.

### 13.4.5 Spatial Reference System Support

A spatial reference system (SRS) for spatial data is a coordinate-based system for geographic locations.

There are different types of spatial reference systems:

- A projected SRS is a projection of a globe onto a flat surface; that is, a flat map. For example, a light bulb inside a globe that shines on a paper cylinder surrounding the globe projects a map onto the paper. The result is georeferenced: Each point maps to a place on the globe. The coordinate system on that plane is Cartesian using a length unit (meters, feet, and so forth), rather than degrees of longitude and latitude.

The globes in this case are ellipsoids; that is, flattened spheres. Earth is a bit shorter in its North-South axis than its East-West axis, so a slightly flattened sphere is more correct, but perfect spheres permit faster calculations.

- A geographic SRS is a nonprojected SRS representing longitude-latitude (or latitude-longitude) coordinates on an ellipsoid, in any angular unit.
- The SRS denoted in MySQL by SRID 0 represents an infinite flat Cartesian plane with no units assigned to its axes. Unlike projected SRSSs, it is not georeferenced and it does not necessarily represent Earth. It is an abstract plane that can be used for anything. SRID 0 is the default SRID for spatial data in MySQL.

MySQL maintains information about available spatial reference systems for spatial data in the data dictionary [mysql.st\\_spatial\\_reference\\_systems](#) table, which can store entries for projected and geographic SRSSs. This data dictionary table is invisible, but SRS entry contents are available through the [INFORMATION\\_SCHEMA.ST\\_SPATIAL\\_REFERENCE\\_SYSTEMS](#) table, implemented as a view on [mysql.st\\_spatial\\_reference\\_systems](#) (see [Section 28.3.36, “The INFORMATION\\_SCHEMA.ST\\_SPATIAL\\_REFERENCE\\_SYSTEMS Table”](#)).

The following example shows what an SRS entry looks like:

```
mysql> SELECT *
 FROM INFORMATION_SCHEMA.ST_SPATIAL_REFERENCE_SYSTEMS
```

```

WHERE SRS_ID = 4326\G
***** 1. row *****
 SRS_NAME: WGS 84
 SRS_ID: 4326
 ORGANIZATION: EPSG
ORGANIZATION_COORDSYS_ID: 4326
 DEFINITION: GEOGCS["WGS 84",DATUM["World Geodetic System 1984",
 SPHEROID["WGS 84",6378137,298.257223563,
 AUTHORITY["EPSG","7030"]],AUTHORITY["EPSG","6326"]],
 PRIMEM["Greenwich",0,AUTHORITY["EPSG","8901"]],
 UNIT["degree",0.017453292519943278,
 AUTHORITY["EPSG","9122"]],
 AXIS["Lat",NORTH],AXIS["Long",EAST],
 AUTHORITY["EPSG","4326"]]
 DESCRIPTION:

```

This entry describes the SRS used for GPS systems. It has the name ([SRS\\_NAME](#)) WGS 84 and the ID ([SRS\\_ID](#)) 4326, which is the ID used by the [European Petroleum Survey Group](#) (EPSG).

SRS definitions in the [DEFINITION](#) column are WKT values, represented as specified in the [Open Geospatial Consortium](#) document [OGC 12-063r5](#).

[SRS\\_ID](#) values represent the same kind of values as the SRID of geometry values or passed as the SRID argument to spatial functions. SRID 0 (the unitless Cartesian plane) is special. It is always a legal spatial reference system ID and can be used in any computations on spatial data that depend on SRID values.

For computations on multiple geometry values, all values must have the same SRID or an error occurs.

SRS definition parsing occurs on demand when definitions are needed by GIS functions. Parsed definitions are stored in the data dictionary cache to enable reuse and avoid incurring parsing overhead for every statement that needs SRS information.

To enable manipulation of SRS entries stored in the data dictionary, MySQL provides these SQL statements:

- [CREATE SPATIAL REFERENCE SYSTEM](#): See [Section 15.1.19, “CREATE SPATIAL REFERENCE SYSTEM Statement”](#). The description for this statement includes additional information about SRS components.
- [DROP SPATIAL REFERENCE SYSTEM](#): See [Section 15.1.31, “DROP SPATIAL REFERENCE SYSTEM Statement”](#).

## 13.4.6 Creating Spatial Columns

MySQL provides a standard way of creating spatial columns for geometry types, for example, with [CREATE TABLE](#) or [ALTER TABLE](#). Spatial columns are supported for [MyISAM](#), [InnoDB](#), [NDB](#), and [ARCHIVE](#) tables. See also the notes about spatial indexes under [Section 13.4.10, “Creating Spatial Indexes”](#).

Columns with a spatial data type can have an SRID attribute, to explicitly indicate the spatial reference system (SRS) for values stored in the column. For implications of an SRID-restricted column, see [Section 13.4.1, “Spatial Data Types”](#).

- Use the [CREATE TABLE](#) statement to create a table with a spatial column:

```
CREATE TABLE geom (g GEOMETRY);
```

- Use the [ALTER TABLE](#) statement to add or drop a spatial column to or from an existing table:

```
ALTER TABLE geom ADD pt POINT;
ALTER TABLE geom DROP pt;
```

### 13.4.7 Populating Spatial Columns

After you have created spatial columns, you can populate them with spatial data.

Values should be stored in internal geometry format, but you can convert them to that format from either Well-Known Text (WKT) or Well-Known Binary (WKB) format. The following examples demonstrate how to insert geometry values into a table by converting WKT values to internal geometry format:

- Perform the conversion directly in the `INSERT` statement:

```
INSERT INTO geom VALUES (ST_GeomFromText('POINT(1 1)'));

SET @g = 'POINT(1 1)';
INSERT INTO geom VALUES (ST_GeomFromText(@g));
```

- Perform the conversion prior to the `INSERT`:

```
SET @g = ST_GeomFromText('POINT(1 1)');
INSERT INTO geom VALUES (@g);
```

The following examples insert more complex geometries into the table:

```
SET @g = 'LINESTRING(0 0,1 1,2 2)';
INSERT INTO geom VALUES (ST_GeomFromText(@g));

SET @g = 'POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 7, 5 5))';
INSERT INTO geom VALUES (ST_GeomFromText(@g));

SET @g =
'GEOMETRYCOLLECTION(POINT(1 1),LINESTRING(0 0,1 1,2 2,3 3,4 4))';
INSERT INTO geom VALUES (ST_GeomFromText(@g));
```

The preceding examples use `ST_GeomFromText()` to create geometry values. You can also use type-specific functions:

```
SET @g = 'POINT(1 1)';
INSERT INTO geom VALUES (ST_PointFromText(@g));

SET @g = 'LINESTRING(0 0,1 1,2 2)';
INSERT INTO geom VALUES (ST_LineStringFromText(@g));

SET @g = 'POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 7, 5 5))';
INSERT INTO geom VALUES (ST_PolygonFromText(@g));

SET @g =
'GEOMETRYCOLLECTION(POINT(1 1),LINESTRING(0 0,1 1,2 2,3 3,4 4))';
INSERT INTO geom VALUES (ST_GeomCollFromText(@g));
```

A client application program that wants to use WKB representations of geometry values is responsible for sending correctly formed WKB in queries to the server. There are several ways to satisfy this requirement. For example:

- Inserting a `POINT(1 1)` value with hex literal syntax:

```
INSERT INTO geom VALUES
(ST_GeomFromWKB(X'010100000000000000000000F03F000000000000F03F'));
```

- An ODBC application can send a WKB representation, binding it to a placeholder using an argument of `BLOB` type:

```
INSERT INTO geom VALUES (ST_GeomFromWKB(?))
```

Other programming interfaces may support a similar placeholder mechanism.

- In a C program, you can escape a binary value using `mysql_real_escape_string_quote()` and include the result in a query string that is sent to the server. See `mysql_real_escape_string_quote()`.

### 13.4.8 Fetching Spatial Data

Geometry values stored in a table can be fetched in internal format. You can also convert them to WKT or WKB format.

- Fetching spatial data in internal format:

Fetching geometry values using internal format can be useful in table-to-table transfers:

```
CREATE TABLE geom2 (g GEOMETRY) SELECT g FROM geom;
```

- Fetching spatial data in WKT format:

The `ST_AsText()` function converts a geometry from internal format to a WKT string.

```
SELECT ST_AsText(g) FROM geom;
```

- Fetching spatial data in WKB format:

The `ST_AsBinary()` function converts a geometry from internal format to a `BLOB` containing the WKB value.

```
SELECT ST_AsBinary(g) FROM geom;
```

### 13.4.9 Optimizing Spatial Analysis

For `MyISAM` and `InnoDB` tables, search operations in columns containing spatial data can be optimized using `SPATIAL` indexes. The most typical operations are:

- Point queries that search for all objects that contain a given point
- Region queries that search for all objects that overlap a given region

MySQL uses **R-Trees with quadratic splitting** for `SPATIAL` indexes on spatial columns. A `SPATIAL` index is built using the minimum bounding rectangle (MBR) of a geometry. For most geometries, the MBR is a minimum rectangle that surrounds the geometries. For a horizontal or a vertical linestring, the MBR is a rectangle degenerated into the linestring. For a point, the MBR is a rectangle degenerated into the point.

It is also possible to create normal indexes on spatial columns. In a non-`SPATIAL` index, you must declare a prefix for any spatial column except for `POINT` columns.

`MyISAM` and `InnoDB` support both `SPATIAL` and non-`SPATIAL` indexes. Other storage engines support non-`SPATIAL` indexes, as described in [Section 15.1.15, “CREATE INDEX Statement”](#).

### 13.4.10 Creating Spatial Indexes

For `InnoDB` and `MyISAM` tables, MySQL can create spatial indexes using syntax similar to that for creating regular indexes, but using the `SPATIAL` keyword. Columns in spatial indexes must be declared `NOT NULL`. The following examples demonstrate how to create spatial indexes:

- With `CREATE TABLE`:

```
CREATE TABLE geom (g GEOMETRY NOT NULL SRID 4326, SPATIAL INDEX(g));
```

- With `ALTER TABLE`:

```
CREATE TABLE geom (g GEOMETRY NOT NULL SRID 4326);
ALTER TABLE geom ADD SPATIAL INDEX(g);
```

- With `CREATE INDEX`:

```
CREATE TABLE geom (g GEOMETRY NOT NULL SRID 4326);
CREATE SPATIAL INDEX g ON geom (g);
```

`SPATIAL INDEX` creates an R-tree index. For storage engines that support nonspatial indexing of spatial columns, the engine creates a B-tree index. A B-tree index on spatial values is useful for exact-value lookups, but not for range scans.

The optimizer can use spatial indexes defined on columns that are SRID-restricted. For more information, see [Section 13.4.1, “Spatial Data Types”](#), and [Section 10.3.3, “SPATIAL Index Optimization”](#).

For more information on indexing spatial columns, see [Section 15.1.15, “CREATE INDEX Statement”](#).

To drop spatial indexes, use `ALTER TABLE` or `DROP INDEX`:

- With `ALTER TABLE`:

```
ALTER TABLE geom DROP INDEX g;
```

- With `DROP INDEX`:

```
DROP INDEX g ON geom;
```

Example: Suppose that a table `geom` contains more than 32,000 geometries, which are stored in the column `g` of type `GEOMETRY`. The table also has an `AUTO_INCREMENT` column `fid` for storing object ID values.

```
mysql> DESCRIBE geom;
+-----+-----+-----+-----+-----+-----+
| Field | Type | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| fid | int(11) | | PRI | NULL | auto_increment |
| g | geometry | | | | |
+-----+-----+-----+-----+-----+-----+
2 rows in set (0.00 sec)

mysql> SELECT COUNT(*) FROM geom;
+-----+
| count(*) |
+-----+
| 32376 |
+-----+
1 row in set (0.00 sec)
```

To add a spatial index on the column `g`, use this statement:

```
mysql> ALTER TABLE geom ADD SPATIAL INDEX(g);
Query OK, 32376 rows affected (4.05 sec)
Records: 32376 Duplicates: 0 Warnings: 0
```

### 13.4.11 Using Spatial Indexes

The optimizer investigates whether available spatial indexes can be involved in the search for queries that use a function such as `MBRContains()` or `MBRWithin()` in the `WHERE` clause. The following query finds all objects that are in the given rectangle:

```
mysql> SET @poly =
```

```

-> 'Polygon((30000 15000,
 31000 15000,
 31000 16000,
 30000 16000,
 30000 15000))';
mysql> SELECT fid,ST_AsText(g) FROM geom WHERE
-> MBRContains(ST_GeomFromText(@poly),g);
+-----+-----+
| fid | ST_AsText(g) |
+-----+-----+
| 21 | LINESTRING(30350.4 15828.8,30350.6 15845.3,30333.8 15845.3,30333.8 15845.3,30350.6 15845.3,30350.4 15828.8) |
| 22 | LINESTRING(30350.6 15871.4,30350.6 15887.8,30334 15887.8,30334 15887.8,30350.6 15887.8,30350.6 15871.4) |
| 23 | LINESTRING(30350.6 15914.2,30350.6 15930.4,30334 15930.4,30334 15930.4,30350.6 15930.4,30350.6 15914.2) |
| 24 | LINESTRING(30290.2 15823.3,30290.2 15839.4,30273.4 15839.4,30273.4 15839.4,30290.2 15839.4,30290.2 15823.3) |

| 13 | LINESTRING(30105 15065.8,30108.4 15050.8,30118 15053.3,30118 15053.3,30108.4 15053.3,30105 15053.3,30105 15065.8) |
| 154 | LINESTRING(30276.2 15143.8,30261.4 15141.3,30263 15131.4,30263 15131.4,30261.4 15131.4,30276.2 15131.4,30276.2 15143.8) |
| 155 | LINESTRING(30269.8 15084.3,30269.4 15093.4,30258.6 15093.3,30258.6 15093.3,30269.4 15093.3,30269.8 15093.3,30269.8 15084.3) |
| 157 | LINESTRING(30128.2 15011.3,30113.2 15010.2,30113.6 15000.4,30113.6 15000.4,30113.2 15000.4,30128.2 15000.4,30128.2 15011.3) |
+-----+-----+
20 rows in set (0.00 sec)

```

Use `EXPLAIN` to check the way this query is executed:

```

mysql> SET @poly =
-> 'Polygon((30000 15000,
 31000 15000,
 31000 16000,
 30000 16000,
 30000 15000))';
mysql> EXPLAIN SELECT fid,ST_AsText(g) FROM geom WHERE
-> MBRContains(ST_GeomFromText(@poly),g)\G
***** 1. row *****
 id: 1
 select_type: SIMPLE
 table: geom
 type: range
possible_keys: g
 key: g
 key_len: 32
 ref: NULL
 rows: 50
 Extra: Using where
1 row in set (0.00 sec)

```

Check what would happen without a spatial index:

```

mysql> SET @poly =
-> 'Polygon((30000 15000,
 31000 15000,
 31000 16000,
 30000 16000,
 30000 15000))';
mysql> EXPLAIN SELECT fid,ST_AsText(g) FROM g IGNORE INDEX (g) WHERE
-> MBRContains(ST_GeomFromText(@poly),g)\G
***** 1. row *****

```

```

 id: 1
select_type: SIMPLE
 table: geom
 type: ALL
possible_keys: NULL
 key: NULL
 key_len: NULL
 ref: NULL
 rows: 32376
 Extra: Using where
1 row in set (0.00 sec)

```

Executing the `SELECT` statement without the spatial index yields the same result but causes the execution time to rise from 0.00 seconds to 0.46 seconds:

```

mysql> SET @poly =
 -> 'Polygon((30000 15000,
 31000 15000,
 31000 16000,
 30000 16000,
 30000 15000))';
mysql> SELECT fid,ST_AsText(g) FROM geom IGNORE INDEX (g) WHERE
 -> MBRContains(ST_GeomFromText(@poly),g);
+-----+-----+

## 13.5 The JSON Data Type

- [Creating JSON Values](#)
- [Normalization, Merging, and Autowrapping of JSON Values](#)
- [Searching and Modifying JSON Values](#)
- [JSON Path Syntax](#)
- [Comparison and Ordering of JSON Values](#)
- [Converting between JSON and non-JSON values](#)
- [Aggregation of JSON Values](#)

MySQL supports a native `JSON` (JavaScript Object Notation) data type defined by [RFC 8259](#) that enables efficient access to data in JSON documents. The `JSON` data type provides these advantages over storing JSON-format strings in a string column:

- Automatic validation of JSON documents stored in `JSON` columns. Invalid documents produce an error.
- Optimized storage format. JSON documents stored in `JSON` columns are converted to an internal format that permits quick read access to document elements. When the server later must read a JSON value stored in this binary format, the value need not be parsed from a text representation. The binary format is structured to enable the server to look up subobjects or nested values directly by key or array index without reading all values before or after them in the document.

MySQL also supports the *JSON Merge Patch* format defined in [RFC 7396](#), using the `JSON_MERGE_PATCH()` function. See the description of this function, as well as [Normalization, Merging, and Autowrapping of JSON Values](#), for examples and further information.

**Note**

This discussion uses `JSON` in monotype to indicate specifically the JSON data type and “JSON” in regular font to indicate JSON data in general.

The space required to store a `JSON` document is roughly the same as for `LONGBLOB` or `LONGTEXT`; see [Section 13.7, “Data Type Storage Requirements”](#), for more information. It is important to keep in mind that the size of any JSON document stored in a `JSON` column is limited to the value of the `max_allowed_packet` system variable. (When the server is manipulating a JSON value internally in memory, it can be larger than this; the limit applies when the server stores it.) You can obtain the amount of space required to store a JSON document using the `JSON_STORAGE_SIZE()` function; note that for a `JSON` column, the storage size—and thus the value returned by this function—is that used by the column prior to any partial updates that may have been performed on it (see the discussion of the JSON partial update optimization later in this section).

Along with the `JSON` data type, a set of SQL functions is available to enable operations on JSON values, such as creation, manipulation, and searching. The following discussion shows examples of these operations. For details about individual functions, see [Section 14.17, “JSON Functions”](#).

A set of spatial functions for operating on GeoJSON values is also available. See [Section 14.16.11, “Spatial GeoJSON Functions”](#).

`JSON` columns, like columns of other binary types, are not indexed directly; instead, you can create an index on a generated column that extracts a scalar value from the `JSON` column. See [Indexing a Generated Column to Provide a JSON Column Index](#), for a detailed example.

The MySQL optimizer also looks for compatible indexes on virtual columns that match JSON expressions.

The `InnoDB` storage engine supports multi-valued indexes on JSON arrays. See [Multi-Valued Indexes](#).

MySQL NDB Cluster supports `JSON` columns and MySQL JSON functions, including creation of an index on a column generated from a `JSON` column as a workaround for being unable to index a `JSON` column. A maximum of 3 `JSON` columns per `NDB` table is supported.

## Partial Updates of JSON Values

In MySQL 9.1, the optimizer can perform a partial, in-place update of a `JSON` column instead of removing the old document and writing the new document in its entirety to the column. This optimization can be performed for an update that meets the following conditions:

- The column being updated was declared as `JSON`.
- The `UPDATE` statement uses any of the three functions `JSON_SET()`, `JSON_REPLACE()`, or `JSON_REMOVE()` to update the column. A direct assignment of the column value (for example, `UPDATE mytable SET jcol = '{"a": 10, "b": 25}'`) cannot be performed as a partial update.

Updates of multiple `JSON` columns in a single `UPDATE` statement can be optimized in this fashion; MySQL can perform partial updates of only those columns whose values are updated using the three functions just listed.

- The input column and the target column must be the same column; a statement such as `UPDATE mytable SET jcol1 = JSON_SET(jcol2, '$.a', 100)` cannot be performed as a partial update.

The update can use nested calls to any of the functions listed in the previous item, in any combination, as long as the input and target columns are the same.

- All changes replace existing array or object values with new ones, and do not add any new elements to the parent object or array.
- The value being replaced must be at least as large as the replacement value. In other words, the new value cannot be any larger than the old one.

A possible exception to this requirement occurs when a previous partial update has left sufficient space for the larger value. You can use the function `JSON_STORAGE_FREE()` see how much space has been freed by any partial updates of a `JSON` column.

Such partial updates can be written to the binary log using a compact format that saves space; this can be enabled by setting the `binlog_row_value_options` system variable to `PARTIAL_JSON`.

It is important to distinguish the partial update of a `JSON` column value stored in a table from writing the partial update of a row to the binary log. It is possible for the complete update of a `JSON` column to be recorded in the binary log as a partial update. This can happen when either (or both) of the last two conditions from the previous list is not met but the other conditions are satisfied.

See also the description of `binlog_row_value_options`.

The next few sections provide basic information regarding the creation and manipulation of JSON values.

## Creating JSON Values

A JSON array contains a list of values separated by commas and enclosed within `[` and `]` characters:

```
["abc", 10, null, true, false]
```

A JSON object contains a set of key-value pairs separated by commas and enclosed within `{` and `}` characters:

```
{ "k1": "value", "k2": 10 }
```

As the examples illustrate, JSON arrays and objects can contain scalar values that are strings or numbers, the JSON null literal, or the JSON boolean true or false literals. Keys in JSON objects must be strings. Temporal (date, time, or datetime) scalar values are also permitted:

```
["12:18:29.000000", "2015-07-29", "2015-07-29 12:18:29.000000"]
```

Nesting is permitted within JSON array elements and JSON object key values:

```
[99, {"id": "HK500", "cost": 75.99}, ["hot", "cold"]]
{"k1": "value", "k2": [10, 20]}
```

You can also obtain JSON values from a number of functions supplied by MySQL for this purpose (see [Section 14.17.2, “Functions That Create JSON Values”](#)) as well as by casting values of other types to the `JSON` type using `CAST(value AS JSON)` (see [Converting between JSON and non-JSON values](#)). The next several paragraphs describe how MySQL handles JSON values provided as input.

In MySQL, JSON values are written as strings. MySQL parses any string used in a context that requires a JSON value, and produces an error if it is not valid as JSON. These contexts include inserting a value into a column that has the `JSON` data type and passing an argument to a function that expects a JSON value (usually shown as `json_doc` or `json_val` in the documentation for MySQL JSON functions), as the following examples demonstrate:

- Attempting to insert a value into a `JSON` column succeeds if the value is a valid JSON value, but fails if it is not:

```
mysql> CREATE TABLE t1 (jdoc JSON);
Query OK, 0 rows affected (0.20 sec)

mysql> INSERT INTO t1 VALUES('{"key1": "value1", "key2": "value2"}');
Query OK, 1 row affected (0.01 sec)

mysql> INSERT INTO t1 VALUES('[1, 2,');
ERROR 3140 (22032) at line 2: Invalid JSON text:
"Invalid value." at position 6 in value (or column) '[1, 2,'.
```

Positions for “at position *N*” in such error messages are 0-based, but should be considered rough indications of where the problem in a value actually occurs.

- The `JSON_TYPE()` function expects a JSON argument and attempts to parse it into a JSON value. It returns the value's JSON type if it is valid and produces an error otherwise:

```
mysql> SELECT JSON_TYPE('["a", "b", 1]');
+-----+
| JSON_TYPE('["a", "b", 1]') |
+-----+
| ARRAY |
+-----+

mysql> SELECT JSON_TYPE('"hello"');
+-----+
| JSON_TYPE('"hello"') |
+-----+
| STRING |
+-----+

mysql> SELECT JSON_TYPE('hello');
ERROR 3146 (22032): Invalid data type for JSON data in argument 1
to function json_type; a JSON string or JSON type is required.
```

MySQL handles strings used in JSON context using the `utf8mb4` character set and `utf8mb4_bin` collation. Strings in other character sets are converted to `utf8mb4` as necessary. (For strings in the `ascii` or `utf8mb3` character sets, no conversion is needed because `ascii` and `utf8mb3` are subsets of `utf8mb4`.)

As an alternative to writing JSON values using literal strings, functions exist for composing JSON values from component elements. `JSON_ARRAY()` takes a (possibly empty) list of values and returns a JSON array containing those values:

```
mysql> SELECT JSON_ARRAY('a', 1, NOW());
```

```
+-----+
| JSON_ARRAY('a', 1, NOW()) |
+-----+
| ["a", 1, "2015-07-27 09:43:47.000000"] |
+-----+
```

`JSON_OBJECT()` takes a (possibly empty) list of key-value pairs and returns a JSON object containing those pairs:

```
mysql> SELECT JSON_OBJECT('key1', 1, 'key2', 'abc');
+-----+
| JSON_OBJECT('key1', 1, 'key2', 'abc') |
+-----+
| {"key1": 1, "key2": "abc"} |
+-----+
```

`JSON_MERGE_PRESERVE()` takes two or more JSON documents and returns the combined result:

```
mysql> SELECT JSON_MERGE_PRESERVE('["a", 1]', '{"key": "value"}');
+-----+
| JSON_MERGE_PRESERVE('["a", 1]', '{"key": "value"}') |
+-----+
| ["a", 1, {"key": "value"}] |
+-----+
1 row in set (0.00 sec)
```

For information about the merging rules, see [Normalization, Merging, and Autowrapping of JSON Values](#).

(MySQL also supports `JSON_MERGE_PATCH()`, which has somewhat different behavior. See [JSON\\_MERGE\\_PATCH\(\) compared with JSON\\_MERGE\\_PRESERVE\(\)](#), for information about the differences between these two functions.)

JSON values can be assigned to user-defined variables:

```
mysql> SET @j = JSON_OBJECT('key', 'value');
mysql> SELECT @j;
+-----+
| @j |
+-----+
| {"key": "value"} |
+-----+
```

However, user-defined variables cannot be of `JSON` data type, so although `@j` in the preceding example looks like a JSON value and has the same character set and collation as a JSON value, it does *not* have the `JSON` data type. Instead, the result from `JSON_OBJECT()` is converted to a string when assigned to the variable.

Strings produced by converting JSON values have a character set of `utf8mb4` and a collation of `utf8mb4_bin`:

```
mysql> SELECT CHARSET(@j), COLLATION(@j);
+-----+-----+
| CHARSET(@j) | COLLATION(@j) |
+-----+-----+
| utf8mb4 | utf8mb4_bin |
+-----+-----+
```

Because `utf8mb4_bin` is a binary collation, comparison of JSON values is case-sensitive.

```
mysql> SELECT JSON_ARRAY('x') = JSON_ARRAY('X');
+-----+
| JSON_ARRAY('x') = JSON_ARRAY('X') |
+-----+
```

```
+-----+
| 0 |
+-----+
```

Case sensitivity also applies to the JSON `null`, `true`, and `false` literals, which always must be written in lowercase:

```
mysql> SELECT JSON_VALID('null'), JSON_VALID('Null'), JSON_VALID('NULL');
+-----+-----+-----+
| JSON_VALID('null') | JSON_VALID('Null') | JSON_VALID('NULL') |
+-----+-----+-----+
| 1 | 0 | 0 |
+-----+-----+-----+

mysql> SELECT CAST('null' AS JSON);
+-----+
| CAST('null' AS JSON) |
+-----+
| null |
+-----+
1 row in set (0.00 sec)

mysql> SELECT CAST('NULL' AS JSON);
ERROR 3141 (22032): Invalid JSON text in argument 1 to function cast_as_json:
"Invalid value." at position 0 in 'NULL'.
```

Case sensitivity of the JSON literals differs from that of the SQL `NULL`, `TRUE`, and `FALSE` literals, which can be written in any lettercase:

```
mysql> SELECT ISNULL(null), ISNULL(Null), ISNULL(NULL);
+-----+-----+-----+
| ISNULL(null) | ISNULL(Null) | ISNULL(NULL) |
+-----+-----+-----+
| 1 | 1 | 1 |
+-----+-----+-----+
```

Sometimes it may be necessary or desirable to insert quote characters ( " or ' ) into a JSON document. Assume for this example that you want to insert some JSON objects containing strings representing sentences that state some facts about MySQL, each paired with an appropriate keyword, into a table created using the SQL statement shown here:

```
mysql> CREATE TABLE facts (sentence JSON);
```

Among these keyword-sentence pairs is this one:

```
mascot: The MySQL mascot is a dolphin named "Sakila".
```

One way to insert this as a JSON object into the `facts` table is to use the MySQL `JSON_OBJECT()` function. In this case, you must escape each quote character using a backslash, as shown here:

```
mysql> INSERT INTO facts VALUES
> (JSON_OBJECT("mascot", "Our mascot is a dolphin named \"Sakila\"."));
```

This does not work in the same way if you insert the value as a JSON object literal, in which case, you must use the double backslash escape sequence, like this:

```
mysql> INSERT INTO facts VALUES
> ('{"mascot": "Our mascot is a dolphin named \\\"Sakila\\\"."}');
```

Using the double backslash keeps MySQL from performing escape sequence processing, and instead causes it to pass the string literal to the storage engine for processing. After inserting the JSON object in

either of the ways just shown, you can see that the backslashes are present in the JSON column value by doing a simple `SELECT`, like this:

```
mysql> SELECT sentence FROM facts;
+-----+
| sentence |
+-----+
| {"mascot": "Our mascot is a dolphin named \"Sakila\".\"} |
+-----+
```

To look up this particular sentence employing `mascot` as the key, you can use the column-path operator `->`, as shown here:

```
mysql> SELECT col->"$.mascot" FROM qtest;
+-----+
| col->"$.mascot" |
+-----+
| "Our mascot is a dolphin named \"Sakila\".\" |
+-----+
1 row in set (0.00 sec)
```

This leaves the backslashes intact, along with the surrounding quote marks. To display the desired value using `mascot` as the key, but without including the surrounding quote marks or any escapes, use the inline path operator `->>`, like this:

```
mysql> SELECT sentence->>"$.mascot" FROM facts;
+-----+
| sentence->>"$.mascot" |
+-----+
| Our mascot is a dolphin named "Sakila". |
+-----+
```

#### Note

The previous example does not work as shown if the `NO_BACKSLASH_ESCAPES` server SQL mode is enabled. If this mode is set, a single backslash instead of double backslashes can be used to insert the JSON object literal, and the backslashes are preserved. If you use the `JSON_OBJECT()` function when performing the insert and this mode is set, you must alternate single and double quotes, like this:

```
mysql> INSERT INTO facts VALUES
> (JSON_OBJECT('mascot', 'Our mascot is a dolphin named "Sakila".'));
```

See the description of the `JSON_UNQUOTE()` function for more information about the effects of this mode on escaped characters in JSON values.

## Normalization, Merging, and Autowrapping of JSON Values

When a string is parsed and found to be a valid JSON document, it is also normalized. This means that members with keys that duplicate a key found later in the document, reading from left to right, are discarded. The object value produced by the following `JSON_OBJECT()` call includes only the second `key1` element because that key name occurs earlier in the value, as shown here:

```
mysql> SELECT JSON_OBJECT('key1', 1, 'key2', 'abc', 'key1', 'def');
+-----+
| JSON_OBJECT('key1', 1, 'key2', 'abc', 'key1', 'def') |
+-----+
| {"key1": "def", "key2": "abc"} |
+-----+
```

Normalization is also performed when values are inserted into JSON columns, as shown here:

```
mysql> CREATE TABLE t1 (c1 JSON);

mysql> INSERT INTO t1 VALUES
 > ('{"x": 17, "x": "red"}'),
 > ('{"x": 17, "x": "red", "x": [3, 5, 7]}');

mysql> SELECT c1 FROM t1;
+-----+
| c1 |
+-----+
| {"x": "red"} |
| {"x": [3, 5, 7]} |
+-----+
```

This “last duplicate key wins” behavior is suggested by [RFC 7159](#) and is implemented by most JavaScript parsers. (Bug #86866, Bug #26369555)

MySQL discards extra whitespace between keys, values, or elements in the original JSON document, and leaves (or inserts, when necessary) a single space following each comma (,) or colon (:) when displaying it. This is done to enhance readability.

MySQL functions that produce JSON values (see [Section 14.17.2, “Functions That Create JSON Values”](#)) always return normalized values.

To make lookups more efficient, MySQL also sorts the keys of a JSON object. *You should be aware that the result of this ordering is subject to change and not guaranteed to be consistent across releases.*

## Merging JSON Values

Two merging algorithms are supported, implemented by the functions `JSON_MERGE_PRESERVE()` and `JSON_MERGE_PATCH()`. These differ in how they handle duplicate keys: `JSON_MERGE_PRESERVE()` retains values for duplicate keys, while `JSON_MERGE_PATCH()` discards all but the last value. The next few paragraphs explain how each of these two functions handles the merging of different combinations of JSON documents (that is, of objects and arrays).

**Merging arrays.** In contexts that combine multiple arrays, the arrays are merged into a single array. `JSON_MERGE_PRESERVE()` does this by concatenating arrays named later to the end of the first array. `JSON_MERGE_PATCH()` considers each argument as an array consisting of a single element (thus having 0 as its index) and then applies “last duplicate key wins” logic to select only the last argument. You can compare the results shown by this query:

```
mysql> SELECT
 -> JSON_MERGE_PRESERVE('[1, 2]', '["a", "b", "c"]', '[true, false]') AS Preserve,
 -> JSON_MERGE_PATCH('[1, 2]', '["a", "b", "c"]', '[true, false]') AS Patch\G
***** 1. row *****
Preserve: [1, 2, "a", "b", "c", true, false]
Patch: [true, false]
```

Multiple objects when merged produce a single object. `JSON_MERGE_PRESERVE()` handles multiple objects having the same key by combining all unique values for that key in an array; this array is then used as the value for that key in the result. `JSON_MERGE_PATCH()` discards values for which duplicate keys are found, working from left to right, so that the result contains only the last value for that key. The following query illustrates the difference in the results for the duplicate key `a`:

```
mysql> SELECT
 -> JSON_MERGE_PRESERVE('{ "a": 1, "b": 2 }', '{ "c": 3, "a": 4 }', '{ "c": 5, "d": 3 }') AS Preserve,
 -> JSON_MERGE_PATCH('{ "a": 3, "b": 2 }', '{ "c": 3, "a": 4 }', '{ "c": 5, "d": 3 }') AS Patch\G
***** 1. row *****
Preserve: { "a": [1, 4], "b": 2, "c": [3, 5], "d": 3 }
Patch: { "a": 4, "b": 2, "c": 5, "d": 3 }
```

Nonarray values used in a context that requires an array value are autowrapped: The value is surrounded by `[` and `]` characters to convert it to an array. In the following statement, each argument is autowrapped as an array (`[1]`, `[2]`). These are then merged to produce a single result array; as in the previous two cases, `JSON_MERGE_PRESERVE()` combines values having the same key while `JSON_MERGE_PATCH()` discards values for all duplicate keys except the last, as shown here:

```
mysql> SELECT
 -> JSON_MERGE_PRESERVE('1', '2') AS Preserve,
 -> JSON_MERGE_PATCH('1', '2') AS Patch\G
***** 1. row *****
Preserve: [1, 2]
Patch: 2
```

Array and object values are merged by autowrapping the object as an array and merging the arrays by combining values or by “last duplicate key wins” according to the choice of merging function (`JSON_MERGE_PRESERVE()` or `JSON_MERGE_PATCH()`, respectively), as can be seen in this example:

```
mysql> SELECT
 -> JSON_MERGE_PRESERVE('[10, 20]', '{"a": "x", "b": "y"}') AS Preserve,
 -> JSON_MERGE_PATCH('[10, 20]', '{"a": "x", "b": "y"}') AS Patch\G
***** 1. row *****
Preserve: [10, 20, {"a": "x", "b": "y"}]
Patch: {"a": "x", "b": "y"}
```

## Searching and Modifying JSON Values

A JSON path expression selects a value within a JSON document.

Path expressions are useful with functions that extract parts of or modify a JSON document, to specify where within that document to operate. For example, the following query extracts from a JSON document the value of the member with the `name` key:

```
mysql> SELECT JSON_EXTRACT('{ "id": 14, "name": "Aztalan" }', '$.name');
+-----+
| JSON_EXTRACT('{ "id": 14, "name": "Aztalan" }', '$.name') |
+-----+
| "Aztalan" |
+-----+
```

Path syntax uses a leading `$` character to represent the JSON document under consideration, optionally followed by selectors that indicate successively more specific parts of the document:

- A period followed by a key name names the member in an object with the given key. The key name must be specified within double quotation marks if the name without quotes is not legal within path expressions (for example, if it contains a space).
- `[N]` appended to a `path` that selects an array names the value at position `N` within the array. Array positions are integers beginning with zero. If `path` does not select an array value, `path[0]` evaluates to the same value as `path`:

```
mysql> SELECT JSON_SET('"x"', '$[0]', 'a');
+-----+
| JSON_SET('"x"', '$[0]', 'a') |
+-----+
| "a" |
+-----+
1 row in set (0.00 sec)
```

- `[M to N]` specifies a subset or range of array values starting with the value at position `M`, and ending with the value at position `N`.

`last` is supported as a synonym for the index of the rightmost array element. Relative addressing of array elements is also supported. If `path` does not select an array value, `path[last]` evaluates to the same value as `path`, as shown later in this section (see [Rightmost array element](#)).

- Paths can contain `*` or `**` wildcards:
  - `.[*]` evaluates to the values of all members in a JSON object.
  - `[*]` evaluates to the values of all elements in a JSON array.
  - `prefix**suffix` evaluates to all paths that begin with the named prefix and end with the named suffix.
- A path that does not exist in the document (evaluates to nonexistent data) evaluates to `NULL`.

Let `$` refer to this JSON array with three elements:

```
[3, {"a": [5, 6], "b": 10}, [99, 100]]
```

Then:

- `$.0` evaluates to `3`.
- `$.1` evaluates to `{"a": [5, 6], "b": 10}`.
- `$.2` evaluates to `[99, 100]`.
- `$.3` evaluates to `NULL` (it refers to the fourth array element, which does not exist).

Because `$.1` and `$.2` evaluate to nonscalar values, they can be used as the basis for more-specific path expressions that select nested values. Examples:

- `$.1.a` evaluates to `[5, 6]`.
- `$.1.a[1]` evaluates to `6`.
- `$.1.b` evaluates to `10`.
- `$.2[0]` evaluates to `99`.

As mentioned previously, path components that name keys must be quoted if the unquoted key name is not legal in path expressions. Let `$` refer to this value:

```
{"a fish": "shark", "a bird": "sparrow"}
```

The keys both contain a space and must be quoted:

- `$. "a fish"` evaluates to `shark`.
- `$. "a bird"` evaluates to `sparrow`.

Paths that use wildcards evaluate to an array that can contain multiple values:

```
mysql> SELECT JSON_EXTRACT('{ "a": 1, "b": 2, "c": [3, 4, 5] }', '$.*');
+-----+
| JSON_EXTRACT('{ "a": 1, "b": 2, "c": [3, 4, 5] }', '$.*') |
+-----+
| [1, 2, [3, 4, 5]] |
+-----+
mysql> SELECT JSON_EXTRACT('{ "a": 1, "b": 2, "c": [3, 4, 5] }', '$.c[*]');
```

```
+-----+
| JSON_EXTRACT('{ "a": 1, "b": 2, "c": [3, 4, 5]}', '$.c[*]') |
+-----+
| [3, 4, 5] |
+-----+
```

In the following example, the path `$.**.b` evaluates to multiple paths (`$.a.b` and `$.c.b`) and produces an array of the matching path values:

```
mysql> SELECT JSON_EXTRACT('{ "a": {"b": 1}, "c": {"b": 2}}', '$**.b');
+-----+
| JSON_EXTRACT('{ "a": {"b": 1}, "c": {"b": 2}}', '$**.b') |
+-----+
| [1, 2] |
+-----+
```

**Ranges from JSON arrays.** You can use ranges with the `to` keyword to specify subsets of JSON arrays. For example, `$.1 to 3` includes the second, third, and fourth elements of an array, as shown here:

```
mysql> SELECT JSON_EXTRACT('[1, 2, 3, 4, 5]', '$[1 to 3]');
+-----+
| JSON_EXTRACT('[1, 2, 3, 4, 5]', '$[1 to 3]') |
+-----+
| [2, 3, 4] |
+-----+
1 row in set (0.00 sec)
```

The syntax is `M to N`, where `M` and `N` are, respectively, the first and last indexes of a range of elements from a JSON array. `N` must be greater than `M`; `M` must be greater than or equal to 0. Array elements are indexed beginning with 0.

You can use ranges in contexts where wildcards are supported.

**Rightmost array element.** The `last` keyword is supported as a synonym for the index of the last element in an array. Expressions of the form `last - N` can be used for relative addressing, and within range definitions, like this:

```
mysql> SELECT JSON_EXTRACT('[1, 2, 3, 4, 5]', '$[last-3 to last-1]');
+-----+
| JSON_EXTRACT('[1, 2, 3, 4, 5]', '$[last-3 to last-1]') |
+-----+
| [2, 3, 4] |
+-----+
1 row in set (0.01 sec)
```

If the path is evaluated against a value that is not an array, the result of the evaluation is the same as if the value had been wrapped in a single-element array:

```
mysql> SELECT JSON_REPLACE('"Sakila"', '$[last]', 10);
+-----+
| JSON_REPLACE('"Sakila"', '$[last]', 10) |
+-----+
| 10 |
+-----+
1 row in set (0.00 sec)
```

You can use `column->path` with a JSON column identifier and JSON path expression as a synonym for `JSON_EXTRACT(column, path)`. See [Section 14.17.3, “Functions That Search JSON Values”](#), for more information. See also [Indexing a Generated Column to Provide a JSON Column Index](#).

Some functions take an existing JSON document, modify it in some way, and return the resulting modified document. Path expressions indicate where in the document to make changes. For example, the

`JSON_SET()`, `JSON_INSERT()`, and `JSON_REPLACE()` functions each take a JSON document, plus one or more path-value pairs that describe where to modify the document and the values to use. The functions differ in how they handle existing and nonexisting values within the document.

Consider this document:

```
mysql> SET @j = '["a", {"b": [true, false]}, [10, 20]]';
```

`JSON_SET()` replaces values for paths that exist and adds values for paths that do not exist:

```
mysql> SELECT JSON_SET(@j, '$[1].b[0]', 1, '$[2][2]', 2);
+-----+
| JSON_SET(@j, '$[1].b[0]', 1, '$[2][2]', 2) |
+-----+
| ["a", {"b": [1, false]}, [10, 20, 2]] |
+-----+
```

In this case, the path `[$[1].b[0]` selects an existing value (`true`), which is replaced with the value following the path argument (`1`). The path `[$[2][2]` does not exist, so the corresponding value (`2`) is added to the value selected by `[$[2]`.

`JSON_INSERT()` adds new values but does not replace existing values:

```
mysql> SELECT JSON_INSERT(@j, '$[1].b[0]', 1, '$[2][2]', 2);
+-----+
| JSON_INSERT(@j, '$[1].b[0]', 1, '$[2][2]', 2) |
+-----+
| ["a", {"b": [true, false]}, [10, 20, 2]] |
+-----+
```

`JSON_REPLACE()` replaces existing values and ignores new values:

```
mysql> SELECT JSON_REPLACE(@j, '$[1].b[0]', 1, '$[2][2]', 2);
+-----+
| JSON_REPLACE(@j, '$[1].b[0]', 1, '$[2][2]', 2) |
+-----+
| ["a", {"b": [1, false]}, [10, 20]] |
+-----+
```

The path-value pairs are evaluated left to right. The document produced by evaluating one pair becomes the new value against which the next pair is evaluated.

`JSON_REMOVE()` takes a JSON document and one or more paths that specify values to be removed from the document. The return value is the original document minus the values selected by paths that exist within the document:

```
mysql> SELECT JSON_REMOVE(@j, '$[2]', '$[1].b[1]', '$[1].b[1]');
+-----+
| JSON_REMOVE(@j, '$[2]', '$[1].b[1]', '$[1].b[1]') |
+-----+
| ["a", {"b": [true]}] |
+-----+
```

The paths have these effects:

- `[$[2]` matches `[10, 20]` and removes it.
- The first instance of `[$[1].b[1]` matches `false` in the `b` element and removes it.
- The second instance of `[$[1].b[1]` matches nothing: That element has already been removed, the path no longer exists, and has no effect.

## JSON Path Syntax

Many of the JSON functions supported by MySQL and described elsewhere in this Manual (see [Section 14.17, “JSON Functions”](#)) require a path expression in order to identify a specific element in a JSON document. A path consists of the path's scope followed by one or more path legs. For paths used in MySQL JSON functions, the scope is always the document being searched or otherwise operated on, represented by a leading `$` character. Path legs are separated by period characters (`.`). Cells in arrays are represented by `[N]`, where `N` is a non-negative integer. Names of keys must be double-quoted strings or valid ECMAScript identifiers (see [Identifier Names and Identifiers](#), in the *ECMAScript Language Specification*). Path expressions, like JSON text, should be encoded using the `ascii`, `utf8mb3`, or `utf8mb4` character set. Other character encodings are implicitly coerced to `utf8mb4`. The complete syntax is shown here:

```
pathExpression:
 scope[(pathLeg)*]

pathLeg:
 member | arrayLocation | doubleAsterisk

member:
 period (keyName | asterisk)

arrayLocation:
 leftBracket (nonNegativeInteger | asterisk) rightBracket

keyName:
 ESIdentifier | doubleQuotedString

doubleAsterisk:
 ' ** '

period:
 '.'

asterisk:
 '*'

leftBracket:
 '['

rightBracket:
 ']'
```

As noted previously, in MySQL, the scope of the path is always the document being operated on, represented as `$`. You can use `'$'` as a synonym for the document in JSON path expressions.

### Note

Some implementations support column references for scopes of JSON paths; MySQL 9.1 does not support these.

The wildcard `*` and `**` tokens are used as follows:

- `.*` represents the values of all members in the object.
- `[*]` represents the values of all cells in the array.
- `[prefix]**suffix` represents all paths beginning with `prefix` and ending with `suffix`. `prefix` is optional, while `suffix` is required; in other words, a path may not end in `**`.

In addition, a path may not contain the sequence `***`.

For path syntax examples, see the descriptions of the various JSON functions that take paths as arguments, such as `JSON_CONTAINS_PATH()`, `JSON_SET()`, and `JSON_REPLACE()`. For examples which include the use of the `*` and `**` wildcards, see the description of the `JSON_SEARCH()` function.

MySQL also supports range notation for subsets of JSON arrays using the `to` keyword (such as `$$[2 to 10]`), as well as the `last` keyword as a synonym for the rightmost element of an array. See [Searching and Modifying JSON Values](#), for more information and examples.

## Comparison and Ordering of JSON Values

JSON values can be compared using the `=`, `<`, `<=`, `>`, `>=`, `<>`, `!=`, and `<=>` operators.

The following comparison operators and functions are not yet supported with JSON values:

- `BETWEEN`
- `IN()`
- `GREATEST()`
- `LEAST()`

A workaround for the comparison operators and functions just listed is to cast JSON values to a native MySQL numeric or string data type so they have a consistent non-JSON scalar type.

Comparison of JSON values takes place at two levels. The first level of comparison is based on the JSON types of the compared values. If the types differ, the comparison result is determined solely by which type has higher precedence. If the two values have the same JSON type, a second level of comparison occurs using type-specific rules.

The following list shows the precedences of JSON types, from highest precedence to the lowest. (The type names are those returned by the `JSON_TYPE()` function.) Types shown together on a line have the same precedence. Any value having a JSON type listed earlier in the list compares greater than any value having a JSON type listed later in the list.

```
BLOB
BIT
OPAQUE
DATETIME
TIME
DATE
BOOLEAN
ARRAY
OBJECT
STRING
INTEGER, DOUBLE
NULL
```

For JSON values of the same precedence, the comparison rules are type specific:

- `BLOB`

The first `N` bytes of the two values are compared, where `N` is the number of bytes in the shorter value. If the first `N` bytes of the two values are identical, the shorter value is ordered before the longer value.

- `BIT`

Same rules as for `BLOB`.

- `OPAQUE`

Same rules as for [BLOB](#). [OPAQUE](#) values are values that are not classified as one of the other types.

- [DATETIME](#)

A value that represents an earlier point in time is ordered before a value that represents a later point in time. If two values originally come from the MySQL [DATETIME](#) and [TIMESTAMP](#) types, respectively, they are equal if they represent the same point in time.

- [TIME](#)

The smaller of two time values is ordered before the larger one.

- [DATE](#)

The earlier date is ordered before the more recent date.

- [ARRAY](#)

Two JSON arrays are equal if they have the same length and values in corresponding positions in the arrays are equal.

If the arrays are not equal, their order is determined by the elements in the first position where there is a difference. The array with the smaller value in that position is ordered first. If all values of the shorter array are equal to the corresponding values in the longer array, the shorter array is ordered first.

Example:

```
[] < ["a"] < ["ab"] < ["ab", "cd", "ef"] < ["ab", "ef"]
```

- [BOOLEAN](#)

The JSON false literal is less than the JSON true literal.

- [OBJECT](#)

Two JSON objects are equal if they have the same set of keys, and each key has the same value in both objects.

Example:

```
{ "a": 1, "b": 2 } = { "b": 2, "a": 1 }
```

The order of two objects that are not equal is unspecified but deterministic.

- [STRING](#)

Strings are ordered lexically on the first *N* bytes of the [utf8mb4](#) representation of the two strings being compared, where *N* is the length of the shorter string. If the first *N* bytes of the two strings are identical, the shorter string is considered smaller than the longer string.

Example:

```
"a" < "ab" < "b" < "bc"
```

This ordering is equivalent to the ordering of SQL strings with collation [utf8mb4\\_bin](#). Because [utf8mb4\\_bin](#) is a binary collation, comparison of JSON values is case-sensitive:

```
"A" < "a"
```

- [INTEGER](#), [DOUBLE](#)

JSON values can contain exact-value numbers and approximate-value numbers. For a general discussion of these types of numbers, see [Section 11.1.2, “Numeric Literals”](#).

The rules for comparing native MySQL numeric types are discussed in [Section 14.3, “Type Conversion in Expression Evaluation”](#), but the rules for comparing numbers within JSON values differ somewhat:

- In a comparison between two columns that use the native MySQL [INT](#) and [DOUBLE](#) numeric types, respectively, it is known that all comparisons involve an integer and a double, so the integer is converted to double for all rows. That is, exact-value numbers are converted to approximate-value numbers.
- On the other hand, if the query compares two JSON columns containing numbers, it cannot be known in advance whether numbers are integer or double. To provide the most consistent behavior across all rows, MySQL converts approximate-value numbers to exact-value numbers. The resulting ordering is consistent and does not lose precision for the exact-value numbers. For example, given the scalars 9223372036854775805, 9223372036854775806, 9223372036854775807 and 9.223372036854776e18, the order is such as this:

```
9223372036854775805 < 9223372036854775806 < 9223372036854775807
< 9.223372036854776e18 = 9223372036854776000 < 9223372036854776001
```

Were JSON comparisons to use the non-JSON numeric comparison rules, inconsistent ordering could occur. The usual MySQL comparison rules for numbers yield these orderings:

- Integer comparison:

```
9223372036854775805 < 9223372036854775806 < 9223372036854775807
```

(not defined for 9.223372036854776e18)

- Double comparison:

```
9223372036854775805 = 9223372036854775806 = 9223372036854775807 = 9.223372036854776e18
```

For comparison of any JSON value to SQL [NULL](#), the result is [UNKNOWN](#).

For comparison of JSON and non-JSON values, the non-JSON value is converted to JSON according to the rules in the following table, then the values compared as described previously.

## Converting between JSON and non-JSON values

The following table provides a summary of the rules that MySQL follows when casting between JSON values and values of other types:

**Table 13.3 JSON Conversion Rules**

other type	CAST(other type AS JSON)	CAST(JSON AS other type)
JSON	No change	No change
utf8 character type ( <a href="#">utf8mb4</a> , <a href="#">utf8mb3</a> , <a href="#">ascii</a> )	The string is parsed into a JSON value.	The JSON value is serialized into a <a href="#">utf8mb4</a> string.
Other character types	Other character encodings are implicitly converted to <a href="#">utf8mb4</a> and treated as described for this character type.	The JSON value is serialized into a <a href="#">utf8mb4</a> string, then cast to the other character encoding. The result may not be meaningful.

other type	CAST(other type AS JSON)	CAST(JSON AS other type)
<a href="#">NULL</a>	Results in a <a href="#">NULL</a> value of type JSON.	Not applicable.
Geometry types	The geometry value is converted into a JSON document by calling <a href="#">ST_AsGeoJSON()</a> .	Illegal operation. Workaround: Pass the result of <a href="#">CAST(json_val AS CHAR)</a> to <a href="#">ST_GeomFromGeoJSON()</a> .
All other types	Results in a JSON document consisting of a single scalar value.	Succeeds if the JSON document consists of a single scalar value of the target type and that scalar value can be cast to the target type. Otherwise, returns <a href="#">NULL</a> and produces a warning.

[ORDER BY](#) and [GROUP BY](#) for JSON values works according to these principles:

- Ordering of scalar JSON values uses the same rules as in the preceding discussion.
- For ascending sorts, SQL [NULL](#) orders before all JSON values, including the JSON null literal; for descending sorts, SQL [NULL](#) orders after all JSON values, including the JSON null literal.
- Sort keys for JSON values are bound by the value of the [max\\_sort\\_length](#) system variable, so keys that differ only after the first [max\\_sort\\_length](#) bytes compare as equal.
- Sorting of nonscalar values is not currently supported and a warning occurs.

For sorting, it can be beneficial to cast a JSON scalar to some other native MySQL type. For example, if a column named [jdoc](#) contains JSON objects having a member consisting of an [id](#) key and a nonnegative value, use this expression to sort by [id](#) values:

```
ORDER BY CAST(JSON_EXTRACT(jdoc, '$.id') AS UNSIGNED)
```

If there happens to be a generated column defined to use the same expression as in the [ORDER BY](#), the MySQL optimizer recognizes that and considers using the index for the query execution plan. See [Section 10.3.11, “Optimizer Use of Generated Column Indexes”](#).

## Aggregation of JSON Values

For aggregation of JSON values, SQL [NULL](#) values are ignored as for other data types. Non-[NULL](#) values are converted to a numeric type and aggregated, except for [MIN\(\)](#), [MAX\(\)](#), and [GROUP\\_CONCAT\(\)](#). The conversion to number should produce a meaningful result for JSON values that are numeric scalars, although (depending on the values) truncation and loss of precision may occur. Conversion to number of other JSON values may not produce a meaningful result.

## 13.6 Data Type Default Values

Data type specifications can have explicit or implicit default values.

A [DEFAULT value](#) clause in a data type specification explicitly indicates a default value for a column. Examples:

```
CREATE TABLE t1 (
 i INT DEFAULT -1,
 c VARCHAR(10) DEFAULT '',
 price DOUBLE(16,2) DEFAULT 0.00
);
```

`SERIAL DEFAULT VALUE` is a special case. In the definition of an integer column, it is an alias for `NOT NULL AUTO_INCREMENT UNIQUE`.

Some aspects of explicit `DEFAULT` clause handling are version dependent, as described following.

- [Explicit Default Handling](#)
- [Implicit Default Handling](#)

## Explicit Default Handling

The default value specified in a `DEFAULT` clause can be a literal constant or an expression. With one exception, enclose expression default values within parentheses to distinguish them from literal constant default values. Examples:

```
CREATE TABLE t1 (
 -- literal defaults
 i INT DEFAULT 0,
 c VARCHAR(10) DEFAULT '',
 -- expression defaults
 f FLOAT DEFAULT (RAND() * RAND()),
 b BINARY(16) DEFAULT (UUID_TO_BIN(UUID())),
 d DATE DEFAULT (CURRENT_DATE + INTERVAL 1 YEAR),
 p POINT DEFAULT (Point(0,0)),
 j JSON DEFAULT (JSON_ARRAY())
);
```

The exception is that, for `TIMESTAMP` and `DATETIME` columns, you can specify the `CURRENT_TIMESTAMP` function as the default, without enclosing parentheses. See [Section 13.2.5, “Automatic Initialization and Updating for TIMESTAMP and DATETIME”](#).

The `BLOB`, `TEXT`, `GEOMETRY`, and `JSON` data types can be assigned a default value only if the value is written as an expression, even if the expression value is a literal:

- This is permitted (literal default specified as expression):

```
CREATE TABLE t2 (b BLOB DEFAULT ('abc'));
```

- This produces an error (literal default not specified as expression):

```
CREATE TABLE t2 (b BLOB DEFAULT 'abc');
```

Expression default values must adhere to the following rules. An error occurs if an expression contains disallowed constructs.

- Literals, built-in functions (both deterministic and nondeterministic), and operators are permitted.
- Subqueries, parameters, variables, stored functions, and loadable functions are not permitted.
- An expression default value cannot depend on a column that has the `AUTO_INCREMENT` attribute.
- An expression default value for one column can refer to other table columns, with the exception that references to generated columns or columns with expression default values must be to columns that occur earlier in the table definition. That is, expression default values cannot contain forward references to generated columns or columns with expression default values.

The ordering constraint also applies to the use of `ALTER TABLE` to reorder table columns. If the resulting table would have an expression default value that contains a forward reference to a generated column or column with an expression default value, the statement fails.

**Note**

If any component of an expression default value depends on the SQL mode, different results may occur for different uses of the table unless the SQL mode is the same during all uses.

For `CREATE TABLE ... LIKE` and `CREATE TABLE ... SELECT`, the destination table preserves expression default values from the original table.

If an expression default value refers to a nondeterministic function, any statement that causes the expression to be evaluated is unsafe for statement-based replication. This includes statements such as `INSERT` and `UPDATE`. In this situation, if binary logging is disabled, the statement is executed as normal. If binary logging is enabled and `binlog_format` is set to `STATEMENT`, the statement is logged and executed but a warning message is written to the error log, because replicas might diverge. When `binlog_format` is set to `MIXED` or `ROW`, the statement is executed as normal.

When inserting a new row, the default value for a column with an expression default can be inserted either by omitting the column name or by specifying the column as `DEFAULT` (just as for columns with literal defaults):

```
mysql> CREATE TABLE t4 (uid BINARY(16) DEFAULT (UUID_TO_BIN(UUID())));
mysql> INSERT INTO t4 () VALUES();
mysql> INSERT INTO t4 () VALUES(DEFAULT);
mysql> SELECT BIN_TO_UUID(uid) AS uid FROM t4;
+-----+
| uid |
+-----+
| f1109174-94c9-11e8-971d-3bf1095aa633 |
| f110cf9a-94c9-11e8-971d-3bf1095aa633 |
+-----+
```

However, the use of `DEFAULT(col_name)` to specify the default value for a named column is permitted only for columns that have a literal default value, not for columns that have an expression default value.

Not all storage engines permit expression default values. For those that do not, an `ER_UNSUPPORTED_ACTION_ON_DEFAULT_VAL_GENERATED` error occurs.

If a default value evaluates to a data type that differs from the declared column type, implicit coercion to the declared type occurs according to the usual MySQL type-conversion rules. See [Section 14.3, “Type Conversion in Expression Evaluation”](#).

## Implicit Default Handling

If a data type specification includes no explicit `DEFAULT` value, MySQL determines the default value as follows:

If the column can take `NULL` as a value, the column is defined with an explicit `DEFAULT NULL` clause.

If the column cannot take `NULL` as a value, MySQL defines the column with no explicit `DEFAULT` clause.

For data entry into a `NOT NULL` column that has no explicit `DEFAULT` clause, if an `INSERT` or `REPLACE` statement includes no value for the column, or an `UPDATE` statement sets the column to `NULL`, MySQL handles the column according to the SQL mode in effect at the time:

- If strict SQL mode is enabled, an error occurs for transactional tables and the statement is rolled back. For nontransactional tables, an error occurs, but if this happens for the second or subsequent row of a multiple-row statement, the preceding rows are inserted.

- If strict mode is not enabled, MySQL sets the column to the implicit default value for the column data type.

Suppose that a table `t` is defined as follows:

```
CREATE TABLE t (i INT NOT NULL);
```

In this case, `i` has no explicit default, so in strict mode each of the following statements produce an error and no row is inserted. When not using strict mode, only the third statement produces an error; the implicit default is inserted for the first two statements, but the third fails because `DEFAULT(i)` cannot produce a value:

```
INSERT INTO t VALUES();
INSERT INTO t VALUES(DEFAULT);
INSERT INTO t VALUES(DEFAULT(i));
```

See [Section 7.1.11, “Server SQL Modes”](#).

For a given table, the `SHOW CREATE TABLE` statement displays which columns have an explicit `DEFAULT` clause.

Implicit defaults are defined as follows:

- For numeric types, the default is `0`, with the exception that for integer or floating-point types declared with the `AUTO_INCREMENT` attribute, the default is the next value in the sequence.
- For date and time types other than `TIMESTAMP`, the default is the appropriate “zero” value for the type. This is also true for `TIMESTAMP` if the `explicit_defaults_for_timestamp` system variable is enabled (see [Section 7.1.8, “Server System Variables”](#)). Otherwise, for the first `TIMESTAMP` column in a table, the default value is the current date and time. See [Section 13.2, “Date and Time Data Types”](#).
- For string types other than `ENUM`, the default value is the empty string. For `ENUM`, the default is the first enumeration value.

## 13.7 Data Type Storage Requirements

- [InnoDB Table Storage Requirements](#)
- [NDB Table Storage Requirements](#)
- [Numeric Type Storage Requirements](#)
- [Date and Time Type Storage Requirements](#)
- [String Type Storage Requirements](#)
- [Spatial Type Storage Requirements](#)
- [JSON Storage Requirements](#)

The storage requirements for table data on disk depend on several factors. Different storage engines represent data types and store raw data differently. Table data might be compressed, either for a column or an entire row, complicating the calculation of storage requirements for a table or column.

Despite differences in storage layout on disk, the internal MySQL APIs that communicate and exchange information about table rows use a consistent data structure that applies across all storage engines.

This section includes guidelines and information for the storage requirements for each data type supported by MySQL, including the internal format and size for storage engines that use a fixed-size representation for data types. Information is listed by category or storage engine.

The internal representation of a table has a maximum row size of 65,535 bytes, even if the storage engine is capable of supporting larger rows. This figure excludes `BLOB` or `TEXT` columns, which contribute only 9 to 12 bytes toward this size. For `BLOB` and `TEXT` data, the information is stored internally in a different area of memory than the row buffer. Different storage engines handle the allocation and storage of this data in different ways, according to the method they use for handling the corresponding types. For more information, see [Chapter 18, \*Alternative Storage Engines\*](#), and [Section 10.4.7, “Limits on Table Column Count and Row Size”](#).

## InnoDB Table Storage Requirements

See [Section 17.10, “InnoDB Row Formats”](#) for information about storage requirements for InnoDB tables.

## NDB Table Storage Requirements

### Important

NDB tables use *4-byte alignment*; all NDB data storage is done in multiples of 4 bytes. Thus, a column value that would typically take 15 bytes requires 16 bytes in an NDB table. For example, in NDB tables, the `TINYINT`, `SMALLINT`, `MEDIUMINT`, and `INTEGER (INT)` column types each require 4 bytes storage per record due to the alignment factor.

Each `BIT(M)` column takes *M* bits of storage space. Although an individual `BIT` column is *not* 4-byte aligned, NDB reserves 4 bytes (32 bits) per row for the first 1-32 bits needed for `BIT` columns, then another 4 bytes for bits 33-64, and so on.

While a `NULL` itself does not require any storage space, NDB reserves 4 bytes per row if the table definition contains any columns allowing `NULL`, up to 32 `NULL` columns. (If an NDB Cluster table is defined with more than 32 `NULL` columns up to 64 `NULL` columns, then 8 bytes per row are reserved.)

Every table using the NDB storage engine requires a primary key; if you do not define a primary key, a “hidden” primary key is created by NDB. This hidden primary key consumes 31-35 bytes per table record.

You can use the `ndb_size.pl` Perl script to estimate NDB storage requirements. It connects to a current MySQL (not NDB Cluster) database and creates a report on how much space that database would require if it used the NDB storage engine. See [Section 25.5.29, “ndb\\_size.pl — NDBCLUSTER Size Requirement Estimator”](#) for more information.

## Numeric Type Storage Requirements

Data Type	Storage Required
<code>TINYINT</code>	1 byte
<code>SMALLINT</code>	2 bytes
<code>MEDIUMINT</code>	3 bytes
<code>INT</code> , <code>INTEGER</code>	4 bytes
<code>BIGINT</code>	8 bytes
<code>FLOAT(p)</code>	4 bytes if $0 \leq p \leq 24$ , 8 bytes if $25 \leq p \leq 53$
<code>FLOAT</code>	4 bytes
<code>DOUBLE [PRECISION]</code> , <code>REAL</code>	8 bytes
<code>DECIMAL(M,D)</code> , <code>NUMERIC(M,D)</code>	Varies; see following discussion

Data Type	Storage Required
<code>BIT(M)</code>	approximately $(M+7)/8$ bytes

Values for `DECIMAL` (and `NUMERIC`) columns are represented using a binary format that packs nine decimal (base 10) digits into four bytes. Storage for the integer and fractional parts of each value are determined separately. Each multiple of nine digits requires four bytes, and the “leftover” digits require some fraction of four bytes. The storage required for excess digits is given by the following table.

Leftover Digits	Number of Bytes
0	0
1	1
2	1
3	2
4	2
5	3
6	3
7	4
8	4

## Date and Time Type Storage Requirements

For `TIME`, `DATETIME`, and `TIMESTAMP` columns, the storage required for tables created before MySQL 5.6.4 differs from tables created from 5.6.4 on. This is due to a change in 5.6.4 that permits these types to have a fractional part, which requires from 0 to 3 bytes.

Data Type	Storage Required Before MySQL 5.6.4	Storage Required as of MySQL 5.6.4
<code>YEAR</code>	1 byte	1 byte
<code>DATE</code>	3 bytes	3 bytes
<code>TIME</code>	3 bytes	3 bytes + fractional seconds storage
<code>DATETIME</code>	8 bytes	5 bytes + fractional seconds storage
<code>TIMESTAMP</code>	4 bytes	4 bytes + fractional seconds storage

As of MySQL 5.6.4, storage for `YEAR` and `DATE` remains unchanged. However, `TIME`, `DATETIME`, and `TIMESTAMP` are represented differently. `DATETIME` is packed more efficiently, requiring 5 rather than 8 bytes for the nonfractional part, and all three parts have a fractional part that requires from 0 to 3 bytes, depending on the fractional seconds precision of stored values.

Fractional Seconds Precision	Storage Required
0	0 bytes
1, 2	1 byte
3, 4	2 bytes
5, 6	3 bytes

For example, `TIME(0)`, `TIME(2)`, `TIME(4)`, and `TIME(6)` use 3, 4, 5, and 6 bytes, respectively. `TIME` and `TIME(0)` are equivalent and require the same storage.

For details about internal representation of temporal values, see [MySQL Internals: Important Algorithms and Structures](#).

## String Type Storage Requirements

In the following table, *M* represents the declared column length in characters for nonbinary string types and bytes for binary string types. *L* represents the actual length in bytes of a given string value.

Data Type	Storage Required
<code>CHAR(M)</code>	The compact family of InnoDB row formats optimize storage for variable-length character sets. See <a href="#">COMPACT Row Format Storage Characteristics</a> . Otherwise, $M \times w$ bytes, $0 \leq M \leq 255$ , where <i>w</i> is the number of bytes required for the maximum-length character in the character set.
<code>BINARY(M)</code>	<i>M</i> bytes, $0 \leq M \leq 255$
<code>VARCHAR(M)</code> , <code>VARBINARY(M)</code>	<i>L</i> + 1 bytes if column values require 0 – 255 bytes, <i>L</i> + 2 bytes if values may require more than 255 bytes
<code>TINYBLOB</code> , <code>TINYTEXT</code>	<i>L</i> + 1 bytes, where $L < 2^8$
<code>BLOB</code> , <code>TEXT</code>	<i>L</i> + 2 bytes, where $L < 2^{16}$
<code>MEDIUMBLOB</code> , <code>MEDIUMTEXT</code>	<i>L</i> + 3 bytes, where $L < 2^{24}$
<code>LONGBLOB</code> , <code>LONGTEXT</code>	<i>L</i> + 4 bytes, where $L < 2^{32}$
<code>ENUM('value1', 'value2', ...)</code>	1 or 2 bytes, depending on the number of enumeration values (65,535 values maximum)
<code>SET('value1', 'value2', ...)</code>	1, 2, 3, 4, or 8 bytes, depending on the number of set members (64 members maximum)

Variable-length string types are stored using a length prefix plus data. The length prefix requires from one to four bytes depending on the data type, and the value of the prefix is *L* (the byte length of the string). For example, storage for a `MEDIUMTEXT` value requires *L* bytes to store the value plus three bytes to store the length of the value.

To calculate the number of bytes used to store a particular `CHAR`, `VARCHAR`, or `TEXT` column value, you must take into account the character set used for that column and whether the value contains multibyte characters. In particular, when using a UTF-8 Unicode character set, you must keep in mind that not all characters use the same number of bytes. `utf8mb3` and `utf8mb4` character sets can require up to three and four bytes per character, respectively. For a breakdown of the storage used for different categories of `utf8mb3` or `utf8mb4` characters, see [Section 12.9, “Unicode Support”](#).

`VARCHAR`, `VARBINARY`, and the `BLOB` and `TEXT` types are variable-length types. For each, the storage requirements depend on these factors:

- The actual length of the column value
- The column's maximum possible length
- The character set used for the column, because some character sets contain multibyte characters

For example, a `VARCHAR(255)` column can hold a string with a maximum length of 255 characters. Assuming that the column uses the `latin1` character set (one byte per character), the actual storage required is the length of the string (*L*), plus one byte to record the length of the string. For the string `'abcd'`, *L* is 4 and the storage requirement is five bytes. If the same column is instead declared to use the `ucs2` double-byte character set, the storage requirement is 10 bytes: The length of `'abcd'` is eight bytes and the column requires two bytes to store lengths because the maximum length is greater than 255 (up to 510 bytes).

The effective maximum number of *bytes* that can be stored in a `VARCHAR` or `VARBINARY` column is subject to the maximum row size of 65,535 bytes, which is shared among all columns. For a `VARCHAR` column that stores multibyte characters, the effective maximum number of *characters* is less. For example, `utf8mb4` characters can require up to four bytes per character, so a `VARCHAR` column that uses the `utf8mb4` character set can be declared to be a maximum of 16,383 characters. See [Section 10.4.7, “Limits on Table Column Count and Row Size”](#).

`InnoDB` encodes fixed-length fields greater than or equal to 768 bytes in length as variable-length fields, which can be stored off-page. For example, a `CHAR(255)` column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with `utf8mb4`.

The `NDB` storage engine supports variable-width columns. This means that a `VARCHAR` column in an `NDB` Cluster table requires the same amount of storage as would any other storage engine, with the exception that such values are 4-byte aligned. Thus, the string `'abcd'` stored in a `VARCHAR(50)` column using the `latin1` character set requires 8 bytes (rather than 5 bytes for the same column value in a `MyISAM` table).

`TEXT`, `BLOB`, and `JSON` columns are implemented differently in the `NDB` storage engine, wherein each row in the column is made up of two separate parts. One of these is of fixed size (256 bytes for `TEXT` and `BLOB`, 4000 bytes for `JSON`), and is actually stored in the original table. The other consists of any data in excess of 256 bytes, which is stored in a hidden blob parts table. The size of the rows in this second table are determined by the exact type of the column, as shown in the following table:

Type	Blob Part Size
<code>BLOB</code> , <code>TEXT</code>	2000
<code>MEDIUMBLOB</code> , <code>MEDIUMTEXT</code>	4000
<code>LONGBLOB</code> , <code>LONGTEXT</code>	13948
<code>JSON</code>	8100

This means that the size of a `TEXT` column is 256 if *size* ≤ 256 (where *size* represents the size of the row); otherwise, the size is 256 + *size* + (2000 × (*size* − 256) % 2000).

No blob parts are stored separately by `NDB` for `TINYBLOB` or `TINYTEXT` column values.

You can increase the size of an `NDB` blob column's blob part to the maximum of 13948 using `NDB_COLUMN` in a column comment when creating or altering the parent table. `NDB` also supports setting the inline size for a `TEXT`, `BLOB`, or `JSON` column, using `NDB_TABLE` in a column comment. See [NDB\\_COLUMN Options](#), for more information.

The size of an `ENUM` object is determined by the number of different enumeration values. One byte is used for enumerations with up to 255 possible values. Two bytes are used for enumerations having between 256 and 65,535 possible values. See [Section 13.3.6, “The ENUM Type”](#).

The size of a `SET` object is determined by the number of different set members. If the set size is *N*, the object occupies  $(N+7) / 8$  bytes, rounded up to 1, 2, 3, 4, or 8 bytes. A `SET` can have a maximum of 64 members. See [Section 13.3.7, “The SET Type”](#).

## Spatial Type Storage Requirements

MySQL stores geometry values using 4 bytes to indicate the SRID followed by the WKB representation of the value. The `LENGTH()` function returns the space in bytes required for value storage.

For descriptions of WKB and internal storage formats for spatial values, see [Section 13.4.3, “Supported Spatial Data Formats”](#).

## JSON Storage Requirements

In general, the storage requirement for a `JSON` column is approximately the same as for a `LONGBLOB` or `LONGTEXT` column; that is, the space consumed by a JSON document is roughly the same as it would be for the document's string representation stored in a column of one of these types. However, there is an overhead imposed by the binary encoding, including metadata and dictionaries needed for lookup, of the individual values stored in the JSON document. For example, a string stored in a JSON document requires 4 to 10 bytes additional storage, depending on the length of the string and the size of the object or array in which it is stored.

In addition, MySQL imposes a limit on the size of any JSON document stored in a `JSON` column such that it cannot be any larger than the value of `max_allowed_packet`.

## 13.8 Choosing the Right Type for a Column

For optimum storage, you should try to use the most precise type in all cases. For example, if an integer column is used for values in the range from 1 to 99999, `MEDIUMINT UNSIGNED` is the best type. Of the types that represent all the required values, this type uses the least amount of storage.

All basic calculations (+, −, \*, and /) with `DECIMAL` columns are done with precision of 65 decimal (base 10) digits. See [Section 13.1.1, “Numeric Data Type Syntax”](#).

If accuracy is not too important or if speed is the highest priority, the `DOUBLE` type may be good enough. For high precision, you can always convert to a fixed-point type stored in a `BIGINT`. This enables you to do all calculations with 64-bit integers and then convert results back to floating-point values as necessary.

## 13.9 Using Data Types from Other Database Engines

To facilitate the use of code written for SQL implementations from other vendors, MySQL maps data types as shown in the following table. These mappings make it easier to import table definitions from other database systems into MySQL.

Other Vendor Type	MySQL Type
<code>BOOL</code>	<code>TINYINT</code>
<code>BOOLEAN</code>	<code>TINYINT</code>
<code>CHARACTER VARYING(M)</code>	<code>VARCHAR(M)</code>
<code>FIXED</code>	<code>DECIMAL</code>
<code>FLOAT4</code>	<code>FLOAT</code>
<code>FLOAT8</code>	<code>DOUBLE</code>
<code>INT1</code>	<code>TINYINT</code>
<code>INT2</code>	<code>SMALLINT</code>
<code>INT3</code>	<code>MEDIUMINT</code>

Other Vendor Type	MySQL Type
INT4	INT
INT8	BIGINT
LONG VARBINARY	MEDIUMBLOB
LONG VARCHAR	MEDIUMTEXT
LONG	MEDIUMTEXT
MIDDLEINT	MEDIUMINT
NUMERIC	DECIMAL

Data type mapping occurs at table creation time, after which the original type specifications are discarded. If you create a table with types used by other vendors and then issue a `DESCRIBE tbl_name` statement, MySQL reports the table structure using the equivalent MySQL types. For example:

```
mysql> CREATE TABLE t (a BOOL, b FLOAT8, c LONG VARCHAR, d NUMERIC);
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> DESCRIBE t;
```

Field	Type	Null	Key	Default	Extra
a	tinyint(1)	YES		NULL	
b	double	YES		NULL	
c	mediumtext	YES		NULL	
d	decimal(10,0)	YES		NULL	

```
4 rows in set (0.01 sec)
```

---

14.25.5 Precision Math Examples .....	2598

Expressions can be used at several points in [SQL](#) statements, such as in the [ORDER BY](#) or [HAVING](#) clauses of [SELECT](#) statements, in the [WHERE](#) clause of a [SELECT](#), [DELETE](#), or [UPDATE](#) statement, or in [SET](#) statements. Expressions can be written using values from several sources, such as literal values, column values, [NULL](#), variables, built-in functions and operators, loadable functions, and stored functions (a type of stored object).

This chapter describes the built-in functions and operators that are permitted for writing expressions in MySQL. For information about loadable functions and stored functions, see [Section 7.7, “MySQL Server Loadable Functions”](#), and [Section 27.2, “Using Stored Routines”](#). For the rules describing how the server interprets references to different kinds of functions, see [Section 11.2.5, “Function Name Parsing and Resolution”](#).

An expression that contains [NULL](#) always produces a [NULL](#) value unless otherwise indicated in the documentation for a particular function or operator.

#### Note

By default, there must be no whitespace between a function name and the parenthesis following it. This helps the MySQL parser distinguish between function

calls and references to tables or columns that happen to have the same name as a function. However, spaces around function arguments are permitted.

To tell the MySQL server to accept spaces after function names by starting it with the `--sql-mode=IGNORE_SPACE` option. (See [Section 7.1.11, “Server SQL Modes”](#).) Individual client programs can request this behavior by using the `CLIENT_IGNORE_SPACE` option for `mysql_real_connect()`. In either case, all function names become reserved words.

For the sake of brevity, some examples in this chapter display the output from the `mysql` program in abbreviated form. Rather than showing examples in this format:

```
mysql> SELECT MOD(29,9);
+-----+
| mod(29,9) |
+-----+
| 2 |
+-----+
1 rows in set (0.00 sec)
```

This format is used instead:

```
mysql> SELECT MOD(29,9);
-> 2
```

## 14.1 Built-In Function and Operator Reference

The following table lists each built-in (native) function and operator and provides a short description of each one. For a table listing functions that are loadable at runtime, see [Section 14.2, “Loadable Function Reference”](#).

**Table 14.1 Built-In Functions and Operators**

Name	Description	Deprecated
<code>&amp;</code>	Bitwise AND	
<code>&gt;</code>	Greater than operator	
<code>&gt;&gt;</code>	Right shift	
<code>&gt;=</code>	Greater than or equal operator	
<code>&lt;</code>	Less than operator	
<code>&lt;&gt;, !=</code>	Not equal operator	
<code>&lt;&lt;</code>	Left shift	
<code>&lt;=</code>	Less than or equal operator	
<code>&lt;=&gt;</code>	NULL-safe equal to operator	
<code>%, MOD</code>	Modulo operator	
<code>*</code>	Multiplication operator	
<code>+</code>	Addition operator	
<code>-</code>	Minus operator	
<code>-</code>	Change the sign of the argument	
<code>-&gt;</code>	Return value from JSON column after evaluating path; equivalent to <code>JSON_EXTRACT()</code> .	

Name	Description	Deprecated
->>	Return value from JSON column after evaluating path and unquoting the result; equivalent to JSON_UNQUOTE(JSON_EXTRACT()).	
/	Division operator	
:=	Assign a value	
=	Assign a value (as part of a <a href="#">SET</a> statement, or as part of the <a href="#">SET</a> clause in an <a href="#">UPDATE</a> statement)	
=	Equal operator	
^	Bitwise XOR	
ABS ( )	Return the absolute value	
ACOS ( )	Return the arc cosine	
ADDDATE ( )	Add time values (intervals) to a date value	
ADDTIME ( )	Add time	
AES_DECRYPT ( )	Decrypt using AES	
AES_ENCRYPT ( )	Encrypt using AES	
AND, &&	Logical AND	
ANY_VALUE ( )	Suppress ONLY_FULL_GROUP_BY value rejection	
ASCII ( )	Return numeric value of left-most character	
ASIN ( )	Return the arc sine	
asynchronous_connection_failover_add_member	Add group member source server configuration information to a replication channel source list	
asynchronous_connection_failover_add_source	Add source server configuration information server to a replication channel source list	
asynchronous_connection_failover_remove_group	Remove a managed group from a replication channel source list	
asynchronous_connection_failover_remove_source	Remove a source server from a replication channel source list	
asynchronous_connection_failover_reset	Remove all settings relating to group replication asynchronous failover	
ATAN ( )	Return the arc tangent	
ATAN2 ( ), ATAN ( )	Return the arc tangent of the two arguments	
AVG ( )	Return the average value of the argument	

Name	Description	Deprecated
<a href="#">BENCHMARK()</a>	Repeatedly execute an expression	
<a href="#">BETWEEN ... AND ...</a>	Whether a value is within a range of values	
<a href="#">BIN()</a>	Return a string containing binary representation of a number	
<a href="#">BIN_TO_UUID()</a>	Convert binary UUID to string	
<a href="#">BINARY</a>	Cast a string to a binary string	Yes
<a href="#">BIT_AND()</a>	Return bitwise AND	
<a href="#">BIT_COUNT()</a>	Return the number of bits that are set	
<a href="#">BIT_LENGTH()</a>	Return length of argument in bits	
<a href="#">BIT_OR()</a>	Return bitwise OR	
<a href="#">BIT_XOR()</a>	Return bitwise XOR	
<a href="#">CAN_ACCESS_COLUMN()</a>	Internal use only	
<a href="#">CAN_ACCESS_DATABASE()</a>	Internal use only	
<a href="#">CAN_ACCESS_TABLE()</a>	Internal use only	
<a href="#">CAN_ACCESS_USER()</a>	Internal use only	
<a href="#">CAN_ACCESS_VIEW()</a>	Internal use only	
<a href="#">CASE</a>	Case operator	
<a href="#">CAST()</a>	Cast a value as a certain type	
<a href="#">CEIL()</a>	Return the smallest integer value not less than the argument	
<a href="#">CEILING()</a>	Return the smallest integer value not less than the argument	
<a href="#">CHAR()</a>	Return the character for each integer passed	
<a href="#">CHAR_LENGTH()</a>	Return number of characters in argument	
<a href="#">CHARACTER_LENGTH()</a>	Synonym for CHAR_LENGTH()	
<a href="#">CHARSET()</a>	Return the character set of the argument	
<a href="#">COALESCE()</a>	Return the first non-NULL argument	
<a href="#">COERCIBILITY()</a>	Return the collation coercibility value of the string argument	
<a href="#">COLLATION()</a>	Return the collation of the string argument	
<a href="#">COMPRESS()</a>	Return result as a binary string	
<a href="#">CONCAT()</a>	Return concatenated string	
<a href="#">CONCAT_WS()</a>	Return concatenate with separator	

Name	Description	Deprecated
<code>CONNECTION_ID()</code>	Return the connection ID (thread ID) for the connection	
<code>CONV()</code>	Convert numbers between different number bases	
<code>CONVERT()</code>	Cast a value as a certain type	
<code>CONVERT_TZ()</code>	Convert from one time zone to another	
<code>COS()</code>	Return the cosine	
<code>COT()</code>	Return the cotangent	
<code>COUNT()</code>	Return a count of the number of rows returned	
<code>COUNT(DISTINCT)</code>	Return the count of a number of different values	
<code>CRC32()</code>	Compute a cyclic redundancy check value	
<code>CUME_DIST()</code>	Cumulative distribution value	
<code>CURDATE()</code>	Return the current date	
<code>CURRENT_DATE()</code> , <code>CURRENT_DATE</code>	Synonyms for <code>CURDATE()</code>	
<code>CURRENT_ROLE()</code>	Return the current active roles	
<code>CURRENT_TIME()</code> , <code>CURRENT_TIME</code>	Synonyms for <code>CURTIME()</code>	
<code>CURRENT_TIMESTAMP()</code> , <code>CURRENT_TIMESTAMP</code>	Synonyms for <code>NOW()</code>	
<code>CURRENT_USER()</code> , <code>CURRENT_USER</code>	The authenticated user name and host name	
<code>CURTIME()</code>	Return the current time	
<code>DATABASE()</code>	Return the default (current) database name	
<code>DATE()</code>	Extract the date part of a date or datetime expression	
<code>DATE_ADD()</code>	Add time values (intervals) to a date value	
<code>DATE_FORMAT()</code>	Format date as specified	
<code>DATE_SUB()</code>	Subtract a time value (interval) from a date	
<code>DATEDIFF()</code>	Subtract two dates	
<code>DAY()</code>	Synonym for <code>DAYOFMONTH()</code>	
<code>DAYNAME()</code>	Return the name of the weekday	
<code>DAYOFMONTH()</code>	Return the day of the month (0-31)	
<code>DAYOFWEEK()</code>	Return the weekday index of the argument	

Name	Description	Deprecated
<code>DAYOFYEAR()</code>	Return the day of the year (1-366)	
<code>DEFAULT()</code>	Return the default value for a table column	
<code>DEGREES()</code>	Convert radians to degrees	
<code>DENSE_RANK()</code>	Rank of current row within its partition, without gaps	
<code>DISTANCE()</code>	Calculates the distance between two vectors per the specified method	
<code>DIV</code>	Integer division	
<code>ELT()</code>	Return string at index number	
<code>EXISTS()</code>	Whether the result of a query contains any rows	
<code>EXP()</code>	Raise to the power of	
<code>EXPORT_SET()</code>	Return a string such that for every bit set in the value bits, you get an on string and for every unset bit, you get an off string	
<code>EXTRACT()</code>	Extract part of a date	
<code>ExtractValue()</code>	Extract a value from an XML string using XPath notation	
<code>FIELD()</code>	Index (position) of first argument in subsequent arguments	
<code>FIND_IN_SET()</code>	Index (position) of first argument within second argument	
<code>FIRST_VALUE()</code>	Value of argument from first row of window frame	
<code>FLOOR()</code>	Return the largest integer value not greater than the argument	
<code>FORMAT()</code>	Return a number formatted to specified number of decimal places	
<code>FORMAT_BYTES()</code>	Convert byte count to value with units	
<code>FORMAT_PICO_TIME()</code>	Convert time in picoseconds to value with units	
<code>FOUND_ROWS()</code>	For a SELECT with a LIMIT clause, the number of rows that would be returned were there no LIMIT clause	
<code>FROM_BASE64()</code>	Decode base64 encoded string and return result	
<code>FROM_DAYS()</code>	Convert a day number to a date	
<code>FROM_UNIXTIME()</code>	Format Unix timestamp as a date	

Name	Description	Deprecated
<code>GeomCollection()</code>	Construct geometry collection from geometries	
<code>GeometryCollection()</code>	Construct geometry collection from geometries	
<code>GET_DD_COLUMN_PRIVILEGES()</code>	Internal use only	
<code>GET_DD_CREATE_OPTIONS()</code>	Internal use only	
<code>GET_DD_INDEX_SUB_PART_LENGTH()</code>	Internal use only	
<code>GET_FORMAT()</code>	Return a date format string	
<code>GET_LOCK()</code>	Get a named lock	
<code>GREATEST()</code>	Return the largest argument	
<code>GROUP_CONCAT()</code>	Return a concatenated string	
<code>group_replication_disable_member()</code>	Disable member action for event specified	
<code>group_replication_enable_member()</code>	Enable member action for event specified	
<code>group_replication_get_communication_protocol()</code>	Get version of group replication communication protocol currently in use	
<code>group_replication_get_write_concurrency()</code>	Get maximum number of consensus instances currently set for group	
<code>group_replication_reset_members()</code>	Reset all member actions to defaults and configuration version number to 1	
<code>group_replication_set_as_primary()</code>	Make a specific group member the primary	
<code>group_replication_set_communication_protocol()</code>	Set version for group replication communication protocol to use	
<code>group_replication_set_write_concurrency()</code>	Set maximum number of consensus instances that can be executed in parallel	
<code>group_replication_switch_to_multi_primary_mode()</code>	Changes the mode of a group running in single-primary mode to multi-primary mode	
<code>group_replication_switch_to_single_primary_mode()</code>	Changes the mode of a group running in multi-primary mode to single-primary mode	
<code>GROUPING()</code>	Distinguish super-aggregate ROLLUP rows from regular rows	
<code>HEX()</code>	Hexadecimal representation of decimal or string value	
<code>HOURLY()</code>	Extract the hour	
<code>ICU_VERSION()</code>	ICU library version	

Name	Description	Deprecated
<code>IF ( )</code>	If/else construct	
<code>IFNULL ( )</code>	Null if/else construct	
<code>IN ( )</code>	Whether a value is within a set of values	
<code>INET_ATON ( )</code>	Return the numeric value of an IP address	
<code>INET_NTOA ( )</code>	Return the IP address from a numeric value	
<code>INSERT ( )</code>	Insert substring at specified position up to specified number of characters	
<code>INSTR ( )</code>	Return the index of the first occurrence of substring	
<code>INTERNAL_AUTO_INCREMENT ( )</code>	Internal use only	
<code>INTERNAL_AVG_ROW_LENGTH ( )</code>	Internal use only	
<code>INTERNAL_CHECK_TIME ( )</code>	Internal use only	
<code>INTERNAL_CHECKSUM ( )</code>	Internal use only	
<code>INTERNAL_DATA_FREE ( )</code>	Internal use only	
<code>INTERNAL_DATA_LENGTH ( )</code>	Internal use only	
<code>INTERNAL_DD_CHAR_LENGTH ( )</code>	Internal use only	
<code>INTERNAL_GET_COMMENT_OR_ERROR ( )</code>	Internal use only	
<code>INTERNAL_GET_ENABLED_ROLE ( )</code>	Internal use only	
<code>INTERNAL_GET_HOSTNAME ( )</code>	Internal use only	
<code>INTERNAL_GET_USERNAME ( )</code>	Internal use only	
<code>INTERNAL_GET_VIEW_WARNING ( )</code>	Internal use only	
<code>INTERNAL_INDEX_COLUMN_CARDINALITY ( )</code>	Internal use only	
<code>INTERNAL_INDEX_LENGTH ( )</code>	Internal use only	
<code>INTERNAL_IS_ENABLED_ROLE ( )</code>	Internal use only	
<code>INTERNAL_IS_MANDATORY_ROLE ( )</code>	Internal use only	
<code>INTERNAL_KEYS_DISABLED ( )</code>	Internal use only	
<code>INTERNAL_MAX_DATA_LENGTH ( )</code>	Internal use only	
<code>INTERNAL_TABLE_ROWS ( )</code>	Internal use only	
<code>INTERNAL_UPDATE_TIME ( )</code>	Internal use only	
<code>INTERVAL ( )</code>	Return the index of the argument that is less than the first argument	
<code>IS</code>	Test a value against a boolean	
<code>IS_FREE_LOCK ( )</code>	Whether the named lock is free	
<code>IS NOT</code>	Test a value against a boolean	
<code>IS NOT NULL</code>	NOT NULL value test	
<code>IS NULL</code>	NULL value test	

Name	Description	Deprecated
<a href="#">IS_USED_LOCK()</a>	Whether the named lock is in use; return connection identifier if true	
<a href="#">IS_UUID()</a>	Whether argument is a valid UUID	
<a href="#">ISNULL()</a>	Test whether the argument is NULL	
<a href="#">JSON_ARRAY()</a>	Create JSON array	
<a href="#">JSON_ARRAY_APPEND()</a>	Append data to JSON document	
<a href="#">JSON_ARRAY_INSERT()</a>	Insert into JSON array	
<a href="#">JSON_ARRAYAGG()</a>	Return result set as a single JSON array	
<a href="#">JSON_CONTAINS()</a>	Whether JSON document contains specific object at path	
<a href="#">JSON_CONTAINS_PATH()</a>	Whether JSON document contains any data at path	
<a href="#">JSON_DEPTH()</a>	Maximum depth of JSON document	
<a href="#">JSON_EXTRACT()</a>	Return data from JSON document	
<a href="#">JSON_INSERT()</a>	Insert data into JSON document	
<a href="#">JSON_KEYS()</a>	Array of keys from JSON document	
<a href="#">JSON_LENGTH()</a>	Number of elements in JSON document	
<a href="#">JSON_MERGE()</a>	Merge JSON documents, preserving duplicate keys. Deprecated synonym for <a href="#">JSON_MERGE_PRESERVE()</a>	Yes
<a href="#">JSON_MERGE_PATCH()</a>	Merge JSON documents, replacing values of duplicate keys	
<a href="#">JSON_MERGE_PRESERVE()</a>	Merge JSON documents, preserving duplicate keys	
<a href="#">JSON_OBJECT()</a>	Create JSON object	
<a href="#">JSON_OBJECTAGG()</a>	Return result set as a single JSON object	
<a href="#">JSON_OVERLAPS()</a>	Compares two JSON documents, returns TRUE (1) if these have any key-value pairs or array elements in common, otherwise FALSE (0)	
<a href="#">JSON_PRETTY()</a>	Print a JSON document in human-readable format	
<a href="#">JSON_QUOTE()</a>	Quote JSON document	
<a href="#">JSON_REMOVE()</a>	Remove data from JSON document	

Name	Description	Deprecated
<code>JSON_REPLACE()</code>	Replace values in JSON document	
<code>JSON_SCHEMA_VALID()</code>	Validate JSON document against JSON schema; returns TRUE/1 if document validates against schema, or FALSE/0 if it does not	
<code>JSON_SCHEMA_VALIDATION_REPORT()</code>	Validate JSON document against JSON schema; returns report in JSON format on outcome on validation including success or failure and reasons for failure	
<code>JSON_SEARCH()</code>	Path to value within JSON document	
<code>JSON_SET()</code>	Insert data into JSON document	
<code>JSON_STORAGE_FREE()</code>	Freed space within binary representation of JSON column value following partial update	
<code>JSON_STORAGE_SIZE()</code>	Space used for storage of binary representation of a JSON document	
<code>JSON_TABLE()</code>	Return data from a JSON expression as a relational table	
<code>JSON_TYPE()</code>	Type of JSON value	
<code>JSON_UNQUOTE()</code>	Unquote JSON value	
<code>JSON_VALID()</code>	Whether JSON value is valid	
<code>JSON_VALUE()</code>	Extract value from JSON document at location pointed to by path provided; return this value as VARCHAR(512) or specified type	
<code>LAG()</code>	Value of argument from row lagging current row within partition	
<code>LAST_DAY</code>	Return the last day of the month for the argument	
<code>LAST_INSERT_ID()</code>	Value of the AUTOINCREMENT column for the last INSERT	
<code>LAST_VALUE()</code>	Value of argument from last row of window frame	
<code>LCASE()</code>	Synonym for LOWER()	
<code>LEAD()</code>	Value of argument from row leading current row within partition	
<code>LEAST()</code>	Return the smallest argument	
<code>LEFT()</code>	Return the leftmost number of characters as specified	

Name	Description	Deprecated
<code>LENGTH()</code>	Return the length of a string in bytes	
<code>LIKE</code>	Simple pattern matching	
<code>LineString()</code>	Construct LineString from Point values	
<code>LN()</code>	Return the natural logarithm of the argument	
<code>LOAD_FILE()</code>	Load the named file	
<code>LOCALTIME(), LOCALTIME</code>	Synonym for NOW()	
<code>LOCALTIMESTAMP, LOCALTIMESTAMP()</code>	Synonym for NOW()	
<code>LOCATE()</code>	Return the position of the first occurrence of substring	
<code>LOG()</code>	Return the natural logarithm of the first argument	
<code>LOG10()</code>	Return the base-10 logarithm of the argument	
<code>LOG2()</code>	Return the base-2 logarithm of the argument	
<code>LOWER()</code>	Return the argument in lowercase	
<code>LPAD()</code>	Return the string argument, left-padded with the specified string	
<code>LTRIM()</code>	Remove leading spaces	
<code>MAKE_SET()</code>	Return a set of comma-separated strings that have the corresponding bit in bits set	
<code>MAKEDATE()</code>	Create a date from the year and day of year	
<code>MAKETIME()</code>	Create time from hour, minute, second	
<code>MASTER_POS_WAIT()</code>	Block until the replica has read and applied all updates up to the specified position	Yes
<code>MATCH()</code>	Perform full-text search	
<code>MAX()</code>	Return the maximum value	
<code>MBRContains()</code>	Whether MBR of one geometry contains MBR of another	
<code>MBRCoveredBy()</code>	Whether one MBR is covered by another	
<code>MBRCovers()</code>	Whether one MBR covers another	
<code>MBRDisjoint()</code>	Whether MBRs of two geometries are disjoint	

Name	Description	Deprecated
<code>MBREquals()</code>	Whether MBRs of two geometries are equal	
<code>MBRIntersects()</code>	Whether MBRs of two geometries intersect	
<code>MBROverlaps()</code>	Whether MBRs of two geometries overlap	
<code>MBRTouches()</code>	Whether MBRs of two geometries touch	
<code>MBRWithin()</code>	Whether MBR of one geometry is within MBR of another	
<code>MD5()</code>	Calculate MD5 checksum	
<code>MEMBER OF()</code>	Returns true (1) if first operand matches any element of JSON array passed as second operand, otherwise returns false (0)	
<code>MICROSECOND()</code>	Return the microseconds from argument	
<code>MID()</code>	Return a substring starting from the specified position	
<code>MIN()</code>	Return the minimum value	
<code>MINUTE()</code>	Return the minute from the argument	
<code>MOD()</code>	Return the remainder	
<code>MONTH()</code>	Return the month from the date passed	
<code>MONTHNAME()</code>	Return the name of the month	
<code>MultiLineString()</code>	Construct MultiLineString from LineString values	
<code>MultiPoint()</code>	Construct MultiPoint from Point values	
<code>MultiPolygon()</code>	Construct MultiPolygon from Polygon values	
<code>NAME_CONST()</code>	Cause the column to have the given name	
<code>NOT, !</code>	Negates value	
<code>NOT BETWEEN ... AND ...</code>	Whether a value is not within a range of values	
<code>NOT EXISTS()</code>	Whether the result of a query contains no rows	
<code>NOT IN()</code>	Whether a value is not within a set of values	
<code>NOT LIKE</code>	Negation of simple pattern matching	

Name	Description	Deprecated
<code>NOT REGEXP</code>	Negation of REGEXP	
<code>NOW()</code>	Return the current date and time	
<code>NTH_VALUE()</code>	Value of argument from N-th row of window frame	
<code>NTILE()</code>	Bucket number of current row within its partition.	
<code>NULLIF()</code>	Return NULL if <code>expr1 = expr2</code>	
<code>OCT()</code>	Return a string containing octal representation of a number	
<code>OCTET_LENGTH()</code>	Synonym for <code>LENGTH()</code>	
<code>OR,   </code>	Logical OR	
<code>ORD()</code>	Return character code for leftmost character of the argument	
<code>PERCENT_RANK()</code>	Percentage rank value	
<code>PERIOD_ADD()</code>	Add a period to a year-month	
<code>PERIOD_DIFF()</code>	Return the number of months between periods	
<code>PI()</code>	Return the value of pi	
<code>Point()</code>	Construct Point from coordinates	
<code>Polygon()</code>	Construct Polygon from LineString arguments	
<code>POSITION()</code>	Synonym for <code>LOCATE()</code>	
<code>POW()</code>	Return the argument raised to the specified power	
<code>POWER()</code>	Return the argument raised to the specified power	
<code>PS_CURRENT_THREAD_ID()</code>	Performance Schema thread ID for current thread	
<code>PS_THREAD_ID()</code>	Performance Schema thread ID for given thread	
<code>QUARTER()</code>	Return the quarter from a date argument	
<code>QUOTE()</code>	Escape the argument for use in an SQL statement	
<code>RADIANS()</code>	Return argument converted to radians	
<code>RAND()</code>	Return a random floating-point value	
<code>RANDOM_BYTES()</code>	Return a random byte vector	
<code>RANK()</code>	Rank of current row within its partition, with gaps	

Name	Description	Deprecated
<a href="#">REGEXP</a>	Whether string matches regular expression	
<a href="#">REGEXP_INSTR()</a>	Starting index of substring matching regular expression	
<a href="#">REGEXP_LIKE()</a>	Whether string matches regular expression	
<a href="#">REGEXP_REPLACE()</a>	Replace substrings matching regular expression	
<a href="#">REGEXP_SUBSTR()</a>	Return substring matching regular expression	
<a href="#">RELEASE_ALL_LOCKS()</a>	Release all current named locks	
<a href="#">RELEASE_LOCK()</a>	Release the named lock	
<a href="#">REPEAT()</a>	Repeat a string the specified number of times	
<a href="#">REPLACE()</a>	Replace occurrences of a specified string	
<a href="#">REVERSE()</a>	Reverse the characters in a string	
<a href="#">RIGHT()</a>	Return the specified rightmost number of characters	
<a href="#">RLIKE</a>	Whether string matches regular expression	
<a href="#">ROLES_GRAPHML()</a>	Return a GraphML document representing memory role subgraphs	
<a href="#">ROUND()</a>	Round the argument	
<a href="#">ROW_COUNT()</a>	The number of rows updated	
<a href="#">ROW_NUMBER()</a>	Number of current row within its partition	
<a href="#">RPAD()</a>	Append string the specified number of times	
<a href="#">RTRIM()</a>	Remove trailing spaces	
<a href="#">SCHEMA()</a>	Synonym for DATABASE()	
<a href="#">SEC_TO_TIME()</a>	Converts seconds to 'hh:mm:ss' format	
<a href="#">SECOND()</a>	Return the second (0-59)	
<a href="#">SESSION_USER()</a>	Synonym for USER()	
<a href="#">SHA1()</a> , <a href="#">SHA()</a>	Calculate an SHA-1 160-bit checksum	
<a href="#">SHA2()</a>	Calculate an SHA-2 checksum	
<a href="#">SIGN()</a>	Return the sign of the argument	
<a href="#">SIN()</a>	Return the sine of the argument	
<a href="#">SLEEP()</a>	Sleep for a number of seconds	

Name	Description	Deprecated
<code>SOUNDEX()</code>	Return a soundex string	
<code>SOUNDS LIKE</code>	Compare sounds	
<code>SOURCE_POS_WAIT()</code>	Block until the replica has read and applied all updates up to the specified position	
<code>SPACE()</code>	Return a string of the specified number of spaces	
<code>SQRT()</code>	Return the square root of the argument	
<code>ST_Area()</code>	Return Polygon or MultiPolygon area	
<code>ST_AsBinary()</code> , <code>ST_AsWKB()</code>	Convert from internal geometry format to WKB	
<code>ST_AsGeoJSON()</code>	Generate GeoJSON object from geometry	
<code>ST_AsText()</code> , <code>ST_AsWKT()</code>	Convert from internal geometry format to WKT	
<code>ST_Buffer()</code>	Return geometry of points within given distance from geometry	
<code>ST_Buffer_Strategy()</code>	Produce strategy option for <code>ST_Buffer()</code>	
<code>ST_Centroid()</code>	Return centroid as a point	
<code>ST_Collect()</code>	Aggregate spatial values into collection	
<code>ST_Contains()</code>	Whether one geometry contains another	
<code>ST_ConvexHull()</code>	Return convex hull of geometry	
<code>ST_Crosses()</code>	Whether one geometry crosses another	
<code>ST_Difference()</code>	Return point set difference of two geometries	
<code>ST_Dimension()</code>	Dimension of geometry	
<code>ST_Disjoint()</code>	Whether one geometry is disjoint from another	
<code>ST_Distance()</code>	The distance of one geometry from another	
<code>ST_Distance_Sphere()</code>	Minimum distance on earth between two geometries	
<code>ST_EndPoint()</code>	End Point of LineString	
<code>ST_Envelope()</code>	Return MBR of geometry	
<code>ST_Equals()</code>	Whether one geometry is equal to another	
<code>ST_ExteriorRing()</code>	Return exterior ring of Polygon	

Name	Description	Deprecated
<code>ST_FrechetDistance()</code>	The discrete Fréchet distance of one geometry from another	
<code>ST_GeoHash()</code>	Produce a geohash value	
<code>ST_GeomCollFromText()</code> , <code>ST_GeometryCollectionFromText()</code> , <code>ST_GeomCollFromTxt()</code>	Return geometry collection from WKT	
<code>ST_GeomCollFromWKB()</code> , <code>ST_GeometryCollectionFromWKB()</code>	Return geometry collection from WKB	
<code>ST_GeometryN()</code>	Return N-th geometry from geometry collection	
<code>ST_GeometryType()</code>	Return name of geometry type	
<code>ST_GeomFromGeoJSON()</code>	Generate geometry from GeoJSON object	
<code>ST_GeomFromText()</code> , <code>ST_GeometryFromText()</code>	Return geometry from WKT	
<code>ST_GeomFromWKB()</code> , <code>ST_GeometryFromWKB()</code>	Return geometry from WKB	
<code>ST_HausdorffDistance()</code>	The discrete Hausdorff distance of one geometry from another	
<code>ST_InteriorRingN()</code>	Return N-th interior ring of Polygon	
<code>ST_Intersection()</code>	Return point set intersection of two geometries	
<code>ST_Intersects()</code>	Whether one geometry intersects another	
<code>ST_IsClosed()</code>	Whether a geometry is closed and simple	
<code>ST_IsEmpty()</code>	Whether a geometry is empty	
<code>ST_IsSimple()</code>	Whether a geometry is simple	
<code>ST_IsValid()</code>	Whether a geometry is valid	
<code>ST_LatFromGeoHash()</code>	Return latitude from geohash value	
<code>ST_Latitude()</code>	Return latitude of Point	
<code>ST_Length()</code>	Return length of LineString	
<code>ST_LineFromText()</code> , <code>ST_LineStringFromText()</code>	Construct LineString from WKT	
<code>ST_LineFromWKB()</code> , <code>ST_LineStringFromWKB()</code>	Construct LineString from WKB	
<code>ST_LineInterpolatePoint()</code>	The point a given percentage along a LineString	
<code>ST_LineInterpolatePoints()</code>	The points a given percentage along a LineString	

Name	Description	Deprecated
<code>ST_LongFromGeoHash()</code>	Return longitude from geohash value	
<code>ST_Longitude()</code>	Return longitude of Point	
<code>ST_MakeEnvelope()</code>	Rectangle around two points	
<code>ST_MLineFromText()</code> , <code>ST_MultiLineStringFromText()</code>	Construct MultiLineString from WKT	
<code>ST_MLineFromWKB()</code> , <code>ST_MultiLineStringFromWKB()</code>	Construct MultiLineString from WKB	
<code>ST_MPointFromText()</code> , <code>ST_MultiPointFromText()</code>	Construct MultiPoint from WKT	
<code>ST_MPointFromWKB()</code> , <code>ST_MultiPointFromWKB()</code>	Construct MultiPoint from WKB	
<code>ST_MPolyFromText()</code> , <code>ST_MultiPolygonFromText()</code>	Construct MultiPolygon from WKT	
<code>ST_MPolyFromWKB()</code> , <code>ST_MultiPolygonFromWKB()</code>	Construct MultiPolygon from WKB	
<code>ST_NumGeometries()</code>	Return number of geometries in geometry collection	
<code>ST_NumInteriorRing()</code> , <code>ST_NumInteriorRings()</code>	Return number of interior rings in Polygon	
<code>ST_NumPoints()</code>	Return number of points in LineString	
<code>ST_Overlaps()</code>	Whether one geometry overlaps another	
<code>ST_PointAtDistance()</code>	The point a given distance along a LineString	
<code>ST_PointFromGeoHash()</code>	Convert geohash value to POINT value	
<code>ST_PointFromText()</code>	Construct Point from WKT	
<code>ST_PointFromWKB()</code>	Construct Point from WKB	
<code>ST_PointN()</code>	Return N-th point from LineString	
<code>ST_PolyFromText()</code> , <code>ST_PolygonFromText()</code>	Construct Polygon from WKT	
<code>ST_PolyFromWKB()</code> , <code>ST_PolygonFromWKB()</code>	Construct Polygon from WKB	
<code>ST_Simplify()</code>	Return simplified geometry	
<code>ST_SRID()</code>	Return spatial reference system ID for geometry	
<code>ST_StartPoint()</code>	Start Point of LineString	
<code>ST_SwapXY()</code>	Return argument with X/Y coordinates swapped	
<code>ST_SymDifference()</code>	Return point set symmetric difference of two geometries	

Name	Description	Deprecated
<code>ST_Touches()</code>	Whether one geometry touches another	
<code>ST_Transform()</code>	Transform coordinates of geometry	
<code>ST_Union()</code>	Return point set union of two geometries	
<code>ST_Validate()</code>	Return validated geometry	
<code>ST_Within()</code>	Whether one geometry is within another	
<code>ST_X()</code>	Return X coordinate of Point	
<code>ST_Y()</code>	Return Y coordinate of Point	
<code>STATEMENT_DIGEST()</code>	Compute statement digest hash value	
<code>STATEMENT_DIGEST_TEXT()</code>	Compute normalized statement digest	
<code>STD()</code>	Return the population standard deviation	
<code>STDDEV()</code>	Return the population standard deviation	
<code>STDDEV_POP()</code>	Return the population standard deviation	
<code>STDDEV_SAMP()</code>	Return the sample standard deviation	
<code>STR_TO_DATE()</code>	Convert a string to a date	
<code>STRCMP()</code>	Compare two strings	
<code>STRING_TO_VECTOR()</code>	Get the binary value of the VECTOR column represented by a conforming string	
<code>SUBDATE()</code>	Synonym for DATE_SUB() when invoked with three arguments	
<code>SUBSTR()</code>	Return the substring as specified	
<code>SUBSTRING()</code>	Return the substring as specified	
<code>SUBSTRING_INDEX()</code>	Return a substring from a string before the specified number of occurrences of the delimiter	
<code>SUBTIME()</code>	Subtract times	
<code>SUM()</code>	Return the sum	
<code>SYSDATE()</code>	Return the time at which the function executes	
<code>SYSTEM_USER()</code>	Synonym for USER()	
<code>TAN()</code>	Return the tangent of the argument	

Name	Description	Deprecated
<code>TIME()</code>	Extract the time portion of the expression passed	
<code>TIME_FORMAT()</code>	Format as time	
<code>TIME_TO_SEC()</code>	Return the argument converted to seconds	
<code>TIMEDIFF()</code>	Subtract time	
<code>TIMESTAMP()</code>	With a single argument, this function returns the date or datetime expression; with two arguments, the sum of the arguments	
<code>TIMESTAMPADD()</code>	Add an interval to a datetime expression	
<code>TIMESTAMPDIFF()</code>	Return the difference of two datetime expressions, using the units specified	
<code>TO_BASE64()</code>	Return the argument converted to a base-64 string	
<code>TO_DAYS()</code>	Return the date argument converted to days	
<code>TO_SECONDS()</code>	Return the date or datetime argument converted to seconds since Year 0	
<code>TRIM()</code>	Remove leading and trailing spaces	
<code>TRUNCATE()</code>	Truncate to specified number of decimal places	
<code>UCASE()</code>	Synonym for UPPER()	
<code>UNCOMPRESS()</code>	Uncompress a string compressed	
<code>UNCOMPRESSED_LENGTH()</code>	Return the length of a string before compression	
<code>UNHEX()</code>	Return a string containing hex representation of a number	
<code>UNIX_TIMESTAMP()</code>	Return a Unix timestamp	
<code>UpdateXML()</code>	Return replaced XML fragment	
<code>UPPER()</code>	Convert to uppercase	
<code>USER()</code>	The user name and host name provided by the client	
<code>UTC_DATE()</code>	Return the current UTC date	
<code>UTC_TIME()</code>	Return the current UTC time	
<code>UTC_TIMESTAMP()</code>	Return the current UTC date and time	

Name	Description	Deprecated
<code>UUID()</code>	Return a Universal Unique Identifier (UUID)	
<code>UUID_SHORT()</code>	Return an integer-valued universal identifier	
<code>UUID_TO_BIN()</code>	Convert string UUID to binary	
<code>VALIDATE_PASSWORD_STRENGTH</code>	Determine strength of password	
<code>VALUES()</code>	Define the values to be used during an INSERT	
<code>VAR_POP()</code>	Return the population standard variance	
<code>VAR_SAMP()</code>	Return the sample variance	
<code>VARIANCE()</code>	Return the population standard variance	
<code>VECTOR_DIM()</code>	Get the length of a vector (that is, the number of entries it contains)	
<code>VECTOR_TO_STRING()</code>	Get the string representation of a VECTOR column, given its value as a binary string	
<code>VERSION()</code>	Return a string that indicates the MySQL server version	
<code>WAIT_FOR_EXECUTED_GTID_SET</code>	Wait until the given GTIDs have executed on the replica.	
<code>WEEK()</code>	Return the week number	
<code>WEEKDAY()</code>	Return the weekday index	
<code>WEEKOFYEAR()</code>	Return the calendar week of the date (1-53)	
<code>WEIGHT_STRING()</code>	Return the weight string for a string	
<code>XOR</code>	Logical XOR	
<code>YEAR()</code>	Return the year	
<code>YEARWEEK()</code>	Return the year and week	
<code> </code>	Bitwise OR	
<code>~</code>	Bitwise inversion	

## 14.2 Loadable Function Reference

The following table lists each function that is loadable at runtime and provides a short description of each one. For a table listing built-in functions and operators, see [Section 14.1, “Built-In Function and Operator Reference”](#)

For general information about loadable functions, see [Section 7.7, “MySQL Server Loadable Functions”](#).

**Table 14.2 Loadable Functions**

Name	Description	Deprecated
<code>asymmetric_decrypt()</code>	Decrypt ciphertext using private or public key	
<code>asymmetric_derive()</code>	Derive symmetric key from asymmetric keys	
<code>asymmetric_encrypt()</code>	Encrypt cleartext using private or public key	
<code>asymmetric_sign()</code>	Generate signature from digest	
<code>asymmetric_verify()</code>	Verify that signature matches digest	
<code>asynchronous_connection_fa</code>	Add a replication source server in a managed group to the source list	
<code>asynchronous_connection_fa</code>	Add a replication source server to the source list	
<code>asynchronous_connection_fa</code>	Remove managed group of replication source servers from the source list	
<code>asynchronous_connection_fa</code>	Remove a replication source server from the source list	
<code>audit_api_message_emit_udf</code>	Add message event to audit log	
<code>audit_log_encryption_password</code>	Fetch audit log encryption password	
<code>audit_log_encryption_password</code>	Set audit log encryption password	
<code>audit_log_filter_flush()</code>	Flush audit log filter tables	
<code>audit_log_filter_remove_fi</code>	Remove audit log filter	
<code>audit_log_filter_remove_us</code>	Unassign audit log filter from user	
<code>audit_log_filter_set_fi</code>	Define audit log filter	
<code>audit_log_filter_set_user</code>	Assign audit log filter to user	
<code>audit_log_read()</code>	Return audit log records	
<code>audit_log_read_bookmark()</code>	Bookmark for most recent audit log event	
<code>audit_log_rotate()</code>	Rotate audit log file	
<code>create_asymmetric_priv_key</code>	Create private key	
<code>create_asymmetric_pub_key</code>	Create public key	
<code>create_dh_parameters()</code>	Generate shared DH secret	
<code>create_digest()</code>	Generate digest from string	
<code>firewall_group_delist()</code>	Remove account from firewall group profile	
<code>firewall_group_enlist()</code>	Add account to firewall group profile	

Name	Description	Deprecated
<code>flush_rewrite_rules()</code>	Load <code>rewrite_rules</code> table into Rewriter cache	
<code>gen_blacklist()</code>	Perform dictionary term replacement	Yes
<code>gen_blocklist()</code>	Perform dictionary term replacement	
<code>gen_blocklist()</code>	Perform dictionary term replacement	
<code>gen_dictionary()</code>	Return random term from dictionary	
<code>gen_dictionary_drop()</code>	Remove dictionary from registry	
<code>gen_dictionary_load()</code>	Load dictionary into registry	
<code>gen_dictionary()</code>	Return random term from dictionary	
<code>gen_range()</code>	Generate random number within range	
<code>gen_range()</code>	Generate random number within range	
<code>gen_rnd_canada_sin()</code>	Generate random Canada Social Insurance Number	
<code>gen_rnd_email()</code>	Generate random email address	
<code>gen_rnd_email()</code>	Generate random email address	
<code>gen_rnd_iban()</code>	Generate random International Bank Account Number	
<code>gen_rnd_pan()</code>	Generate random payment card Primary Account Number	
<code>gen_rnd_pan()</code>	Generate random payment card Primary Account Number	
<code>gen_rnd_ssn()</code>	Generate random US Social Security Number	
<code>gen_rnd_ssn()</code>	Generate random US Social Security Number	
<code>gen_rnd_uk_nin()</code>	Generate random United Kingdom National Insurance Number	
<code>gen_rnd_us_phone()</code>	Generate random US phone number	
<code>gen_rnd_us_phone()</code>	Generate random US phone number	
<code>gen_rnd_uuid()</code>	Generate random Universally Unique Identifier	
<code>group_replication_disable_member()</code>	Enable a member action so that the member does not take it in the specified situation	

Name	Description	Deprecated
<code>group_replication_enable_member()</code>	Enable a member action for the member to take in the specified situation	
<code>group_replication_get_communicator_group_id()</code>	Return Group Replication protocol version	
<code>group_replication_get_write_instances()</code>	Return maximum number of consensus instances executable in parallel	
<code>group_replication_reset_member_actions()</code>	Reset the member actions configuration to the default settings	
<code>group_replication_set_as_primary()</code>	Assign group member as new primary	
<code>group_replication_set_communicator_group_id()</code>	Set Group Replication protocol version	
<code>group_replication_set_write_instances()</code>	Set maximum number of consensus instances executable in parallel	
<code>group_replication_switch_to_multi_primary_mode()</code>	Change group from single-primary to multi-primary mode	
<code>group_replication_switch_to_single_primary_mode()</code>	Change group from multi-primary to single-primary mode	
<code>keyring_aws_rotate_cmk()</code>	Rotate AWS customer master key	
<code>keyring_aws_rotate_keys()</code>	Rotate keys in keyring_aws storage file	
<code>keyring_hashicorp_update_config()</code>	Cause runtime keyring_hashicorp reconfiguration	
<code>keyring_key_fetch()</code>	Fetch keyring key value	
<code>keyring_key_generate()</code>	Generate random keyring key	
<code>keyring_key_length_fetch()</code>	Return keyring key length	
<code>keyring_key_remove()</code>	Remove keyring key	
<code>keyring_key_store()</code>	Store key in keyring	
<code>keyring_key_type_fetch()</code>	Return keyring key type	
<code>load_rewrite_rules()</code>	Rewriter plugin helper routine	
<code>mask_canada_sin()</code>	Mask Canada Social Insurance Number	
<code>mask_iban()</code>	Mask International Bank Account Number	
<code>mask_inner()</code>	Mask interior part of string	
<code>mask_inner()</code>	Mask interior part of string	
<code>mask_outer()</code>	Mask left and right parts of string	
<code>mask_outer()</code>	Mask left and right parts of string	

Name	Description	Deprecated
<code>mask_pan()</code>	Mask payment card Primary Account Number part of string	
<code>mask_pan()</code>	Mask payment card Primary Account Number part of string	
<code>mask_pan_relaxed()</code>	Mask payment card Primary Account Number part of string	
<code>mask_pan_relaxed()</code>	Mask payment card Primary Account Number part of string	
<code>mask_ssn()</code>	Mask US Social Security Number	
<code>mask_ssn()</code>	Mask US Social Security Number	
<code>mask_uk_nin()</code>	Mask United Kingdom National Insurance Number	
<code>mask_uuid()</code>	Mask Universally Unique Identifier part of string	
<code>masking_dictionaries_flush()</code>	Cause masking_dictionaries cache to be reloaded from table	
<code>masking_dictionary_remove()</code>	Remove dictionary from the database table	
<code>masking_dictionary_term_add()</code>	Add new term to the dictionary	
<code>masking_dictionary_term_remove()</code>	Remove existing term from the dictionary	
<code>mle_session_reset()</code>	Clean up all MLE-related state information	
<code>mle_session_state()</code>	Display state and other information about MLE stored program that was most recently executed	
<code>mle_set_session_state()</code>	Determine rules for converting integers from MySQL types to JavaScript types	
<code>mysql_firewall_flush_status()</code>	Reset firewall status variables	
<code>mysql_query_attribute_string()</code>	Fetch query attribute value	
<code>normalize_statement()</code>	Normalize SQL statement to digest form	
<code>option_tracker_option_register()</code>	Register an option with the Option Tracker	
<code>option_tracker_option_unregister()</code>	Deregister an option from the Option Tracker	
<code>option_tracker_usage_get()</code>	Get usage data for an option registered with the Option Tracker	
<code>option_tracker_usage_set()</code>	Set usage data for an option registered with the Option Tracker	
<code>read_firewall_group_allowlist()</code>	Update firewall group profile recorded-statement cache	

Name	Description	Deprecated
<code>read_firewall_groups()</code>	Update firewall group profile cache	
<code>read_firewall_users()</code>	Update firewall account profile cache	Yes
<code>read_firewall_whitelist()</code>	Update firewall account profile recorded-statement cache	Yes
<code>service_get_read_locks()</code>	Acquire locking service shared locks	
<code>service_get_write_locks()</code>	Acquire locking service exclusive locks	
<code>service_release_locks()</code>	Release locking service locks	
<code>set_firewall_group_mode()</code>	Establish firewall group profile operational mode	
<code>set_firewall_mode()</code>	Establish firewall account profile operational mode	Yes
<code>version_tokens_delete()</code>	Delete tokens from version tokens list	
<code>version_tokens_edit()</code>	Modify version tokens list	
<code>version_tokens_lock_exclusive()</code>	Acquire exclusive locks on version tokens	
<code>version_tokens_lock_shared()</code>	Acquire shared locks on version tokens	
<code>version_tokens_set()</code>	Set version tokens list	
<code>version_tokens_show()</code>	Return version tokens list	
<code>version_tokens_unlock()</code>	Release version tokens locks	

## 14.3 Type Conversion in Expression Evaluation

When an operator is used with operands of different types, type conversion occurs to make the operands compatible. Some conversions occur implicitly. For example, MySQL automatically converts strings to numbers as necessary, and vice versa.

```
mysql> SELECT 1+'1';
-> 2
mysql> SELECT CONCAT(2,' test');
-> '2 test'
```

It is also possible to convert a number to a string explicitly using the `CAST()` function. Conversion occurs implicitly with the `CONCAT()` function because it expects string arguments.

```
mysql> SELECT 38.8, CAST(38.8 AS CHAR);
-> 38.8, '38.8'
mysql> SELECT 38.8, CONCAT(38.8);
-> 38.8, '38.8'
```

See later in this section for information about the character set of implicit number-to-string conversions, and for modified rules that apply to `CREATE TABLE ... SELECT` statements.

The following rules describe how conversion occurs for comparison operations:

- If one or both arguments are `NULL`, the result of the comparison is `NULL`, except for the `NULL`-safe `<=>` equality comparison operator. For `NULL <=> NULL`, the result is true. No conversion is needed.
- If both arguments in a comparison operation are strings, they are compared as strings.
- If both arguments are integers, they are compared as integers.
- Hexadecimal values are treated as binary strings if not compared to a number.
- If one of the arguments is a `TIMESTAMP` or `DATETIME` column and the other argument is a constant, the constant is converted to a timestamp before the comparison is performed. This is done to be more ODBC-friendly. This is not done for the arguments to `IN()`. To be safe, always use complete datetime, date, or time strings when doing comparisons. For example, to achieve best results when using `BETWEEN` with date or time values, use `CAST()` to explicitly convert the values to the desired data type.

A single-row subquery from a table or tables is not considered a constant. For example, if a subquery returns an integer to be compared to a `DATETIME` value, the comparison is done as two integers. The integer is not converted to a temporal value. To compare the operands as `DATETIME` values, use `CAST()` to explicitly convert the subquery value to `DATETIME`.

- If one of the arguments is a decimal value, comparison depends on the other argument. The arguments are compared as decimal values if the other argument is a decimal or integer value, or as floating-point values if the other argument is a floating-point value.
- In all other cases, the arguments are compared as floating-point (double-precision) numbers. For example, a comparison of string and numeric operands takes place as a comparison of floating-point numbers.

For information about conversion of values from one temporal type to another, see [Section 13.2.8, “Conversion Between Date and Time Types”](#).

Comparison of JSON values takes place at two levels. The first level of comparison is based on the JSON types of the compared values. If the types differ, the comparison result is determined solely by which type has higher precedence. If the two values have the same JSON type, a second level of comparison occurs using type-specific rules. For comparison of JSON and non-JSON values, the non-JSON value is converted to JSON and the values compared as JSON values. For details, see [Comparison and Ordering of JSON Values](#).

The following examples illustrate conversion of strings to numbers for comparison operations:

```
mysql> SELECT 1 > '6x';
-> 0
mysql> SELECT 7 > '6x';
-> 1
mysql> SELECT 0 > 'x6';
-> 0
mysql> SELECT 0 = 'x6';
-> 1
```

For comparisons of a string column with a number, MySQL cannot use an index on the column to look up the value quickly. If `str_col` is an indexed string column, the index cannot be used when performing the lookup in the following statement:

```
SELECT * FROM tbl_name WHERE str_col=1;
```

The reason for this is that there are many different strings that may convert to the value `1`, such as `'1'`, `'1'`, or `'1a'`.

Another issue can arise when comparing a string column with integer 0. Consider table `t1` created and populated as shown here:

```
mysql> CREATE TABLE t1 (
-> c1 INT NOT NULL AUTO_INCREMENT,
-> c2 INT DEFAULT NULL,
-> c3 VARCHAR(25) DEFAULT NULL,
-> PRIMARY KEY (c1)
->);
Query OK, 0 rows affected (0.03 sec)

mysql> INSERT INTO t1 VALUES ROW(1, 52, 'grape'), ROW(2, 139, 'apple'),
-> ROW(3, 37, 'peach'), ROW(4, 221, 'watermelon'),
-> ROW(5, 83, 'pear');
Query OK, 5 rows affected (0.01 sec)
Records: 5 Duplicates: 0 Warnings: 0
```

Observe the result when selecting from this table and comparing `c3`, which is a `VARCHAR` column, with integer 0:

```
mysql> SELECT * FROM t1 WHERE c3 = 0;
+-----+-----+-----+
| c1 | c2 | c3 |
+-----+-----+-----+
| 1 | 52 | grape |
| 2 | 139 | apple |
| 3 | 37 | peach |
| 4 | 221 | watermelon |
| 5 | 83 | pear |
+-----+-----+-----+
5 rows in set, 5 warnings (0.00 sec)
```

*This occurs even when using strict SQL mode.* To prevent this from happening, quote the value, as shown here:

```
mysql> SELECT * FROM t1 WHERE c3 = '0';
Empty set (0.00 sec)
```

This does *not* occur when `SELECT` is part of a data definition statement such as `CREATE TABLE ... SELECT`; in strict mode, the statement fails due to the invalid comparison:

```
mysql> CREATE TABLE t2 SELECT * FROM t1 WHERE c3 = 0;
ERROR 1292 (22007): Truncated incorrect DOUBLE value: 'grape'
```

When the 0 is quoted, the statement succeeds, but the table created contains no rows because there were none matching '0', as shown here:

```
mysql> CREATE TABLE t2 SELECT * FROM t1 WHERE c3 = '0';
Query OK, 0 rows affected (0.03 sec)
Records: 0 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM t2;
Empty set (0.00 sec)
```

This is a known issue, which is due to the fact that strict mode is not applied when processing `SELECT`. See also [Strict SQL Mode](#).

Comparisons between floating-point numbers and large integer values are approximate because the integer is converted to double-precision floating point before comparison, which is not capable of representing all 64-bit integers exactly. For example, the integer value  $2^{53} + 1$  is not representable as a float, and is rounded to  $2^{53}$  or  $2^{53} + 2$  before a float comparison, depending on the platform.

To illustrate, only the first of the following comparisons compares equal values, but both comparisons return true (1):

```
mysql> SELECT '9223372036854775807' = 9223372036854775807;
-> 1
mysql> SELECT '9223372036854775807' = 9223372036854775806;
-> 1
```

When conversions from string to floating-point and from integer to floating-point occur, they do not necessarily occur the same way. The integer may be converted to floating-point by the CPU, whereas the string is converted digit by digit in an operation that involves floating-point multiplications. Also, results can be affected by factors such as computer architecture or the compiler version or optimization level. One way to avoid such problems is to use `CAST()` so that a value is not converted implicitly to a float-point number:

```
mysql> SELECT CAST('9223372036854775807' AS UNSIGNED) = 9223372036854775806;
-> 0
```

For more information about floating-point comparisons, see [Section B.3.4.8, “Problems with Floating-Point Values”](#).

The server includes `dtoa`, a conversion library that provides the basis for improved conversion between string or `DECIMAL` values and approximate-value (`FLOAT/DOUBLE`) numbers:

- Consistent conversion results across platforms, which eliminates, for example, Unix versus Windows conversion differences.
- Accurate representation of values in cases where results previously did not provide sufficient precision, such as for values close to IEEE limits.
- Conversion of numbers to string format with the best possible precision. The precision of `dtoa` is always the same or better than that of the standard C library functions.

Because the conversions produced by this library differ in some cases from non-`dtoa` results, the potential exists for incompatibilities in applications that rely on previous results. For example, applications that depend on a specific exact result from previous conversions might need adjustment to accommodate additional precision.

The `dtoa` library provides conversions with the following properties. *D* represents a value with a `DECIMAL` or string representation, and *F* represents a floating-point number in native binary (IEEE) format.

- *F* -> *D* conversion is done with the best possible precision, returning *D* as the shortest string that yields *F* when read back in and rounded to the nearest value in native binary format as specified by IEEE.
- *D* -> *F* conversion is done such that *F* is the nearest native binary number to the input decimal string *D*.

These properties imply that *F* -> *D* -> *F* conversions are lossless unless *F* is `-inf`, `+inf`, or `NaN`. The latter values are not supported because the SQL standard defines them as invalid values for `FLOAT` or `DOUBLE`.

For *D* -> *F* -> *D* conversions, a sufficient condition for losslessness is that *D* uses 15 or fewer digits of precision, is not a denormal value, `-inf`, `+inf`, or `NaN`. In some cases, the conversion is lossless even if *D* has more than 15 digits of precision, but this is not always the case.

Implicit conversion of a numeric or temporal value to string produces a value that has a character set and collation determined by the `character_set_connection` and `collation_connection` system variables. (These variables commonly are set with `SET NAMES`. For information about connection character sets, see [Section 12.4, “Connection Character Sets and Collations”](#).)

This means that such a conversion results in a character (nonbinary) string (a `CHAR`, `VARCHAR`, or `LONGTEXT` value), except in the case that the connection character set is set to `binary`. In that case, the conversion result is a binary string (a `BINARY`, `VARBINARY`, or `LONGBLOB` value).

For integer expressions, the preceding remarks about expression *evaluation* apply somewhat differently for expression *assignment*; for example, in a statement such as this:

```
CREATE TABLE t SELECT integer_expr;
```

```
CREATE TABLE t SELECT 00000000000000000000;
```

```
CREATE TABLE t SELECT 000000000000000000000000;
```

[illegible]

Name	Description	Deprecated
&	Bitwise AND	
>	Greater than operator	
>>	Right shift	
>=	Greater than or equal operator	
<	Less than operator	
<>, !=	Not equal operator	
<<	Left shift	
<=	Less than or equal operator	
<=>	NULL-safe equal to operator	
%, MOD	Modulo operator	
*	Multiplication operator	
+	Addition operator	
-	Minus operator	
-	Change the sign of the argument	
->	Return value from JSON column after evaluating path; equivalent to JSON_EXTRACT().	
->>	Return value from JSON column after evaluating path and unquoting the result; equivalent to JSON_UNQUOTE(JSON_EXTRACT()).	
/	Division operator	
:=	Assign a value	
=	Assign a value (as part of a <a href="#">SET</a> statement, or as part of the <a href="#">SET</a> clause in an <a href="#">UPDATE</a> statement)	
=	Equal operator	
^	Bitwise XOR	
AND, &&	Logical AND	
BETWEEN ... AND ...	Whether a value is within a range of values	

Name	Description	Deprecated
<code>BINARY</code>	Cast a string to a binary string	Yes
<code>CASE</code>	Case operator	
<code>DIV</code>	Integer division	
<code>EXISTS()</code>	Whether the result of a query contains any rows	
<code>IN()</code>	Whether a value is within a set of values	
<code>IS</code>	Test a value against a boolean	
<code>IS NOT</code>	Test a value against a boolean	
<code>IS NOT NULL</code>	NOT NULL value test	
<code>IS NULL</code>	NULL value test	
<code>LIKE</code>	Simple pattern matching	
<code>MEMBER OF()</code>	Returns true (1) if first operand matches any element of JSON array passed as second operand, otherwise returns false (0)	
<code>NOT, !</code>	Negates value	
<code>NOT BETWEEN ... AND ...</code>	Whether a value is not within a range of values	
<code>NOT EXISTS()</code>	Whether the result of a query contains no rows	
<code>NOT IN()</code>	Whether a value is not within a set of values	
<code>NOT LIKE</code>	Negation of simple pattern matching	
<code>NOT REGEXP</code>	Negation of REGEXP	
<code>OR,   </code>	Logical OR	
<code>REGEXP</code>	Whether string matches regular expression	
<code>RLIKE</code>	Whether string matches regular expression	
<code>SOUNDS LIKE</code>	Compare sounds	
<code>XOR</code>	Logical XOR	
<code> </code>	Bitwise OR	
<code>~</code>	Bitwise inversion	

### 14.4.1 Operator Precedence

Operator precedences are shown in the following list, from highest precedence to the lowest. Operators that are shown together on a line have the same precedence.

```

INTERVAL
BINARY, COLLATE
!
- (unary minus), ~ (unary bit inversion)

```

```

^
*, /, DIV, %, MOD
-, +
<<, >>
&
|
= (comparison), <=>, >=, >, <=, <, <>, !=, IS, LIKE, REGEXP, IN, MEMBER OF
BETWEEN, CASE, WHEN, THEN, ELSE
NOT
AND, &&
XOR
OR, ||
= (assignment), :=

```

The precedence of `=` depends on whether it is used as a comparison operator (`=`) or as an assignment operator (`:=`). When used as a comparison operator, it has the same precedence as `<=>`, `>=`, `>`, `<=`, `<`, `<>`, `!=`, `IS`, `LIKE`, `REGEXP`, and `IN()`. When used as an assignment operator, it has the same precedence as `:=`. [Section 15.7.6.1, “SET Syntax for Variable Assignment”](#), and [Section 11.4, “User-Defined Variables”](#), explain how MySQL determines which interpretation of `=` should apply.

For operators that occur at the same precedence level within an expression, evaluation proceeds left to right, with the exception that assignments evaluate right to left.

The precedence and meaning of some operators depends on the SQL mode:

- By default, `||` is a logical `OR` operator. With `PIPES_AS_CONCAT` enabled, `||` is string concatenation, with a precedence between `^` and the unary operators.
- By default, `!` has a higher precedence than `NOT`. With `HIGH_NOT_PRECEDENCE` enabled, `!` and `NOT` have the same precedence.

See [Section 7.1.11, “Server SQL Modes”](#).

The precedence of operators determines the order of evaluation of terms in an expression. To override this order and group terms explicitly, use parentheses. For example:

```

mysql> SELECT 1+2*3;
 -> 7
mysql> SELECT (1+2)*3;
 -> 9

```

## 14.4.2 Comparison Functions and Operators

Table 14.4 Comparison Operators

Name	Description
<code>&gt;</code>	Greater than operator
<code>&gt;=</code>	Greater than or equal operator
<code>&lt;</code>	Less than operator
<code>&lt;&gt;</code> , <code>!=</code>	Not equal operator
<code>&lt;=</code>	Less than or equal operator
<code>&lt;=&gt;</code>	NULL-safe equal to operator
<code>=</code>	Equal operator
<code>BETWEEN ... AND ...</code>	Whether a value is within a range of values
<code>COALESCE()</code>	Return the first non-NULL argument
<code>EXISTS()</code>	Whether the result of a query contains any rows

Name	Description
<code>GREATEST()</code>	Return the largest argument
<code>IN()</code>	Whether a value is within a set of values
<code>INTERVAL()</code>	Return the index of the argument that is less than the first argument
<code>IS</code>	Test a value against a boolean
<code>IS NOT</code>	Test a value against a boolean
<code>IS NOT NULL</code>	NOT NULL value test
<code>IS NULL</code>	NULL value test
<code>ISNULL()</code>	Test whether the argument is NULL
<code>LEAST()</code>	Return the smallest argument
<code>LIKE</code>	Simple pattern matching
<code>NOT BETWEEN ... AND ...</code>	Whether a value is not within a range of values
<code>NOT EXISTS()</code>	Whether the result of a query contains no rows
<code>NOT IN()</code>	Whether a value is not within a set of values
<code>NOT LIKE</code>	Negation of simple pattern matching
<code>STRCMP()</code>	Compare two strings

Comparison operations result in a value of 1 (`TRUE`), 0 (`FALSE`), or `NULL`. These operations work for both numbers and strings. Strings are automatically converted to numbers and numbers to strings as necessary.

The following relational comparison operators can be used to compare not only scalar operands, but row operands:

```
= > < >= <= <> !=
```

The descriptions for those operators later in this section detail how they work with row operands. For additional examples of row comparisons in the context of row subqueries, see [Section 15.2.15.5, “Row Subqueries”](#).

Some of the functions in this section return values other than 1 (`TRUE`), 0 (`FALSE`), or `NULL`. `LEAST()` and `GREATEST()` are examples of such functions; [Section 14.3, “Type Conversion in Expression Evaluation”](#), describes the rules for comparison operations performed by these and similar functions for determining their return values.

#### Note

In previous versions of MySQL, when evaluating an expression containing `LEAST()` or `GREATEST()`, the server attempted to guess the context in which the function was used, and to coerce the function's arguments to the data type of the expression as a whole. For example, the arguments to `LEAST("11", "45", "2")` are evaluated and sorted as strings, so that this expression returns "11".

The function is executed using the arguments as provided, performing data type conversions to one or more of the arguments if and only if they are not all of the same type. Any type coercion mandated by an expression that makes use of the return value is now performed following function execution. This means that `LEAST("11", "45", "2") + 0` evaluates to "11" + 0 and thus to integer 11.

To convert a value to a specific type for comparison purposes, you can use the `CAST()` function. String values can be converted to a different character set using `CONVERT()`. See [Section 14.10, “Cast Functions and Operators”](#).

By default, string comparisons are not case-sensitive and use the current character set. The default is `utf8mb4`.

- `=`

Equal:

```
mysql> SELECT 1 = 0;
-> 0
mysql> SELECT '0' = 0;
-> 1
mysql> SELECT '0.0' = 0;
-> 1
mysql> SELECT '0.01' = 0;
-> 0
mysql> SELECT '.01' = 0.01;
-> 1
```

For row comparisons, `(a, b) = (x, y)` is equivalent to:

```
(a = x) AND (b = y)
```

- `<=>`

**NULL-safe equal.** This operator performs an equality comparison like the `=` operator, but returns `1` rather than `NULL` if both operands are `NULL`, and `0` rather than `NULL` if one operand is `NULL`.

The `<=>` operator is equivalent to the standard SQL `IS NOT DISTINCT FROM` operator.

```
mysql> SELECT 1 <=> 1, NULL <=> NULL, 1 <=> NULL;
-> 1, 1, 0
mysql> SELECT 1 = 1, NULL = NULL, 1 = NULL;
-> 1, NULL, NULL
```

For row comparisons, `(a, b) <=> (x, y)` is equivalent to:

```
(a <=> x) AND (b <=> y)
```

- `<>`, `!=`

Not equal:

```
mysql> SELECT '.01' <> '0.01';
-> 1
mysql> SELECT .01 <> '0.01';
-> 0
mysql> SELECT 'zapp' <> 'zappp';
-> 1
```

For row comparisons, `(a, b) <> (x, y)` and `(a, b) != (x, y)` are equivalent to:

```
(a <> x) OR (b <> y)
```

- `<=`

Less than or equal:

```
mysql> SELECT 0.1 <= 2;
-> 1
```

For row comparisons,  $(a, b) \leq (x, y)$  is equivalent to:

```
(a < x) OR ((a = x) AND (b <= y))
```

- **<**

Less than:

```
mysql> SELECT 2 < 2;
-> 0
```

For row comparisons,  $(a, b) < (x, y)$  is equivalent to:

```
(a < x) OR ((a = x) AND (b < y))
```

- **>=**

Greater than or equal:

```
mysql> SELECT 2 >= 2;
-> 1
```

For row comparisons,  $(a, b) \geq (x, y)$  is equivalent to:

```
(a > x) OR ((a = x) AND (b >= y))
```

- **>**

Greater than:

```
mysql> SELECT 2 > 2;
-> 0
```

For row comparisons,  $(a, b) > (x, y)$  is equivalent to:

```
(a > x) OR ((a = x) AND (b > y))
```

- ***expr* BETWEEN *min* AND *max***

If *expr* is greater than or equal to *min* and *expr* is less than or equal to *max*, **BETWEEN** returns 1, otherwise it returns 0. This is equivalent to the expression  $(min \leq expr \text{ AND } expr \leq max)$  if all the arguments are of the same type. Otherwise type conversion takes place according to the rules described in [Section 14.3, “Type Conversion in Expression Evaluation”](#), but applied to all the three arguments.

```
mysql> SELECT 2 BETWEEN 1 AND 3, 2 BETWEEN 3 AND 1;
-> 1, 0
mysql> SELECT 1 BETWEEN 2 AND 3;
-> 0
mysql> SELECT 'b' BETWEEN 'a' AND 'c';
-> 1
mysql> SELECT 2 BETWEEN 2 AND '3';
-> 1
mysql> SELECT 2 BETWEEN 2 AND 'x-3';
-> 0
```

For best results when using **BETWEEN** with date or time values, use **CAST()** to explicitly convert the values to the desired data type. Examples: If you compare a **DATETIME** to two **DATE** values, convert the **DATE** values to **DATETIME** values. If you use a string constant such as '2001-1-1' in a comparison to a **DATE**, cast the string to a **DATE**.

- `expr NOT BETWEEN min AND max`

This is the same as `NOT (expr BETWEEN min AND max)`.

- `COALESCE(value,...)`

Returns the first non-`NULL` value in the list, or `NULL` if there are no non-`NULL` values.

The return type of `COALESCE()` is the aggregated type of the argument types.

```
mysql> SELECT COALESCE(NULL,1);
-> 1
mysql> SELECT COALESCE(NULL,NULL,NULL);
-> NULL
```

- `EXISTS(query)`

Whether the result of a query contains any rows.

```
CREATE TABLE t (col VARCHAR(3));
INSERT INTO t VALUES ('aaa', 'bbb', 'ccc', 'eee');

SELECT EXISTS (SELECT * FROM t WHERE col LIKE 'c%');
-> 1

SELECT EXISTS (SELECT * FROM t WHERE col LIKE 'd%');
-> 0
```

- `NOT EXISTS(query)`

Whether the result of a query contains no rows:

```
SELECT NOT EXISTS (SELECT * FROM t WHERE col LIKE 'c%');
-> 0

SELECT NOT EXISTS (SELECT * FROM t WHERE col LIKE 'd%');
-> 1
```

- `GREATEST(value1,value2,...)`

With two or more arguments, returns the largest (maximum-valued) argument. The arguments are compared using the same rules as for `LEAST()`.

```
mysql> SELECT GREATEST(2,0);
-> 2
mysql> SELECT GREATEST(34.0,3.0,5.0,767.0);
-> 767.0
mysql> SELECT GREATEST('B','A','C');
-> 'C'
```

`GREATEST()` returns `NULL` if any argument is `NULL`.

- `expr IN (value,...)`

Returns `1` (true) if `expr` is equal to any of the values in the `IN()` list, else returns `0` (false).

Type conversion takes place according to the rules described in [Section 14.3, “Type Conversion in Expression Evaluation”](#), applied to all the arguments. If no type conversion is needed for the values in the `IN()` list, they are all non-`JSON` constants of the same type, and `expr` can be compared to each of them as a value of the same type (possibly after type conversion), an optimization takes place. The values the list are sorted and the search for `expr` is done using a binary search, which makes the `IN()` operation very quick.

```
mysql> SELECT 2 IN (0,3,5,7);
-> 0
mysql> SELECT 'wefwf' IN ('wee','wefwf','weg');
-> 1
```

`IN()` can be used to compare row constructors:

```
mysql> SELECT (3,4) IN ((1,2), (3,4));
-> 1
mysql> SELECT (3,4) IN ((1,2), (3,5));
-> 0
```

You should never mix quoted and unquoted values in an `IN()` list because the comparison rules for quoted values (such as strings) and unquoted values (such as numbers) differ. Mixing types may therefore lead to inconsistent results. For example, do not write an `IN()` expression like this:

```
SELECT val1 FROM tbl1 WHERE val1 IN (1,2,'a');
```

Instead, write it like this:

```
SELECT val1 FROM tbl1 WHERE val1 IN ('1','2','a');
```

Implicit type conversion may produce nonintuitive results:

```
mysql> SELECT 'a' IN (0), 0 IN ('b');
-> 1, 1
```

In both cases, the comparison values are converted to floating-point values, yielding 0.0 in each case, and a comparison result of 1 (true).

The number of values in the `IN()` list is only limited by the `max_allowed_packet` value.

To comply with the SQL standard, `IN()` returns `NULL` not only if the expression on the left hand side is `NULL`, but also if no match is found in the list and one of the expressions in the list is `NULL`.

`IN()` syntax can also be used to write certain types of subqueries. See [Section 15.2.15.3, “Subqueries with ANY, IN, or SOME”](#).

- `expr NOT IN (value,...)`

This is the same as `NOT (expr IN (value,...))`.

- `INTERVAL(N,N1,N2,N3,...)`

Returns 0 if  $N \leq N1$ , 1 if  $N \leq N2$  and so on, or -1 if  $N$  is `NULL`. All arguments are treated as integers. It is required that  $N1 \leq N2 \leq N3 \leq \dots \leq Nn$  for this function to work correctly. This is because a binary search is used (very fast).

```
mysql> SELECT INTERVAL(23, 1, 15, 17, 30, 44, 200);
-> 3
mysql> SELECT INTERVAL(10, 1, 10, 100, 1000);
-> 2
mysql> SELECT INTERVAL(22, 23, 30, 44, 200);
-> 0
```

- `IS boolean_value`

Tests a value against a boolean value, where `boolean_value` can be `TRUE`, `FALSE`, or `UNKNOWN`.

```
mysql> SELECT 1 IS TRUE, 0 IS FALSE, NULL IS UNKNOWN;
```

```
-> 1, 1, 1
```

- `IS NOT boolean_value`

Tests a value against a boolean value, where *boolean\_value* can be `TRUE`, `FALSE`, or `UNKNOWN`.

```
mysql> SELECT 1 IS NOT UNKNOWN, 0 IS NOT UNKNOWN, NULL IS NOT UNKNOWN;
-> 1, 1, 0
```

- `IS NULL`

Tests whether a value is `NULL`.

```
mysql> SELECT 1 IS NULL, 0 IS NULL, NULL IS NULL;
-> 0, 0, 1
```

To work well with ODBC programs, MySQL supports the following extra features when using `IS NULL`:

- If `sql_auto_is_null` variable is set to 1, then after a statement that successfully inserts an automatically generated `AUTO_INCREMENT` value, you can find that value by issuing a statement of the following form:

```
SELECT * FROM tbl_name WHERE auto_col IS NULL
```

If the statement returns a row, the value returned is the same as if you invoked the `LAST_INSERT_ID()` function. For details, including the return value after a multiple-row insert, see [Section 14.15, “Information Functions”](#). If no `AUTO_INCREMENT` value was successfully inserted, the `SELECT` statement returns no row.

The behavior of retrieving an `AUTO_INCREMENT` value by using an `IS NULL` comparison can be disabled by setting `sql_auto_is_null = 0`. See [Section 7.1.8, “Server System Variables”](#).

The default value of `sql_auto_is_null` is 0.

- For `DATE` and `DATETIME` columns that are declared as `NOT NULL`, you can find the special date `'0000-00-00'` by using a statement like this:

```
SELECT * FROM tbl_name WHERE date_column IS NULL
```

This is needed to get some ODBC applications to work because ODBC does not support a `'0000-00-00'` date value.

See [Obtaining Auto-Increment Values](#), and the description for the `FLAG_AUTO_IS_NULL` option at [Connector/ODBC Connection Parameters](#).

- `IS NOT NULL`

Tests whether a value is not `NULL`.

```
mysql> SELECT 1 IS NOT NULL, 0 IS NOT NULL, NULL IS NOT NULL;
-> 1, 1, 0
```

- `ISNULL(expr)`

If *expr* is `NULL`, `ISNULL()` returns 1, otherwise it returns 0.

```
mysql> SELECT ISNULL(1+1);
-> 0
mysql> SELECT ISNULL(1/0);
```

```
-> 1
```

`ISNULL( )` can be used instead of `=` to test whether a value is `NULL`. (Comparing a value to `NULL` using `=` always yields `NULL`.)

The `ISNULL( )` function shares some special behaviors with the `IS NULL` comparison operator. See the description of `IS NULL`.

- `LEAST(value1,value2,...)`

With two or more arguments, returns the smallest (minimum-valued) argument. The arguments are compared using the following rules:

- If any argument is `NULL`, the result is `NULL`. No comparison is needed.
- If all arguments are integer-valued, they are compared as integers.
- If at least one argument is double precision, they are compared as double-precision values. Otherwise, if at least one argument is a `DECIMAL` value, they are compared as `DECIMAL` values.
- If the arguments comprise a mix of numbers and strings, they are compared as strings.
- If any argument is a nonbinary (character) string, the arguments are compared as nonbinary strings.
- In all other cases, the arguments are compared as binary strings.

The return type of `LEAST( )` is the aggregated type of the comparison argument types.

```
mysql> SELECT LEAST(2,0);
-> 0
mysql> SELECT LEAST(34.0,3.0,5.0,767.0);
-> 3.0
mysql> SELECT LEAST('B','A','C');
-> 'A'
```

### 14.4.3 Logical Operators

Table 14.5 Logical Operators

Name	Description
<code>AND, &amp;&amp;</code>	Logical AND
<code>NOT, !</code>	Negates value
<code>OR,   </code>	Logical OR
<code>XOR</code>	Logical XOR

In SQL, all logical operators evaluate to `TRUE`, `FALSE`, or `NULL` (`UNKNOWN`). In MySQL, these are implemented as 1 (`TRUE`), 0 (`FALSE`), and `NULL`. Most of this is common to different SQL database servers, although some servers may return any nonzero value for `TRUE`.

MySQL evaluates any nonzero, non-`NULL` value to `TRUE`. For example, the following statements all assess to `TRUE`:

```
mysql> SELECT 10 IS TRUE;
-> 1
mysql> SELECT -10 IS TRUE;
-> 1
mysql> SELECT 'string' IS NOT NULL;
-> 1
```

- NOT, !

Logical NOT. Evaluates to 1 if the operand is 0, to 0 if the operand is nonzero, and NOT NULL returns NULL.

```
mysql> SELECT NOT 10;
-> 0
mysql> SELECT NOT 0;
-> 1
mysql> SELECT NOT NULL;
-> NULL
mysql> SELECT ! (1+1);
-> 0
mysql> SELECT ! 1+1;
-> 1
```

The last example produces 1 because the expression evaluates the same way as (!1)+1.

The ! operator is a nonstandard extension, and is deprecated; expect it to be removed in a future version of MySQL. Applications, where necessary, should be adjusted to use the standard SQL NOT operator instead.

- AND, &&

Logical AND. Evaluates to 1 if all operands are nonzero and not NULL, to 0 if one or more operands are 0, otherwise NULL is returned.

```
mysql> SELECT 1 AND 1;
-> 1
mysql> SELECT 1 AND 0;
-> 0
mysql> SELECT 1 AND NULL;
-> NULL
mysql> SELECT 0 AND NULL;
-> 0
mysql> SELECT NULL AND 0;
-> 0
```

The && operator is a nonstandard extension and is deprecated; expect support for it to be removed in a future version of MySQL. Applications, where necessary, should be adjusted to use the standard SQL AND operator instead.

- OR, ||

Logical OR. When both operands are non-NULL, the result is 1 if any operand is nonzero, and 0 otherwise. With a NULL operand, the result is 1 if the other operand is nonzero, and NULL otherwise. If both operands are NULL, the result is NULL.

```
mysql> SELECT 1 OR 1;
-> 1
mysql> SELECT 1 OR 0;
-> 1
mysql> SELECT 0 OR 0;
-> 0
mysql> SELECT 0 OR NULL;
-> NULL
mysql> SELECT 1 OR NULL;
-> 1
```

```
-> 1
```

**Note**

If the `PIPES_AS_CONCAT` SQL mode is enabled, `||` signifies the SQL-standard string concatenation operator (like `CONCAT( )`).

The `||` operator is a nonstandard extension, and is deprecated; expect support for it to be removed in a future version of MySQL. Applications, where necessary, should be adjusted to use the standard SQL `OR` operator instead. Exception: Deprecation does not apply if `PIPES_AS_CONCAT` is enabled because, in that case, `||` signifies string concatenation.

- **XOR**

Logical XOR. Returns `NULL` if either operand is `NULL`. For non-`NULL` operands, evaluates to `1` if an odd number of operands is nonzero, otherwise `0` is returned.

```
mysql> SELECT 1 XOR 1;
-> 0
mysql> SELECT 1 XOR 0;
-> 1
mysql> SELECT 1 XOR NULL;
-> NULL
mysql> SELECT 1 XOR 1 XOR 1;
-> 1
```

`a XOR b` is mathematically equal to `(a AND (NOT b)) OR ((NOT a) and b)`.

## 14.4.4 Assignment Operators

**Table 14.6 Assignment Operators**

Name	Description
<code>:=</code>	Assign a value
<code>=</code>	Assign a value (as part of a <code>SET</code> statement, or as part of the <code>SET</code> clause in an <code>UPDATE</code> statement)

- **:=**

Assignment operator. Causes the user variable on the left hand side of the operator to take on the value to its right. The value on the right hand side may be a literal value, another variable storing a value, or any legal expression that yields a scalar value, including the result of a query (provided that this value is a scalar value). You can perform multiple assignments in the same `SET` statement. You can perform multiple assignments in the same statement.

Unlike `=`, the `:=` operator is never interpreted as a comparison operator. This means you can use `:=` in any valid SQL statement (not just in `SET` statements) to assign a value to a variable.

```
mysql> SELECT @var1, @var2;
-> NULL, NULL
mysql> SELECT @var1 := 1, @var2;
-> 1, NULL
mysql> SELECT @var1, @var2;
-> 1, NULL
mysql> SELECT @var1, @var2 := @var1;
-> 1, 1
mysql> SELECT @var1, @var2;
-> 1, 1
```

```
mysql> SELECT @var1:=COUNT(*) FROM t1;
-> 4
mysql> SELECT @var1;
-> 4
```

You can make value assignments using `:=` in other statements besides `SELECT`, such as `UPDATE`, as shown here:

```
mysql> SELECT @var1;
-> 4
mysql> SELECT * FROM t1;
-> 1, 3, 5, 7

mysql> UPDATE t1 SET c1 = 2 WHERE c1 = @var1:= 1;
Query OK, 1 row affected (0.00 sec)
Rows matched: 1 Changed: 1 Warnings: 0

mysql> SELECT @var1;
-> 1
mysql> SELECT * FROM t1;
-> 2, 3, 5, 7
```

While it is also possible both to set and to read the value of the same variable in a single SQL statement using the `:=` operator, this is not recommended. [Section 11.4, “User-Defined Variables”](#), explains why you should avoid doing this.

- `=`

This operator is used to perform value assignments in two cases, described in the next two paragraphs.

Within a `SET` statement, `=` is treated as an assignment operator that causes the user variable on the left hand side of the operator to take on the value to its right. (In other words, when used in a `SET` statement, `=` is treated identically to `:=`.) The value on the right hand side may be a literal value, another variable storing a value, or any legal expression that yields a scalar value, including the result of a query (provided that this value is a scalar value). You can perform multiple assignments in the same `SET` statement.

In the `SET` clause of an `UPDATE` statement, `=` also acts as an assignment operator; in this case, however, it causes the column named on the left hand side of the operator to assume the value given to the right, provided any `WHERE` conditions that are part of the `UPDATE` are met. You can make multiple assignments in the same `SET` clause of an `UPDATE` statement.

In any other context, `=` is treated as a [comparison operator](#).

```
mysql> SELECT @var1, @var2;
-> NULL, NULL
mysql> SELECT @var1 := 1, @var2;
-> 1, NULL
mysql> SELECT @var1, @var2;
-> 1, NULL
mysql> SELECT @var1, @var2 := @var1;
-> 1, 1
mysql> SELECT @var1, @var2;
-> 1, 1
```

For more information, see [Section 15.7.6.1, “SET Syntax for Variable Assignment”](#), [Section 15.2.17, “UPDATE Statement”](#), and [Section 15.2.15, “Subqueries”](#).

## 14.5 Flow Control Functions

Table 14.7 Flow Control Operators

Name	Description
<code>CASE</code>	Case operator
<code>IF()</code>	If/else construct
<code>IFNULL()</code>	Null if/else construct
<code>NULLIF()</code>	Return NULL if <code>expr1 = expr2</code>

- `CASE value WHEN compare_value THEN result [WHEN compare_value THEN result ...] [ELSE result] END`

`CASE WHEN condition THEN result [WHEN condition THEN result ...] [ELSE result] END`

The first `CASE` syntax returns the `result` for the first `value=compare_value` comparison that is true. The second syntax returns the result for the first condition that is true. If no comparison or condition is true, the result after `ELSE` is returned, or `NULL` if there is no `ELSE` part.

#### Note

The syntax of the `CASE operator` described here differs slightly from that of the SQL `CASE statement` described in [Section 15.6.5.1, “CASE Statement”](#), for use inside stored programs. The `CASE` statement cannot have an `ELSE NULL` clause, and it is terminated with `END CASE` instead of `END`.

The return type of a `CASE` expression result is the aggregated type of all result values:

- If all types are numeric, the aggregated type is also numeric:
  - If at least one argument is double precision, the result is double precision.
  - Otherwise, if at least one argument is `DECIMAL`, the result is `DECIMAL`.
  - Otherwise, the result is an integer type (with one exception):
    - If all integer types are all signed or all unsigned, the result is the same sign and the precision is the highest of all specified integer types (that is, `TINYINT`, `SMALLINT`, `MEDIUMINT`, `INT`, or `BIGINT`).
    - If there is a combination of signed and unsigned integer types, the result is signed and the precision may be higher. For example, if the types are signed `INT` and unsigned `INT`, the result is signed `BIGINT`.
    - The exception is unsigned `BIGINT` combined with any signed integer type. The result is `DECIMAL` with sufficient precision and scale 0.
- If all types are `BIT`, the result is `BIT`. Otherwise, `BIT` arguments are treated similar to `BIGINT`.
- If all types are `YEAR`, the result is `YEAR`. Otherwise, `YEAR` arguments are treated similar to `INT`.
- If all types are character string (`CHAR` or `VARCHAR`), the result is `VARCHAR` with maximum length determined by the longest character length of the operands.
- If all types are character or binary string, the result is `VARBINARY`.

- `SET` and `ENUM` are treated similar to `VARCHAR`; the result is `VARCHAR`.
- If all types are `JSON`, the result is `JSON`.
- If all types are temporal, the result is temporal:
  - If all temporal types are `DATE`, `TIME`, or `TIMESTAMP`, the result is `DATE`, `TIME`, or `TIMESTAMP`, respectively.
  - Otherwise, for a mix of temporal types, the result is `DATETIME`.
- If all types are `GEOMETRY`, the result is `GEOMETRY`.
- If any type is `BLOB`, the result is `BLOB`.
- For all other type combinations, the result is `VARCHAR`.
- Literal `NULL` operands are ignored for type aggregation.

```
mysql> SELECT CASE 1 WHEN 1 THEN 'one'
-> WHEN 2 THEN 'two' ELSE 'more' END;
-> 'one'
mysql> SELECT CASE WHEN 1>0 THEN 'true' ELSE 'false' END;
-> 'true'
mysql> SELECT CASE BINARY 'B'
-> WHEN 'a' THEN 1 WHEN 'b' THEN 2 END;
-> NULL
```

- `IF(expr1,expr2,expr3)`

If `expr1` is `TRUE` (`expr1 <> 0` and `expr1 IS NOT NULL`), `IF()` returns `expr2`. Otherwise, it returns `expr3`.

#### Note

There is also an `IF statement`, which differs from the `IF()` function described here. See [Section 15.6.5.2, “IF Statement”](#).

If only one of `expr2` or `expr3` is explicitly `NULL`, the result type of the `IF()` function is the type of the non-`NULL` expression.

The default return type of `IF()` (which may matter when it is stored into a temporary table) is calculated as follows:

- If `expr2` or `expr3` produce a string, the result is a string.
  - If `expr2` and `expr3` are both strings, the result is case-sensitive if either string is case-sensitive.
- If `expr2` or `expr3` produce a floating-point value, the result is a floating-point value.
- If `expr2` or `expr3` produce an integer, the result is an integer.

```
mysql> SELECT IF(1>2,2,3);
-> 3
mysql> SELECT IF(1<2,'yes','no');
-> 'yes'
mysql> SELECT IF(STRCMP('test','test1'),'no','yes');
-> 'no'
```

- `IFNULL(expr1,expr2)`

If `expr1` is not `NULL`, `IFNULL()` returns `expr1`; otherwise it returns `expr2`.

```
mysql> SELECT IFNULL(1,0);
-> 1
mysql> SELECT IFNULL(NULL,10);
-> 10
mysql> SELECT IFNULL(1/0,10);
-> 10
mysql> SELECT IFNULL(1/0,'yes');
-> 'yes'
```

The default return type of `IFNULL(expr1,expr2)` is the more “general” of the two expressions, in the order `STRING`, `REAL`, or `INTEGER`. Consider the case of a table based on expressions or where MySQL must internally store a value returned by `IFNULL()` in a temporary table:

```
mysql> CREATE TABLE tmp SELECT IFNULL(1,'test') AS test;
mysql> DESCRIBE tmp;
+-----+-----+-----+-----+-----+-----+
| Field | Type | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| test | varbinary(4) | NO | | | |
+-----+-----+-----+-----+-----+-----+
```

In this example, the type of the `test` column is `VARBINARY(4)` (a string type).

- `NULLIF(expr1,expr2)`

Returns `NULL` if `expr1 = expr2` is true, otherwise returns `expr1`. This is the same as `CASE WHEN expr1 = expr2 THEN NULL ELSE expr1 END`.

The return value has the same type as the first argument.

```
mysql> SELECT NULLIF(1,1);
-> NULL
mysql> SELECT NULLIF(1,2);
-> 1
```

#### Note

MySQL evaluates `expr1` twice if the arguments are not equal.

For each of these functions, if the first argument contains only characters present in the character set and collation used by the second argument (and it is constant), the latter character set and collation is used to make the comparison. System variable values are handled as column values of the same character and collation. Some queries using these functions with system variables may be rejected with `Illegal mix of collations` as a result. In such cases, you should cast the system variable to the correct character set and collation.

## 14.6 Numeric Functions and Operators

Table 14.8 Numeric Functions and Operators

Name	Description
<code>%, MOD</code>	Modulo operator
<code>*</code>	Multiplication operator
<code>+</code>	Addition operator

Name	Description
-	Minus operator
-	Change the sign of the argument
/	Division operator
ABS ( )	Return the absolute value
ACOS ( )	Return the arc cosine
ASIN ( )	Return the arc sine
ATAN ( )	Return the arc tangent
ATAN2 ( ), ATAN ( )	Return the arc tangent of the two arguments
CEIL ( )	Return the smallest integer value not less than the argument
CEILING ( )	Return the smallest integer value not less than the argument
CONV ( )	Convert numbers between different number bases
COS ( )	Return the cosine
COT ( )	Return the cotangent
CRC32 ( )	Compute a cyclic redundancy check value
DEGREES ( )	Convert radians to degrees
DIV	Integer division
EXP ( )	Raise to the power of
FLOOR ( )	Return the largest integer value not greater than the argument
LN ( )	Return the natural logarithm of the argument
LOG ( )	Return the natural logarithm of the first argument
LOG10 ( )	Return the base-10 logarithm of the argument
LOG2 ( )	Return the base-2 logarithm of the argument
MOD ( )	Return the remainder
PI ( )	Return the value of pi
POW ( )	Return the argument raised to the specified power
POWER ( )	Return the argument raised to the specified power
RADIANS ( )	Return argument converted to radians
RAND ( )	Return a random floating-point value
ROUND ( )	Round the argument
SIGN ( )	Return the sign of the argument
SIN ( )	Return the sine of the argument
SQRT ( )	Return the square root of the argument
TAN ( )	Return the tangent of the argument
TRUNCATE ( )	Truncate to specified number of decimal places

## 14.6.1 Arithmetic Operators

**Table 14.9 Arithmetic Operators**

Name	Description
<code>%</code> , <code>MOD</code>	Modulo operator
<code>*</code>	Multiplication operator
<code>+</code>	Addition operator
<code>-</code>	Minus operator
<code>-</code>	Change the sign of the argument
<code>/</code>	Division operator
<code>DIV</code>	Integer division

The usual arithmetic operators are available. The result is determined according to the following rules:

- In the case of `-`, `+`, and `*`, the result is calculated with `BIGINT` (64-bit) precision if both operands are integers.
- If both operands are integers and any of them are unsigned, the result is an unsigned integer. For subtraction, if the `NO_UNSIGNED_SUBTRACTION` SQL mode is enabled, the result is signed even if any operand is unsigned.
- If any of the operands of a `+`, `-`, `/`, `*`, `%` is a real or string value, the precision of the result is the precision of the operand with the maximum precision.
- In division performed with `/`, the scale of the result when using two exact-value operands is the scale of the first operand plus the value of the `div_precision_increment` system variable (which is 4 by default). For example, the result of the expression `5.05 / 0.014` has a scale of six decimal places (`360.714286`).

These rules are applied for each operation, such that nested calculations imply the precision of each component. Hence, `(14620 / 9432456) / (24250 / 9432456)`, resolves first to `(0.0014) / (0.0026)`, with the final result having 8 decimal places (`0.60288653`).

Because of these rules and the way they are applied, care should be taken to ensure that components and subcomponents of a calculation use the appropriate level of precision. See [Section 14.10, “Cast Functions and Operators”](#).

For information about handling of overflow in numeric expression evaluation, see [Section 13.1.7, “Out-of-Range and Overflow Handling”](#).

Arithmetic operators apply to numbers. For other types of values, alternative operations may be available. For example, to add date values, use `DATE_ADD()`; see [Section 14.7, “Date and Time Functions”](#).

- `+`

Addition:

```
mysql> SELECT 3+5;
-> 8
```

- `-`

Subtraction:

```
mysql> SELECT 3-5;
-> -2
```

- `-`

Unary minus. This operator changes the sign of the operand.

```
mysql> SELECT - 2;
-> -2
```

#### Note

If this operator is used with a `BIGINT`, the return value is also a `BIGINT`. This means that you should avoid using `-` on integers that may have the value of  $-2^{63}$ .

- `*`

Multiplication:

```
mysql> SELECT 3*5;
-> 15
mysql> SELECT 18014398509481984*18014398509481984.0;
-> 324518553658426726783156020576256.0
mysql> SELECT 18014398509481984*18014398509481984;
-> out-of-range error
```

The last expression produces an error because the result of the integer multiplication exceeds the 64-bit range of `BIGINT` calculations. (See [Section 13.1, “Numeric Data Types”](#).)

- `/`

Division:

```
mysql> SELECT 3/5;
-> 0.60
```

Division by zero produces a `NULL` result:

```
mysql> SELECT 102/(1-1);
-> NULL
```

A division is calculated with `BIGINT` arithmetic only if performed in a context where its result is converted to an integer.

- `DIV`

Integer division. Discards from the division result any fractional part to the right of the decimal point.

If either operand has a noninteger type, the operands are converted to `DECIMAL` and divided using `DECIMAL` arithmetic before converting the result to `BIGINT`. If the result exceeds `BIGINT` range, an error occurs.

```
mysql> SELECT 5 DIV 2, -5 DIV 2, 5 DIV -2, -5 DIV -2;
-> 2, -2, -2, 2
```

- `N % M, N MOD M`

Modulo operation. Returns the remainder of `N` divided by `M`. For more information, see the description for the `MOD()` function in [Section 14.6.2, “Mathematical Functions”](#).

## 14.6.2 Mathematical Functions

**Table 14.10 Mathematical Functions**

Name	Description
<code>ABS ( )</code>	Return the absolute value
<code>ACOS ( )</code>	Return the arc cosine
<code>ASIN ( )</code>	Return the arc sine
<code>ATAN ( )</code>	Return the arc tangent
<code>ATAN2 ( ), ATAN ( )</code>	Return the arc tangent of the two arguments
<code>CEIL ( )</code>	Return the smallest integer value not less than the argument
<code>CEILING ( )</code>	Return the smallest integer value not less than the argument
<code>CONV ( )</code>	Convert numbers between different number bases
<code>COS ( )</code>	Return the cosine
<code>COT ( )</code>	Return the cotangent
<code>CRC32 ( )</code>	Compute a cyclic redundancy check value
<code>DEGREES ( )</code>	Convert radians to degrees
<code>EXP ( )</code>	Raise to the power of
<code>FLOOR ( )</code>	Return the largest integer value not greater than the argument
<code>LN ( )</code>	Return the natural logarithm of the argument
<code>LOG ( )</code>	Return the natural logarithm of the first argument
<code>LOG10 ( )</code>	Return the base-10 logarithm of the argument
<code>LOG2 ( )</code>	Return the base-2 logarithm of the argument
<code>MOD ( )</code>	Return the remainder
<code>PI ( )</code>	Return the value of pi
<code>POW ( )</code>	Return the argument raised to the specified power
<code>POWER ( )</code>	Return the argument raised to the specified power
<code>RADIANS ( )</code>	Return argument converted to radians
<code>RAND ( )</code>	Return a random floating-point value
<code>ROUND ( )</code>	Round the argument
<code>SIGN ( )</code>	Return the sign of the argument
<code>SIN ( )</code>	Return the sine of the argument
<code>SQRT ( )</code>	Return the square root of the argument
<code>TAN ( )</code>	Return the tangent of the argument
<code>TRUNCATE ( )</code>	Truncate to specified number of decimal places

All mathematical functions return `NULL` in the event of an error.

- `ABS (X)`

Returns the absolute value of `X`, or `NULL` if `X` is `NULL`.

The result type is derived from the argument type. An implication of this is that `ABS(-9223372036854775808)` produces an error because the result cannot be stored in a signed `BIGINT` value.

```
mysql> SELECT ABS(2);
-> 2
mysql> SELECT ABS(-32);
-> 32
```

This function is safe to use with `BIGINT` values.

- `ACOS(X)`

Returns the arc cosine of `X`, that is, the value whose cosine is `X`. Returns `NULL` if `X` is not in the range `-1` to `1`, or if `X` is `NULL`.

```
mysql> SELECT ACOS(1);
-> 0
mysql> SELECT ACOS(1.0001);
-> NULL
mysql> SELECT ACOS(0);
-> 1.5707963267949
```

- `ASIN(X)`

Returns the arc sine of `X`, that is, the value whose sine is `X`. Returns `NULL` if `X` is not in the range `-1` to `1`, or if `X` is `NULL`.

```
mysql> SELECT ASIN(0.2);
-> 0.20135792079033
mysql> SELECT ASIN('foo');
```

ASIN('foo')
0

```
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS;
```

Level	Code	Message
Warning	1292	Truncated incorrect DOUBLE value: 'foo'

- `ATAN(X)`

Returns the arc tangent of `X`, that is, the value whose tangent is `X`. Returns `NULL` if `X` is `NULL`.

```
mysql> SELECT ATAN(2);
-> 1.1071487177941
mysql> SELECT ATAN(-2);
-> -1.1071487177941
```

- `ATAN(Y,X)`, `ATAN2(Y,X)`

Returns the arc tangent of the two variables `X` and `Y`. It is similar to calculating the arc tangent of `Y / X`, except that the signs of both arguments are used to determine the quadrant of the result. Returns `NULL` if `X` or `Y` is `NULL`.

```
mysql> SELECT ATAN(-2,2);
```

```
-> -0.78539816339745
mysql> SELECT ATAN2(PI(),0);
-> 1.5707963267949
```

- `CEIL(X)`

`CEIL( )` is a synonym for `CEILING( )`.

- `CEILING(X)`

Returns the smallest integer value not less than *X*. Returns `NULL` if *X* is `NULL`.

```
mysql> SELECT CEILING(1.23);
-> 2
mysql> SELECT CEILING(-1.23);
-> -1
```

For exact-value numeric arguments, the return value has an exact-value numeric type. For string or floating-point arguments, the return value has a floating-point type.

- `CONV(N,from_base,to_base)`

Converts numbers between different number bases. Returns a string representation of the number *N*, converted from base *from\_base* to base *to\_base*. Returns `NULL` if any argument is `NULL`. The argument *N* is interpreted as an integer, but may be specified as an integer or a string. The minimum base is 2 and the maximum base is 36. If *from\_base* is a negative number, *N* is regarded as a signed number. Otherwise, *N* is treated as unsigned. `CONV( )` works with 64-bit precision.

`CONV( )` returns `NULL` if any of its arguments are `NULL`.

```
mysql> SELECT CONV('a',16,2);
-> '1010'
mysql> SELECT CONV('6E',18,8);
-> '172'
mysql> SELECT CONV(-17,10,-18);
-> '-H'
mysql> SELECT CONV(10+'10'+'10'+X'0a',10,10);
-> '40'
```

- `COS(X)`

Returns the cosine of *X*, where *X* is given in radians. Returns `NULL` if *X* is `NULL`.

```
mysql> SELECT COS(PI());
-> -1
```

- `COT(X)`

Returns the cotangent of *X*. Returns `NULL` if *X* is `NULL`.

```
mysql> SELECT COT(12);
-> -1.5726734063977
mysql> SELECT COT(0);
-> out-of-range error
```

- `CRC32(expr)`

Computes a cyclic redundancy check value and returns a 32-bit unsigned value. The result is `NULL` if the argument is `NULL`. The argument is expected to be a string and (if possible) is treated as one if it is not.

```
mysql> SELECT CRC32('MySQL');
-> 3259397556
```

```
mysql> SELECT CRC32('mysql');
-> 2501908538
```

- [DEGREES\(X\)](#)

Returns the argument *X*, converted from radians to degrees. Returns [NULL](#) if *X* is [NULL](#).

```
mysql> SELECT DEGREES(PI());
-> 180
mysql> SELECT DEGREES(PI() / 2);
-> 90
```

- [EXP\(X\)](#)

Returns the value of *e* (the base of natural logarithms) raised to the power of *X*. The inverse of this function is [LOG\(\)](#) (using a single argument only) or [LN\(\)](#).

If *X* is [NULL](#), this function returns [NULL](#).

```
mysql> SELECT EXP(2);
-> 7.3890560989307
mysql> SELECT EXP(-2);
-> 0.13533528323661
mysql> SELECT EXP(0);
-> 1
```

- [FLOOR\(X\)](#)

Returns the largest integer value not greater than *X*. Returns [NULL](#) if *X* is [NULL](#).

```
mysql> SELECT FLOOR(1.23), FLOOR(-1.23);
-> 1, -2
```

For exact-value numeric arguments, the return value has an exact-value numeric type. For string or floating-point arguments, the return value has a floating-point type.

- [FORMAT\(X,D\)](#)

Formats the number *X* to a format like '*#,###,###.##*', rounded to *D* decimal places, and returns the result as a string. For details, see [Section 14.8, "String Functions and Operators"](#).

- [HEX\(N\\_or\\_S\)](#)

This function can be used to obtain a hexadecimal representation of a decimal number or a string; the manner in which it does so varies according to the argument's type. See this function's description in [Section 14.8, "String Functions and Operators"](#), for details.

- [LN\(X\)](#)

Returns the natural logarithm of *X*; that is, the base-*e* logarithm of *X*. If *X* is less than or equal to 0.0E0, the function returns [NULL](#) and a warning "Invalid argument for logarithm" is reported. Returns [NULL](#) if *X* is [NULL](#).

```
mysql> SELECT LN(2);
-> 0.69314718055995
mysql> SELECT LN(-2);
-> NULL
```

This function is synonymous with [LOG\(X\)](#). The inverse of this function is the [EXP\(\)](#) function.

- [LOG\(X\)](#), [LOG\(B,X\)](#)

If called with one parameter, this function returns the natural logarithm of  $X$ . If  $X$  is less than or equal to 0.0E0, the function returns `NULL` and a warning “Invalid argument for logarithm” is reported. Returns `NULL` if  $X$  or  $B$  is `NULL`.

The inverse of this function (when called with a single argument) is the `EXP ( )` function.

```
mysql> SELECT LOG(2);
 -> 0.69314718055995
mysql> SELECT LOG(-2);
 -> NULL
```

If called with two parameters, this function returns the logarithm of  $X$  to the base  $B$ . If  $X$  is less than or equal to 0, or if  $B$  is less than or equal to 1, then `NULL` is returned.

```
mysql> SELECT LOG(2,65536);
 -> 16
mysql> SELECT LOG(10,100);
 -> 2
mysql> SELECT LOG(1,100);
 -> NULL
```

$\text{LOG}(B, X)$  is equivalent to  $\text{LOG}(X) / \text{LOG}(B)$ .

- `LOG2(X)`

Returns the base-2 logarithm of  $X$ . If  $X$  is less than or equal to 0.0E0, the function returns `NULL` and a warning “Invalid argument for logarithm” is reported. Returns `NULL` if  $X$  is `NULL`.

```
mysql> SELECT LOG2(65536);
 -> 16
mysql> SELECT LOG2(-100);
 -> NULL
```

`LOG2 ( )` is useful for finding out how many bits a number requires for storage. This function is equivalent to the expression  $\text{LOG}(X) / \text{LOG}(2)$ .

- `LOG10(X)`

Returns the base-10 logarithm of  $X$ . If  $X$  is less than or equal to 0.0E0, the function returns `NULL` and a warning “Invalid argument for logarithm” is reported. Returns `NULL` if  $X$  is `NULL`.

```
mysql> SELECT LOG10(2);
 -> 0.30102999566398
mysql> SELECT LOG10(100);
 -> 2
mysql> SELECT LOG10(-100);
 -> NULL
```

$\text{LOG10}(X)$  is equivalent to  $\text{LOG}(10, X)$ .

- `MOD(N,M), N % M, N MOD M`

Modulo operation. Returns the remainder of  $N$  divided by  $M$ . Returns `NULL` if  $M$  or  $N$  is `NULL`.

```
mysql> SELECT MOD(234, 10);
 -> 4
mysql> SELECT 253 % 7;
 -> 1
mysql> SELECT MOD(29,9);
 -> 2
mysql> SELECT 29 MOD 9;
```

```
-> 2
```

This function is safe to use with `BIGINT` values.

`MOD( )` also works on values that have a fractional part and returns the exact remainder after division:

```
mysql> SELECT MOD(34.5,3);
-> 1.5
```

`MOD(N,0)` returns `NULL`.

- `PI( )`

Returns the value of  $\pi$  (pi). The default number of decimal places displayed is seven, but MySQL uses the full double-precision value internally.

Because the return value of this function is a double-precision value, its exact representation may vary between platforms or implementations. This also applies to any expressions making use of `PI( )`. See [Section 13.1.4, “Floating-Point Types \(Approximate Value\) - FLOAT, DOUBLE”](#).

```
mysql> SELECT PI();
-> 3.141593
mysql> SELECT PI()+0.00000000000000000000;
-> 3.141592653589793000
```

- `POW(X,Y)`

Returns the value of `X` raised to the power of `Y`. Returns `NULL` if `X` or `Y` is `NULL`.

```
mysql> SELECT POW(2,2);
-> 4
mysql> SELECT POW(2,-2);
-> 0.25
```

- `POWER(X,Y)`

This is a synonym for `POW( )`.

- `RADIANS(X)`

Returns the argument `X`, converted from degrees to radians. (Note that  $\pi$  radians equals 180 degrees.) Returns `NULL` if `X` is `NULL`.

```
mysql> SELECT RADIANS(90);
-> 1.5707963267949
```

- `RAND([N])`

Returns a random floating-point value `v` in the range  $0 \leq v < 1.0$ . To obtain a random integer `R` in the range  $i \leq R < j$ , use the expression `FLOOR(i + RAND() * (j - i))`. For example, to obtain a random integer in the range the range  $7 \leq R < 12$ , use the following statement:

```
SELECT FLOOR(7 + (RAND() * 5));
```

If an integer argument `N` is specified, it is used as the seed value:

- With a constant initializer argument, the seed is initialized once when the statement is prepared, prior to execution.
- With a nonconstant initializer argument (such as a column name), the seed is initialized with the value for each invocation of `RAND( )`.

One implication of this behavior is that for equal argument values, `RAND(N)` returns the same value each time, and thus produces a repeatable sequence of column values. In the following example, the sequence of values produced by `RAND(3)` is the same both places it occurs.

```
mysql> CREATE TABLE t (i INT);
Query OK, 0 rows affected (0.42 sec)

mysql> INSERT INTO t VALUES(1),(2),(3);
Query OK, 3 rows affected (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 0

mysql> SELECT i, RAND() FROM t;
+-----+-----+
| i | RAND() |
+-----+-----+
| 1 | 0.61914388706828 |
| 2 | 0.93845168309142 |
| 3 | 0.83482678498591 |
+-----+-----+
3 rows in set (0.00 sec)

mysql> SELECT i, RAND(3) FROM t;
+-----+-----+
| i | RAND(3) |
+-----+-----+
| 1 | 0.90576975597606 |
| 2 | 0.37307905813035 |
| 3 | 0.14808605345719 |
+-----+-----+
3 rows in set (0.00 sec)

mysql> SELECT i, RAND() FROM t;
+-----+-----+
| i | RAND() |
+-----+-----+
| 1 | 0.35877890638893 |
| 2 | 0.28941420772058 |
| 3 | 0.37073435016976 |
+-----+-----+
3 rows in set (0.00 sec)

mysql> SELECT i, RAND(3) FROM t;
+-----+-----+
| i | RAND(3) |
+-----+-----+
| 1 | 0.90576975597606 |
| 2 | 0.37307905813035 |
| 3 | 0.14808605345719 |
+-----+-----+
3 rows in set (0.01 sec)
```

`RAND()` in a `WHERE` clause is evaluated for every row (when selecting from one table) or combination of rows (when selecting from a multiple-table join). Thus, for optimizer purposes, `RAND()` is not a constant value and cannot be used for index optimizations. For more information, see [Section 10.2.1.20, “Function Call Optimization”](#).

Use of a column with `RAND()` values in an `ORDER BY` or `GROUP BY` clause may yield unexpected results because for either clause a `RAND()` expression can be evaluated multiple times for the same

row, each time returning a different result. If the goal is to retrieve rows in random order, you can use a statement like this:

```
SELECT * FROM tbl_name ORDER BY RAND();
```

To select a random sample from a set of rows, combine `ORDER BY RAND()` with `LIMIT`:

```
SELECT * FROM table1, table2 WHERE a=b AND c<d ORDER BY RAND() LIMIT 1000;
```

`RAND()` is not meant to be a perfect random generator. It is a fast way to generate random numbers on demand that is portable between platforms for the same MySQL version.

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- `ROUND(X), ROUND(X,D)`

Rounds the argument `X` to `D` decimal places. The rounding algorithm depends on the data type of `X`. `D` defaults to 0 if not specified. `D` can be negative to cause `D` digits left of the decimal point of the value `X` to become zero. The maximum absolute value for `D` is 30; any digits in excess of 30 (or -30) are truncated. If `X` or `D` is `NULL`, the function returns `NULL`.

```
mysql> SELECT ROUND(-1.23);
-> -1
mysql> SELECT ROUND(-1.58);
-> -2
mysql> SELECT ROUND(1.58);
-> 2
mysql> SELECT ROUND(1.298, 1);
-> 1.3
mysql> SELECT ROUND(1.298, 0);
-> 1
mysql> SELECT ROUND(23.298, -1);
-> 20
mysql> SELECT ROUND(.12345678901234567890123456789012345, 35);
-> 0.123456789012345678901234567890
```

The return value has the same type as the first argument (assuming that it is integer, double, or decimal). This means that for an integer argument, the result is an integer (no decimal places):

```
mysql> SELECT ROUND(150.000,2), ROUND(150,2);
+-----+-----+
| ROUND(150.000,2) | ROUND(150,2) |
+-----+-----+
| 150.00 | 150 |
+-----+-----+
```

`ROUND()` uses the following rules depending on the type of the first argument:

- For exact-value numbers, `ROUND()` uses the “round half away from zero” or “round toward nearest” rule: A value with a fractional part of .5 or greater is rounded up to the next integer if positive or down to the next integer if negative. (In other words, it is rounded away from zero.) A value with a fractional part less than .5 is rounded down to the next integer if positive or up to the next integer if negative.
- For approximate-value numbers, the result depends on the C library. On many systems, this means that `ROUND()` uses the “round to nearest even” rule: A value with a fractional part exactly halfway between two integers is rounded to the nearest even integer.

The following example shows how rounding differs for exact and approximate values:

```
mysql> SELECT ROUND(2.5), ROUND(25E-1);
```

ROUND(2.5)	ROUND(25E-1)
3	2

For more information, see [Section 14.25, “Precision Math”](#).

The data type returned by `ROUND()` (and `TRUNCATE()`) is determined according to the rules listed here:

- When the first argument is of any integer type, the return type is always `BIGINT`.
- When the first argument is of any floating-point type or of any non-numeric type, the return type is always `DOUBLE`.
- When the first argument is a `DECIMAL` value, the return type is also `DECIMAL`.
- The type attributes for the return value are also copied from the first argument, except in the case of `DECIMAL`, when the second argument is a constant value.

When the desired number of decimal places is less than the scale of the argument, the scale and the precision of the result are adjusted accordingly.

In addition, for `ROUND()` (but not for the `TRUNCATE()` function), the precision is extended by one place to accommodate rounding that increases the number of significant digits. If the second argument is negative, the return type is adjusted such that its scale is 0, with a corresponding precision. For example, `ROUND(99.999, 2)` returns `100.00`—the first argument is `DECIMAL(5, 3)`, and the return type is `DECIMAL(5, 2)`.

If the second argument is negative, the return type has scale 0 and a corresponding precision; `ROUND(99.999, -1)` returns `100`, which is `DECIMAL(3, 0)`.

- `SIGN(X)`

Returns the sign of the argument as `-1`, `0`, or `1`, depending on whether `X` is negative, zero, or positive. Returns `NULL` if `X` is `NULL`.

```
mysql> SELECT SIGN(-32);
-> -1
mysql> SELECT SIGN(0);
-> 0
mysql> SELECT SIGN(234);
-> 1
```

- `SIN(X)`

Returns the sine of `X`, where `X` is given in radians. Returns `NULL` if `X` is `NULL`.

```
mysql> SELECT SIN(PI());
-> 1.2246063538224e-16
mysql> SELECT ROUND(SIN(PI()));
-> 0
```

- `SQRT(X)`

Returns the square root of a nonnegative number `X`. If `X` is `NULL`, the function returns `NULL`.

```
mysql> SELECT SQRT(4);
-> 2
mysql> SELECT SQRT(20);
-> 4.4721359549996
```

```
mysql> SELECT SQRT(-16);
-> NULL
```

- **TAN(*X*)**

Returns the tangent of *X*, where *X* is given in radians. Returns **NULL** if *X* is **NULL**.

```
mysql> SELECT TAN(PI());
-> -1.2246063538224e-16
mysql> SELECT TAN(PI()+1);
-> 1.5574077246549
```

- **TRUNCATE(*X*,*D*)**

Returns the number *X*, truncated to *D* decimal places. If *D* is 0, the result has no decimal point or fractional part. *D* can be negative to cause *D* digits left of the decimal point of the value *X* to become zero. If *X* or *D* is **NULL**, the function returns **NULL**.

```
mysql> SELECT TRUNCATE(1.223,1);
-> 1.2
mysql> SELECT TRUNCATE(1.999,1);
-> 1.9
mysql> SELECT TRUNCATE(1.999,0);
-> 1
mysql> SELECT TRUNCATE(-1.999,1);
-> -1.9
mysql> SELECT TRUNCATE(122,-2);
-> 100
mysql> SELECT TRUNCATE(10.28*100,0);
-> 1028
```

All numbers are rounded toward zero.

The data type returned by **TRUNCATE()** follows the same rules that determine the return type of the **ROUND()** function; for details, see the description for **ROUND()**.

## 14.7 Date and Time Functions

This section describes the functions that can be used to manipulate temporal values. See [Section 13.2, “Date and Time Data Types”](#), for a description of the range of values each date and time type has and the valid formats in which values may be specified.

**Table 14.11 Date and Time Functions**

Name	Description
<b>ADDDATE()</b>	Add time values (intervals) to a date value
<b>ADDTIME()</b>	Add time
<b>CONVERT_TZ()</b>	Convert from one time zone to another
<b>CURDATE()</b>	Return the current date
<b>CURRENT_DATE()</b> , <b>CURRENT_DATE</b>	Synonyms for <b>CURDATE()</b>
<b>CURRENT_TIME()</b> , <b>CURRENT_TIME</b>	Synonyms for <b>CURTIME()</b>
<b>CURRENT_TIMESTAMP()</b> , <b>CURRENT_TIMESTAMP</b>	Synonyms for <b>NOW()</b>
<b>CURTIME()</b>	Return the current time
<b>DATE()</b>	Extract the date part of a date or datetime expression
<b>DATE_ADD()</b>	Add time values (intervals) to a date value

Name	Description
DATE_FORMAT ( )	Format date as specified
DATE_SUB ( )	Subtract a time value (interval) from a date
DATEDIFF ( )	Subtract two dates
DAY ( )	Synonym for DAYOFMONTH()
DAYNAME ( )	Return the name of the weekday
DAYOFMONTH ( )	Return the day of the month (0-31)
DAYOFWEEK ( )	Return the weekday index of the argument
DAYOFYEAR ( )	Return the day of the year (1-366)
EXTRACT ( )	Extract part of a date
FROM_DAYS ( )	Convert a day number to a date
FROM_UNIXTIME ( )	Format Unix timestamp as a date
GET_FORMAT ( )	Return a date format string
HOUR ( )	Extract the hour
LAST_DAY	Return the last day of the month for the argument
LOCALTIME ( ), LOCALTIME	Synonym for NOW()
LOCALTIMESTAMP, LOCALTIMESTAMP ( )	Synonym for NOW()
MAKEDATE ( )	Create a date from the year and day of year
MAKETIME ( )	Create time from hour, minute, second
MICROSECOND ( )	Return the microseconds from argument
MINUTE ( )	Return the minute from the argument
MONTH ( )	Return the month from the date passed
MONTHNAME ( )	Return the name of the month
NOW ( )	Return the current date and time
PERIOD_ADD ( )	Add a period to a year-month
PERIOD_DIFF ( )	Return the number of months between periods
QUARTER ( )	Return the quarter from a date argument
SEC_TO_TIME ( )	Converts seconds to 'hh:mm:ss' format
SECOND ( )	Return the second (0-59)
STR_TO_DATE ( )	Convert a string to a date
SUBDATE ( )	Synonym for DATE_SUB() when invoked with three arguments
SUBTIME ( )	Subtract times
SYSDATE ( )	Return the time at which the function executes
TIME ( )	Extract the time portion of the expression passed
TIME_FORMAT ( )	Format as time
TIME_TO_SEC ( )	Return the argument converted to seconds
TIMEDIFF ( )	Subtract time

Name	Description
<code>TIMESTAMP()</code>	With a single argument, this function returns the date or datetime expression; with two arguments, the sum of the arguments
<code>TIMESTAMPADD()</code>	Add an interval to a datetime expression
<code>TIMESTAMPDIFF()</code>	Return the difference of two datetime expressions, using the units specified
<code>TO_DAYS()</code>	Return the date argument converted to days
<code>TO_SECONDS()</code>	Return the date or datetime argument converted to seconds since Year 0
<code>UNIX_TIMESTAMP()</code>	Return a Unix timestamp
<code>UTC_DATE()</code>	Return the current UTC date
<code>UTC_TIME()</code>	Return the current UTC time
<code>UTC_TIMESTAMP()</code>	Return the current UTC date and time
<code>WEEK()</code>	Return the week number
<code>WEEKDAY()</code>	Return the weekday index
<code>WEEKOFYEAR()</code>	Return the calendar week of the date (1-53)
<code>YEAR()</code>	Return the year
<code>YEARWEEK()</code>	Return the year and week

Here is an example that uses date functions. The following query selects all rows with a `date_col` value from within the last 30 days:

```
mysql> SELECT something FROM tbl_name
 -> WHERE DATE_SUB(CURDATE(),INTERVAL 30 DAY) <= date_col;
```

The query also selects rows with dates that lie in the future.

Functions that expect date values usually accept datetime values and ignore the time part. Functions that expect time values usually accept datetime values and ignore the date part.

Functions that return the current date or time each are evaluated only once per query at the start of query execution. This means that multiple references to a function such as `NOW()` within a single query always produce the same result. (For our purposes, a single query also includes a call to a stored program (stored routine, trigger, or event) and all subprograms called by that program.) This principle also applies to `CURDATE()`, `CURTIME()`, `UTC_DATE()`, `UTC_TIME()`, `UTC_TIMESTAMP()`, and to any of their synonyms.

The `CURRENT_TIMESTAMP()`, `CURRENT_TIME()`, `CURRENT_DATE()`, and `FROM_UNIXTIME()` functions return values in the current session time zone, which is available as the session value of the `time_zone` system variable. In addition, `UNIX_TIMESTAMP()` assumes that its argument is a datetime value in the session time zone. See [Section 7.1.15, “MySQL Server Time Zone Support”](#).

Some date functions can be used with “zero” dates or incomplete dates such as `'2001-11-00'`, whereas others cannot. Functions that extract parts of dates typically work with incomplete dates and thus can return 0 when you might otherwise expect a nonzero value. For example:

```
mysql> SELECT DAYOFMONTH('2001-11-00'), MONTH('2005-00-00');
 -> 0, 0
```

Other functions expect complete dates and return `NULL` for incomplete dates. These include functions that perform date arithmetic or that map parts of dates to names. For example:

```
mysql> SELECT DATE_ADD('2006-05-00',INTERVAL 1 DAY);
-> NULL
mysql> SELECT DAYNAME('2006-05-00');
-> NULL
```

Several functions are strict when passed a `DATE()` function value as their argument and reject incomplete dates with a day part of zero: `CONVERT_TZ()`, `DATE_ADD()`, `DATE_SUB()`, `DAYOFYEAR()`, `TIMESTAMPDIFF()`, `TO_DAYS()`, `TO_SECONDS()`, `WEEK()`, `WEEKDAY()`, `WEEKOFYEAR()`, `YEARWEEK()`.

Fractional seconds for `TIME`, `DATETIME`, and `TIMESTAMP` values are supported, with up to microsecond precision. Functions that take temporal arguments accept values with fractional seconds. Return values from temporal functions include fractional seconds as appropriate.

- `ADDDATE(date,INTERVAL expr unit)`, `ADDDATE(date,days)`

When invoked with the `INTERVAL` form of the second argument, `ADDDATE()` is a synonym for `DATE_ADD()`. The related function `SUBDATE()` is a synonym for `DATE_SUB()`. For information on the `INTERVAL unit` argument, see [Temporal Intervals](#).

```
mysql> SELECT DATE_ADD('2008-01-02', INTERVAL 31 DAY);
-> '2008-02-02'
mysql> SELECT ADDDATE('2008-01-02', INTERVAL 31 DAY);
-> '2008-02-02'
```

When invoked with the `days` form of the second argument, MySQL treats it as an integer number of days to be added to `expr`.

```
mysql> SELECT ADDDATE('2008-01-02', 31);
-> '2008-02-02'
```

This function returns `NULL` if `date` or `days` is `NULL`.

- `ADDTIME(expr1,expr2)`

`ADDTIME()` adds `expr2` to `expr1` and returns the result. `expr1` is a time or datetime expression, and `expr2` is a time expression. Returns `NULL` if `expr1` or `expr2` is `NULL`.

The return type of this function and of the `SUBTIME()` function is determined as follows:

- If the first argument is a dynamic parameter (such as in a prepared statement), the return type is `TIME`.
- Otherwise, the resolved type of the function is derived from the resolved type of the first argument.

```
mysql> SELECT ADDTIME('2007-12-31 23:59:59.999999', '1 1:1:1.000002');
-> '2008-01-02 01:01:01.000001'
mysql> SELECT ADDTIME('01:00:00.999999', '02:00:00.999998');
-> '03:00:01.999997'
```

- `CONVERT_TZ(dt,from_tz,to_tz)`

`CONVERT_TZ()` converts a datetime value `dt` from the time zone given by `from_tz` to the time zone given by `to_tz` and returns the resulting value. Time zones are specified as described in [Section 7.1.15, "MySQL Server Time Zone Support"](#). This function returns `NULL` if any of the arguments are invalid, or if any of them are `NULL`.

On 32-bit platforms, the supported range of values for this function is the same as for the `TIMESTAMP` type (see [Section 13.2.1, "Date and Time Data Type Syntax"](#), for range information). On 64-bit platforms, the maximum supported value is '3001-01-18 23:59:59.999999' UTC.

Regardless of platform or MySQL version, if the value falls out of the supported range when converted from *from\_tz* to UTC, no conversion occurs.

```
mysql> SELECT CONVERT_TZ('2004-01-01 12:00:00','GMT','MET');
-> '2004-01-01 13:00:00'
mysql> SELECT CONVERT_TZ('2004-01-01 12:00:00','+00:00','+10:00');
-> '2004-01-01 22:00:00'
```

#### Note

To use named time zones such as 'MET' or 'Europe/Amsterdam', the time zone tables must be properly set up. For instructions, see [Section 7.1.15, “MySQL Server Time Zone Support”](#).

- `CURDATE()`

Returns the current date as a value in 'YYYY-MM-DD' or YYYYMMDD format, depending on whether the function is used in string or numeric context.

```
mysql> SELECT CURDATE();
-> '2008-06-13'
mysql> SELECT CURDATE() + 0;
-> 20080613
```

- `CURRENT_DATE`, `CURRENT_DATE()`

`CURRENT_DATE` and `CURRENT_DATE()` are synonyms for `CURDATE()`.

- `CURRENT_TIME`, `CURRENT_TIME([fsp])`

`CURRENT_TIME` and `CURRENT_TIME()` are synonyms for `CURTIME()`.

- `CURRENT_TIMESTAMP`, `CURRENT_TIMESTAMP([fsp])`

`CURRENT_TIMESTAMP` and `CURRENT_TIMESTAMP()` are synonyms for `NOW()`.

- `CURTIME([fsp])`

Returns the current time as a value in 'hh:mm:ss' or hhmmss format, depending on whether the function is used in string or numeric context. The value is expressed in the session time zone.

If the *fsp* argument is given to specify a fractional seconds precision from 0 to 6, the return value includes a fractional seconds part of that many digits.

```
mysql> SELECT CURTIME();
+-----+
| CURTIME() |
+-----+
| 19:25:37 |
+-----+

mysql> SELECT CURTIME() + 0;
+-----+
| CURTIME() + 0 |
+-----+
| 192537 |
+-----+

mysql> SELECT CURTIME(3);
+-----+
| CURTIME(3) |
```

```
+-----+
| 19:25:37.840 |
+-----+
```

- `DATE(expr)`

Extracts the date part of the date or datetime expression *expr*. Returns `NULL` if *expr* is `NULL`.

```
mysql> SELECT DATE('2003-12-31 01:02:03');
-> '2003-12-31'
```

- `DATEDIFF(expr1,expr2)`

`DATEDIFF()` returns *expr1* - *expr2* expressed as a value in days from one date to the other. *expr1* and *expr2* are date or date-and-time expressions. Only the date parts of the values are used in the calculation.

```
mysql> SELECT DATEDIFF('2007-12-31 23:59:59','2007-12-30');
-> 1
mysql> SELECT DATEDIFF('2010-11-30 23:59:59','2010-12-31');
-> -31
```

This function returns `NULL` if *expr1* or *expr2* is `NULL`.

- `DATE_ADD(date,INTERVAL expr unit),DATE_SUB(date,INTERVAL expr unit)`

These functions perform date arithmetic. The *date* argument specifies the starting date or datetime value. *expr* is an expression specifying the interval value to be added or subtracted from the starting date. *expr* is evaluated as a string; it may start with a - for negative intervals. *unit* is a keyword indicating the units in which the expression should be interpreted.

For more information about temporal interval syntax, including a full list of *unit* specifiers, the expected form of the *expr* argument for each *unit* value, and rules for operand interpretation in temporal arithmetic, see [Temporal Intervals](#).

The return value depends on the arguments:

- If *date* is `NULL`, the function returns `NULL`.
- `DATE` if the *date* argument is a `DATE` value and your calculations involve only `YEAR`, `MONTH`, and `DAY` parts (that is, no time parts).
- `TIME` if the *date* argument is a `TIME` value and the calculations involve only `HOURS`, `MINUTES`, and `SECONDS` parts (that is, no date parts).
- `DATETIME` if the first argument is a `DATETIME` (or `TIMESTAMP`) value, or if the first argument is a `DATE` and the *unit* value uses `HOURS`, `MINUTES`, or `SECONDS`, or if the first argument is of type `TIME` and the *unit* value uses `YEAR`, `MONTH`, or `DAY`.
- If the first argument is a dynamic parameter (for example, of a prepared statement), its resolved type is `DATE` if the second argument is an interval that contains some combination of `YEAR`, `MONTH`, or `DAY` values only; otherwise, its type is `DATETIME`.
- String otherwise (type `VARCHAR`).

To ensure that the result is `DATETIME`, you can use `CAST()` to convert the first argument to `DATETIME`.

```
mysql> SELECT DATE_ADD('2018-05-01',INTERVAL 1 DAY);
-> '2018-05-02'
mysql> SELECT DATE_SUB('2018-05-01',INTERVAL 1 YEAR);
```

```

mysql> SELECT DATE_ADD('2020-12-31 23:59:59',
 -> INTERVAL 1 SECOND);
 -> '2021-01-01 00:00:00'
mysql> SELECT DATE_ADD('2018-12-31 23:59:59',
 -> INTERVAL 1 DAY);
 -> '2019-01-01 23:59:59'
mysql> SELECT DATE_ADD('2100-12-31 23:59:59',
 -> INTERVAL '1:1' MINUTE_SECOND);
 -> '2101-01-01 00:01:00'
mysql> SELECT DATE_SUB('2025-01-01 00:00:00',
 -> INTERVAL '1 1:1:1' DAY_SECOND);
 -> '2024-12-30 22:58:59'
mysql> SELECT DATE_ADD('1900-01-01 00:00:00',
 -> INTERVAL '-1 10' DAY_HOUR);
 -> '1899-12-30 14:00:00'
mysql> SELECT DATE_SUB('1998-01-02', INTERVAL 31 DAY);
 -> '1997-12-02'
mysql> SELECT DATE_ADD('1992-12-31 23:59:59.000002',
 -> INTERVAL '1.999999' SECOND_MICROSECOND);
 -> '1993-01-01 00:00:01.000001'

```

When adding a `MONTH` interval to a `DATE` or `DATETIME` value, and the resulting date includes a day that does not exist in the given month, the day is adjusted to the last day of the month, as shown here:

```

mysql> SELECT DATE_ADD('2024-03-30', INTERVAL 1 MONTH) AS d1,
 > DATE_ADD('2024-03-31', INTERVAL 1 MONTH) AS d2;
+-----+-----+
| d1 | d2 |
+-----+-----+
| 2024-04-30 | 2024-04-30 |
+-----+-----+
1 row in set (0.00 sec)

```

- `DATE_FORMAT(date, format)`

Formats the *date* value according to the *format* string. If either argument is `NULL`, the function returns `NULL`.

The specifiers shown in the following table may be used in the *format* string. The `%` character is required before format specifier characters. The specifiers apply to other functions as well: `STR_TO_DATE()`, `TIME_FORMAT()`, `UNIX_TIMESTAMP()`.

Specifier	Description
<code>%a</code>	Abbreviated weekday name ( <code>Sun..Sat</code> )
<code>%b</code>	Abbreviated month name ( <code>Jan..Dec</code> )
<code>%c</code>	Month, numeric ( <code>0..12</code> )
<code>%D</code>	Day of the month with English suffix ( <code>0th, 1st, 2nd, 3rd, ...</code> )
<code>%d</code>	Day of the month, numeric ( <code>00..31</code> )
<code>%e</code>	Day of the month, numeric ( <code>0..31</code> )
<code>%f</code>	Microseconds ( <code>000000..999999</code> )
<code>%H</code>	Hour ( <code>00..23</code> )
<code>%h</code>	Hour ( <code>01..12</code> )
<code>%I</code>	Hour ( <code>01..12</code> )
<code>%i</code>	Minutes, numeric ( <code>00..59</code> )

Specifier	Description
%j	Day of year (001..366)
%k	Hour (0..23)
%l	Hour (1..12)
%M	Month name (January..December)
%m	Month, numeric (00..12)
%p	AM or PM
%r	Time, 12-hour (hh:mm:ss followed by AM or PM)
%S	Seconds (00..59)
%s	Seconds (00..59)
%T	Time, 24-hour (hh:mm:ss)
%U	Week (00..53), where Sunday is the first day of the week; WEEK( ) mode 0
%u	Week (00..53), where Monday is the first day of the week; WEEK( ) mode 1
%V	Week (01..53), where Sunday is the first day of the week; WEEK( ) mode 2; used with %x
%v	Week (01..53), where Monday is the first day of the week; WEEK( ) mode 3; used with %x
%W	Weekday name (Sunday..Saturday)
%w	Day of the week (0=Sunday..6=Saturday)
%X	Year for the week where Sunday is the first day of the week, numeric, four digits; used with %v
%x	Year for the week, where Monday is the first day of the week, numeric, four digits; used with %v
%Y	Year, numeric, four digits
%y	Year, numeric (two digits)
%%	A literal % character
%x	x, for any “x” not listed above

Ranges for the month and day specifiers begin with zero due to the fact that MySQL permits the storing of incomplete dates such as '2014-00-00'.

The language used for day and month names and abbreviations is controlled by the value of the `lc_time_names` system variable (Section 12.16, “MySQL Server Locale Support”).

For the %U, %u, %V, and %v specifiers, see the description of the WEEK( ) function for information about the mode values. The mode affects how week numbering occurs.

DATE\_FORMAT( ) returns a string with a character set and collation given by `character_set_connection` and `collation_connection` so that it can return month and weekday names containing non-ASCII characters.

```
mysql> SELECT DATE_FORMAT('2009-10-04 22:23:00', '%W %M %Y');
-> 'Sunday October 2009'
mysql> SELECT DATE_FORMAT('2007-10-04 22:23:00', '%H:%i:%s');
-> '22:23:00'
```

```
mysql> SELECT DATE_FORMAT('1900-10-04 22:23:00',
-> '%D %y %a %d %m %b %j');
-> '4th 00 Thu 04 10 Oct 277'
mysql> SELECT DATE_FORMAT('1997-10-04 22:23:00',
-> '%H %k %I %r %T %S %w');
-> '22 22 10 10:23:00 PM 22:23:00 00 6'
mysql> SELECT DATE_FORMAT('1999-01-01', '%X %V');
-> '1998 52'
mysql> SELECT DATE_FORMAT('2006-06-00', '%d');
-> '00'
```

- `DATE_SUB(date, INTERVAL expr unit)`

See the description for `DATE_ADD()`.

- `DAY(date)`

`DAY()` is a synonym for `DAYOFMONTH()`.

- `DAYNAME(date)`

Returns the name of the weekday for `date`. The language used for the name is controlled by the value of the `lc_time_names` system variable (see [Section 12.16, “MySQL Server Locale Support”](#)). Returns `NULL` if `date` is `NULL`.

```
mysql> SELECT DAYNAME('2007-02-03');
-> 'Saturday'
```

- `DAYOFMONTH(date)`

Returns the day of the month for `date`, in the range 1 to 31, or 0 for dates such as '0000-00-00' or '2008-00-00' that have a zero day part. Returns `NULL` if `date` is `NULL`.

```
mysql> SELECT DAYOFMONTH('2007-02-03');
-> 3
```

- `DAYOFWEEK(date)`

Returns the weekday index for `date` (1 = Sunday, 2 = Monday, ..., 7 = Saturday). These index values correspond to the ODBC standard. Returns `NULL` if `date` is `NULL`.

```
mysql> SELECT DAYOFWEEK('2007-02-03');
-> 7
```

- `DAYOFYEAR(date)`

Returns the day of the year for `date`, in the range 1 to 366. Returns `NULL` if `date` is `NULL`.

```
mysql> SELECT DAYOFYEAR('2007-02-03');
-> 34
```

- `EXTRACT(unit FROM date)`

The `EXTRACT()` function uses the same kinds of `unit` specifiers as `DATE_ADD()` or `DATE_SUB()`, but extracts parts from the date rather than performing date arithmetic. For information on the `unit` argument, see [Temporal Intervals](#). Returns `NULL` if `date` is `NULL`.

```
mysql> SELECT EXTRACT(YEAR FROM '2019-07-02');
-> 2019
mysql> SELECT EXTRACT(YEAR_MONTH FROM '2019-07-02 01:02:03');
-> 201907
mysql> SELECT EXTRACT(DAY_MINUTE FROM '2019-07-02 01:02:03');
-> 20102
```

```
mysql> SELECT EXTRACT(MICROSECOND
-> FROM '2003-01-02 10:30:00.000123');
-> 123
```

- `FROM_DAYS(N)`

Given a day number *N*, returns a `DATE` value. Returns `NULL` if *N* is `NULL`.

```
mysql> SELECT FROM_DAYS(730669);
-> '2000-07-03'
```

Use `FROM_DAYS()` with caution on old dates. It is not intended for use with values that precede the advent of the Gregorian calendar (1582). See [Section 13.2.7, “What Calendar Is Used By MySQL?”](#).

- `FROM_UNIXTIME(unix_timestamp[, format])`

Returns a representation of *unix\_timestamp* as a datetime or character string value. The value returned is expressed using the session time zone. (Clients can set the session time zone as described in [Section 7.1.15, “MySQL Server Time Zone Support”](#).) *unix\_timestamp* is an internal timestamp value representing seconds since '1970-01-01 00:00:00' UTC, such as produced by the `UNIX_TIMESTAMP()` function.

If *format* is omitted, this function returns a `DATETIME` value.

If *unix\_timestamp* or *format* is `NULL`, this function returns `NULL`.

If *unix\_timestamp* is an integer, the fractional seconds precision of the `DATETIME` is zero. When *unix\_timestamp* is a decimal value, the fractional seconds precision of the `DATETIME` is the same as the precision of the decimal value, up to a maximum of 6. When *unix\_timestamp* is a floating point number, the fractional seconds precision of the datetime is 6.

On 32-bit platforms, the maximum useful value for *unix\_timestamp* is 2147483647.999999, which returns '2038-01-19 03:14:07.999999' UTC. On 64-bit platforms, the effective maximum is 32536771199.999999, which returns '3001-01-18 23:59:59.999999' UTC. Regardless of platform or version, a greater value for *unix\_timestamp* than the effective maximum returns 0.

*format* is used to format the result in the same way as the format string used for the `DATE_FORMAT()` function. If *format* is supplied, the value returned is a `VARCHAR`.

```
mysql> SELECT FROM_UNIXTIME(1447430881);
-> '2015-11-13 10:08:01'
mysql> SELECT FROM_UNIXTIME(1447430881) + 0;
-> 20151113100801
mysql> SELECT FROM_UNIXTIME(1447430881,
-> '%Y %D %M %h:%i:%s %x');
-> '2015 13th November 10:08:01 2015'
```

#### Note

If you use `UNIX_TIMESTAMP()` and `FROM_UNIXTIME()` to convert between values in a non-UTC time zone and Unix timestamp values, the conversion is lossy because the mapping is not one-to-one in both directions. For details, see the description of the `UNIX_TIMESTAMP()` function.

- `GET_FORMAT( {DATE|TIME|DATETIME} , { 'EUR' | 'USA' | 'JIS' | 'ISO' | 'INTERNAL' } )`

Returns a format string. This function is useful in combination with the `DATE_FORMAT( )` and the `STR_TO_DATE( )` functions.

If *format* is `NULL`, this function returns `NULL`.

The possible values for the first and second arguments result in several possible format strings (for the specifiers used, see the table in the `DATE_FORMAT( )` function description). ISO format refers to ISO 9075, not ISO 8601.

Function Call	Result
<code>GET_FORMAT( DATE , 'USA' )</code>	<code>'%m.%d.%Y'</code>
<code>GET_FORMAT( DATE , 'JIS' )</code>	<code>'%Y-%m-%d'</code>
<code>GET_FORMAT( DATE , 'ISO' )</code>	<code>'%Y-%m-%d'</code>
<code>GET_FORMAT( DATE , 'EUR' )</code>	<code>'%d.%m.%Y'</code>
<code>GET_FORMAT( DATE , 'INTERNAL' )</code>	<code>'%Y%m%d'</code>
<code>GET_FORMAT( DATETIME , 'USA' )</code>	<code>'%Y-%m-%d %H.%i.%s'</code>
<code>GET_FORMAT( DATETIME , 'JIS' )</code>	<code>'%Y-%m-%d %H:%i:%s'</code>
<code>GET_FORMAT( DATETIME , 'ISO' )</code>	<code>'%Y-%m-%d %H:%i:%s'</code>
<code>GET_FORMAT( DATETIME , 'EUR' )</code>	<code>'%Y-%m-%d %H.%i.%s'</code>
<code>GET_FORMAT( DATETIME , 'INTERNAL' )</code>	<code>'%Y%m%d%H%i%s'</code>
<code>GET_FORMAT( TIME , 'USA' )</code>	<code>'%h:%i:%s %p'</code>
<code>GET_FORMAT( TIME , 'JIS' )</code>	<code>'%H:%i:%s'</code>
<code>GET_FORMAT( TIME , 'ISO' )</code>	<code>'%H:%i:%s'</code>
<code>GET_FORMAT( TIME , 'EUR' )</code>	<code>'%H.%i.%s'</code>
<code>GET_FORMAT( TIME , 'INTERNAL' )</code>	<code>'%H%i%s'</code>

`TIMESTAMP` can also be used as the first argument to `GET_FORMAT( )`, in which case the function returns the same values as for `DATETIME`.

```
mysql> SELECT DATE_FORMAT('2003-10-03',GET_FORMAT(DATE,'EUR'));
-> '03.10.2003'
mysql> SELECT STR_TO_DATE('10.31.2003',GET_FORMAT(DATE,'USA'));
-> '2003-10-31'
```

- `HOUR( time )`

Returns the hour for *time*. The range of the return value is 0 to 23 for time-of-day values. However, the range of `TIME` values actually is much larger, so `HOUR` can return values greater than 23. Returns `NULL` if *time* is `NULL`.

```
mysql> SELECT HOUR('10:05:03');
-> 10
mysql> SELECT HOUR('272:59:59');
-> 272
```

- `LAST_DAY(date)`

Takes a date or datetime value and returns the corresponding value for the last day of the month. Returns `NULL` if the argument is invalid or `NULL`.

```
mysql> SELECT LAST_DAY('2003-02-05');
 -> '2003-02-28'
mysql> SELECT LAST_DAY('2004-02-05');
 -> '2004-02-29'
mysql> SELECT LAST_DAY('2004-01-01 01:01:01');
 -> '2004-01-31'
mysql> SELECT LAST_DAY('2003-03-32');
 -> NULL
```

- `LOCALTIME, LOCALTIME([fsp])`

`LOCALTIME` and `LOCALTIME()` are synonyms for `NOW()`.

- `LOCALTIMESTAMP, LOCALTIMESTAMP([fsp])`

`LOCALTIMESTAMP` and `LOCALTIMESTAMP()` are synonyms for `NOW()`.

- `MAKEDATE(year, dayofyear)`

Returns a date, given year and day-of-year values. `dayofyear` must be greater than 0 or the result is `NULL`. The result is also `NULL` if either argument is `NULL`.

```
mysql> SELECT MAKEDATE(2011,31), MAKEDATE(2011,32);
 -> '2011-01-31', '2011-02-01'
mysql> SELECT MAKEDATE(2011,365), MAKEDATE(2014,365);
 -> '2011-12-31', '2014-12-31'
mysql> SELECT MAKEDATE(2011,0);
 -> NULL
```

- `MAKETIME(hour, minute, second)`

Returns a time value calculated from the `hour`, `minute`, and `second` arguments. Returns `NULL` if any of its arguments are `NULL`.

The `second` argument can have a fractional part.

```
mysql> SELECT MAKETIME(12,15,30);
 -> '12:15:30'
```

- `MICROSECOND(expr)`

Returns the microseconds from the time or datetime expression `expr` as a number in the range from 0 to 999999. Returns `NULL` if `expr` is `NULL`.

```
mysql> SELECT MICROSECOND('12:00:00.123456');
 -> 123456
mysql> SELECT MICROSECOND('2019-12-31 23:59:59.000010');
 -> 10
```

- `MINUTE(time)`

Returns the minute for `time`, in the range 0 to 59, or `NULL` if `time` is `NULL`.

```
mysql> SELECT MINUTE('2008-02-03 10:05:03');
 -> 5
```

- `MONTH(date)`

Returns the month for *date*, in the range 1 to 12 for January to December, or 0 for dates such as '0000-00-00' or '2008-00-00' that have a zero month part. Returns *NULL* if *date* is *NULL*.

```
mysql> SELECT MONTH('2008-02-03');
-> 2
```

- `MONTHNAME(date)`

Returns the full name of the month for *date*. The language used for the name is controlled by the value of the `lc_time_names` system variable (Section 12.16, “MySQL Server Locale Support”). Returns *NULL* if *date* is *NULL*.

```
mysql> SELECT MONTHNAME('2008-02-03');
-> 'February'
```

- `NOW([fsp])`

Returns the current date and time as a value in '*YYYY-MM-DD hh:mm:ss*' or *YYYYMMDDhhmmss* format, depending on whether the function is used in string or numeric context. The value is expressed in the session time zone.

If the *fsp* argument is given to specify a fractional seconds precision from 0 to 6, the return value includes a fractional seconds part of that many digits.

```
mysql> SELECT NOW();
-> '2007-12-15 23:50:26'
mysql> SELECT NOW() + 0;
-> 20071215235026.000000
```

`NOW()` returns a constant time that indicates the time at which the statement began to execute. (Within a stored function or trigger, `NOW()` returns the time at which the function or triggering statement began to execute.) This differs from the behavior for `SYSDATE()`, which returns the exact time at which it executes.

```
mysql> SELECT NOW(), SLEEP(2), NOW();
+-----+-----+-----+
| NOW() | SLEEP(2) | NOW() |
+-----+-----+-----+
| 2006-04-12 13:47:36 | 0 | 2006-04-12 13:47:36 |
+-----+-----+-----+

mysql> SELECT SYSDATE(), SLEEP(2), SYSDATE();
+-----+-----+-----+
| SYSDATE() | SLEEP(2) | SYSDATE() |
+-----+-----+-----+
| 2006-04-12 13:47:44 | 0 | 2006-04-12 13:47:46 |
+-----+-----+-----+
```

In addition, the `SET TIMESTAMP` statement affects the value returned by `NOW()` but not by `SYSDATE()`. This means that timestamp settings in the binary log have no effect on invocations of `SYSDATE()`. Setting the timestamp to a nonzero value causes each subsequent invocation of `NOW()` to return that value. Setting the timestamp to zero cancels this effect so that `NOW()` once again returns the current date and time.

See the description for `SYSDATE()` for additional information about the differences between the two functions.

- `PERIOD_ADD(P,N)`

Adds *N* months to period *P* (in the format *YYMM* or *YYYYMM*). Returns a value in the format *YYYYMM*.

**Note**

The period argument *P* is *not* a date value.

This function returns `NULL` if *P* or *N* is `NULL`.

```
mysql> SELECT PERIOD_ADD(200801,2);
-> 200803
```

- `PERIOD_DIFF(P1,P2)`

Returns the number of months between periods *P1* and *P2*. *P1* and *P2* should be in the format `YYMM` or `YYYYMM`. Note that the period arguments *P1* and *P2* are *not* date values.

This function returns `NULL` if *P1* or *P2* is `NULL`.

```
mysql> SELECT PERIOD_DIFF(200802,200703);
-> 11
```

- `QUARTER(date)`

Returns the quarter of the year for *date*, in the range 1 to 4, or `NULL` if *date* is `NULL`.

```
mysql> SELECT QUARTER('2008-04-01');
-> 2
```

- `SECOND(time)`

Returns the second for *time*, in the range 0 to 59, or `NULL` if *time* is `NULL`.

```
mysql> SELECT SECOND('10:05:03');
-> 3
```

- `SEC_TO_TIME(seconds)`

Returns the *seconds* argument, converted to hours, minutes, and seconds, as a `TIME` value. The range of the result is constrained to that of the `TIME` data type. A warning occurs if the argument corresponds to a value outside that range.

The function returns `NULL` if *seconds* is `NULL`.

```
mysql> SELECT SEC_TO_TIME(2378);
-> '00:39:38'
mysql> SELECT SEC_TO_TIME(2378) + 0;
-> 3938
```

- `STR_TO_DATE(str,format)`

This is the inverse of the `DATE_FORMAT()` function. It takes a string *str* and a format string *format*. `STR_TO_DATE()` returns a `DATETIME` value if the format string contains both date and time parts, or a `DATE` or `TIME` value if the string contains only date or time parts. If *str* or *format* is `NULL`, the function returns `NULL`. If the date, time, or datetime value extracted from *str* cannot be parsed according to the rules followed by the server, `STR_TO_DATE()` returns `NULL` and produces a warning.

The server scans *str* attempting to match *format* to it. The format string can contain literal characters and format specifiers beginning with `%`. Literal characters in *format* must match literally in *str*. Format

specifiers in *format* must match a date or time part in *str*. For the specifiers that can be used in *format*, see the `DATE_FORMAT()` function description.

```
mysql> SELECT STR_TO_DATE('01,5,2013','%d,%m,%Y');
-> '2013-05-01'
mysql> SELECT STR_TO_DATE('May 1, 2013','%M %d,%Y');
-> '2013-05-01'
```

Scanning starts at the beginning of *str* and fails if *format* is found not to match. Extra characters at the end of *str* are ignored.

```
mysql> SELECT STR_TO_DATE('a09:30:17','a%h:%i:%s');
-> '09:30:17'
mysql> SELECT STR_TO_DATE('a09:30:17','%h:%i:%s');
-> NULL
mysql> SELECT STR_TO_DATE('09:30:17a','%h:%i:%s');
-> '09:30:17'
```

Unspecified date or time parts have a value of 0, so incompletely specified values in *str* produce a result with some or all parts set to 0:

```
mysql> SELECT STR_TO_DATE('abc','abc');
-> '0000-00-00'
mysql> SELECT STR_TO_DATE('9','%m');
-> '0000-09-00'
mysql> SELECT STR_TO_DATE('9','%s');
-> '00:00:09'
```

Range checking on the parts of date values is as described in [Section 13.2.2, “The DATE, DATETIME, and TIMESTAMP Types”](#). This means, for example, that “zero” dates or dates with part values of 0 are permitted unless the SQL mode is set to disallow such values.

```
mysql> SELECT STR_TO_DATE('00/00/0000','%m/%d/%Y');
-> '0000-00-00'
mysql> SELECT STR_TO_DATE('04/31/2004','%m/%d/%Y');
-> '2004-04-31'
```

If the `NO_ZERO_DATE` SQL mode is enabled, zero dates are disallowed. In that case, `STR_TO_DATE()` returns `NULL` and generates a warning:

```
mysql> SET sql_mode = '';
mysql> SELECT STR_TO_DATE('00/00/0000','%m/%d/%Y');
+-----+
| STR_TO_DATE('00/00/0000','%m/%d/%Y') |
+-----+
| 0000-00-00 |
+-----+
mysql> SET sql_mode = 'NO_ZERO_DATE';
mysql> SELECT STR_TO_DATE('00/00/0000','%m/%d/%Y');
+-----+
| STR_TO_DATE('00/00/0000','%m/%d/%Y') |
+-----+
| NULL |
+-----+
mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Warning
Code: 1411
```

Message: Incorrect datetime value: '00/00/0000' for function str\_to\_date

In some previous versions of MySQL, it was possible to pass an invalid date string such as '2021-11-31' to this function. In MySQL 9.1, `STR_TO_DATE()` performs complete range checking and raises an error if the date after conversion would be invalid.

#### Note

You cannot use format `"%X%V"` to convert a year-week string to a date because the combination of a year and week does not uniquely identify a year and month if the week crosses a month boundary. To convert a year-week to a date, you should also specify the weekday:

```
mysql> SELECT STR_TO_DATE('200442 Monday', '%X%V %W');
-> '2004-10-18'
```

You should also be aware that, for dates and the date portions of datetime values, `STR_TO_DATE()` checks (only) the individual year, month, and day of month values for validity. More precisely, this means that the year is checked to be sure that it is in the range 0-9999 inclusive, the month is checked to ensure that it is in the range 1-12 inclusive, and the day of month is checked to make sure that it is in the range 1-31 inclusive, but the server does not check the values in combination. For example, `SELECT STR_TO_DATE('23-2-31', '%Y-%m-%d')` returns `2023-02-31`. Enabling or disabling the `ALLOW_INVALID_DATES` server SQL mode has no effect on this behavior. See [Section 13.2.2, “The DATE, DATETIME, and TIMESTAMP Types”](#), for more information.

- `SUBDATE(date, INTERVAL expr unit), SUBDATE(expr, days)`

When invoked with the `INTERVAL` form of the second argument, `SUBDATE()` is a synonym for `DATE_SUB()`. For information on the `INTERVAL unit` argument, see the discussion for `DATE_ADD()`.

```
mysql> SELECT DATE_SUB('2008-01-02', INTERVAL 31 DAY);
-> '2007-12-02'
mysql> SELECT SUBDATE('2008-01-02', INTERVAL 31 DAY);
-> '2007-12-02'
```

The second form enables the use of an integer value for `days`. In such cases, it is interpreted as the number of days to be subtracted from the date or datetime expression `expr`.

```
mysql> SELECT SUBDATE('2008-01-02 12:00:00', 31);
-> '2007-12-02 12:00:00'
```

This function returns `NULL` if any of its arguments are `NULL`.

- `SUBTIME(expr1, expr2)`

`SUBTIME()` returns `expr1 - expr2` expressed as a value in the same format as `expr1`. `expr1` is a time or datetime expression, and `expr2` is a time expression.

Resolution of this function's return type is performed as it is for the `ADDTIME()` function; see the description of that function for more information.

```
mysql> SELECT SUBTIME('2007-12-31 23:59:59.999999', '1 1:1:1.000002');
-> '2007-12-30 22:58:58.999997'
mysql> SELECT SUBTIME('01:00:00.999999', '02:00:00.999998');
-> '-00:59:59.999999'
```

This function returns `NULL` if `expr1` or `expr2` is `NULL`.

- `SYSDATE([fsp])`

Returns the current date and time as a value in `'YYYY-MM-DD hh:mm:ss'` or `YYYYMMDDhhmmss` format, depending on whether the function is used in string or numeric context.

If the `fsp` argument is given to specify a fractional seconds precision from 0 to 6, the return value includes a fractional seconds part of that many digits.

`SYSDATE()` returns the time at which it executes. This differs from the behavior for `NOW()`, which returns a constant time that indicates the time at which the statement began to execute. (Within a stored function or trigger, `NOW()` returns the time at which the function or triggering statement began to execute.)

```
mysql> SELECT NOW(), SLEEP(2), NOW();
+-----+-----+-----+
| NOW() | SLEEP(2) | NOW() |
+-----+-----+-----+
| 2006-04-12 13:47:36 | 0 | 2006-04-12 13:47:36 |
+-----+-----+-----+

mysql> SELECT SYSDATE(), SLEEP(2), SYSDATE();
+-----+-----+-----+
| SYSDATE() | SLEEP(2) | SYSDATE() |
+-----+-----+-----+
| 2006-04-12 13:47:44 | 0 | 2006-04-12 13:47:46 |
+-----+-----+-----+
```

In addition, the `SET TIMESTAMP` statement affects the value returned by `NOW()` but not by `SYSDATE()`. This means that timestamp settings in the binary log have no effect on invocations of `SYSDATE()`.

Because `SYSDATE()` can return different values even within the same statement, and is not affected by `SET TIMESTAMP`, it is nondeterministic and therefore unsafe for replication if statement-based binary logging is used. If that is a problem, you can use row-based logging.

Alternatively, you can use the `--sysdate-is-now` option to cause `SYSDATE()` to be an alias for `NOW()`. This works if the option is used on both the replication source server and the replica.

The nondeterministic nature of `SYSDATE()` also means that indexes cannot be used for evaluating expressions that refer to it.

- `TIME(expr)`

Extracts the time part of the time or datetime expression `expr` and returns it as a string. Returns `NULL` if `expr` is `NULL`.

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

```
mysql> SELECT TIME('2003-12-31 01:02:03');
-> '01:02:03'
mysql> SELECT TIME('2003-12-31 01:02:03.000123');
-> '01:02:03.000123'
```

- `TIMEDIFF(expr1,expr2)`

`TIMEDIFF()` returns `expr1 - expr2` expressed as a time value. `expr1` and `expr2` are strings which are converted to `TIME` or `DATETIME` expressions; these must be of the same type following conversion. Returns `NULL` if `expr1` or `expr2` is `NULL`.

The result returned by `TIMEDIFF()` is limited to the range allowed for `TIME` values. Alternatively, you can use either of the functions `TIMESTAMPDIFF()` and `UNIX_TIMESTAMP()`, both of which return integers.

```
mysql> SELECT TIMEDIFF('2000-01-01 00:00:00',
-> '2000-01-01 00:00:00.000001');
-> '-00:00:00.000001'
mysql> SELECT TIMEDIFF('2008-12-31 23:59:59.000001',
-> '2008-12-30 01:01:01.000002');
-> '46:58:57.999999'
```

- `TIMESTAMP(expr)`, `TIMESTAMP(expr1,expr2)`

With a single argument, this function returns the date or datetime expression `expr` as a datetime value. With two arguments, it adds the time expression `expr2` to the date or datetime expression `expr1` and returns the result as a datetime value. Returns `NULL` if `expr`, `expr1`, or `expr2` is `NULL`.

```
mysql> SELECT TIMESTAMP('2003-12-31');
-> '2003-12-31 00:00:00'
mysql> SELECT TIMESTAMP('2003-12-31 12:00:00','12:00:00');
-> '2004-01-01 00:00:00'
```

- `TIMESTAMPADD(unit,interval,datetime_expr)`

Adds the integer expression `interval` to the date or datetime expression `datetime_expr`. The unit for `interval` is given by the `unit` argument, which should be one of the following values: `MICROSECOND` (microseconds), `SECOND`, `MINUTE`, `HOURL`, `DAY`, `WEEK`, `MONTH`, `QUARTER`, or `YEAR`.

The `unit` value may be specified using one of keywords as shown, or with a prefix of `SQL_TSI_`. For example, `DAY` and `SQL_TSI_DAY` both are legal.

This function returns `NULL` if `interval` or `datetime_expr` is `NULL`.

```
mysql> SELECT TIMESTAMPADD(MINUTE, 1, '2003-01-02');
-> '2003-01-02 00:01:00'
mysql> SELECT TIMESTAMPADD(WEEK,1,'2003-01-02');
-> '2003-01-09'
```

When adding a `MONTH` interval to a `DATE` or `DATETIME` value, and the resulting date includes a day that does not exist in the given month, the day is adjusted to the last day of the month, as shown here:

```
mysql> SELECT TIMESTAMPADD(MONTH, 1, DATE '2024-03-30') AS t1,
-> TIMESTAMPADD(MONTH, 1, DATE '2024-03-31') AS t2;
+-----+-----+
| t1 | t2 |
+-----+-----+
| 2024-04-30 | 2024-04-30 |
+-----+-----+
1 row in set (0.00 sec)
```

- `TIMESTAMPDIFF(unit,datetime_expr1,datetime_expr2)`

Returns `datetime_expr2 - datetime_expr1`, where `datetime_expr1` and `datetime_expr2` are date or datetime expressions. One expression may be a date and the other a datetime; a date value is treated as a datetime having the time part `'00:00:00'` where necessary. The unit for the result (an

integer) is given by the *unit* argument. The legal values for *unit* are the same as those listed in the description of the `TIMESTAMPADD()` function.

This function returns `NULL` if *datetime\_expr1* or *datetime\_expr2* is `NULL`.

```
mysql> SELECT TIMESTAMPDIFF(MONTH,'2003-02-01','2003-05-01');
-> 3
mysql> SELECT TIMESTAMPDIFF(YEAR,'2002-05-01','2001-01-01');
-> -1
mysql> SELECT TIMESTAMPDIFF(MINUTE,'2003-02-01','2003-05-01 12:05:55');
-> 128885
```

#### Note

The order of the date or datetime arguments for this function is the opposite of that used with the `TIMESTAMP()` function when invoked with 2 arguments.

- `TIME_FORMAT(time,format)`

This is used like the `DATE_FORMAT()` function, but the *format* string may contain format specifiers only for hours, minutes, seconds, and microseconds. Other specifiers produce a `NULL` or 0. `TIME_FORMAT()` returns `NULL` if *time* or *format* is `NULL`.

If the *time* value contains an hour part that is greater than 23, the `%H` and `%k` hour format specifiers produce a value larger than the usual range of 0..23. The other hour format specifiers produce the hour value modulo 12.

```
mysql> SELECT TIME_FORMAT('100:00:00', '%H %k %h %I %l');
-> '100 100 04 04 4'
```

- `TIME_TO_SEC(time)`

Returns the *time* argument, converted to seconds. Returns `NULL` if *time* is `NULL`.

```
mysql> SELECT TIME_TO_SEC('22:23:00');
-> 80580
mysql> SELECT TIME_TO_SEC('00:39:38');
-> 2378
```

- `TO_DAYS(date)`

Given a date *date*, returns a day number (the number of days since year 0). Returns `NULL` if *date* is `NULL`.

```
mysql> SELECT TO_DAYS(950501);
-> 728779
mysql> SELECT TO_DAYS('2007-10-07');
-> 733321
```

`TO_DAYS()` is not intended for use with values that precede the advent of the Gregorian calendar (1582), because it does not take into account the days that were lost when the calendar was changed. For dates before 1582 (and possibly a later year in other locales), results from this function are not reliable. See [Section 13.2.7, “What Calendar Is Used By MySQL?”](#), for details.

Remember that MySQL converts two-digit year values in dates to four-digit form using the rules in [Section 13.2, “Date and Time Data Types”](#). For example, '2008-10-07' and '08-10-07' are seen as identical dates:

```
mysql> SELECT TO_DAYS('2008-10-07'), TO_DAYS('08-10-07');
```

```
-> 733687, 733687
```

In MySQL, the zero date is defined as '0000-00-00', even though this date is itself considered invalid. This means that, for '0000-00-00' and '0000-01-01', `TO_DAYS()` returns the values shown here:

```
mysql> SELECT TO_DAYS('0000-00-00');
+-----+
| to_days('0000-00-00') |
+-----+
| NULL |
+-----+
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Warning | 1292 | Incorrect datetime value: '0000-00-00' |
+-----+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT TO_DAYS('0000-01-01');
+-----+
| to_days('0000-01-01') |
+-----+
| 1 |
+-----+
1 row in set (0.00 sec)
```

This is true whether or not the `ALLOW_INVALID_DATES` SQL server mode is enabled.

- `TO_SECONDS(expr)`

Given a date or datetime *expr*, returns the number of seconds since the year 0. If *expr* is not a valid date or datetime value (including `NULL`), it returns `NULL`.

```
mysql> SELECT TO_SECONDS(950501);
-> 62966505600
mysql> SELECT TO_SECONDS('2009-11-29');
-> 63426672000
mysql> SELECT TO_SECONDS('2009-11-29 13:43:32');
-> 63426721412
mysql> SELECT TO_SECONDS(NOW());
-> 63426721458
```

Like `TO_DAYS()`, `TO_SECONDS()` is not intended for use with values that precede the advent of the Gregorian calendar (1582), because it does not take into account the days that were lost when the calendar was changed. For dates before 1582 (and possibly a later year in other locales), results from this function are not reliable. See [Section 13.2.7, “What Calendar Is Used By MySQL?”](#), for details.

Like `TO_DAYS()`, `TO_SECONDS()`, converts two-digit year values in dates to four-digit form using the rules in [Section 13.2, “Date and Time Data Types”](#).

In MySQL, the zero date is defined as '0000-00-00', even though this date is itself considered invalid. This means that, for '0000-00-00' and '0000-01-01', `TO_SECONDS()` returns the values shown here:

```
mysql> SELECT TO_SECONDS('0000-00-00');
+-----+
| TO_SECONDS('0000-00-00') |
+-----+
| NULL |
+-----+
```

```

+-----+
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Warning | 1292 | Incorrect datetime value: '0000-00-00' |
+-----+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT TO_SECONDS('0000-01-01');
+-----+
| TO_SECONDS('0000-01-01') |
+-----+
| 86400 |
+-----+
1 row in set (0.00 sec)

```

This is true whether or not the `ALLOW_INVALID_DATES` SQL server mode is enabled.

- `UNIX_TIMESTAMP([date])`

If `UNIX_TIMESTAMP()` is called with no *date* argument, it returns a Unix timestamp representing seconds since '1970-01-01 00:00:00' UTC.

If `UNIX_TIMESTAMP()` is called with a *date* argument, it returns the value of the argument as seconds since '1970-01-01 00:00:00' UTC. The server interprets *date* as a value in the session time zone and converts it to an internal Unix timestamp value in UTC. (Clients can set the session time zone as described in [Section 7.1.15, “MySQL Server Time Zone Support”](#).) The *date* argument may be a `DATE`, `DATETIME`, or `TIMESTAMP` string, or a number in `YYMMDD`, `YYMMDDhhmmss`, `YYYYMMDD`, or `YYYYMMDDhhmmss` format. If the argument includes a time part, it may optionally include a fractional seconds part.

The return value is an integer if no argument is given or the argument does not include a fractional seconds part, or `DECIMAL` if an argument is given that includes a fractional seconds part.

When the *date* argument is a `TIMESTAMP` column, `UNIX_TIMESTAMP()` returns the internal timestamp value directly, with no implicit “string-to-Unix-timestamp” conversion.

The valid range of argument values is the same as for the `TIMESTAMP` data type: '1970-01-01 00:00:01.000000' UTC to '2038-01-19 03:14:07.999999' UTC for 32-bit platforms; for MySQL running on 64-bit platforms, the valid range of argument values for `UNIX_TIMESTAMP()` is '1970-01-01 00:00:01.000000' UTC to '3001-01-19 03:14:07.999999' UTC (corresponding to 32536771199.999999 seconds).

Regardless of MySQL version or platform architecture, if you pass an out-of-range date to `UNIX_TIMESTAMP()`, it returns 0. If *date* is `NULL`, it returns `NULL`.

```

mysql> SELECT UNIX_TIMESTAMP();
-> 1447431666
mysql> SELECT UNIX_TIMESTAMP('2015-11-13 10:20:19');
-> 1447431619
mysql> SELECT UNIX_TIMESTAMP('2015-11-13 10:20:19.012');
-> 1447431619.012

```

If you use `UNIX_TIMESTAMP()` and `FROM_UNIXTIME()` to convert between values in a non-UTC time zone and Unix timestamp values, the conversion is lossy because the mapping is not one-to-one in both directions. For example, due to conventions for local time zone changes such as Daylight Saving Time

(DST), it is possible for `UNIX_TIMESTAMP()` to map two values that are distinct in a non-UTC time zone to the same Unix timestamp value. `FROM_UNIXTIME()` maps that value back to only one of the original values. Here is an example, using values that are distinct in the `MET` time zone:

```
mysql> SET time_zone = 'MET';
mysql> SELECT UNIX_TIMESTAMP('2005-03-27 03:00:00');
+-----+
| UNIX_TIMESTAMP('2005-03-27 03:00:00') |
+-----+
| 1111885200 |
+-----+
mysql> SELECT UNIX_TIMESTAMP('2005-03-27 02:00:00');
+-----+
| UNIX_TIMESTAMP('2005-03-27 02:00:00') |
+-----+
| 1111885200 |
+-----+
mysql> SELECT FROM_UNIXTIME(1111885200);
+-----+
| FROM_UNIXTIME(1111885200) |
+-----+
| 2005-03-27 03:00:00 |
+-----+
```

#### Note

To use named time zones such as `'MET'` or `'Europe/Amsterdam'`, the time zone tables must be properly set up. For instructions, see [Section 7.1.15, “MySQL Server Time Zone Support”](#).

If you want to subtract `UNIX_TIMESTAMP()` columns, you might want to cast them to signed integers. See [Section 14.10, “Cast Functions and Operators”](#).

- `UTC_DATE`, `UTC_DATE()`

Returns the current UTC date as a value in `'YYYY-MM-DD'` or `YYYYMMDD` format, depending on whether the function is used in string or numeric context.

```
mysql> SELECT UTC_DATE(), UTC_DATE() + 0;
-> '2003-08-14', 20030814
```

- `UTC_TIME`, `UTC_TIME([fsp])`

Returns the current UTC time as a value in `'hh:mm:ss'` or `hhmmss` format, depending on whether the function is used in string or numeric context.

If the `fsp` argument is given to specify a fractional seconds precision from 0 to 6, the return value includes a fractional seconds part of that many digits.

```
mysql> SELECT UTC_TIME(), UTC_TIME() + 0;
-> '18:07:53', 180753.000000
```

- `UTC_TIMESTAMP`, `UTC_TIMESTAMP([fsp])`

Returns the current UTC date and time as a value in `'YYYY-MM-DD hh:mm:ss'` or `YYYYMMDDhhmmss` format, depending on whether the function is used in string or numeric context.

If the `fsp` argument is given to specify a fractional seconds precision from 0 to 6, the return value includes a fractional seconds part of that many digits.

```
mysql> SELECT UTC_TIMESTAMP(), UTC_TIMESTAMP() + 0;
-> '2003-08-14 18:08:04', 20030814180804.000000
```

- `WEEK(date[,mode])`

This function returns the week number for *date*. The two-argument form of `WEEK()` enables you to specify whether the week starts on Sunday or Monday and whether the return value should be in the range from 0 to 53 or from 1 to 53. If the *mode* argument is omitted, the value of the `default_week_format` system variable is used. See [Section 7.1.8, “Server System Variables”](#). For a `NULL` date value, the function returns `NULL`.

The following table describes how the *mode* argument works.

Mode	First day of week	Range	Week 1 is the first week ...
0	Sunday	0-53	with a Sunday in this year
1	Monday	0-53	with 4 or more days this year
2	Sunday	1-53	with a Sunday in this year
3	Monday	1-53	with 4 or more days this year
4	Sunday	0-53	with 4 or more days this year
5	Monday	0-53	with a Monday in this year
6	Sunday	1-53	with 4 or more days this year
7	Monday	1-53	with a Monday in this year

For *mode* values with a meaning of “with 4 or more days this year,” weeks are numbered according to ISO 8601:1988:

- If the week containing January 1 has 4 or more days in the new year, it is week 1.
- Otherwise, it is the last week of the previous year, and the next week is week 1.

```
mysql> SELECT WEEK('2008-02-20');
-> 7
mysql> SELECT WEEK('2008-02-20',0);
-> 7
mysql> SELECT WEEK('2008-02-20',1);
-> 8
mysql> SELECT WEEK('2008-12-31',1);
-> 53
```

If a date falls in the last week of the previous year, MySQL returns 0 if you do not use 2, 3, 6, or 7 as the optional *mode* argument:

```
mysql> SELECT YEAR('2000-01-01'), WEEK('2000-01-01',0);
-> 2000, 0
```

One might argue that `WEEK()` should return 52 because the given date actually occurs in the 52nd week of 1999. `WEEK()` returns 0 instead so that the return value is “the week number in the given year.” This

makes use of the `WEEK()` function reliable when combined with other functions that extract a date part from a date.

If you prefer a result evaluated with respect to the year that contains the first day of the week for the given date, use 0, 2, 5, or 7 as the optional *mode* argument.

```
mysql> SELECT WEEK('2000-01-01',2);
-> 52
```

Alternatively, use the `YEARWEEK()` function:

```
mysql> SELECT YEARWEEK('2000-01-01');
-> 199952
mysql> SELECT MID(YEARWEEK('2000-01-01'),5,2);
-> '52'
```

- `WEEKDAY(date)`

Returns the weekday index for *date* (0 = Monday, 1 = Tuesday, ... 6 = Sunday). Returns `NULL` if *date* is `NULL`.

```
mysql> SELECT WEEKDAY('2008-02-03 22:23:00');
-> 6
mysql> SELECT WEEKDAY('2007-11-06');
-> 1
```

- `WEEKOFYEAR(date)`

Returns the calendar week of the date as a number in the range from 1 to 53. Returns `NULL` if *date* is `NULL`.

`WEEKOFYEAR()` is a compatibility function that is equivalent to `WEEK(date,3)`.

```
mysql> SELECT WEEKOFYEAR('2008-02-20');
-> 8
```

- `YEAR(date)`

Returns the year for *date*, in the range 1000 to 9999, or 0 for the “zero” date. Returns `NULL` if *date* is `NULL`.

```
mysql> SELECT YEAR('1987-01-01');
-> 1987
```

- `YEARWEEK(date)`, `YEARWEEK(date,mode)`

Returns year and week for a date. The year in the result may be different from the year in the date argument for the first and the last week of the year. Returns `NULL` if *date* is `NULL`.

The *mode* argument works exactly like the *mode* argument to `WEEK()`. For the single-argument syntax, a *mode* value of 0 is used. Unlike `WEEK()`, the value of `default_week_format` does not influence `YEARWEEK()`.

```
mysql> SELECT YEARWEEK('1987-01-01');
-> 198652
```

The week number is different from what the `WEEK()` function would return (0) for optional arguments 0 or 1, as `WEEK()` then returns the week in the context of the given year.

## 14.8 String Functions and Operators

**Table 14.12 String Functions and Operators**

Name	Description
ASCII ( )	Return numeric value of left-most character
BIN ( )	Return a string containing binary representation of a number
BIT_LENGTH ( )	Return length of argument in bits
CHAR ( )	Return the character for each integer passed
CHAR_LENGTH ( )	Return number of characters in argument
CHARACTER_LENGTH ( )	Synonym for CHAR_LENGTH ( )
CONCAT ( )	Return concatenated string
CONCAT_WS ( )	Return concatenate with separator
ELT ( )	Return string at index number
EXPORT_SET ( )	Return a string such that for every bit set in the value bits, you get an on string and for every unset bit, you get an off string
FIELD ( )	Index (position) of first argument in subsequent arguments
FIND_IN_SET ( )	Index (position) of first argument within second argument
FORMAT ( )	Return a number formatted to specified number of decimal places
FROM_BASE64 ( )	Decode base64 encoded string and return result
HEX ( )	Hexadecimal representation of decimal or string value
INSERT ( )	Insert substring at specified position up to specified number of characters
INSTR ( )	Return the index of the first occurrence of substring
LCASE ( )	Synonym for LOWER ( )
LEFT ( )	Return the leftmost number of characters as specified
LENGTH ( )	Return the length of a string in bytes
LIKE	Simple pattern matching
LOAD_FILE ( )	Load the named file
LOCATE ( )	Return the position of the first occurrence of substring
LOWER ( )	Return the argument in lowercase
LPAD ( )	Return the string argument, left-padded with the specified string
LTRIM ( )	Remove leading spaces
MAKE_SET ( )	Return a set of comma-separated strings that have the corresponding bit in bits set
MATCH ( )	Perform full-text search

Name	Description
<code>MID()</code>	Return a substring starting from the specified position
<code>NOT LIKE</code>	Negation of simple pattern matching
<code>NOT REGEXP</code>	Negation of REGEXP
<code>OCT()</code>	Return a string containing octal representation of a number
<code>OCTET_LENGTH()</code>	Synonym for <code>LENGTH()</code>
<code>ORD()</code>	Return character code for leftmost character of the argument
<code>POSITION()</code>	Synonym for <code>LOCATE()</code>
<code>QUOTE()</code>	Escape the argument for use in an SQL statement
<code>REGEXP</code>	Whether string matches regular expression
<code>REGEXP_INSTR()</code>	Starting index of substring matching regular expression
<code>REGEXP_LIKE()</code>	Whether string matches regular expression
<code>REGEXP_REPLACE()</code>	Replace substrings matching regular expression
<code>REGEXP_SUBSTR()</code>	Return substring matching regular expression
<code>REPEAT()</code>	Repeat a string the specified number of times
<code>REPLACE()</code>	Replace occurrences of a specified string
<code>REVERSE()</code>	Reverse the characters in a string
<code>RIGHT()</code>	Return the specified rightmost number of characters
<code>RLIKE</code>	Whether string matches regular expression
<code>RPAD()</code>	Append string the specified number of times
<code>RTRIM()</code>	Remove trailing spaces
<code>SOUNDEX()</code>	Return a soundex string
<code>SOUNDS LIKE</code>	Compare sounds
<code>SPACE()</code>	Return a string of the specified number of spaces
<code>STRCMP()</code>	Compare two strings
<code>SUBSTR()</code>	Return the substring as specified
<code>SUBSTRING()</code>	Return the substring as specified
<code>SUBSTRING_INDEX()</code>	Return a substring from a string before the specified number of occurrences of the delimiter
<code>TO_BASE64()</code>	Return the argument converted to a base-64 string
<code>TRIM()</code>	Remove leading and trailing spaces
<code>UCASE()</code>	Synonym for <code>UPPER()</code>
<code>UNHEX()</code>	Return a string containing hex representation of a number
<code>UPPER()</code>	Convert to uppercase
<code>WEIGHT_STRING()</code>	Return the weight string for a string

String-valued functions return `NULL` if the length of the result would be greater than the value of the `max_allowed_packet` system variable. See [Section 7.1.1, “Configuring the Server”](#).

For functions that operate on string positions, the first position is numbered 1.

For functions that take length arguments, noninteger arguments are rounded to the nearest integer.

- `ASCII(str)`

Returns the numeric value of the leftmost character of the string `str`. Returns 0 if `str` is the empty string. Returns `NULL` if `str` is `NULL`. `ASCII()` works for 8-bit characters.

```
mysql> SELECT ASCII('2');
-> 50
mysql> SELECT ASCII(2);
-> 50
mysql> SELECT ASCII('dx');
-> 100
```

See also the `ORD()` function.

- `BIN(N)`

Returns a string representation of the binary value of `N`, where `N` is a longlong (`BIGINT`) number. This is equivalent to `CONV(N,10,2)`. Returns `NULL` if `N` is `NULL`.

```
mysql> SELECT BIN(12);
-> '1100'
```

- `BIT_LENGTH(str)`

Returns the length of the string `str` in bits. Returns `NULL` if `str` is `NULL`.

```
mysql> SELECT BIT_LENGTH('text');
-> 32
```

- `CHAR(N,... [USING charset_name])`

`CHAR()` interprets each argument `N` as an integer and returns a string consisting of the characters given by the code values of those integers. `NULL` values are skipped.

```
mysql> SELECT CHAR(77,121,83,81,'76');
+-----+
| CHAR(77,121,83,81,'76') |
+-----+
| 0x4D7953514C |
+-----+
1 row in set (0.00 sec)

mysql> SELECT CHAR(77,77.3,'77.3');
+-----+
| CHAR(77,77.3,'77.3') |
+-----+
| 0x4D4D4D |
+-----+
1 row in set (0.00 sec)
```

By default, `CHAR()` returns a binary string. To produce a string in a given character set, use the optional `USING` clause:

```
mysql> SELECT CHAR(77,121,83,81,'76' USING utf8mb4);
+-----+
| CHAR(77,121,83,81,'76' USING utf8mb4) |
```

```

+-----+
| MySQL |
+-----+
1 row in set (0.00 sec)

mysql> SELECT CHAR(77,77.3,'77.3' USING utf8mb4);
+-----+
| CHAR(77,77.3,'77.3' USING utf8mb4) |
+-----+
| MMM |
+-----+
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Warning | 1292 | Truncated incorrect INTEGER value: '77.3' |
+-----+-----+-----+
1 row in set (0.00 sec)

```

If **USING** is given and the result string is illegal for the given character set, a warning is issued. Also, if strict SQL mode is enabled, the result from **CHAR( )** becomes **NULL**.

If **CHAR( )** is invoked from within the **mysql** client, binary strings display using hexadecimal notation, depending on the value of the **--binary-as-hex**. For more information about that option, see [Section 6.5.1, “mysql — The MySQL Command-Line Client”](#).

**CHAR( )** arguments larger than 255 are converted into multiple result bytes. For example, **CHAR(256)** is equivalent to **CHAR(1,0)**, and **CHAR(256\*256)** is equivalent to **CHAR(1,0,0)**:

```

mysql> SELECT HEX(CHAR(1,0)), HEX(CHAR(256));
+-----+-----+
| HEX(CHAR(1,0)) | HEX(CHAR(256)) |
+-----+-----+
| 0100 | 0100 |
+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT HEX(CHAR(1,0,0)), HEX(CHAR(256*256));
+-----+-----+
| HEX(CHAR(1,0,0)) | HEX(CHAR(256*256)) |
+-----+-----+
| 010000 | 010000 |
+-----+-----+
1 row in set (0.00 sec)

```

- **CHAR\_LENGTH(*str*)**

Returns the length of the string *str*, measured in code points. A multibyte character counts as a single code point. This means that, for a string containing two 3-byte characters, **LENGTH( )** returns **6**, whereas **CHAR\_LENGTH( )** returns **2**, as shown here:

```

mysql> SET @dolphin:='海豚';
Query OK, 0 rows affected (0.01 sec)

mysql> SELECT LENGTH(@dolphin), CHAR_LENGTH(@dolphin);
+-----+-----+
| LENGTH(@dolphin) | CHAR_LENGTH(@dolphin) |
+-----+-----+
| 6 | 2 |
+-----+-----+

```

```
1 row in set (0.00 sec)
```

`CHAR_LENGTH()` returns `NULL` if `str` is `NULL`.

- `CHARACTER_LENGTH(str)`

`CHARACTER_LENGTH()` is a synonym for `CHAR_LENGTH()`.

- `CONCAT(str1,str2,...)`

Returns the string that results from concatenating the arguments. May have one or more arguments. If all arguments are nonbinary strings, the result is a nonbinary string. If the arguments include any binary strings, the result is a binary string. A numeric argument is converted to its equivalent nonbinary string form.

`CONCAT()` returns `NULL` if any argument is `NULL`.

```
mysql> SELECT CONCAT('My', 'S', 'QL');
-> 'MySQL'
mysql> SELECT CONCAT('My', NULL, 'QL');
-> NULL
mysql> SELECT CONCAT(14.3);
-> '14.3'
```

For quoted strings, concatenation can be performed by placing the strings next to each other:

```
mysql> SELECT 'My' 'S' 'QL';
-> 'MySQL'
```

If `CONCAT()` is invoked from within the `mysql` client, binary string results display using hexadecimal notation, depending on the value of the `--binary-as-hex`. For more information about that option, see [Section 6.5.1, “mysql — The MySQL Command-Line Client”](#).

- `CONCAT_WS(separator,str1,str2,...)`

`CONCAT_WS()` stands for Concatenate With Separator and is a special form of `CONCAT()`. The first argument is the separator for the rest of the arguments. The separator is added between the strings to be concatenated. The separator can be a string, as can the rest of the arguments. If the separator is `NULL`, the result is `NULL`.

```
mysql> SELECT CONCAT_WS(',', 'First name', 'Second name', 'Last Name');
-> 'First name,Second name,Last Name'
mysql> SELECT CONCAT_WS(',', 'First name', NULL, 'Last Name');
-> 'First name,Last Name'
```

`CONCAT_WS()` does not skip empty strings. However, it does skip any `NULL` values after the separator argument.

- `ELT(N,str1,str2,str3,...)`

`ELT()` returns the *N*th element of the list of strings: `str1` if *N* = 1, `str2` if *N* = 2, and so on. Returns `NULL` if *N* is less than 1, greater than the number of arguments, or `NULL`. `ELT()` is the complement of `FIELD()`.

```
mysql> SELECT ELT(1, 'Aa', 'Bb', 'Cc', 'Dd');
-> 'Aa'
mysql> SELECT ELT(4, 'Aa', 'Bb', 'Cc', 'Dd');
-> 'Dd'
```

- `EXPORT_SET(bits,on,off[,separator[,number_of_bits]])`

Returns a string such that for every bit set in the value *bits*, you get an *on* string and for every bit not set in the value, you get an *off* string. Bits in *bits* are examined from right to left (from low-order to high-order bits). Strings are added to the result from left to right, separated by the *separator* string (the default being the comma character ,). The number of bits examined is given by *number\_of\_bits*, which has a default of 64 if not specified. *number\_of\_bits* is silently clipped to 64 if larger than 64. It is treated as an unsigned integer, so a value of -1 is effectively the same as 64.

```
mysql> SELECT EXPORT_SET(5,'Y','N',' ',4);
-> 'Y,N,Y,N'
mysql> SELECT EXPORT_SET(6,'1','0',' ',10);
-> '0,1,1,0,0,0,0,0,0,0'
```

- `FIELD(str,str1,str2,str3,...)`

Returns the index (position) of *str* in the *str1*, *str2*, *str3*, ... list. Returns 0 if *str* is not found.

If all arguments to `FIELD()` are strings, all arguments are compared as strings. If all arguments are numbers, they are compared as numbers. Otherwise, the arguments are compared as double.

If *str* is `NULL`, the return value is 0 because `NULL` fails equality comparison with any value. `FIELD()` is the complement of `ELT()`.

```
mysql> SELECT FIELD('Bb', 'Aa', 'Bb', 'Cc', 'Dd', 'Ff');
-> 2
mysql> SELECT FIELD('Gg', 'Aa', 'Bb', 'Cc', 'Dd', 'Ff');
-> 0
```

- `FIND_IN_SET(str,strlist)`

Returns a value in the range of 1 to *N* if the string *str* is in the string list *strlist* consisting of *N* substrings. A string list is a string composed of substrings separated by , characters. If the first argument is a constant string and the second is a column of type `SET`, the `FIND_IN_SET()` function is optimized to use bit arithmetic. Returns 0 if *str* is not in *strlist* or if *strlist* is the empty string. Returns `NULL` if either argument is `NULL`. This function does not work properly if the first argument contains a comma (,) character.

```
mysql> SELECT FIND_IN_SET('b','a,b,c,d');
-> 2
```

- `FORMAT(X,D[,locale])`

Formats the number *X* to a format like '#,###,###.##', rounded to *D* decimal places, and returns the result as a string. If *D* is 0, the result has no decimal point or fractional part. If *X* or *D* is `NULL`, the function returns `NULL`.

The optional third parameter enables a locale to be specified to be used for the result number's decimal point, thousands separator, and grouping between separators. Permissible locale values are the same as the legal values for the `lc_time_names` system variable (see [Section 12.16, "MySQL Server Locale Support"](#)). If the locale is `NULL` or not specified, the default locale is `'en_US'`.

```
mysql> SELECT FORMAT(12332.123456, 4);
-> '12,332.1235'
mysql> SELECT FORMAT(12332.1,4);
-> '12,332.1000'
mysql> SELECT FORMAT(12332.2,0);
-> '12,332'
mysql> SELECT FORMAT(12332.2,2,'de_DE');
-> '12.332,20'
```

- `FROM_BASE64(str)`

Takes a string encoded with the base-64 encoded rules used by `TO_BASE64()` and returns the decoded result as a binary string. The result is `NULL` if the argument is `NULL` or not a valid base-64 string. See the description of `TO_BASE64()` for details about the encoding and decoding rules.

```
mysql> SELECT TO_BASE64('abc'), FROM_BASE64(TO_BASE64('abc'));
 -> 'JWJj', 'abc'
```

If `FROM_BASE64()` is invoked from within the `mysql` client, binary strings display using hexadecimal notation. You can disable this behavior by setting the value of the `--binary-as-hex` to 0 when starting the `mysql` client. For more information about that option, see [Section 6.5.1, “mysql — The MySQL Command-Line Client”](#).

- `HEX(str), HEX(N)`

For a string argument `str`, `HEX()` returns a hexadecimal string representation of `str` where each byte of each character in `str` is converted to two hexadecimal digits. (Multibyte characters therefore become more than two digits.) The inverse of this operation is performed by the `UNHEX()` function.

For a numeric argument `N`, `HEX()` returns a hexadecimal string representation of the value of `N` treated as a longlong (`BIGINT`) number. This is equivalent to `CONV(N,10,16)`. The inverse of this operation is performed by `CONV(HEX(N),16,10)`.

For a `NULL` argument, this function returns `NULL`.

```
mysql> SELECT X'616263', HEX('abc'), UNHEX(HEX('abc'));
 -> 'abc', 616263, 'abc'
mysql> SELECT HEX(255), CONV(HEX(255),16,10);
 -> 'FF', 255
```

- `INSERT(str,pos,len,newstr)`

Returns the string `str`, with the substring beginning at position `pos` and `len` characters long replaced by the string `newstr`. Returns the original string if `pos` is not within the length of the string. Replaces the rest of the string from position `pos` if `len` is not within the length of the rest of the string. Returns `NULL` if any argument is `NULL`.

```
mysql> SELECT INSERT('Quadratic', 3, 4, 'What');
 -> 'QuWhattic'
mysql> SELECT INSERT('Quadratic', -1, 4, 'What');
 -> 'Quadratic'
mysql> SELECT INSERT('Quadratic', 3, 100, 'What');
 -> 'QuWhat'
```

This function is multibyte safe.

- `INSTR(str,substr)`

Returns the position of the first occurrence of substring `substr` in string `str`. This is the same as the two-argument form of `LOCATE()`, except that the order of the arguments is reversed.

```
mysql> SELECT INSTR('foobarbar', 'bar');
 -> 4
mysql> SELECT INSTR('xbar', 'foobar');
 -> 0
```

This function is multibyte safe, and is case-sensitive only if at least one argument is a binary string. If either argument is `NULL`, this functions returns `NULL`.

- `LCASE(str)`

`LCASE()` is a synonym for `LOWER()`.

`LCASE()` used in a view is rewritten as `LOWER()` when storing the view's definition. (Bug #12844279)

- `LEFT(str, len)`

Returns the leftmost `len` characters from the string `str`, or `NULL` if any argument is `NULL`.

```
mysql> SELECT LEFT('foobarbar', 5);
-> 'fooba'
```

This function is multibyte safe.

- `LENGTH(str)`

Returns the length of the string `str`, measured in bytes. A multibyte character counts as multiple bytes. This means that for a string containing five 2-byte characters, `LENGTH()` returns 10, whereas `CHAR_LENGTH()` returns 5. Returns `NULL` if `str` is `NULL`.

```
mysql> SELECT LENGTH('text');
-> 4
```

#### Note

The `Length()` OpenGIS spatial function is named `ST_Length()` in MySQL.

- `LOAD_FILE(file_name)`

Reads the file and returns the file contents as a string. To use this function, the file must be located on the server host, you must specify the full path name to the file, and you must have the `FILE` privilege. The file must be readable by the server and its size less than `max_allowed_packet` bytes. If the `secure_file_priv` system variable is set to a nonempty directory name, the file to be loaded must be located in that directory.

If the file does not exist or cannot be read because one of the preceding conditions is not satisfied, the function returns `NULL`.

The `character_set_filesystem` system variable controls interpretation of file names that are given as literal strings.

```
mysql> UPDATE t
 SET blob_col=LOAD_FILE('/tmp/picture')
 WHERE id=1;
```

- `LOCATE(substr, str)`, `LOCATE(substr, str, pos)`

The first syntax returns the position of the first occurrence of substring `substr` in string `str`. The second syntax returns the position of the first occurrence of substring `substr` in string `str`, starting at position `pos`. Returns 0 if `substr` is not in `str`. Returns `NULL` if any argument is `NULL`.

```
mysql> SELECT LOCATE('bar', 'foobarbar');
-> 4
mysql> SELECT LOCATE('xbar', 'foobar');
-> 0
mysql> SELECT LOCATE('bar', 'foobarbar', 5);
-> 7
```

This function is multibyte safe, and is case-sensitive only if at least one argument is a binary string.

- `LOWER(str)`

Returns the string `str` with all characters changed to lowercase according to the current character set mapping, or `NULL` if `str` is `NULL`. The default character set is `utf8mb4`.

```
mysql> SELECT LOWER('QUADRATICALLY');
-> 'quadratically'
```

`LOWER()` (and `UPPER()`) are ineffective when applied to binary strings (`BINARY`, `VARBINARY`, `BLOB`). To perform lettercase conversion of a binary string, first convert it to a nonbinary string using a character set appropriate for the data stored in the string:

```
mysql> SET @str = BINARY 'New York';
mysql> SELECT LOWER(@str), LOWER(CONVERT(@str USING utf8mb4));
+-----+-----+
| LOWER(@str) | LOWER(CONVERT(@str USING utf8mb4)) |
+-----+-----+
| New York | new york |
+-----+-----+
```

For collations of Unicode character sets, `LOWER()` and `UPPER()` work according to the Unicode Collation Algorithm (UCA) version in the collation name, if there is one, and UCA 4.0.0 if no version is specified. For example, `utf8mb4_0900_ai_ci` and `utf8mb3_unicode_520_ci` work according to UCA 9.0.0 and 5.2.0, respectively, whereas `utf8mb3_unicode_ci` works according to UCA 4.0.0. See [Section 12.10.1, “Unicode Character Sets”](#).

This function is multibyte safe.

`LCASE()` used within views is rewritten as `LOWER()`.

- `LPAD(str, len, padstr)`

Returns the string `str`, left-padded with the string `padstr` to a length of `len` characters. If `str` is longer than `len`, the return value is shortened to `len` characters.

```
mysql> SELECT LPAD('hi', 4, '??');
-> '??hi'
mysql> SELECT LPAD('hi', 1, '??');
-> 'h'
```

Returns `NULL` if any of its arguments are `NULL`.

- `LTRIM(str)`

Returns the string `str` with leading space characters removed. Returns `NULL` if `str` is `NULL`.

```
mysql> SELECT LTRIM(' barbar');
-> 'barbar'
```

This function is multibyte safe.

- `MAKE_SET(bits, str1, str2, ...)`

Returns a set value (a string containing substrings separated by `,` characters) consisting of the strings that have the corresponding bit in `bits` set. `str1` corresponds to bit 0, `str2` to bit 1, and so on. `NULL` values in `str1`, `str2`, ... are not appended to the result.

```
mysql> SELECT MAKE_SET(1, 'a', 'b', 'c');
-> 'a'
mysql> SELECT MAKE_SET(1 | 4, 'hello', 'nice', 'world');
-> 'hello,world'
```

```
mysql> SELECT MAKE_SET(1 | 4, 'hello', 'nice', NULL, 'world');
-> 'hello'
mysql> SELECT MAKE_SET(0, 'a', 'b', 'c');
-> ''
```

- `MID(str, pos)`, `MID(str FROM pos)`, `MID(str, pos, len)`, `MID(str FROM pos FOR len)`  
`MID(str, pos, len)` is a synonym for `SUBSTRING(str, pos, len)`.

- `OCT(N)`

Returns a string representation of the octal value of *N*, where *N* is a longlong (`BIGINT`) number. This is equivalent to `CONV(N, 10, 8)`. Returns `NULL` if *N* is `NULL`.

```
mysql> SELECT OCT(12);
-> '14'
```

- `OCTET_LENGTH(str)`

`OCTET_LENGTH()` is a synonym for `LENGTH()`.

- `ORD(str)`

If the leftmost character of the string *str* is a multibyte character, returns the code for that character, calculated from the numeric values of its constituent bytes using this formula:

```
(1st byte code)
+ (2nd byte code * 256)
+ (3rd byte code * 256^2) ...
```

If the leftmost character is not a multibyte character, `ORD()` returns the same value as the `ASCII()` function. The function returns `NULL` if *str* is `NULL`.

```
mysql> SELECT ORD('2');
-> 50
```

- `POSITION(substr IN str)`

`POSITION(substr IN str)` is a synonym for `LOCATE(substr, str)`.

- `QUOTE(str)`

Quotes a string to produce a result that can be used as a properly escaped data value in an SQL statement. The string is returned enclosed by single quotation marks and with each instance of backslash (`\`), single quote (`'`), ASCII `NUL`, and Control+Z preceded by a backslash. If the argument is `NULL`, the return value is the word “NULL” without enclosing single quotation marks.

```
mysql> SELECT QUOTE('Don\'t!');
-> 'Don\'t!'
mysql> SELECT QUOTE(NULL);
-> NULL
```

For comparison, see the quoting rules for literal strings and within the C API in [Section 11.1.1, “String Literals”](#), and `mysql_real_escape_string_quote()`.

- `REPEAT(str, count)`

Returns a string consisting of the string *str* repeated *count* times. If *count* is less than 1, returns an empty string. Returns `NULL` if *str* or *count* is `NULL`.

```
mysql> SELECT REPEAT('MySQL', 3);
```

```
-> 'MySQLMySQLMySQL'
```

- `REPLACE(str, from_str, to_str)`

Returns the string `str` with all occurrences of the string `from_str` replaced by the string `to_str`. `REPLACE()` performs a case-sensitive match when searching for `from_str`.

```
mysql> SELECT REPLACE('www.mysql.com', 'w', 'Ww');
-> 'WwWwWw.mysql.com'
```

This function is multibyte safe. It returns `NULL` if any of its arguments are `NULL`.

- `REVERSE(str)`

Returns the string `str` with the order of the characters reversed, or `NULL` if `str` is `NULL`.

```
mysql> SELECT REVERSE('abc');
-> 'cba'
```

This function is multibyte safe.

- `RIGHT(str, len)`

Returns the rightmost `len` characters from the string `str`, or `NULL` if any argument is `NULL`.

```
mysql> SELECT RIGHT('foobarbar', 4);
-> 'rbar'
```

This function is multibyte safe.

- `RPAD(str, len, padstr)`

Returns the string `str`, right-padded with the string `padstr` to a length of `len` characters. If `str` is longer than `len`, the return value is shortened to `len` characters. If `str`, `padstr`, or `len` is `NULL`, the function returns `NULL`.

```
mysql> SELECT RPAD('hi',5,'?');
-> 'hi???'
mysql> SELECT RPAD('hi',1,'?');
-> 'h'
```

This function is multibyte safe.

- `RTRIM(str)`

Returns the string `str` with trailing space characters removed.

```
mysql> SELECT RTRIM('barbar ');
-> 'barbar'
```

This function is multibyte safe, and returns `NULL` if `str` is `NULL`.

- `SOUNDEX(str)`

Returns a soundex string from `str`, or `NULL` if `str` is `NULL`. Two strings that sound almost the same should have identical soundex strings. A standard soundex string is four characters long, but the `SOUNDEX()` function returns an arbitrarily long string. You can use `SUBSTRING()` on the result to get

a standard soundex string. All nonalphabetic characters in *str* are ignored. All international alphabetic characters outside the A-Z range are treated as vowels.

### Important

When using `SOUNDEX()`, you should be aware of the following limitations:

- This function, as currently implemented, is intended to work well with strings that are in the English language only. Strings in other languages may not produce reliable results.
- This function is not guaranteed to provide consistent results with strings that use multibyte character sets, including `utf-8`. See Bug #22638 for more information.

```
mysql> SELECT SOUNDEX('Hello');
-> 'H400'
mysql> SELECT SOUNDEX('Quadratically');
-> 'Q36324'
```

### Note

This function implements the original Soundex algorithm, not the more popular enhanced version (also described by D. Knuth). The difference is that original version discards vowels first and duplicates second, whereas the enhanced version discards duplicates first and vowels second.

- `expr1 SOUNDS LIKE expr2`

This is the same as `SOUNDEX(expr1) = SOUNDEX(expr2)`.

- `SPACE(N)`

Returns a string consisting of *N* space characters, or `NULL` if *N* is `NULL`.

```
mysql> SELECT SPACE(6);
-> ' '
```

- `SUBSTR(str,pos)`, `SUBSTR(str FROM pos)`, `SUBSTR(str,pos,len)`, `SUBSTR(str FROM pos FOR len)`

`SUBSTR()` is a synonym for `SUBSTRING()`.

- `SUBSTRING(str,pos)`, `SUBSTRING(str FROM pos)`, `SUBSTRING(str,pos,len)`, `SUBSTRING(str FROM pos FOR len)`

The forms without a *len* argument return a substring from string *str* starting at position *pos*. The forms with a *len* argument return a substring *len* characters long from string *str*, starting at position *pos*. The forms that use `FROM` are standard SQL syntax. It is also possible to use a negative value for *pos*. In this case, the beginning of the substring is *pos* characters from the end of the string, rather than the beginning. A negative value may be used for *pos* in any of the forms of this function. A value of 0 for *pos* returns an empty string.

For all forms of `SUBSTRING()`, the position of the first character in the string from which the substring is to be extracted is reckoned as 1.

```
mysql> SELECT SUBSTRING('Quadratically',5);
-> 'ratically'
mysql> SELECT SUBSTRING('foobarbar' FROM 4);
-> 'barbar'
mysql> SELECT SUBSTRING('Quadratically',5,6);
```

```

-> 'ratika'
mysql> SELECT SUBSTRING('Sakila', -3);
-> 'ila'
mysql> SELECT SUBSTRING('Sakila', -5, 3);
-> 'aki'
mysql> SELECT SUBSTRING('Sakila' FROM -4 FOR 2);
-> 'ki'

```

This function is multibyte safe. It returns `NULL` if any of its arguments are `NULL`.

If `len` is less than 1, the result is the empty string.

- `SUBSTRING_INDEX(str, delim, count)`

Returns the substring from string `str` before `count` occurrences of the delimiter `delim`. If `count` is positive, everything to the left of the final delimiter (counting from the left) is returned. If `count` is negative, everything to the right of the final delimiter (counting from the right) is returned. `SUBSTRING_INDEX()` performs a case-sensitive match when searching for `delim`.

```

mysql> SELECT SUBSTRING_INDEX('www.mysql.com', '.', 2);
-> 'www.mysql'
mysql> SELECT SUBSTRING_INDEX('www.mysql.com', '.', -2);
-> 'mysql.com'

```

This function is multibyte safe.

`SUBSTRING_INDEX()` returns `NULL` if any of its arguments are `NULL`.

- `TO_BASE64(str)`

Converts the string argument to base-64 encoded form and returns the result as a character string with the connection character set and collation. If the argument is not a string, it is converted to a string before conversion takes place. The result is `NULL` if the argument is `NULL`. Base-64 encoded strings can be decoded using the `FROM_BASE64()` function.

```

mysql> SELECT TO_BASE64('abc'), FROM_BASE64(TO_BASE64('abc'));
-> 'JWJj', 'abc'

```

Different base-64 encoding schemes exist. These are the encoding and decoding rules used by `TO_BASE64()` and `FROM_BASE64()`:

- The encoding for alphabet value 62 is '+'.
- The encoding for alphabet value 63 is '/'.
- Encoded output consists of groups of 4 printable characters. Each 3 bytes of the input data are encoded using 4 characters. If the last group is incomplete, it is padded with '=' characters to a length of 4.
- A newline is added after each 76 characters of encoded output to divide long output into multiple lines.
- Decoding recognizes and ignores newline, carriage return, tab, and space.
- `TRIM([ {BOTH | LEADING | TRAILING} [remstr] FROM] str), TRIM([remstr FROM] str)`

Returns the string `str` with all `remstr` prefixes or suffixes removed. If none of the specifiers `BOTH`, `LEADING`, or `TRAILING` is given, `BOTH` is assumed. `remstr` is optional and, if not specified, spaces are removed.

```

mysql> SELECT TRIM(' bar ');

```

```

-> 'bar'
mysql> SELECT TRIM(LEADING 'x' FROM 'xxxbarxxx');
-> 'barxxx'
mysql> SELECT TRIM(BOTH 'x' FROM 'xxxbarxxx');
-> 'bar'
mysql> SELECT TRIM(TRAILING 'xyz' FROM 'barxyz');
-> 'barx'

```

This function is multibyte safe. It returns `NULL` if any of its arguments are `NULL`.

- `UCASE(str)`

`UCASE()` is a synonym for `UPPER()`.

`UCASE()` used within views is rewritten as `UPPER()`.

- `UNHEX(str)`

For a string argument `str`, `UNHEX(str)` interprets each pair of characters in the argument as a hexadecimal number and converts it to the byte represented by the number. The return value is a binary string.

```

mysql> SELECT UNHEX('4D7953514C');
-> 'MySQL'
mysql> SELECT X'4D7953514C';
-> 'MySQL'
mysql> SELECT UNHEX(HEX('string'));
-> 'string'
mysql> SELECT HEX(UNHEX('1267'));
-> '1267'

```

The characters in the argument string must be legal hexadecimal digits: `'0' .. '9'`, `'A' .. 'F'`, `'a' .. 'f'`. If the argument contains any nonhexadecimal digits, or is itself `NULL`, the result is `NULL`:

```

mysql> SELECT UNHEX('GG');
+-----+
| UNHEX('GG') |
+-----+
| NULL |
+-----+

mysql> SELECT UNHEX(NULL);
+-----+
| UNHEX(NULL) |
+-----+
| NULL |
+-----+

```

A `NULL` result can also occur if the argument to `UNHEX()` is a `BINARY` column, because values are padded with `0x00` bytes when stored but those bytes are not stripped on retrieval. For example, `'41'` is stored into a `CHAR(3)` column as `'41 '` and retrieved as `'41'` (with the trailing pad space stripped), so `UNHEX()` for the column value returns `X'41'`. By contrast, `'41'` is stored into a `BINARY(3)` column as `'41\0'` and retrieved as `'41\0'` (with the trailing pad `0x00` byte not stripped). `'\0'` is not a legal hexadecimal digit, so `UNHEX()` for the column value returns `NULL`.

For a numeric argument `N`, the inverse of `HEX(N)` is not performed by `UNHEX()`. Use `CONV(HEX(N), 16, 10)` instead. See the description of `HEX()`.

If `UNHEX()` is invoked from within the `mysql` client, binary strings display using hexadecimal notation, depending on the value of the `--binary-as-hex`. For more information about that option, see [Section 6.5.1, “mysql — The MySQL Command-Line Client”](#).

- `UPPER(str)`

Returns the string `str` with all characters changed to uppercase according to the current character set mapping, or `NULL` if `str` is `NULL`. The default character set is `utf8mb4`.

```
mysql> SELECT UPPER('Hej');
-> 'HEJ'
```

See the description of `LOWER()` for information that also applies to `UPPER()`. This included information about how to perform lettercase conversion of binary strings (`BINARY`, `VARBINARY`, `BLOB`) for which these functions are ineffective, and information about case folding for Unicode character sets.

This function is multibyte safe.

`UCASE()` used within views is rewritten as `UPPER()`.

- `WEIGHT_STRING(str [AS {CHAR|BINARY}(N)] [flags])`

This function returns the weight string for the input string. The return value is a binary string that represents the comparison and sorting value of the string, or `NULL` if the argument is `NULL`. It has these properties:

- If `WEIGHT_STRING(str1) = WEIGHT_STRING(str2)`, then `str1 = str2` (`str1` and `str2` are considered equal)
- If `WEIGHT_STRING(str1) < WEIGHT_STRING(str2)`, then `str1 < str2` (`str1` sorts before `str2`)

`WEIGHT_STRING()` is a debugging function intended for internal use. Its behavior can change without notice between MySQL versions. It can be used for testing and debugging of collations, especially if you are adding a new collation. See [Section 12.14, “Adding a Collation to a Character Set”](#).

This list briefly summarizes the arguments. More details are given in the discussion following the list.

- `str`: The input string expression.
- `AS` clause: Optional; cast the input string to a given type and length.
- `flags`: Optional; unused.

The input string, `str`, is a string expression. If the input is a nonbinary (character) string such as a `CHAR`, `VARCHAR`, or `TEXT` value, the return value contains the collation weights for the string. If the input is a binary (byte) string such as a `BINARY`, `VARBINARY`, or `BLOB` value, the return value is the same as the input (the weight for each byte in a binary string is the byte value). If the input is `NULL`, `WEIGHT_STRING()` returns `NULL`.

Examples:

```
mysql> SET @s = _utf8mb4 'AB' COLLATE utf8mb4_0900_ai_ci;
mysql> SELECT @s, HEX(@s), HEX(WEIGHT_STRING(@s));
+-----+-----+-----+
| @s | HEX(@s) | HEX(WEIGHT_STRING(@s)) |
+-----+-----+-----+
| AB | 4142 | 1C471C60 |
+-----+-----+-----+
```

```
mysql> SET @s = _utf8mb4 'ab' COLLATE utf8mb4_0900_ai_ci;
mysql> SELECT @s, HEX(@s), HEX(WEIGHT_STRING(@s));
+-----+-----+-----+
```

```

+-----+-----+-----+
| @s | HEX(@s) | HEX(WEIGHT_STRING(@s)) |
+-----+-----+-----+
| ab | 6162 | 1C471C60 |
+-----+-----+-----+

```

```

mysql> SET @s = CAST('AB' AS BINARY);
mysql> SELECT @s, HEX(@s), HEX(WEIGHT_STRING(@s));
+-----+-----+-----+
| @s | HEX(@s) | HEX(WEIGHT_STRING(@s)) |
+-----+-----+-----+
| AB | 4142 | 4142 |
+-----+-----+-----+

```

```

mysql> SET @s = CAST('ab' AS BINARY);
mysql> SELECT @s, HEX(@s), HEX(WEIGHT_STRING(@s));
+-----+-----+-----+
| @s | HEX(@s) | HEX(WEIGHT_STRING(@s)) |
+-----+-----+-----+
| ab | 6162 | 6162 |
+-----+-----+-----+

```

The preceding examples use `HEX()` to display the `WEIGHT_STRING()` result. Because the result is a binary value, `HEX()` can be especially useful when the result contains nonprinting values, to display it in printable form:

```

mysql> SET @s = CONVERT(X'C39F' USING utf8mb4) COLLATE utf8mb4_czech_ci;
mysql> SELECT HEX(WEIGHT_STRING(@s));
+-----+
| HEX(WEIGHT_STRING(@s)) |
+-----+
| 0FEA0FEA |
+-----+

```

For non-NULL return values, the data type of the value is `VARBINARY` if its length is within the maximum length for `VARBINARY`, otherwise the data type is `BLOB`.

The `AS` clause may be given to cast the input string to a nonbinary or binary string and to force it to a given length:

- `AS CHAR(N)` casts the string to a nonbinary string and pads it on the right with spaces to a length of `N` characters. `N` must be at least 1. If `N` is less than the length of the input string, the string is truncated to `N` characters. No warning occurs for truncation.
- `AS BINARY(N)` is similar but casts the string to a binary string, `N` is measured in bytes (not characters), and padding uses `0x00` bytes (not spaces).

```

mysql> SET NAMES 'latin1';
mysql> SELECT HEX(WEIGHT_STRING('ab' AS CHAR(4)));
+-----+
| HEX(WEIGHT_STRING('ab' AS CHAR(4))) |
+-----+
| 41422020 |
+-----+
mysql> SET NAMES 'utf8mb4';
mysql> SELECT HEX(WEIGHT_STRING('ab' AS CHAR(4)));
+-----+
| HEX(WEIGHT_STRING('ab' AS CHAR(4))) |
+-----+
| 1C471C60 |
+-----+

```

```

mysql> SELECT HEX(WEIGHT_STRING('ab' AS BINARY(4)));
+-----+
| HEX(WEIGHT_STRING('ab' AS BINARY(4))) |
+-----+

```

```
+-----+
| 61620000 |
+-----+
```

The *flags* clause currently is unused.

If `WEIGHT_STRING()` is invoked from within the `mysql` client, binary strings display using hexadecimal notation, depending on the value of the `--binary-as-hex`. For more information about that option, see [Section 6.5.1, “mysql — The MySQL Command-Line Client”](#).

### 14.8.1 String Comparison Functions and Operators

Table 14.13 String Comparison Functions and Operators

Name	Description
<code>LIKE</code>	Simple pattern matching
<code>NOT LIKE</code>	Negation of simple pattern matching
<code>STRCMP()</code>	Compare two strings

If a string function is given a binary string as an argument, the resulting string is also a binary string. A number converted to a string is treated as a binary string. This affects only comparisons.

Normally, if any expression in a string comparison is case-sensitive, the comparison is performed in case-sensitive fashion.

If a string function is invoked from within the `mysql` client, binary strings display using hexadecimal notation, depending on the value of the `--binary-as-hex`. For more information about that option, see [Section 6.5.1, “mysql — The MySQL Command-Line Client”](#).

- `expr LIKE pat [ESCAPE 'escape_char']`

Pattern matching using an SQL pattern. Returns 1 (TRUE) or 0 (FALSE). If either *expr* or *pat* is NULL, the result is NULL.

The pattern need not be a literal string. For example, it can be specified as a string expression or table column. In the latter case, the column must be defined as one of the MySQL string types (see [Section 13.3, “String Data Types”](#)).

Per the SQL standard, `LIKE` performs matching on a per-character basis, thus it can produce results different from the `=` comparison operator:

```
mysql> SELECT 'ä' LIKE 'ae' COLLATE latin1_german2_ci;
+-----+
| 'ä' LIKE 'ae' COLLATE latin1_german2_ci |
+-----+
| 0 |
+-----+
mysql> SELECT 'ä' = 'ae' COLLATE latin1_german2_ci;
+-----+
| 'ä' = 'ae' COLLATE latin1_german2_ci |
+-----+
| 1 |
+-----+
```

In particular, trailing spaces are always significant. This differs from comparisons performed with the `=` operator, for which the significance of trailing spaces in nonbinary strings (`CHAR`, `VARCHAR`, and `TEXT` values) depends on the pad attribute of the collation used for the comparison. For more information, see [Trailing Space Handling in Comparisons](#).

With `LIKE` you can use the following two wildcard characters in the pattern:

- `%` matches any number of characters, even zero characters.
- `_` matches exactly one character.

```
mysql> SELECT 'David!' LIKE 'David_';
 -> 1
mysql> SELECT 'David!' LIKE '%D%v%';
 -> 1
```

To test for literal instances of a wildcard character, precede it by the escape character. If you do not specify the `ESCAPE` character, `\` is assumed, unless the `NO_BACKSLASH_ESCAPES` SQL mode is enabled. In that case, no escape character is used.

- `\%` matches one `%` character.
- `\_` matches one `_` character.

```
mysql> SELECT 'David!' LIKE 'David_%';
 -> 0
mysql> SELECT 'David_' LIKE 'David_%';
 -> 1
```

To specify a different escape character, use the `ESCAPE` clause:

```
mysql> SELECT 'David_' LIKE 'David|_' ESCAPE '|';
 -> 1
```

The escape sequence should be one character long to specify the escape character, or empty to specify that no escape character is used. The expression must evaluate as a constant at execution time. If the `NO_BACKSLASH_ESCAPES` SQL mode is enabled, the sequence cannot be empty.

The following statements illustrate that string comparisons are not case-sensitive unless one of the operands is case-sensitive (uses a case-sensitive collation or is a binary string):

```
mysql> SELECT 'abc' LIKE 'ABC';
 -> 1
mysql> SELECT 'abc' LIKE _utf8mb4 'ABC' COLLATE utf8mb4_0900_as_cs;
 -> 0
mysql> SELECT 'abc' LIKE _utf8mb4 'ABC' COLLATE utf8mb4_bin;
 -> 0
mysql> SELECT 'abc' LIKE BINARY 'ABC';
 -> 0
```

As an extension to standard SQL, MySQL permits `LIKE` on numeric expressions.

```
mysql> SELECT 10 LIKE '1%';
 -> 1
```

MySQL attempts in such cases to perform implicit conversion of the expression to a string. See [Section 14.3, “Type Conversion in Expression Evaluation”](#).

#### Note

MySQL uses C escape syntax in strings (for example, `\n` to represent the newline character). If you want a `LIKE` string to contain a literal `\`, you must double it. (Unless the `NO_BACKSLASH_ESCAPES` SQL mode is enabled, in which case no escape character is used.) For example, to search for `\n`, specify it as `\\n`. To search for `\`, specify it as `\\`; this is because the backslashes are

stripped once by the parser and again when the pattern match is made, leaving a single backslash to be matched against.

Exception: At the end of the pattern string, backslash can be specified as `\\`. At the end of the string, backslash stands for itself because there is nothing following to escape. Suppose that a table contains the following values:

```
mysql> SELECT filename FROM t1;
```

filename
C:
C:\
C:\Programs
C:\Programs\

To test for values that end with backslash, you can match the values using either of the following patterns:

```
mysql> SELECT filename, filename LIKE '%\\' FROM t1;
```

filename	filename LIKE '%\\'
C:	0
C:\	1
C:\Programs	0
C:\Programs\	1

```
mysql> SELECT filename, filename LIKE '%\\\\' FROM t1;
```

filename	filename LIKE '%\\\\'
C:	0
C:\	1
C:\Programs	0
C:\Programs\	1

- `expr NOT LIKE pat [ESCAPE 'escape_char']`

This is the same as `NOT (expr LIKE pat [ESCAPE 'escape_char'])`.

#### Note

Aggregate queries involving `NOT LIKE` comparisons with columns containing `NULL` may yield unexpected results. For example, consider the following table and data:

```
CREATE TABLE foo (bar VARCHAR(10));
INSERT INTO foo VALUES (NULL), (NULL);
```

The query `SELECT COUNT(*) FROM foo WHERE bar LIKE '%baz%';` returns 0. You might assume that `SELECT COUNT(*) FROM foo WHERE bar NOT LIKE '%baz%';` would return 2. However, this is not the case: The second query returns 0. This is because `NULL NOT LIKE expr` always returns `NULL`, regardless of the value of `expr`. The same is true for aggregate queries involving

`NULL` and comparisons using `NOT RLIKE` or `NOT REGEXP`. In such cases, you must test explicitly for `NOT NULL` using `OR` (and not `AND`), as shown here:

```
SELECT COUNT(*) FROM foo WHERE bar NOT LIKE '%baz%' OR bar IS NULL;
```

- `STRCMP(expr1,expr2)`

`STRCMP()` returns `0` if the strings are the same, `-1` if the first argument is smaller than the second according to the current sort order, and `NULL` if either argument is `NULL`. It returns `1` otherwise.

```
mysql> SELECT STRCMP('text', 'text2');
-> -1
mysql> SELECT STRCMP('text2', 'text');
-> 1
mysql> SELECT STRCMP('text', 'text');
-> 0
```

`STRCMP()` performs the comparison using the collation of the arguments.

```
mysql> SET @s1 = _utf8mb4 'x' COLLATE utf8mb4_0900_ai_ci;
mysql> SET @s2 = _utf8mb4 'X' COLLATE utf8mb4_0900_ai_ci;
mysql> SET @s3 = _utf8mb4 'x' COLLATE utf8mb4_0900_as_cs;
mysql> SET @s4 = _utf8mb4 'X' COLLATE utf8mb4_0900_as_cs;
mysql> SELECT STRCMP(@s1, @s2), STRCMP(@s3, @s4);
+-----+-----+
| STRCMP(@s1, @s2) | STRCMP(@s3, @s4) |
+-----+-----+
| 0 | -1 |
+-----+-----+
```

If the collations are incompatible, one of the arguments must be converted to be compatible with the other. See [Section 12.8.4, “Collation Coercibility in Expressions”](#).

```
mysql> SET @s1 = _utf8mb4 'x' COLLATE utf8mb4_0900_ai_ci;
mysql> SET @s2 = _utf8mb4 'X' COLLATE utf8mb4_0900_ai_ci;
mysql> SET @s3 = _utf8mb4 'x' COLLATE utf8mb4_0900_as_cs;
mysql> SET @s4 = _utf8mb4 'X' COLLATE utf8mb4_0900_as_cs;
-->
mysql> SELECT STRCMP(@s1, @s3);
ERROR 1267 (HY000): Illegal mix of collations (utf8mb4_0900_ai_ci,IMPLICIT)
and (utf8mb4_0900_as_cs,IMPLICIT) for operation 'strcmp'
mysql> SELECT STRCMP(@s1, @s3 COLLATE utf8mb4_0900_ai_ci);
+-----+
| STRCMP(@s1, @s3 COLLATE utf8mb4_0900_ai_ci) |
+-----+
| 0 |
+-----+
```

## 14.8.2 Regular Expressions

**Table 14.14 Regular Expression Functions and Operators**

Name	Description
<code>NOT REGEXP</code>	Negation of <code>REGEXP</code>
<code>REGEXP</code>	Whether string matches regular expression
<code>REGEXP_INSTR()</code>	Starting index of substring matching regular expression
<code>REGEXP_LIKE()</code>	Whether string matches regular expression
<code>REGEXP_REPLACE()</code>	Replace substrings matching regular expression
<code>REGEXP_SUBSTR()</code>	Return substring matching regular expression

Name	Description
<a href="#">RLIKE</a>	Whether string matches regular expression

A regular expression is a powerful way of specifying a pattern for a complex search. This section discusses the functions and operators available for regular expression matching and illustrates, with examples, some of the special characters and constructs that can be used for regular expression operations. See also [Section 5.3.4.7, “Pattern Matching”](#).

MySQL implements regular expression support using International Components for Unicode (ICU), which provides full Unicode support and is multibyte safe.

Use of a binary string with any of the MySQL regular expression functions is rejected with [ER\\_CHARACTER\\_SET\\_MISMATCH](#).

- [Regular Expression Function and Operator Descriptions](#)
- [Regular Expression Syntax](#)
- [Regular Expression Resource Control](#)

## Regular Expression Function and Operator Descriptions

- `expr NOT REGEXP pat, expr NOT RLIKE pat`

This is the same as `NOT (expr REGEXP pat)`.

- `expr REGEXP pat, expr RLIKE pat`

Returns 1 if the string `expr` matches the regular expression specified by the pattern `pat`, 0 otherwise. If `expr` or `pat` is `NULL`, the return value is `NULL`.

`REGEXP` and `RLIKE` are synonyms for `REGEXP_LIKE()`.

For additional information about how matching occurs, see the description for `REGEXP_LIKE()`.

```
mysql> SELECT 'Michael!' REGEXP '.*';
+-----+
| 'Michael!' REGEXP '.*' |
+-----+
| 1 |
+-----+
mysql> SELECT 'new*\n*line' REGEXP 'new*.**line';
+-----+
| 'new*\n*line' REGEXP 'new*.**line' |
+-----+
| 0 |
+-----+
mysql> SELECT 'a' REGEXP '^[a-d]';
+-----+
| 'a' REGEXP '^[a-d]' |
+-----+
| 1 |
+-----+
```

- `REGEXP_INSTR(expr, pat[, pos[, occurrence[, return_option[, match_type]]])`

Returns the starting index of the substring of the string `expr` that matches the regular expression specified by the pattern `pat`, 0 if there is no match. If `expr` or `pat` is `NULL`, the return value is `NULL`. Character indexes begin at 1.

`REGEXP_INSTR()` takes these optional arguments:

- *pos*: The position in *expr* at which to start the search. If omitted, the default is 1.
- *occurrence*: Which occurrence of a match to search for. If omitted, the default is 1.
- *return\_option*: Which type of position to return. If this value is 0, `REGEXP_INSTR()` returns the position of the matched substring's first character. If this value is 1, `REGEXP_INSTR()` returns the position following the matched substring. If omitted, the default is 0.
- *match\_type*: A string that specifies how to perform matching. The meaning is as described for `REGEXP_LIKE()`.

For additional information about how matching occurs, see the description for `REGEXP_LIKE()`.

```
mysql> SELECT REGEXP_INSTR('dog cat dog', 'dog');
+-----+
| REGEXP_INSTR('dog cat dog', 'dog') |
+-----+
| 1 |
+-----+
mysql> SELECT REGEXP_INSTR('dog cat dog', 'dog', 2);
+-----+
| REGEXP_INSTR('dog cat dog', 'dog', 2) |
+-----+
| 9 |
+-----+
mysql> SELECT REGEXP_INSTR('aa aaa aaaa', 'a{2}');
+-----+
| REGEXP_INSTR('aa aaa aaaa', 'a{2}') |
+-----+
| 1 |
+-----+
mysql> SELECT REGEXP_INSTR('aa aaa aaaa', 'a{4}');
+-----+
| REGEXP_INSTR('aa aaa aaaa', 'a{4}') |
+-----+
| 8 |
+-----+
```

- `REGEXP_LIKE(expr, pat[, match_type])`

Returns 1 if the string `expr` matches the regular expression specified by the pattern `pat`, 0 otherwise. If `expr` or `pat` is `NULL`, the return value is `NULL`.

The pattern can be an extended regular expression, the syntax for which is discussed in [Regular Expression Syntax](#). The pattern need not be a literal string. For example, it can be specified as a string expression or table column.

The optional `match_type` argument is a string that may contain any or all the following characters specifying how to perform matching:

- `c`: Case-sensitive matching.
- `i`: Case-insensitive matching.
- `m`: Multiple-line mode. Recognize line terminators within the string. The default behavior is to match line terminators only at the start and end of the string expression.
- `n`: The `.` character matches line terminators. The default is for `.` matching to stop at the end of a line.
- `u`: Unix-only line endings. Only the newline character is recognized as a line ending by the `.`, `^`, and `$` match operators.

If characters specifying contradictory options are specified within `match_type`, the rightmost one takes precedence.

By default, regular expression operations use the character set and collation of the `expr` and `pat` arguments when deciding the type of a character and performing the comparison. If the arguments have different character sets or collations, coercibility rules apply as described in [Section 12.8.4, “Collation Coercibility in Expressions”](#). Arguments may be specified with explicit collation indicators to change comparison behavior.

```
mysql> SELECT REGEXP_LIKE('CamelCase', 'CAMELCASE');
+-----+
| REGEXP_LIKE('CamelCase', 'CAMELCASE') |
+-----+
| 1 |
+-----+
mysql> SELECT REGEXP_LIKE('CamelCase', 'CAMELCASE' COLLATE utf8mb4_0900_as_cs);
+-----+
| REGEXP_LIKE('CamelCase', 'CAMELCASE' COLLATE utf8mb4_0900_as_cs) |
+-----+
| 0 |
+-----+
```

`match_type` may be specified with the `c` or `i` characters to override the default case sensitivity. Exception: If either argument is a binary string, the arguments are handled in case-sensitive fashion as binary strings, even if `match_type` contains the `i` character.

#### Note

MySQL uses C escape syntax in strings (for example, `\n` to represent the newline character). If you want your `expr` or `pat` argument to contain a literal `\`, you must double it. (Unless the `NO_BACKSLASH_ESCAPES` SQL mode is enabled, in which case no escape character is used.)

```
mysql> SELECT REGEXP_LIKE('Michael!', '.*');
+-----+
| 1 |
+-----+
```

```
| REGEXP_LIKE('Michael!', '.*') |
+-----+
| 1 |
+-----+
mysql> SELECT REGEXP_LIKE('new*\n*line', 'new*.**line');
+-----+
| REGEXP_LIKE('new*\n*line', 'new*.**line') |
+-----+
| 0 |
+-----+
mysql> SELECT REGEXP_LIKE('a', '^[a-d]');
+-----+
| REGEXP_LIKE('a', '^[a-d]') |
+-----+
| 1 |
+-----+
```

```
mysql> SELECT REGEXP_LIKE('abc', 'ABC');
+-----+
| REGEXP_LIKE('abc', 'ABC') |
+-----+
| 1 |
+-----+
mysql> SELECT REGEXP_LIKE('abc', 'ABC', 'c');
+-----+
| REGEXP_LIKE('abc', 'ABC', 'c') |
+-----+
| 0 |
+-----+
```

- `REGEXP_REPLACE(expr, pat, repl[, pos[, occurrence[, match_type]])`

Replaces occurrences in the string `expr` that match the regular expression specified by the pattern `pat` with the replacement string `repl`, and returns the resulting string. If `expr`, `pat`, or `repl` is `NULL`, the return value is `NULL`.

`REGEXP_REPLACE()` takes these optional arguments:

- `pos`: The position in `expr` at which to start the search. If omitted, the default is 1.
- `occurrence`: Which occurrence of a match to replace. If omitted, the default is 0 (which means “replace all occurrences”).
- `match_type`: A string that specifies how to perform matching. The meaning is as described for `REGEXP_LIKE()`.

The result returned by this function uses the character set and collation of the expression searched for matches.

For additional information about how matching occurs, see the description for `REGEXP_LIKE()`.

```
mysql> SELECT REGEXP_REPLACE('a b c', 'b', 'X');
+-----+
| REGEXP_REPLACE('a b c', 'b', 'X') |
+-----+
| a X c |
+-----+
mysql> SELECT REGEXP_REPLACE('abc def ghi', '[a-z]+', 'X', 1, 3);
+-----+
| REGEXP_REPLACE('abc def ghi', '[a-z]+', 'X', 1, 3) |
+-----+
| abc def X |
+-----+
```

- `REGEXP_SUBSTR(expr, pat[, pos[, occurrence[, match_type]]])`

Returns the substring of the string `expr` that matches the regular expression specified by the pattern `pat`, `NULL` if there is no match. If `expr` or `pat` is `NULL`, the return value is `NULL`.

`REGEXP_SUBSTR()` takes these optional arguments:

- `pos`: The position in `expr` at which to start the search. If omitted, the default is 1.
- `occurrence`: Which occurrence of a match to search for. If omitted, the default is 1.
- `match_type`: A string that specifies how to perform matching. The meaning is as described for `REGEXP_LIKE()`.

The result returned by this function uses the character set and collation of the expression searched for matches.

For additional information about how matching occurs, see the description for `REGEXP_LIKE()`.

```
mysql> SELECT REGEXP_SUBSTR('abc def ghi', '[a-z]+');
+-----+
| REGEXP_SUBSTR('abc def ghi', '[a-z]+') |
+-----+
| abc |
+-----+
mysql> SELECT REGEXP_SUBSTR('abc def ghi', '[a-z]+', 1, 3);
+-----+
| REGEXP_SUBSTR('abc def ghi', '[a-z]+', 1, 3) |
+-----+
| ghi |
+-----+
```

## Regular Expression Syntax

A regular expression describes a set of strings. The simplest regular expression is one that has no special characters in it. For example, the regular expression `hello` matches `hello` and nothing else.

Nontrivial regular expressions use certain special constructs so that they can match more than one string. For example, the regular expression `hello|world` contains the `|` alternation operator and matches either the `hello` or `world`.

As a more complex example, the regular expression `B[an]*s` matches any of the strings `Bananas`, `Baaaaas`, `Bs`, and any other string starting with a `B`, ending with an `s`, and containing any number of `a` or `n` characters in between.

The following list covers some of the basic special characters and constructs that can be used in regular expressions. For information about the full regular expression syntax supported by the ICU library used to implement regular expression support, visit the [International Components for Unicode web site](#).

- `^`

Match the beginning of a string.

```
mysql> SELECT REGEXP_LIKE('fo\info', '^fo$'); -> 0
mysql> SELECT REGEXP_LIKE('fofo', '^fo$'); -> 1
```

- `$`

Match the end of a string.

```
mysql> SELECT REGEXP_LIKE('fo\no', '^fo\no$'); -> 1
```

```
mysql> SELECT REGEXP_LIKE('fo\no', '^fo$'); -> 0
```

- .

Match any character (including carriage return and newline, although to match these in the middle of a string, the `m` (multiple line) match-control character or the `(?m)` within-pattern modifier must be given).

```
mysql> SELECT REGEXP_LIKE('fofo', '^f.*$'); -> 1
mysql> SELECT REGEXP_LIKE('fo\r\nfo', '^f.*$'); -> 0
mysql> SELECT REGEXP_LIKE('fo\r\nfo', '^f.*$', 'm'); -> 1
mysql> SELECT REGEXP_LIKE('fo\r\nfo', '(?m)^f.*$'); -> 1
```

- a\*

Match any sequence of zero or more `a` characters.

```
mysql> SELECT REGEXP_LIKE('Ban', '^Ba*n'); -> 1
mysql> SELECT REGEXP_LIKE('Baaan', '^Ba*n'); -> 1
mysql> SELECT REGEXP_LIKE('Bn', '^Ba*n'); -> 1
```

- a+

Match any sequence of one or more `a` characters.

```
mysql> SELECT REGEXP_LIKE('Ban', '^Ba+n'); -> 1
mysql> SELECT REGEXP_LIKE('Bn', '^Ba+n'); -> 0
```

- a?

Match either zero or one `a` character.

```
mysql> SELECT REGEXP_LIKE('Bn', '^Ba?n'); -> 1
mysql> SELECT REGEXP_LIKE('Ban', '^Ba?n'); -> 1
mysql> SELECT REGEXP_LIKE('Baan', '^Ba?n'); -> 0
```

- de|abc

Alternation; match either of the sequences `de` or `abc`.

```
mysql> SELECT REGEXP_LIKE('pi', 'pi|apa'); -> 1
mysql> SELECT REGEXP_LIKE('axe', 'pi|apa'); -> 0
mysql> SELECT REGEXP_LIKE('apa', 'pi|apa'); -> 1
mysql> SELECT REGEXP_LIKE('apa', '^(pi|apa)$'); -> 1
mysql> SELECT REGEXP_LIKE('pi', '^(pi|apa)$'); -> 1
mysql> SELECT REGEXP_LIKE('pix', '^(pi|apa)$'); -> 0
```

- (abc)\*

Match zero or more instances of the sequence `abc`.

```
mysql> SELECT REGEXP_LIKE('pi', '^(pi)*$'); -> 1
mysql> SELECT REGEXP_LIKE('pip', '^(pi)*$'); -> 0
mysql> SELECT REGEXP_LIKE('pypi', '^(pi)*$'); -> 1
```

- {1}, {2,3}

Repetition; `{n}` and `{m,n}` notation provide a more general way of writing regular expressions that match many occurrences of the previous atom (or “piece”) of the pattern. `m` and `n` are integers.

- a\*

Can be written as `a{0,}`.

- `a+`

Can be written as `a{1,}`.

- `a?`

Can be written as `a{0,1}`.

To be more precise, `a{n}` matches exactly *n* instances of *a*. `a{n,}` matches *n* or more instances of *a*. `a{m,n}` matches *m* through *n* instances of *a*, inclusive. If both *m* and *n* are given, *m* must be less than or equal to *n*.

```
mysql> SELECT REGEXP_LIKE('abcde', 'a[bcd]{2}e'); -> 0
mysql> SELECT REGEXP_LIKE('abcde', 'a[bcd]{3}e'); -> 1
mysql> SELECT REGEXP_LIKE('abcde', 'a[bcd]{1,10}e'); -> 1
```

- `[a-dX]`, `[^a-dX]`

Matches any character that is (or is not, if `^` is used) either *a*, *b*, *c*, *d* or *X*. A `-` character between two other characters forms a range that matches all characters from the first character to the second. For example, `[0-9]` matches any decimal digit. To include a literal `]` character, it must immediately follow the opening bracket `[`. To include a literal `-` character, it must be written first or last. Any character that does not have a defined special meaning inside a `[ ]` pair matches only itself.

```
mysql> SELECT REGEXP_LIKE('aXbc', '[a-dXYZ]'); -> 1
mysql> SELECT REGEXP_LIKE('aXbc', '^[a-dXYZ]$'); -> 0
mysql> SELECT REGEXP_LIKE('aXbc', '^[a-dXYZ]+$'); -> 1
mysql> SELECT REGEXP_LIKE('aXbc', '^[^a-dXYZ]+$'); -> 0
mysql> SELECT REGEXP_LIKE('gheis', '^[^a-dXYZ]+$'); -> 1
mysql> SELECT REGEXP_LIKE('gheisa', '^[^a-dXYZ]+$'); -> 0
```

- `[=character_class=]`

Within a bracket expression (written using `[` and `]`), `[=character_class=]` represents an equivalence class. It matches all characters with the same collation value, including itself. For example, if `o` and `(+)` are the members of an equivalence class, `[ [=o= ]]`, `[ [= (+)= ]]`, and `[ o (+) ]` are all synonymous. An equivalence class may not be used as an endpoint of a range.

- `[ :character_class: ]`

Within a bracket expression (written using `[` and `]`), `[ :character_class: ]` represents a character class that matches all characters belonging to that class. The following table lists the standard class names. These names stand for the character classes defined in the `ctype(3)` manual page. A particular locale may provide other class names. A character class may not be used as an endpoint of a range.

Character Class Name	Meaning
<code>alnum</code>	Alphanumeric characters
<code>alpha</code>	Alphabetic characters
<code>blank</code>	Whitespace characters
<code>cntrl</code>	Control characters
<code>digit</code>	Digit characters
<code>graph</code>	Graphic characters
<code>lower</code>	Lowercase alphabetic characters

Character Class Name	Meaning
<code>print</code>	Graphic or space characters
<code>punct</code>	Punctuation characters
<code>space</code>	Space, tab, newline, and carriage return
<code>upper</code>	Uppercase alphabetic characters
<code>xdigit</code>	Hexadecimal digit characters

```
mysql> SELECT REGEXP_LIKE('justalnums', '[:alnum:]]+'); -> 1
mysql> SELECT REGEXP_LIKE('!!!', '[:alnum:]]+'); -> 0
```

To use a literal instance of a special character in a regular expression, precede it by two backslash (\) characters. The MySQL parser interprets one of the backslashes, and the regular expression library interprets the other. For example, to match the string `1+2` that contains the special `+` character, only the last of the following regular expressions is the correct one:

```
mysql> SELECT REGEXP_LIKE('1+2', '1+2'); -> 0
mysql> SELECT REGEXP_LIKE('1+2', '1\+2'); -> 0
mysql> SELECT REGEXP_LIKE('1+2', '1\\+2'); -> 1
```

## Regular Expression Resource Control

`REGEXP_LIKE()` and similar functions use resources that can be controlled by setting system variables:

- The match engine uses memory for its internal stack. To control the maximum available memory for the stack in bytes, set the `regexp_stack_limit` system variable.
- The match engine operates in steps. To control the maximum number of steps performed by the engine (and thus indirectly the execution time), set the `regexp_time_limit` system variable. Because this limit is expressed as number of steps, it affects execution time only indirectly. Typically, it is on the order of milliseconds.

## 14.8.3 Character Set and Collation of Function Results

MySQL has many operators and functions that return a string. This section answers the question: What is the character set and collation of such a string?

For simple functions that take string input and return a string result as output, the output's character set and collation are the same as those of the principal input value. For example, `UPPER(X)` returns a string with the same character string and collation as `X`. The same applies for `INSTR()`, `LCASE()`, `LOWER()`, `LTRIM()`, `MID()`, `REPEAT()`, `REPLACE()`, `REVERSE()`, `RIGHT()`, `RPAD()`, `RTRIM()`, `SOUNDEX()`, `SUBSTRING()`, `TRIM()`, `UCASE()`, and `UPPER()`.

### Note

The `REPLACE()` function, unlike all other functions, always ignores the collation of the string input and performs a case-sensitive comparison.

If a string input or function result is a binary string, the string has the `binary` character set and collation. This can be checked by using the `CHARSET()` and `COLLATION()` functions, both of which return `binary` for a binary string argument:

```
mysql> SELECT CHARSET(BINARY 'a'), COLLATION(BINARY 'a');
+-----+-----+
| CHARSET(BINARY 'a') | COLLATION(BINARY 'a') |
+-----+-----+
| binary | binary |
```

For operations that combine multiple string inputs and return a single string output, the “aggregation rules” of standard SQL apply for determining the collation of the result:

- If an explicit `COLLATE Y` occurs, use `Y`.
- If explicit `COLLATE Y` and `COLLATE Z` occur, raise an error.
- Otherwise, if all collations are `Y`, use `Y`.
- Otherwise, the result has no collation.

For example, with `CASE ... WHEN a THEN b WHEN b THEN c COLLATE X END`, the resulting collation is `X`. The same applies for `UNION`, `||`, `CONCAT()`, `ELT()`, `GREATEST()`, `IF()`, and `LEAST()`.

For operations that convert to character data, the character set and collation of the strings that result from the operations are defined by the `character_set_connection` and `collation_connection` system variables that determine the default connection character set and collation (see [Section 12.4, “Connection Character Sets and Collations”](#)). This applies only to `BIN_TO_UUID()`, `CAST()`, `CONV()`, `FORMAT()`, `HEX()`, and `SPACE()`.

An exception to the preceding principle occurs for expressions for virtual generated columns. In such expressions, the table character set is used for `BIN_TO_UUID()`, `CONV()`, or `HEX()` results, regardless of connection character set.

If there is any question about the character set or collation of the result returned by a string function, use the `CHARSET()` or `COLLATION()` function to find out:

```
mysql> SELECT USER(), CHARSET(USER()), COLLATION(USER());
+-----+-----+-----+
| USER() | CHARSET(USER()) | COLLATION(USER()) |
+-----+-----+-----+
| test@localhost | utf8mb3 | utf8mb3_general_ci |
+-----+-----+-----+
mysql> SELECT CHARSET(COMPRESS('abc')), COLLATION(COMPRESS('abc'));
+-----+-----+
| CHARSET(COMPRESS('abc')) | COLLATION(COMPRESS('abc')) |
+-----+-----+
| binary | binary |
+-----+-----+
```

## 14.9 Full-Text Search Functions

`MATCH (col1,col2,...) AGAINST (expr [search_modifier])`

```
search_modifier:
{
 IN NATURAL LANGUAGE MODE
 | IN NATURAL LANGUAGE MODE WITH QUERY EXPANSION
 | IN BOOLEAN MODE
 | WITH QUERY EXPANSION
}
```

MySQL has support for full-text indexing and searching:

- A full-text index in MySQL is an index of type `FULLTEXT`.
- Full-text indexes can be used only with `InnoDB` or `MyISAM` tables, and can be created only for `CHAR`, `VARCHAR`, or `TEXT` columns.

- MySQL provides a built-in full-text ngram parser that supports Chinese, Japanese, and Korean (CJK), and an installable MeCab full-text parser plugin for Japanese. Parsing differences are outlined in [Section 14.9.8, “ngram Full-Text Parser”](#), and [Section 14.9.9, “MeCab Full-Text Parser Plugin”](#).
- A `FULLTEXT` index definition can be given in the `CREATE TABLE` statement when a table is created, or added later using `ALTER TABLE` or `CREATE INDEX`.
- For large data sets, it is much faster to load your data into a table that has no `FULLTEXT` index and then create the index after that, than to load data into a table that has an existing `FULLTEXT` index.

Full-text searching is performed using `MATCH() AGAINST()` syntax. `MATCH()` takes a comma-separated list that names the columns to be searched. `AGAINST` takes a string to search for, and an optional modifier that indicates what type of search to perform. The search string must be a string value that is constant during query evaluation. This rules out, for example, a table column because that can differ for each row.

MySQL does not permit the use of a rollup column with `MATCH()`; more specifically, any query matching all of the criteria listed here is rejected with `ER_FULLTEXT_WITH_ROLLUP`:

- `MATCH()` appears in the `SELECT` list, `GROUP BY` clause, `HAVING` clause, or `ORDER BY` clause of a query block.
- The query block contains a `GROUP BY ... WITH ROLLUP` clause.
- The argument of the call to the `MATCH()` function is one of the grouping columns.

Some examples of such queries are shown here:

```
MATCH() in SELECT list...
SELECT MATCH (a) AGAINST ('abc') FROM t GROUP BY a WITH ROLLUP;
SELECT 1 FROM t GROUP BY a, MATCH (a) AGAINST ('abc') WITH ROLLUP;

...in HAVING clause...
SELECT 1 FROM t GROUP BY a WITH ROLLUP HAVING MATCH (a) AGAINST ('abc');

...and in ORDER BY clause
SELECT 1 FROM t GROUP BY a WITH ROLLUP ORDER BY MATCH (a) AGAINST ('abc');
```

The use of `MATCH()` with a rollup column in the `WHERE` clause is permitted.

There are three types of full-text searches:

- A natural language search interprets the search string as a phrase in natural human language (a phrase in free text). There are no special operators, with the exception of double quote (") characters. The stopwords list applies. For more information about stopwords lists, see [Section 14.9.4, “Full-Text Stopwords”](#).

Full-text searches are natural language searches if the `IN NATURAL LANGUAGE MODE` modifier is given or if no modifier is given. For more information, see [Section 14.9.1, “Natural Language Full-Text Searches”](#).

- A boolean search interprets the search string using the rules of a special query language. The string contains the words to search for. It can also contain operators that specify requirements such that a word must be present or absent in matching rows, or that it should be weighted higher or lower than usual. Certain common words (stopwords) are omitted from the search index and do not match if present in the search string. The `IN BOOLEAN MODE` modifier specifies a boolean search. For more information, see [Section 14.9.2, “Boolean Full-Text Searches”](#).
- A query expansion search is a modification of a natural language search. The search string is used to perform a natural language search. Then words from the most relevant rows returned by the search are

added to the search string and the search is done again. The query returns the rows from the second search. The `IN NATURAL LANGUAGE MODE WITH QUERY EXPANSION` or `WITH QUERY EXPANSION` modifier specifies a query expansion search. For more information, see [Section 14.9.3, “Full-Text Searches with Query Expansion”](#).

For information about `FULLTEXT` query performance, see [Section 10.3.5, “Column Indexes”](#).

For more information about `InnoDB FULLTEXT` indexes, see [Section 17.6.2.4, “InnoDB Full-Text Indexes”](#).

Constraints on full-text searching are listed in [Section 14.9.5, “Full-Text Restrictions”](#).

The `myisam_ftdump` utility dumps the contents of a `MyISAM` full-text index. This may be helpful for debugging full-text queries. See [Section 6.6.3, “myisam\\_ftdump — Display Full-Text Index information”](#).

## 14.9.1 Natural Language Full-Text Searches

By default or with the `IN NATURAL LANGUAGE MODE` modifier, the `MATCH()` function performs a natural language search for a string against a *text collection*. A collection is a set of one or more columns included in a `FULLTEXT` index. The search string is given as the argument to `AGAINST()`. For each row in the table, `MATCH()` returns a relevance value; that is, a similarity measure between the search string and the text in that row in the columns named in the `MATCH()` list.

```
mysql> CREATE TABLE articles (
-> id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
-> title VARCHAR(200),
-> body TEXT,
-> FULLTEXT (title,body)
->) ENGINE=InnoDB;
Query OK, 0 rows affected (0.08 sec)

mysql> INSERT INTO articles (title,body) VALUES
-> ('MySQL Tutorial','DBMS stands for DataBase ...'),
-> ('How To Use MySQL Well','After you went through a ...'),
-> ('Optimizing MySQL','In this tutorial, we show ...'),
-> ('1001 MySQL Tricks','1. Never run mysqld as root. 2. ...'),
-> ('MySQL vs. YourSQL','In the following database comparison ...'),
-> ('MySQL Security','When configured properly, MySQL ...');
Query OK, 6 rows affected (0.01 sec)
Records: 6 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM articles
-> WHERE MATCH (title,body)
-> AGAINST ('database' IN NATURAL LANGUAGE MODE);
+-----+-----+-----+
| id | title | body |
+-----+-----+-----+
| 1 | MySQL Tutorial | DBMS stands for DataBase ... |
| 5 | MySQL vs. YourSQL | In the following database comparison ... |
+-----+-----+-----+
2 rows in set (0.00 sec)
```

By default, the search is performed in case-insensitive fashion. To perform a case-sensitive full-text search, use a case-sensitive or binary collation for the indexed columns. For example, a column that uses the `utf8mb4` character set of can be assigned a collation of `utf8mb4_0900_as_cs` or `utf8mb4_bin` to make it case-sensitive for full-text searches.

When `MATCH()` is used in a `WHERE` clause, as in the example shown earlier, the rows returned are automatically sorted with the highest relevance first as long as the following conditions are met:

- There must be no explicit `ORDER BY` clause.

- The search must be performed using a full-text index scan rather than a table scan.
- If the query joins tables, the full-text index scan must be the leftmost non-constant table in the join.

Given the conditions just listed, it is usually less effort to specify using `ORDER BY` an explicit sort order when one is necessary or desired.

Relevance values are nonnegative floating-point numbers. Zero relevance means no similarity. Relevance is computed based on the number of words in the row (document), the number of unique words in the row, the total number of words in the collection, and the number of rows that contain a particular word.

#### Note

The term “document” may be used interchangeably with the term “row”, and both terms refer to the indexed part of the row. The term “collection” refers to the indexed columns and encompasses all rows.

To simply count matches, you could use a query like this:

```
mysql> SELECT COUNT(*) FROM articles
-> WHERE MATCH (title,body)
-> AGAINST ('database' IN NATURAL LANGUAGE MODE);
+-----+
| COUNT(*) |
+-----+
| 2 |
+-----+
1 row in set (0.00 sec)
```

You might find it quicker to rewrite the query as follows:

```
mysql> SELECT
-> COUNT(IF(MATCH (title,body) AGAINST ('database' IN NATURAL LANGUAGE MODE), 1, NULL))
-> AS count
-> FROM articles;
+-----+
| count |
+-----+
| 2 |
+-----+
1 row in set (0.03 sec)
```

The first query does some extra work (sorting the results by relevance) but also can use an index lookup based on the `WHERE` clause. The index lookup might make the first query faster if the search matches few rows. The second query performs a full table scan, which might be faster than the index lookup if the search term was present in most rows.

For natural-language full-text searches, the columns named in the `MATCH()` function must be the same columns included in some `FULLTEXT` index in your table. For the preceding query, note that the columns named in the `MATCH()` function (`title` and `body`) are the same as those named in the definition of the `article` table's `FULLTEXT` index. To search the `title` or `body` separately, you would create separate `FULLTEXT` indexes for each column.

You can also perform a boolean search or a search with query expansion. These search types are described in [Section 14.9.2, “Boolean Full-Text Searches”](#), and [Section 14.9.3, “Full-Text Searches with Query Expansion”](#).

A full-text search that uses an index can name columns only from a single table in the `MATCH()` clause because an index cannot span multiple tables. For `MyISAM` tables, a boolean search can be done in the absence of an index (albeit more slowly), in which case it is possible to name columns from multiple tables.

The preceding example is a basic illustration that shows how to use the `MATCH()` function where rows are returned in order of decreasing relevance. The next example shows how to retrieve the relevance values explicitly. Returned rows are not ordered because the `SELECT` statement includes neither `WHERE` nor `ORDER BY` clauses:

```
mysql> SELECT id, MATCH (title,body)
-> AGAINST ('Tutorial' IN NATURAL LANGUAGE MODE) AS score
-> FROM articles;
```

id	score
1	0.22764469683170319
2	0
3	0.22764469683170319
4	0
5	0
6	0

6 rows in set (0.00 sec)

The following example is more complex. The query returns the relevance values and it also sorts the rows in order of decreasing relevance. To achieve this result, specify `MATCH()` twice: once in the `SELECT` list and once in the `WHERE` clause. This causes no additional overhead, because the MySQL optimizer notices that the two `MATCH()` calls are identical and invokes the full-text search code only once.

```
mysql> SELECT id, body, MATCH (title,body)
-> AGAINST ('Security implications of running MySQL as root'
-> IN NATURAL LANGUAGE MODE) AS score
-> FROM articles
-> WHERE MATCH (title,body)
-> AGAINST('Security implications of running MySQL as root'
-> IN NATURAL LANGUAGE MODE);
```

id	body	score
4	1. Never run mysqld as root. 2. ...	1.5219271183014
6	When configured properly, MySQL ...	1.3114095926285

2 rows in set (0.00 sec)

A phrase that is enclosed within double quote (") characters matches only rows that contain the phrase *literally, as it was typed*. The full-text engine splits the phrase into words and performs a search in the `FULLTEXT` index for the words. Nonword characters need not be matched exactly: Phrase searching requires only that matches contain exactly the same words as the phrase and in the same order. For example, "test phrase" matches "test, phrase". If the phrase contains no words that are in the index, the result is empty. For example, if all words are either stopwords or shorter than the minimum length of indexed words, the result is empty.

The MySQL `FULLTEXT` implementation regards any sequence of true word characters (letters, digits, and underscores) as a word. That sequence may also contain apostrophes ('), but not more than one in a row. This means that `aaa'bbb` is regarded as one word, but `aaa 'bbb` is regarded as two words. Apostrophes at the beginning or the end of a word are stripped by the `FULLTEXT` parser; `'aaa'bbb'` would be parsed as `aaa'bbb`.

The built-in `FULLTEXT` parser determines where words start and end by looking for certain delimiter characters; for example, (space), , (comma), and . (period). If words are not separated by delimiters (as in, for example, Chinese), the built-in `FULLTEXT` parser cannot determine where a word begins or ends. To be able to add words or other indexed terms in such languages to a `FULLTEXT` index that uses the built-in `FULLTEXT` parser, you must preprocess them so that they are separated by some arbitrary delimiter. Alternatively, you can create `FULLTEXT` indexes using the ngram parser plugin (for Chinese, Japanese, or Korean) or the MeCab parser plugin (for Japanese).

It is possible to write a plugin that replaces the built-in full-text parser. For details, see [The MySQL Plugin API](#). For example parser plugin source code, see the `plugin/fulltext` directory of a MySQL source distribution.

Some words are ignored in full-text searches:

- Any word that is too short is ignored. The default minimum length of words that are found by full-text searches is three characters for [InnoDB](#) search indexes, or four characters for [MyISAM](#). You can control the cutoff by setting a configuration option before creating the index: `innodb_ft_min_token_size` configuration option for [InnoDB](#) search indexes, or `ft_min_word_len` for [MyISAM](#).

#### Note

This behavior does not apply to `FULLTEXT` indexes that use the ngram parser. For the ngram parser, token length is defined by the `ngram_token_size` option.

- Words in the stopwords list are ignored. A stopword is a word such as “the” or “some” that is so common that it is considered to have zero semantic value. There is a built-in stopwords list, but it can be overridden by a user-defined list. The stopwords lists and related configuration options are different for [InnoDB](#) search indexes and [MyISAM](#) ones. Stopword processing is controlled by the configuration options `innodb_ft_enable_stopword`, `innodb_ft_server_stopword_table`, and `innodb_ft_user_stopword_table` for [InnoDB](#) search indexes, and `ft_stopword_file` for [MyISAM](#) ones.

See [Section 14.9.4, “Full-Text Stopwords”](#) to view default stopwords lists and how to change them. The default minimum word length can be changed as described in [Section 14.9.6, “Fine-Tuning MySQL Full-Text Search”](#).

Every correct word in the collection and in the query is weighted according to its significance in the collection or query. Thus, a word that is present in many documents has a lower weight, because it has lower semantic value in this particular collection. Conversely, if the word is rare, it receives a higher weight. The weights of the words are combined to compute the relevance of the row. This technique works best with large collections.

#### MyISAM Limitation

For very small tables, word distribution does not adequately reflect their semantic value, and this model may sometimes produce bizarre results for search indexes on [MyISAM](#) tables. For example, although the word “MySQL” is present in every row of the `articles` table shown earlier, a search for the word in a [MyISAM](#) search index produces no results:

```
mysql> SELECT * FROM articles
-> WHERE MATCH (title,body)
-> AGAINST ('MySQL' IN NATURAL LANGUAGE MODE);
Empty set (0.00 sec)
```

The search result is empty because the word “MySQL” is present in at least 50% of the rows, and so is effectively treated as a stopword. This filtering technique is more suitable for large data sets, where you might not want the result set to return every second row from a 1GB table, than for small data sets where it might cause poor results for popular terms.

The 50% threshold can surprise you when you first try full-text searching to see how it works, and makes [InnoDB](#) tables more suited to experimentation with full-text searches. If you create a [MyISAM](#) table and insert only one or two rows of text into it, every word in the text occurs in at least 50% of the rows. As a result, no search

returns any results until the table contains more rows. Users who need to bypass the 50% limitation can build search indexes on [InnoDB](#) tables, or use the boolean search mode explained in [Section 14.9.2, “Boolean Full-Text Searches”](#).

## 14.9.2 Boolean Full-Text Searches

MySQL can perform boolean full-text searches using the `IN BOOLEAN MODE` modifier. With this modifier, certain characters have special meaning at the beginning or end of words in the search string. In the following query, the `+` and `-` operators indicate that a word must be present or absent, respectively, for a match to occur. Thus, the query retrieves all the rows that contain the word “MySQL” but that do *not* contain the word “YourSQL”:

```
mysql> SELECT * FROM articles WHERE MATCH (title,body)
-> AGAINST ('+MySQL -YourSQL' IN BOOLEAN MODE);
```

id	title	body
1	MySQL Tutorial	DBMS stands for DataBase ...
2	How To Use MySQL Well	After you went through a ...
3	Optimizing MySQL	In this tutorial, we show ...
4	1001 MySQL Tricks	1. Never run mysqld as root. 2. ...
6	MySQL Security	When configured properly, MySQL ...

### Note

In implementing this feature, MySQL uses what is sometimes referred to as *implied Boolean logic*, in which

- `+` stands for [AND](#)
- `-` stands for [NOT](#)
- `[no operator]` implies [OR](#)

Boolean full-text searches have these characteristics:

- They do not automatically sort rows in order of decreasing relevance.
- [InnoDB](#) tables require a [FULLTEXT](#) index on all columns of the `MATCH( )` expression to perform boolean queries. Boolean queries against a [MyISAM](#) search index can work even without a [FULLTEXT](#) index, although a search executed in this fashion would be quite slow.
- The minimum and maximum word length full-text parameters apply to [FULLTEXT](#) indexes created using the built-in [FULLTEXT](#) parser and MeCab parser plugin. `innodb_ft_min_token_size` and `innodb_ft_max_token_size` are used for [InnoDB](#) search indexes. `ft_min_word_len` and `ft_max_word_len` are used for [MyISAM](#) search indexes.

Minimum and maximum word length full-text parameters do not apply to [FULLTEXT](#) indexes created using the ngram parser. ngram token size is defined by the `ngram_token_size` option.

- The stopword list applies, controlled by `innodb_ft_enable_stopword`, `innodb_ft_server_stopword_table`, and `innodb_ft_user_stopword_table` for [InnoDB](#) search indexes, and `ft_stopword_file` for [MyISAM](#) ones.
- [InnoDB](#) full-text search does not support the use of multiple operators on a single search word, as in this example: `'++apple'`. Use of multiple operators on a single search word returns a syntax error to standard out. [MyISAM](#) full-text search successfully processes the same search, ignoring all operators except for the operator immediately adjacent to the search word.

- [InnoDB](#) full-text search only supports leading plus or minus signs. For example, [InnoDB](#) supports '+apple' but does not support 'apple+'. Specifying a trailing plus or minus sign causes [InnoDB](#) to report a syntax error.
- [InnoDB](#) full-text search does not support the use of a leading plus sign with wildcard ('+\*'), a plus and minus sign combination ('+-'), or leading a plus and minus sign combination ('+-apple'). These invalid queries return a syntax error.
- [InnoDB](#) full-text search does not support the use of the @ symbol in boolean full-text searches. The @ symbol is reserved for use by the @distance proximity search operator.
- They do not use the 50% threshold that applies to [MyISAM](#) search indexes.

The boolean full-text search capability supports the following operators:

- +

A leading or trailing plus sign indicates that this word *must* be present in each row that is returned. [InnoDB](#) only supports leading plus signs.

- -

A leading or trailing minus sign indicates that this word must *not* be present in any of the rows that are returned. [InnoDB](#) only supports leading minus signs.

Note: The - operator acts only to exclude rows that are otherwise matched by other search terms. Thus, a boolean-mode search that contains only terms preceded by - returns an empty result. It does not return “all rows except those containing any of the excluded terms.”

- (no operator)

By default (when neither + nor - is specified), the word is optional, but the rows that contain it are rated higher. This mimics the behavior of `MATCH( ) AGAINST( )` without the `IN BOOLEAN MODE` modifier.

- @distance

This operator works on [InnoDB](#) tables only. It tests whether two or more words all start within a specified distance from each other, measured in words. Specify the search words within a double-quoted string immediately before the @distance operator, for example, `MATCH(col1) AGAINST('"word1 word2 word3" @8' IN BOOLEAN MODE)`

- > <

These two operators are used to change a word's contribution to the relevance value that is assigned to a row. The > operator increases the contribution and the < operator decreases it. See the example following this list.

- ( )

Parentheses group words into subexpressions. Parenthesized groups can be nested.

- ~

A leading tilde acts as a negation operator, causing the word's contribution to the row's relevance to be negative. This is useful for marking “noise” words. A row containing such a word is rated lower than others, but is not excluded altogether, as it would be with the - operator.

- \*

The asterisk serves as the truncation (or wildcard) operator. Unlike the other operators, it is *appended* to the word to be affected. Words match if they begin with the word preceding the `*` operator.

If a word is specified with the truncation operator, it is not stripped from a boolean query, even if it is too short or a stopwords. Whether a word is too short is determined from the `innodb_ft_min_token_size` setting for InnoDB tables, or `ft_min_word_len` for MyISAM tables. These options are not applicable to `FULLTEXT` indexes that use the ngram parser.

The wildcarded word is considered as a prefix that must be present at the start of one or more words. If the minimum word length is 4, a search for `'+word +the*'` could return fewer rows than a search for `'+word +the'`, because the second query ignores the too-short search term `the`.

- `"`

A phrase that is enclosed within double quote (`"`) characters matches only rows that contain the phrase *literally, as it was typed*. The full-text engine splits the phrase into words and performs a search in the `FULLTEXT` index for the words. Nonword characters need not be matched exactly: Phrase searching requires only that matches contain exactly the same words as the phrase and in the same order. For example, `"test phrase"` matches `"test, phrase"`.

If the phrase contains no words that are in the index, the result is empty. The words might not be in the index because of a combination of factors: if they do not exist in the text, are stopwords, or are shorter than the minimum length of indexed words.

The following examples demonstrate some search strings that use boolean full-text operators:

- `'apple banana'`

Find rows that contain at least one of the two words.

- `'+apple +juice'`

Find rows that contain both words.

- `'+apple macintosh'`

Find rows that contain the word “apple”, but rank rows higher if they also contain “macintosh”.

- `'+apple -macintosh'`

Find rows that contain the word “apple” but not “macintosh”.

- `'+apple ~macintosh'`

Find rows that contain the word “apple”, but if the row also contains the word “macintosh”, rate it lower than if row does not. This is “softer” than a search for `'+apple -macintosh'`, for which the presence of “macintosh” causes the row not to be returned at all.

- `'+apple +(>turnover <strudel)'`

Find rows that contain the words “apple” and “turnover”, or “apple” and “strudel” (in any order), but rank “apple turnover” higher than “apple strudel”.

- `'apple*'`

Find rows that contain words such as “apple”, “apples”, “applesauce”, or “applet”.

- `'"some words"'`

Find rows that contain the exact phrase “some words” (for example, rows that contain “some words of wisdom” but not “some noise words”). Note that the " characters that enclose the phrase are operator characters that delimit the phrase. They are not the quotation marks that enclose the search string itself.

## Relevancy Rankings for InnoDB Boolean Mode Search

InnoDB full-text search is modeled on the Sphinx full-text search engine, and the algorithms used are based on BM25 and TF-IDF ranking algorithms. For these reasons, relevancy rankings for InnoDB boolean full-text search may differ from MyISAM relevancy rankings.

InnoDB uses a variation of the “term frequency-inverse document frequency” (TF-IDF) weighting system to rank a document's relevance for a given full-text search query. The TF-IDF weighting is based on how frequently a word appears in a document, offset by how frequently the word appears in all documents in the collection. In other words, the more frequently a word appears in a document, and the less frequently the word appears in the document collection, the higher the document is ranked.

## How Relevancy Ranking is Calculated

The term frequency (TF) value is the number of times that a word appears in a document. The inverse document frequency (IDF) value of a word is calculated using the following formula, where `total_records` is the number of records in the collection, and `matching_records` is the number of records that the search term appears in.

```
${IDF} = log10(${total_records} / ${matching_records})
```

When a document contains a word multiple times, the IDF value is multiplied by the TF value:

```
${TF} * ${IDF}
```

Using the TF and IDF values, the relevancy ranking for a document is calculated using this formula:

```
${rank} = ${TF} * ${IDF} * ${IDF}
```

The formula is demonstrated in the following examples.

## Relevancy Ranking for a Single Word Search

This example demonstrates the relevancy ranking calculation for a single-word search.

```
mysql> CREATE TABLE articles (
-> id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
-> title VARCHAR(200),
-> body TEXT,
-> FULLTEXT (title,body)
->) ENGINE=InnoDB;
Query OK, 0 rows affected (1.04 sec)

mysql> INSERT INTO articles (title,body) VALUES
-> ('MySQL Tutorial','This database tutorial ...'),
-> ('How To Use MySQL','After you went through a ...'),
-> ('Optimizing Your Database','In this database tutorial ...'),
-> ('MySQL vs. YoursQL','When comparing databases ...'),
-> ('MySQL Security','When configured properly, MySQL ...'),
-> ('Database, Database, Database','database database database'),
-> ('1001 MySQL Tricks','1. Never run mysqld as root. 2. ...'),
-> ('MySQL Full-Text Indexes', 'MySQL fulltext indexes use a ...');
Query OK, 8 rows affected (0.06 sec)
Records: 8 Duplicates: 0 Warnings: 0
```

```
mysql> SELECT id, title, body,
-> MATCH (title,body) AGAINST ('database' IN BOOLEAN MODE) AS score
-> FROM articles ORDER BY score DESC;
```

id	title	body	score
6	Database, Database, Database	database database database	1.0886961221694946
3	Optimizing Your Database	In this database tutorial ...	0.36289870738983154
1	MySQL Tutorial	This database tutorial ...	0.18144935369491577
2	How To Use MySQL	After you went through a ...	0
4	MySQL vs. YourSQL	When comparing databases ...	0
5	MySQL Security	When configured properly, MySQL ...	0
7	1001 MySQL Tricks	1. Never run mysqld as root. 2. ...	0
8	MySQL Full-Text Indexes	MySQL fulltext indexes use a ..	0

8 rows in set (0.00 sec)

There are 8 records in total, with 3 that match the “database” search term. The first record ([id 6](#)) contains the search term 6 times and has a relevancy ranking of [1.0886961221694946](#). This ranking value is calculated using a **TF** value of 6 (the “database” search term appears 6 times in record [id 6](#)) and an **IDF** value of 0.42596873216370745, which is calculated as follows (where 8 is the total number of records and 3 is the number of records that the search term appears in):

```
${IDF} = LOG10(8 / 3) = 0.42596873216370745
```

The **TF** and **IDF** values are then entered into the ranking formula:

```
${rank} = ${TF} * ${IDF} * ${IDF}
```

Performing the calculation in the MySQL command-line client returns a ranking value of 1.088696164686938.

```
mysql> SELECT 6*LOG10(8/3)*LOG10(8/3);
+-----+
| 6*LOG10(8/3)*LOG10(8/3) |
+-----+
| 1.088696164686938 |
+-----+
1 row in set (0.00 sec)
```

#### Note

You may notice a slight difference in the ranking values returned by the `SELECT ... MATCH ... AGAINST` statement and the MySQL command-line client ([1.0886961221694946](#) versus [1.088696164686938](#)). The difference is due to how the casts between integers and floats/doubles are performed internally by **InnoDB** (along with related precision and rounding decisions), and how they are performed elsewhere, such as in the MySQL command-line client or other types of calculators.

## Relevancy Ranking for a Multiple Word Search

This example demonstrates the relevancy ranking calculation for a multiple-word full-text search based on the `articles` table and data used in the previous example.

If you search on more than one word, the relevancy ranking value is a sum of the relevancy ranking value for each word, as shown in this formula:

```
${rank} = ${TF} * ${IDF} * ${IDF} + ${TF} * ${IDF} * ${IDF}
```

Performing a search on two terms ('mysql tutorial') returns the following results:

```
mysql> SELECT id, title, body, MATCH (title,body)
-> AGAINST ('mysql tutorial' IN BOOLEAN MODE) AS score
-> FROM articles ORDER BY score DESC;
```

id	title	body	score
1	MySQL Tutorial	This database tutorial ...	0.7405621409416199
3	Optimizing Your Database	In this database tutorial ...	0.3624762296676636
5	MySQL Security	When configured properly, MySQL ...	0.031219376251101494
8	MySQL Full-Text Indexes	MySQL fulltext indexes use a ..	0.031219376251101494
2	How To Use MySQL	After you went through a ...	0.015609688125550747
4	MySQL vs. YourSQL	When comparing databases ...	0.015609688125550747
7	1001 MySQL Tricks	1. Never run mysqld as root. 2. ...	0.015609688125550747
6	Database, Database, Database	database database database	0

8 rows in set (0.00 sec)

In the first record (`id 8`), 'mysql' appears once and 'tutorial' appears twice. There are six matching records for 'mysql' and two matching records for 'tutorial'. The MySQL command-line client returns the expected ranking value when inserting these values into the ranking formula for a multiple word search:

```
mysql> SELECT (1*log10(8/6)*log10(8/6)) + (2*log10(8/2)*log10(8/2));
```

(1*log10(8/6)*log10(8/6)) + (2*log10(8/2)*log10(8/2))
0.7405621541938003

1 row in set (0.00 sec)

#### Note

The slight difference in the ranking values returned by the `SELECT ... MATCH ... AGAINST` statement and the MySQL command-line client is explained in the preceding example.

### 14.9.3 Full-Text Searches with Query Expansion

Full-text search supports query expansion (and in particular, its variant “blind query expansion”). This is generally useful when a search phrase is too short, which often means that the user is relying on implied knowledge that the full-text search engine lacks. For example, a user searching for “database” may really mean that “MySQL”, “Oracle”, “DB2”, and “RDBMS” all are phrases that should match “databases” and should be returned, too. This is implied knowledge.

Blind query expansion (also known as automatic relevance feedback) is enabled by adding `WITH QUERY EXPANSION` or `IN NATURAL LANGUAGE MODE WITH QUERY EXPANSION` following the search phrase. It works by performing the search twice, where the search phrase for the second search is the original search phrase concatenated with the few most highly relevant documents from the first search. Thus, if one of these documents contains the word “databases” and the word “MySQL”, the second search finds the documents that contain the word “MySQL” even if they do not contain the word “database”. The following example shows this difference:

```
mysql> SELECT * FROM articles
WHERE MATCH (title,body)
AGAINST ('database' IN NATURAL LANGUAGE MODE);
```

id	title	body
1	MySQL Tutorial	DBMS stands for DataBase ...
5	MySQL vs. YourSQL	In the following database comparison ...

2 rows in set (0.00 sec)

```
mysql> SELECT * FROM articles
 WHERE MATCH (title,body)
 AGAINST ('database' WITH QUERY EXPANSION);
```

id	title	body
5	MySQL vs. YourSQL	In the following database comparison ...
1	MySQL Tutorial	DBMS stands for DataBase ...
3	Optimizing MySQL	In this tutorial we show ...
6	MySQL Security	When configured properly, MySQL ...
2	How To Use MySQL Well	After you went through a ...
4	1001 MySQL Tricks	1. Never run mysqld as root. 2. ...

```
6 rows in set (0.00 sec)
```

Another example could be searching for books by Georges Simenon about Maigret, when a user is not sure how to spell “Maigret”. A search for “Megre and the reluctant witnesses” finds only “Maigret and the Reluctant Witnesses” without query expansion. A search with query expansion finds all books with the word “Maigret” on the second pass.

#### Note

Because blind query expansion tends to increase noise significantly by returning nonrelevant documents, use it only when a search phrase is short.

## 14.9.4 Full-Text Stopwords

The stopword list is loaded and searched for full-text queries using the server character set and collation (the values of the `character_set_server` and `collation_server` system variables). False hits or misses might occur for stopword lookups if the stopword file or columns used for full-text indexing or searches have a character set or collation different from `character_set_server` or `collation_server`.

Case sensitivity of stopword lookups depends on the server collation. For example, lookups are case-insensitive if the collation is `utf8mb4_0900_ai_ci`, whereas lookups are case-sensitive if the collation is `utf8mb4_0900_as_cs` or `utf8mb4_bin`.

- [Stopwords for InnoDB Search Indexes](#)
- [Stopwords for MyISAM Search Indexes](#)

### Stopwords for InnoDB Search Indexes

**InnoDB** has a relatively short list of default stopwords, because documents from technical, literary, and other sources often use short words as keywords or in significant phrases. For example, you might search for “to be or not to be” and expect to get a sensible result, rather than having all those words ignored.

To see the default **InnoDB** stopword list, query the Information Schema `INNODB_FT_DEFAULT_STOPWORD` table.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_DEFAULT_STOPWORD;
```

value
a
about
an
are
as
at

```

| be
| by
| com

+-----+
36 rows in set (0.00 sec)

```

To define your own stopwords list for all [InnoDB](#) tables, define a table with the same structure as the [INNODB\\_FT\\_DEFAULT\\_STOPWORD](#) table, populate it with stopwords, and set the value of the [innodb\\_ft\\_server\\_stopword\\_table](#) option to a value in the form [db\\_name/table\\_name](#) before creating the full-text index. The stopwords table must have a single [VARCHAR](#) column named [value](#). The following example demonstrates creating and configuring a new global stopwords table for [InnoDB](#).

```

-- Create a new stopwords table

mysql> CREATE TABLE my_stopwords(value VARCHAR(30)) ENGINE = INNODB;
Query OK, 0 rows affected (0.01 sec)

-- Insert stopwords (for simplicity, a single stopwords is used in this example)

mysql> INSERT INTO my_stopwords(value) VALUES ('Ishmael');
Query OK, 1 row affected (0.00 sec)

-- Create the table

mysql> CREATE TABLE opening_lines (
id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
opening_line TEXT(500),
author VARCHAR(200),
title VARCHAR(200)
) ENGINE=InnoDB;
Query OK, 0 rows affected (0.01 sec)

-- Insert data into the table

mysql> INSERT INTO opening_lines(opening_line,author,title) VALUES
('Call me Ishmael.','Herman Melville','Moby-Dick'),
('A screaming comes across the sky.','Thomas Pynchon','Gravity\'s Rainbow'),
('I am an invisible man.','Ralph Ellison','Invisible Man'),
('Where now? Who now? When now?','Samuel Beckett','The Unnamable'),

```

```
('It was love at first sight.', 'Joseph Heller', 'Catch-22'),
('All this happened, more or less.', 'Kurt Vonnegut', 'Slaughterhouse-Five'),
('Mrs. Dalloway said she would buy the flowers herself.', 'Virginia Woolf', 'Mrs. Dalloway'),
('It was a pleasure to burn.', 'Ray Bradbury', 'Fahrenheit 451');
Query OK, 8 rows affected (0.00 sec)
Records: 8 Duplicates: 0 Warnings: 0

-- Set the innodb_ft_server_stopword_table option to the new stopwords table

mysql> SET GLOBAL innodb_ft_server_stopword_table = 'test/my_stopwords';
Query OK, 0 rows affected (0.00 sec)

-- Create the full-text index (which rebuilds the table if no FTS_DOC_ID column is defined)

mysql> CREATE FULLTEXT INDEX idx ON opening_lines(opening_line);
Query OK, 0 rows affected, 1 warning (1.17 sec)
Records: 0 Duplicates: 0 Warnings: 1
```

Verify that the specified stopwords ('Ishmael') does not appear by querying the Information Schema `INNODB_FT_INDEX_TABLE` table.

### Note

By default, words less than 3 characters in length or greater than 84 characters in length do not appear in an `InnoDB` full-text search index. Maximum and minimum word length values are configurable using the `innodb_ft_max_token_size` and `innodb_ft_min_token_size` variables. This default behavior does not apply to the ngram parser plugin. ngram token size is defined by the `ngram_token_size` option.

```
mysql> SET GLOBAL innodb_ft_aux_table='test/opening_lines';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT word FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_TABLE LIMIT 15;
+-----+
| word |
+-----+
| across |
| all |
| burn |
| buy |
| call |
| comes |
| dalloway |
| first |
| flowers |
| happened |
| herself |
| invisible |
| less |
| love |
| man |
+-----+
15 rows in set (0.00 sec)
```

To create stopwords lists on a table-by-table basis, create other stopwords tables and use the `innodb_ft_user_stopword_table` option to specify the stopwords table that you want to use before you create the full-text index.

## Stopwords for MyISAM Search Indexes

The stopwords file is loaded and searched using `latin1` if `character_set_server` is `ucs2`, `utf16`, `utf16le`, or `utf32`.

To override the default stopwords list for MyISAM tables, set the `ft_stopword_file` system variable. (See [Section 7.1.8, “Server System Variables”](#).) The variable value should be the path name of the file containing the stopwords list, or the empty string to disable stopwords filtering. The server looks for the file in the data directory unless an absolute path name is given to specify a different directory. After changing the value of this variable or the contents of the stopwords file, restart the server and rebuild your `FULLTEXT` indexes.

The stopwords list is free-form, separating stopwords with any nonalphanumeric character such as newline, space, or comma. Exceptions are the underscore character (`_`) and a single apostrophe (`'`) which are treated as part of a word. The character set of the stopwords list is the server's default character set; see [Section 12.3.2, “Server Character Set and Collation”](#).

The following list shows the default stopwords for `MyISAM` search indexes. In a MySQL source distribution, you can find this list in the `storage/myisam/ft_static.c` file.

### 14.9.5 Full-Text Restrictions

- Full-text searches are supported for [InnoDB](#) and [MyISAM](#) tables only.
- Full-text searches are not supported for partitioned tables. See [Section 26.6, “Restrictions and Limitations on Partitioning”](#).

- Full-text searches can be used with most multibyte character sets. The exception is that for Unicode, the `utf8mb3` or `utf8mb4` character set can be used, but not the `ucs2` character set. Although `FULLTEXT` indexes on `ucs2` columns cannot be used, you can perform `IN BOOLEAN MODE` searches on a `ucs2` column that has no such index.

The remarks for `utf8mb3` also apply to `utf8mb4`, and the remarks for `ucs2` also apply to `utf16`, `utf16le`, and `utf32`.

- Ideographic languages such as Chinese and Japanese do not have word delimiters. Therefore, the built-in full-text parser *cannot determine where words begin and end in these and other such languages*.

A character-based ngram full-text parser that supports Chinese, Japanese, and Korean (CJK), and a word-based MeCab parser plugin that supports Japanese are provided for use with `InnoDB` and `MyISAM` tables.

- Although the use of multiple character sets within a single table is supported, all columns in a `FULLTEXT` index must use the same character set and collation.
- The `MATCH( )` column list must match exactly the column list in some `FULLTEXT` index definition for the table, unless this `MATCH( )` is `IN BOOLEAN MODE` on a `MyISAM` table. For `MyISAM` tables, boolean-mode searches can be done on nonindexed columns, although they are likely to be slow.
- The argument to `AGAINST( )` must be a string value that is constant during query evaluation. This rules out, for example, a table column because that can differ for each row.

The argument to `MATCH( )` cannot use a rollup column.

- Index hints are more limited for `FULLTEXT` searches than for non-`FULLTEXT` searches. See [Section 10.9.4, “Index Hints”](#).
- For `InnoDB`, all DML operations (`INSERT`, `UPDATE`, `DELETE`) involving columns with full-text indexes are processed at transaction commit time. For example, for an `INSERT` operation, an inserted string is tokenized and decomposed into individual words. The individual words are then added to full-text index tables when the transaction is committed. As a result, full-text searches only return committed data.
- The `'%` character is not a supported wildcard character for full-text searches.

## 14.9.6 Fine-Tuning MySQL Full-Text Search

MySQL's full-text search capability has few user-tunable parameters. You can exert more control over full-text searching behavior if you have a MySQL source distribution because some changes require source code modifications. See [Section 2.8, “Installing MySQL from Source”](#).

Full-text search is carefully tuned for effectiveness. Modifying the default behavior in most cases can actually decrease effectiveness. *Do not alter the MySQL sources unless you know what you are doing.*

Most full-text variables described in this section must be set at server startup time. A server restart is required to change them; they cannot be modified while the server is running.

Some variable changes require that you rebuild the `FULLTEXT` indexes in your tables. Instructions for doing so are given later in this section.

- [Configuring Minimum and Maximum Word Length](#)
- [Configuring the Natural Language Search Threshold](#)
- [Modifying Boolean Full-Text Search Operators](#)

- [Character Set Modifications](#)
- [Rebuilding InnoDB Full-Text Indexes](#)
- [Optimizing InnoDB Full-Text Indexes](#)
- [Rebuilding MyISAM Full-Text Indexes](#)

## Configuring Minimum and Maximum Word Length

The minimum and maximum lengths of words to be indexed are defined by the `innodb_ft_min_token_size` and `innodb_ft_max_token_size` for [InnoDB](#) search indexes, and `ft_min_word_len` and `ft_max_word_len` for [MyISAM](#) ones.

### Note

Minimum and maximum word length full-text parameters do not apply to [FULLTEXT](#) indexes created using the ngram parser. ngram token size is defined by the `ngram_token_size` option.

After changing any of these options, rebuild your [FULLTEXT](#) indexes for the change to take effect. For example, to make two-character words searchable, you could put the following lines in an option file:

```
[mysqld]
innodb_ft_min_token_size=2
ft_min_word_len=2
```

Then restart the server and rebuild your [FULLTEXT](#) indexes. For [MyISAM](#) tables, note the remarks regarding `myisamchk` in the instructions that follow for rebuilding [MyISAM](#) full-text indexes.

## Configuring the Natural Language Search Threshold

For [MyISAM](#) search indexes, the 50% threshold for natural language searches is determined by the particular weighting scheme chosen. To disable it, look for the following line in `storage/myisam/ftdefs.h`:

```
#define GWS_IN_USE GWS_PROB
```

Change that line to this:

```
#define GWS_IN_USE GWS_FREQ
```

Then recompile MySQL. There is no need to rebuild the indexes in this case.

### Note

By making this change, you *severely* decrease MySQL's ability to provide adequate relevance values for the `MATCH()` function. If you really need to search for such common words, it would be better to search using `IN BOOLEAN MODE` instead, which does not observe the 50% threshold.

## Modifying Boolean Full-Text Search Operators

To change the operators used for boolean full-text searches on [MyISAM](#) tables, set the `ft_boolean_syntax` system variable. ([InnoDB](#) does not have an equivalent setting.) This variable can be changed while the server is running, but you must have privileges sufficient to set global system

variables (see [Section 7.1.9.1, “System Variable Privileges”](#)). No rebuilding of indexes is necessary in this case.

## Character Set Modifications

For the built-in full-text parser, you can change the set of characters that are considered word characters in several ways, as described in the following list. After making the modification, rebuild the indexes for each table that contains any `FULLTEXT` indexes. Suppose that you want to treat the hyphen character ('-') as a word character. Use one of these methods:

- Modify the MySQL source: In `storage/innobase/handler/ha_innodb.cc` (for InnoDB), or in `storage/myisam/ftdefs.h` (for MyISAM), see the `true_word_char()` and `misc_word_char()` macros. Add '-' to one of those macros and recompile MySQL.
- Modify a character set file: This requires no recompilation. The `true_word_char()` macro uses a “character type” table to distinguish letters and numbers from other characters. You can edit the contents of the `<ctype><map>` array in one of the character set XML files to specify that '-' is a “letter.” Then use the given character set for your `FULLTEXT` indexes. For information about the `<ctype><map>` array format, see [Section 12.13.1, “Character Definition Arrays”](#).
- Add a new collation for the character set used by the indexed columns, and alter the columns to use that collation. For general information about adding collations, see [Section 12.14, “Adding a Collation to a Character Set”](#). For an example specific to full-text indexing, see [Section 14.9.7, “Adding a User-Defined Collation for Full-Text Indexing”](#).

## Rebuilding InnoDB Full-Text Indexes

For the changes to take effect, `FULLTEXT` indexes must be rebuilt after modifying any of the following full-text index variables: `innodb_ft_min_token_size`; `innodb_ft_max_token_size`; `innodb_ft_server_stopword_table`; `innodb_ft_user_stopword_table`; `innodb_ft_enable_stopword`; `ngram_token_size`. Modifying `innodb_ft_min_token_size`, `innodb_ft_max_token_size`, or `ngram_token_size` requires restarting the server.

To rebuild `FULLTEXT` indexes for an InnoDB table, use `ALTER TABLE` with the `DROP INDEX` and `ADD INDEX` options to drop and re-create each index.

## Optimizing InnoDB Full-Text Indexes

Running `OPTIMIZE TABLE` on a table with a full-text index rebuilds the full-text index, removing deleted Document IDs and consolidating multiple entries for the same word, where possible.

To optimize a full-text index, enable `innodb_optimize_fulltext_only` and run `OPTIMIZE TABLE`.

```
mysql> set GLOBAL innodb_optimize_fulltext_only=ON;
Query OK, 0 rows affected (0.01 sec)

mysql> OPTIMIZE TABLE opening_lines;
+-----+-----+-----+-----+
| Table | Op | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.opening_lines | optimize | status | OK |
+-----+-----+-----+-----+
1 row in set (0.01 sec)
```

To avoid lengthy rebuild times for full-text indexes on large tables, you can use the `innodb_ft_num_word_optimize` option to perform the optimization in stages. The `innodb_ft_num_word_optimize` option defines the number of words that are optimized each time

`OPTIMIZE TABLE` is run. The default setting is 2000, which means that 2000 words are optimized each time `OPTIMIZE TABLE` is run. Subsequent `OPTIMIZE TABLE` operations continue from where the preceding `OPTIMIZE TABLE` operation ended.

## Rebuilding MyISAM Full-Text Indexes

If you modify full-text variables that affect indexing (`ft_min_word_len`, `ft_max_word_len`, or `ft_stopword_file`), or if you change the stopwords file itself, you must rebuild your `FULLTEXT` indexes after making the changes and restarting the server.

To rebuild the `FULLTEXT` indexes for a `MyISAM` table, it is sufficient to do a `QUICK` repair operation:

```
mysql> REPAIR TABLE tbl_name QUICK;
```

Alternatively, use `ALTER TABLE` as just described. In some cases, this may be faster than a repair operation.

Each table that contains any `FULLTEXT` index must be repaired as just shown. Otherwise, queries for the table may yield incorrect results, and modifications to the table causes the server to see the table as corrupt and in need of repair.

If you use `myisamchk` to perform an operation that modifies `MyISAM` table indexes (such as repair or analyze), the `FULLTEXT` indexes are rebuilt using the *default* full-text parameter values for minimum word length, maximum word length, and stopwords file unless you specify otherwise. This can result in queries failing.

The problem occurs because these parameters are known only by the server. They are not stored in `MyISAM` index files. To avoid the problem if you have modified the minimum or maximum word length or stopwords file values used by the server, specify the same `ft_min_word_len`, `ft_max_word_len`, and `ft_stopword_file` values for `myisamchk` that you use for `mysqld`. For example, if you have set the minimum word length to 3, you can repair a table with `myisamchk` like this:

```
myisamchk --recover --ft_min_word_len=3 tbl_name.MYI
```

To ensure that `myisamchk` and the server use the same values for full-text parameters, place each one in both the `[mysqld]` and `[myisamchk]` sections of an option file:

```
[mysqld]
ft_min_word_len=3

[myisamchk]
ft_min_word_len=3
```

An alternative to using `myisamchk` for `MyISAM` table index modification is to use the `REPAIR TABLE`, `ANALYZE TABLE`, `OPTIMIZE TABLE`, or `ALTER TABLE` statements. These statements are performed by the server, which knows the proper full-text parameter values to use.

## 14.9.7 Adding a User-Defined Collation for Full-Text Indexing

### Warning

User-defined collations are deprecated; you should expect support for them to be removed in a future version of MySQL. The server issues a warning for any use of `COLLATE user_defined_collation` in an SQL statement; a warning is also issued when the server is started with `--collation-server` set equal to the name of a user-defined collation.

This section describes how to add a user-defined collation for full-text searches using the built-in full-text parser. The sample collation is like `latin1_swedish_ci` but treats the `' - '` character as a letter rather than as a punctuation character so that it can be indexed as a word character. General information about adding collations is given in [Section 12.14, “Adding a Collation to a Character Set”](#); it is assumed that you have read it and are familiar with the files involved.

To add a collation for full-text indexing, use the following procedure. The instructions here add a collation for a simple character set, which as discussed in [Section 12.14, “Adding a Collation to a Character Set”](#), can be created using a configuration file that describes the character set properties. For a complex character set such as Unicode, create collations using C source files that describe the character set properties.

1. Add a collation to the `Index.xml` file. The permitted range of IDs for user-defined collations is given in [Section 12.14.2, “Choosing a Collation ID”](#). The ID must be unused, so choose a value different from 1025 if that ID is already taken on your system.

```
<charset name="latin1">
...
<collation name="latin1_fulltext_ci" id="1025"/>
</charset>
```

2. Declare the sort order for the collation in the `latin1.xml` file. In this case, the order can be copied from `latin1_swedish_ci`:

```
<collation name="latin1_fulltext_ci">
<map>
00 01 02 03 04 05 06 07 08 09 0A 0B 0C 0D 0E 0F
10 11 12 13 14 15 16 17 18 19 1A 1B 1C 1D 1E 1F
20 21 22 23 24 25 26 27 28 29 2A 2B 2C 2D 2E 2F
30 31 32 33 34 35 36 37 38 39 3A 3B 3C 3D 3E 3F
40 41 42 43 44 45 46 47 48 49 4A 4B 4C 4D 4E 4F
50 51 52 53 54 55 56 57 58 59 5A 5B 5C 5D 5E 5F
60 41 42 43 44 45 46 47 48 49 4A 4B 4C 4D 4E 4F
50 51 52 53 54 55 56 57 58 59 5A 7B 7C 7D 7E 7F
80 81 82 83 84 85 86 87 88 89 8A 8B 8C 8D 8E 8F
90 91 92 93 94 95 96 97 98 99 9A 9B 9C 9D 9E 9F
A0 A1 A2 A3 A4 A5 A6 A7 A8 A9 AA AB AC AD AE AF
B0 B1 B2 B3 B4 B5 B6 B7 B8 B9 BA BB BC BD BE BF
41 41 41 41 5C 5B 5C 43 45 45 45 45 49 49 49 49
44 4E 4F 4F 4F 4F 5D D7 D8 55 55 55 59 59 DE DF
41 41 41 41 5C 5B 5C 43 45 45 45 45 49 49 49 49
44 4E 4F 4F 4F 4F 5D F7 D8 55 55 55 59 59 DE FF
</map>
</collation>
```

3. Modify the `ctype` array in `latin1.xml`. Change the value corresponding to 0x2D (which is the code for the `' - '` character) from 10 (punctuation) to 01 (uppercase letter). In the following array, this is the element in the fourth row down, third value from the end.

```
<ctype>
<map>
00
20 20 20 20 20 20 20 20 20 28 28 28 28 28 20 20
20 20 20 20 20 20 20 20 20 20 20 20 20 20 20 20
48 10 10 10 10 10 10 10 10 10 10 10 10 01 10 10
84 84 84 84 84 84 84 84 84 84 10 10 10 10 10 10
10 81 81 81 81 81 81 01 01 01 01 01 01 01 01 01
01 01 01 01 01 01 01 01 01 01 01 10 10 10 10 10
10 82 82 82 82 82 82 02 02 02 02 02 02 02 02 02
02 02 02 02 02 02 02 02 02 02 02 10 10 10 10 20
10 00 10 02 10 10 10 10 10 10 10 01 10 01 00 01 00
00 10 10 10 10 10 10 10 10 10 02 10 02 00 02 01
48 10 10 10 10 10 10 10 10 10 10 10 10 10 10 10
```

```

10 10 10 10 10 10 10 10 10 10 10 10 10 10 10
01 01 01 01 01 01 01 01 01 01 01 01 01 01 01
01 01 01 01 01 01 01 10 01 01 01 01 01 01 02
02 02 02 02 02 02 02 02 02 02 02 02 02 02 02
02 02 02 02 02 02 02 10 02 02 02 02 02 02 02
</map>
</ctype>

```

4. Restart the server.
5. To employ the new collation, include it in the definition of columns that are to use it:

```

mysql> DROP TABLE IF EXISTS t1;
Query OK, 0 rows affected (0.13 sec)

mysql> CREATE TABLE t1 (
 a TEXT CHARACTER SET latin1 COLLATE latin1_fulltext_ci,
 FULLTEXT INDEX(a)
) ENGINE=InnoDB;
Query OK, 0 rows affected (0.47 sec)

```

6. Test the collation to verify that hyphen is considered as a word character:

```

mysql> INSERT INTO t1 VALUES ('----'),('....'),('abcd');
Query OK, 3 rows affected (0.22 sec)
Records: 3 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM t1 WHERE MATCH a AGAINST ('----' IN BOOLEAN MODE);
+-----+
| a |
+-----+
| ---- |
+-----+
1 row in set (0.00 sec)

```

## 14.9.8 ngram Full-Text Parser

The built-in MySQL full-text parser uses the white space between words as a delimiter to determine where words begin and end, which is a limitation when working with ideographic languages that do not use word delimiters. To address this limitation, MySQL provides an ngram full-text parser that supports Chinese, Japanese, and Korean (CJK). The ngram full-text parser is supported for use with [InnoDB](#) and [MyISAM](#).

### Note

MySQL also provides a MeCab full-text parser plugin for Japanese, which tokenizes documents into meaningful words. For more information, see [Section 14.9.9, “MeCab Full-Text Parser Plugin”](#).

An ngram is a contiguous sequence of *n* characters from a given sequence of text. The ngram parser tokenizes a sequence of text into a contiguous sequence of *n* characters. For example, you can tokenize “abcd” for different values of *n* using the ngram full-text parser.

```

n=1: 'a', 'b', 'c', 'd'
n=2: 'ab', 'bc', 'cd'
n=3: 'abc', 'bcd'
n=4: 'abcd'

```

The ngram full-text parser is a built-in server plugin. As with other built-in server plugins, it is automatically loaded when the server is started.

The full-text search syntax described in [Section 14.9, “Full-Text Search Functions”](#) applies to the ngram parser plugin. Differences in parsing behavior are described in this section. Full-text-related configuration

options, except for minimum and maximum word length options (`innodb_ft_min_token_size`, `innodb_ft_max_token_size`, `ft_min_word_len`, `ft_max_word_len`) are also applicable.

## Configuring ngram Token Size

The ngram parser has a default ngram token size of 2 (bigram). For example, with a token size of 2, the ngram parser parses the string “abc def” into four tokens: “ab”, “bc”, “de” and “ef”.

ngram token size is configurable using the `ngram_token_size` configuration option, which has a minimum value of 1 and maximum value of 10.

Typically, `ngram_token_size` is set to the size of the largest token that you want to search for. If you only intend to search for single characters, set `ngram_token_size` to 1. A smaller token size produces a smaller full-text search index, and faster searches. If you need to search for words comprised of more than one character, set `ngram_token_size` accordingly. For example, “Happy Birthday” is “生日快乐” in simplified Chinese, where “生日” is “birthday”, and “快乐” translates as “happy”. To search on two-character words such as these, set `ngram_token_size` to a value of 2 or higher.

As a read-only variable, `ngram_token_size` may only be set as part of a startup string or in a configuration file:

- Startup string:

```
mysqld --ngram_token_size=2
```

- Configuration file:

```
[mysqld]
ngram_token_size=2
```

### Note

The following minimum and maximum word length configuration options are ignored for `FULLTEXT` indexes that use the ngram parser: `innodb_ft_min_token_size`, `innodb_ft_max_token_size`, `ft_min_word_len`, and `ft_max_word_len`.

## Creating a FULLTEXT Index that Uses the ngram Parser

To create a `FULLTEXT` index that uses the ngram parser, specify `WITH PARSEER ngram` with `CREATE TABLE`, `ALTER TABLE`, or `CREATE INDEX`.

The following example demonstrates creating a table with an `ngram FULLTEXT` index, inserting sample data (Simplified Chinese text), and viewing tokenized data in the Information Schema `INNODB_FT_INDEX_CACHE` table.

```
mysql> USE test;

mysql> CREATE TABLE articles (
 id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
 title VARCHAR(200),
 body TEXT,
 FULLTEXT (title,body) WITH PARSEER ngram
) ENGINE=InnoDB CHARACTER SET utf8mb4;

mysql> SET NAMES utf8mb4;

INSERT INTO articles (title,body) VALUES
('数据库管理','在本教程中我将向你展示如何管理数据库'),
('数据库应用开发','学习开发数据库应用程序');
```

```
mysql> SET GLOBAL innodb_ft_aux_table="test/articles";

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_CACHE ORDER BY doc_id, position;
```

To add a [FULLTEXT](#) index to an existing table, you can use [ALTER TABLE](#) or [CREATE INDEX](#). For example:

```
CREATE TABLE articles (
 id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
 title VARCHAR(200),
 body TEXT
) ENGINE=InnoDB CHARACTER SET utf8mb4;

ALTER TABLE articles ADD FULLTEXT INDEX ft_index (title,body) WITH PARSE ngram;

Or:

CREATE FULLTEXT INDEX ft_index ON articles (title,body) WITH PARSE ngram;
```

## ngram Parser Space Handling

The ngram parser eliminates spaces when parsing. For example:

- “ab cd” is parsed to “ab”, “cd”
- “a bc” is parsed to “bc”

## ngram Parser Stopword Handling

The built-in MySQL full-text parser compares words to entries in the stopwords list. If a word is equal to an entry in the stopwords list, the word is excluded from the index. For the ngram parser, stopwords handling is performed differently. Instead of excluding tokens that are equal to entries in the stopwords list, the ngram parser excludes tokens that *contain* stopwords. For example, assuming [ngram\\_token\\_size=2](#), a document that contains “a,b” is parsed to “a,” and “,b”. If a comma (“,”) is defined as a stopwords, both “a,” and “,b” are excluded from the index because they contain a comma.

By default, the ngram parser uses the default stopwords list, which contains a list of English stopwords. For a stopwords list applicable to Chinese, Japanese, or Korean, you must create your own. For information about creating a stopwords list, see [Section 14.9.4, “Full-Text Stopwords”](#).

Stopwords greater in length than [ngram\\_token\\_size](#) are ignored.

## ngram Parser Term Search

For *natural language mode* search, the search term is converted to a union of ngram terms. For example, the string “abc” (assuming [ngram\\_token\\_size=2](#)) is converted to “ab bc”. Given two documents, one containing “ab” and the other containing “abc”, the search term “ab bc” matches both documents.

For *boolean mode* search, the search term is converted to an ngram phrase search. For example, the string 'abc' (assuming [ngram\\_token\\_size=2](#)) is converted to “ab bc”. Given two documents, one containing 'ab' and the other containing 'abc', the search phrase “ab bc” only matches the document containing 'abc'.

## ngram Parser Wildcard Search

Because an ngram [FULLTEXT](#) index contains only ngrams, and does not contain information about the beginning of terms, wildcard searches may return unexpected results. The following behaviors apply to wildcard searches using ngram [FULLTEXT](#) search indexes:

- If the prefix term of a wildcard search is shorter than ngram token size, the query returns all indexed rows that contain ngram tokens starting with the prefix term. For example, assuming `ngram_token_size=2`, a search on “a\*” returns all rows starting with “a”.
- If the prefix term of a wildcard search is longer than ngram token size, the prefix term is converted to an ngram phrase and the wildcard operator is ignored. For example, assuming `ngram_token_size=2`, an “abc\*” wildcard search is converted to “ab bc”.

## ngram Parser Phrase Search

Phrase searches are converted to ngram phrase searches. For example, The search phrase “abc” is converted to “ab bc”, which returns documents containing “abc” and “ab bc”.

The search phrase “abc def” is converted to “ab bc de ef”, which returns documents containing “abc def” and “ab bc de ef”. A document that contains “abcdef” is not returned.

## 14.9.9 MeCab Full-Text Parser Plugin

The built-in MySQL full-text parser uses the white space between words as a delimiter to determine where words begin and end, which is a limitation when working with ideographic languages that do not use word delimiters. To address this limitation for Japanese, MySQL provides a MeCab full-text parser plugin. The MeCab full-text parser plugin is supported for use with [InnoDB](#) and [MyISAM](#).

### Note

MySQL also provides an ngram full-text parser plugin that supports Japanese. For more information, see [Section 14.9.8, “ngram Full-Text Parser”](#).

The MeCab full-text parser plugin is a full-text parser plugin for Japanese that tokenizes a sequence of text into meaningful words. For example, MeCab tokenizes “データベース管理” (“Database Management”) into “データベース” (“Database”) and “管理” (“Management”). By comparison, the [ngram](#) full-text parser tokenizes text into a contiguous sequence of *n* characters, where *n* represents a number between 1 and 10.

In addition to tokenizing text into meaningful words, MeCab indexes are typically smaller than ngram indexes, and MeCab full-text searches are generally faster. One drawback is that it may take longer for the MeCab full-text parser to tokenize documents, compared to the ngram full-text parser.

The full-text search syntax described in [Section 14.9, “Full-Text Search Functions”](#) applies to the MeCab parser plugin. Differences in parsing behavior are described in this section. Full-text related configuration options are also applicable.

For additional information about the MeCab parser, refer to the [MeCab: Yet Another Part-of-Speech and Morphological Analyzer](#) project on Github.

## Installing the MeCab Parser Plugin

The MeCab parser plugin requires [mecab](#) and [mecab-ipadic](#).

On supported Fedora, Debian and Ubuntu platforms (except Ubuntu 12.04 where the system [mecab](#) version is too old), MySQL dynamically links to the system [mecab](#) installation if it is installed to the default location. On other supported Unix-like platforms, [libmecab.so](#) is statically linked in [libpluginmecab.so](#), which is located in the MySQL plugin directory. [mecab-ipadic](#) is included in MySQL binaries and is located in `MYSQL_HOME\lib\mecab`.

You can install [mecab](#) and [mecab-ipadic](#) using a native package management utility (on Fedora, Debian, and Ubuntu), or you can build [mecab](#) and [mecab-ipadic](#) from source. For information about

installing `mecab` and `mecab-ipadic` using a native package management utility, see [Installing MeCab From a Binary Distribution \(Optional\)](#). If you want to build `mecab` and `mecab-ipadic` from source, see [Building MeCab From Source \(Optional\)](#).

On Windows, `libmecab.dll` is found in the MySQL `bin` directory. `mecab-ipadic` is located in `MYSQL_HOME/lib/mecab`.

To install and configure the MeCab parser plugin, perform the following steps:

1. In the MySQL configuration file, set the `mecab_rc_file` configuration option to the location of the `mecabrc` configuration file, which is the configuration file for MeCab. If you are using the MeCab package distributed with MySQL, the `mecabrc` file is located in `MYSQL_HOME/lib/mecab/etc/`.

```
[mysqld]
loose-mecab-rc-file=MYSQL_HOME/lib/mecab/etc/mecabrc
```

The `loose` prefix is an [option modifier](#). The `mecab_rc_file` option is not recognized by MySQL until the MeCab parser plugin is installed but it must be set before attempting to install the MeCab parser plugin. The `loose` prefix allows you restart MySQL without encountering an error due to an unrecognized variable.

If you use your own MeCab installation, or build MeCab from source, the location of the `mecabrc` configuration file may differ.

For information about the MySQL configuration file and its location, see [Section 6.2.2.2, “Using Option Files”](#).

2. Also in the MySQL configuration file, set the minimum token size to 1 or 2, which are the values recommended for use with the MeCab parser. For `InnoDB` tables, minimum token size is defined by the `innodb_ft_min_token_size` configuration option, which has a default value of 3. For `MyISAM` tables, minimum token size is defined by `ft_min_word_len`, which has a default value of 4.

```
[mysqld]
innodb_ft_min_token_size=1
```

3. Modify the `mecabrc` configuration file to specify the dictionary you want to use. The `mecab-ipadic` package distributed with MySQL binaries includes three dictionaries (`ipadic_euc-jp`, `ipadic_sjis`, and `ipadic_utf-8`). The `mecabrc` configuration file packaged with MySQL contains an entry similar to the following:

```
dicdir = /path/to/mysql/lib/mecab/lib/mecab/dic/ipadic_euc-jp
```

To use the `ipadic_utf-8` dictionary, for example, modify the entry as follows:

```
dicdir=MYSQL_HOME/lib/mecab/dic/ipadic_utf-8
```

If you are using your own MeCab installation or have built MeCab from source, the default `dicdir` entry in the `mecabrc` file is likely to differ, as are the dictionaries and their location.

#### Note

After the MeCab parser plugin is installed, you can use the `mecab_charset` status variable to view the character set used with MeCab. The three MeCab dictionaries provided with the MySQL binary support the following character sets.

- The `ipadic_euc-jp` dictionary supports the `ujis` and `eucjpms` character sets.

- The `ipadic_sjis` dictionary supports the `sjis` and `cp932` character sets.
- The `ipadic_utf-8` dictionary supports the `utf8mb3` and `utf8mb4` character sets.

`mecab_charset` only reports the first supported character set. For example, the `ipadic_utf-8` dictionary supports both `utf8mb3` and `utf8mb4`. `mecab_charset` always reports `utf8` when this dictionary is in use.

4. Restart MySQL.

5. Install the MeCab parser plugin:

The MeCab parser plugin is installed using `INSTALL PLUGIN`. The plugin name is `mecab`, and the shared library name is `libpluginmecab.so`. For additional information about installing plugins, see [Section 7.6.1, “Installing and Uninstalling Plugins”](#).

```
INSTALL PLUGIN mecab SONAME 'libpluginmecab.so';
```

Once installed, the MeCab parser plugin loads at every normal MySQL restart.

6. Verify that the MeCab parser plugin is loaded using the `SHOW PLUGINS` statement.

```
mysql> SHOW PLUGINS;
```

A `mecab` plugin should appear in the list of plugins.

## Creating a FULLTEXT Index that uses the MeCab Parser

To create a `FULLTEXT` index that uses the mecab parser, specify `WITH PARSE` `ngram` with `CREATE TABLE`, `ALTER TABLE`, or `CREATE INDEX`.

This example demonstrates creating a table with a `mecab FULLTEXT` index, inserting sample data, and viewing tokenized data in the Information Schema `INNODB_FT_INDEX_CACHE` table:

```
mysql> USE test;

mysql> CREATE TABLE articles (
 id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
 title VARCHAR(200),
 body TEXT,
 FULLTEXT (title,body) WITH PARSE mecab
) ENGINE=InnoDB CHARACTER SET utf8mb4;

mysql> SET NAMES utf8mb4;

mysql> INSERT INTO articles (title,body) VALUES
 ('データベース管理','このチュートリアルでは、私はどのようにデータベースを管理する方法を紹介します'),
 ('データベースアプリケーション開発','データベースアプリケーションを開発することを学ぶ');

mysql> SET GLOBAL innodb_ft_aux_table="test/articles";

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_CACHE ORDER BY doc_id, position;
```

To add a `FULLTEXT` index to an existing table, you can use `ALTER TABLE` or `CREATE INDEX`. For example:

```
CREATE TABLE articles (
 id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
 title VARCHAR(200),
```

```
body TEXT
) ENGINE=InnoDB CHARACTER SET utf8mb4;

ALTER TABLE articles ADD FULLTEXT INDEX ft_index (title,body) WITH PARSER mecab;

Or:

CREATE FULLTEXT INDEX ft_index ON articles (title,body) WITH PARSER mecab;
```

## MeCab Parser Space Handling

The MeCab parser uses spaces as separators in query strings. For example, the MeCab parser tokenizes データベース管理 as データベース and 管理.

## MeCab Parser Stopword Handling

By default, the MeCab parser uses the default stopword list, which contains a short list of English stopwords. For a stopword list applicable to Japanese, you must create your own. For information about creating stopword lists, see [Section 14.9.4, “Full-Text Stopwords”](#).

## MeCab Parser Term Search

For natural language mode search, the search term is converted to a union of tokens. For example, データベース管理 is converted to データベース 管理.

```
SELECT COUNT(*) FROM articles
WHERE MATCH(title,body) AGAINST('データベース管理' IN NATURAL LANGUAGE MODE);
```

For boolean mode search, the search term is converted to a search phrase. For example, データベース管理 is converted to データベース 管理.

```
SELECT COUNT(*) FROM articles
WHERE MATCH(title,body) AGAINST('データベース管理' IN BOOLEAN MODE);
```

## MeCab Parser Wildcard Search

Wildcard search terms are not tokenized. A search on データベース管理\* is performed on the prefix, データベース管理.

```
SELECT COUNT(*) FROM articles
WHERE MATCH(title,body) AGAINST('データベース*' IN BOOLEAN MODE);
```

## MeCab Parser Phrase Search

Phrases are tokenized. For example, データベース管理 is tokenized as データベース 管理.

```
SELECT COUNT(*) FROM articles
WHERE MATCH(title,body) AGAINST('"データベース管理"' IN BOOLEAN MODE);
```

## Installing MeCab From a Binary Distribution (Optional)

This section describes how to install [mecab](#) and [mecab-ipadic](#) from a binary distribution using a native package management utility. For example, on Fedora, you can use Yum to perform the installation:

```
$> yum mecab-devel
```

On Debian or Ubuntu, you can perform an APT installation:

```
$> apt-get install mecab
$> apt-get install mecab-ipadic
```

## Installing MeCab From Source (Optional)

If you want to build `mecab` and `mecab-ipadic` from source, basic installation steps are provided below. For additional information, refer to the MeCab documentation.

1. Download the tar.gz packages for `mecab` and `mecab-ipadic` from <http://taku910.github.io/mecab/#download>. As of February, 2016, the latest available packages are `mecab-0.996.tar.gz` and `mecab-ipadic-2.7.0-20070801.tar.gz`.

2. Install `mecab`:

```
$> tar zxvf mecab-0.996.tar
$> cd mecab-0.996
$> ./configure
$> make
$> make check
$> su
$> make install
```

3. Install `mecab-ipadic`:

```
$> tar zxvf mecab-ipadic-2.7.0-20070801.tar
$> cd mecab-ipadic-2.7.0-20070801
$> ./configure
$> make
$> su
$> make install
```

4. Compile MySQL using the `WITH_MECAB` CMake option. Set the `WITH_MECAB` option to `system` if you have installed `mecab` and `mecab-ipadic` to the default location.

```
-DWITH_MECAB=system
```

If you defined a custom installation directory, set `WITH_MECAB` to the custom directory. For example:

```
-DWITH_MECAB=/path/to/mecab
```

## 14.10 Cast Functions and Operators

Table 14.15 Cast Functions and Operators

Name	Description	Deprecated
<code>BINARY</code>	Cast a string to a binary string	Yes
<code>CAST( )</code>	Cast a value as a certain type	
<code>CONVERT( )</code>	Cast a value as a certain type	

Cast functions and operators enable conversion of values from one data type to another.

- [Cast Function and Operator Descriptions](#)
- [Character Set Conversions](#)
- [Character Set Conversions for String Comparisons](#)
- [Cast Operations on Spatial Types](#)

- [Other Uses for Cast Operations](#)

## Cast Function and Operator Descriptions

- `BINARY expr`

The `BINARY` operator converts the expression to a binary string (a string that has the `binary` character set and `binary` collation). A common use for `BINARY` is to force a character string comparison to be done byte by byte using numeric byte values rather than character by character. The `BINARY` operator also causes trailing spaces in comparisons to be significant. For information about the differences between the `binary` collation of the `binary` character set and the `_bin` collations of nonbinary character sets, see [Section 12.8.5, “The binary Collation Compared to \\_bin Collations”](#).

The `BINARY` operator is deprecated; you should expect its removal in a future version of MySQL. Use `CAST(... AS BINARY)` instead.

```
mysql> SET NAMES utf8mb4 COLLATE utf8mb4_general_ci;
-> OK
mysql> SELECT 'a' = 'A';
-> 1
mysql> SELECT BINARY 'a' = 'A';
-> 0
mysql> SELECT 'a' = 'a ';
-> 1
mysql> SELECT BINARY 'a' = 'a ';
-> 0
```

In a comparison, `BINARY` affects the entire operation; it can be given before either operand with the same result.

To convert a string expression to a binary string, these constructs are equivalent:

```
CONVERT(expr USING BINARY)
CAST(expr AS BINARY)
BINARY expr
```

If a value is a string literal, it can be designated as a binary string without converting it by using the `_binary` character set introducer:

```
mysql> SELECT 'a' = 'A';
-> 1
mysql> SELECT _binary 'a' = 'A';
-> 0
```

For information about introducers, see [Section 12.3.8, “Character Set Introducers”](#).

The `BINARY` operator in expressions differs in effect from the `BINARY` attribute in character column definitions. For a character column defined with the `BINARY` attribute, MySQL assigns the table default character set and the binary (`_bin`) collation of that character set. Every nonbinary character set has a `_bin` collation. For example, if the table default character set is `utf8mb4`, these two column definitions are equivalent:

```
CHAR(10) BINARY
CHAR(10) CHARACTER SET utf8mb4 COLLATE utf8mb4_bin
```

The use of `CHARACTER SET binary` in the definition of a `CHAR`, `VARCHAR`, or `TEXT` column causes the column to be treated as the corresponding binary string data type. For example, the following pairs of definitions are equivalent:

```
CHAR(10) CHARACTER SET binary
```

```

BINARY(10)

VARCHAR(10) CHARACTER SET binary
VARBINARY(10)

TEXT CHARACTER SET binary
BLOB

```

If `BINARY` is invoked from within the `mysql` client, binary strings display using hexadecimal notation, depending on the value of the `--binary-as-hex`. For more information about that option, see [Section 6.5.1, “mysql — The MySQL Command-Line Client”](#).

- `CAST(expr AS type [ARRAY])`

```

CAST(timestamp_value AT TIME ZONE timezone_specifier AS
DATETIME[(precision)])

```

```

timezone_specifier: [INTERVAL] '+00:00' | 'UTC'

```

With `CAST(expr AS type)` syntax, the `CAST()` function takes an expression of any type and produces a result value of the specified type. This operation may also be expressed as `CONVERT(expr, type)`, which is equivalent. If *expr* is `NULL`, `CAST()` returns `NULL`.

These *type* values are permitted:

- `BINARY[(N)]`

Produces a string with the `VARBINARY` data type, except that when the expression *expr* is empty (zero length), the result type is `BINARY(0)`. If the optional length *N* is given, `BINARY(N)` causes the cast to use no more than *N* bytes of the argument. Values shorter than *N* bytes are padded with `0x00` bytes to a length of *N*. If the optional length *N* is not given, MySQL calculates the maximum length from the expression. If the supplied or calculated length is greater than an internal threshold, the result type is `BLOB`. If the length is still too long, the result type is `LONGBLOB`.

For a description of how casting to `BINARY` affects comparisons, see [Section 13.3.3, “The BINARY and VARBINARY Types”](#).

- `CHAR[(N)] [charset_info]`

Produces a string with the `VARCHAR` data type, unless the expression *expr* is empty (zero length), in which case the result type is `CHAR(0)`. If the optional length *N* is given, `CHAR(N)` causes the cast to use no more than *N* characters of the argument. No padding occurs for values shorter than *N* characters. If the optional length *N* is not given, MySQL calculates the maximum length from the expression. If the supplied or calculated length is greater than an internal threshold, the result type is `TEXT`. If the length is still too long, the result type is `LONGTEXT`.

With no *charset\_info* clause, `CHAR` produces a string with the default character set. To specify the character set explicitly, these *charset\_info* values are permitted:

- `CHARACTER SET charset_name`: Produces a string with the given character set.
- `ASCII`: Shorthand for `CHARACTER SET latin1`.

- **UNICODE**: Shorthand for `CHARACTER SET ucs2`.

In all cases, the string has the character set default collation.

- **DATE**

Produces a **DATE** value.

- **DATETIME** [ (*M*) ]

Produces a **DATETIME** value. If the optional *M* value is given, it specifies the fractional seconds precision.

- **DECIMAL** [ (*M* [ , *D* ] ) ]

Produces a **DECIMAL** value. If the optional *M* and *D* values are given, they specify the maximum number of digits (the precision) and the number of digits following the decimal point (the scale). If *D* is omitted, 0 is assumed. If *M* is omitted, 10 is assumed.

- **DOUBLE**

Produces a **DOUBLE** result.

- **FLOAT** [ (*p*) ]

If the precision *p* is not specified, produces a result of type **FLOAT**. If *p* is provided and  $0 \leq p \leq 24$ , the result is of type **FLOAT**. If  $25 \leq p \leq 53$ , the result is of type **DOUBLE**. If  $p < 0$  or  $p > 53$ , an error is returned.

- **JSON**

Produces a **JSON** value. For details on the rules for conversion of values between **JSON** and other types, see [Comparison and Ordering of JSON Values](#).

- **NCHAR** [ (*N*) ]

Like **CHAR**, but produces a string with the national character set. See [Section 12.3.7, “The National Character Set”](#).

Unlike **CHAR**, **NCHAR** does not permit trailing character set information to be specified.

- **REAL**

Produces a result of type **REAL**. This is actually **FLOAT** if the `REAL_AS_FLOAT` SQL mode is enabled; otherwise the result is of type **DOUBLE**.

- **SIGNED** [ **INTEGER** ]

Produces a signed **BIGINT** value.

- *spatial\_type*

`CAST()` and `CONVERT()` support casting geometry values from one spatial type to another, for certain combinations of spatial types. For details, see [Cast Operations on Spatial Types](#).

- **TIME** [ (*M*) ]

Produces a **TIME** value. If the optional **M** value is given, it specifies the fractional seconds precision.

- **UNSIGNED [INTEGER]**

Produces an unsigned **BIGINT** value.

- **YEAR**

Produces a **YEAR** value. These rules govern conversion to **YEAR** as follows:

- For a four-digit number in the range 1901-2155 inclusive, or for a string which can be interpreted as a four-digit number in this range, return the corresponding **YEAR** value.
- For a number consisting of one or two digits, or for a string which can be interpreted as such a number, return a **YEAR** value as follows:
  - If the number is in the range 1-69 inclusive, add 2000 and return the sum.
  - If the number is in the range 70-99 inclusive, add 1900 and return the sum.
- For a string which evaluates to 0, return 2000.
- For the number 0, return 0.
- For a **DATE**, **DATETIME**, or **TIMESTAMP** value, return the **YEAR** portion of the value. For a **TIME** value, return the current year.

If you do not specify the type of a **TIME** argument, you may get a different result from what you expect, as shown here:

```
mysql> SELECT CAST("11:35:00" AS YEAR), CAST(TIME "11:35:00" AS YEAR);
+-----+-----+
| CAST("11:35:00" AS YEAR) | CAST(TIME "11:35:00" AS YEAR) |
+-----+-----+
| 2011 | 2021 |
+-----+-----+
```

- If the argument is of type **DECIMAL**, **DOUBLE**, **DECIMAL**, or **REAL**, round the value to the nearest integer, then attempt to cast the value to **YEAR** using the rules for integer values, as shown here:

```
mysql> SELECT CAST(1944.35 AS YEAR), CAST(1944.50 AS YEAR);
+-----+-----+
| CAST(1944.35 AS YEAR) | CAST(1944.50 AS YEAR) |
+-----+-----+
| 1944 | 1945 |
+-----+-----+

mysql> SELECT CAST(66.35 AS YEAR), CAST(66.50 AS YEAR);
+-----+-----+
| CAST(66.35 AS YEAR) | CAST(66.50 AS YEAR) |
+-----+-----+
| 2066 | 2067 |
+-----+-----+
```

- An argument of type **GEOMETRY** cannot be converted to **YEAR**.

- For a value that cannot be successfully converted to `YEAR`, return `NULL`.

A string value containing non-numeric characters which must be truncated prior to conversion raises a warning, as shown here:

```
mysql> SELECT CAST("1979aaa" AS YEAR);
+-----+
| CAST("1979aaa" AS YEAR) |
+-----+
| 1979 |
+-----+
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Warning | 1292 | Truncated incorrect YEAR value: '1979aaa' |
+-----+-----+-----+
```

InnoDB allows the use of an additional `ARRAY` keyword for creating a multi-valued index on a `JSON` array as part of `CREATE INDEX`, `CREATE TABLE`, and `ALTER TABLE` statements. `ARRAY` is not supported except when used to create a multi-valued index in one of these statements, in which case it is required. The column being indexed must be a column of type `JSON`. With `ARRAY`, the *type* following the `AS` keyword may specify any of the types supported by `CAST()`, with the exceptions of `BINARY`, `JSON`, and `YEAR`. For syntax information and examples, as well as other relevant information, see [Multi-Valued Indexes](#).

#### Note

`CONVERT()`, unlike `CAST()`, does *not* support multi-valued index creation or the `ARRAY` keyword.

`CAST()` supports retrieval of a `TIMESTAMP` value as being in UTC, using the `AT TIMEZONE` operator. The only supported time zone is UTC; this can be specified as either of `'+00:00'` or `'UTC'`. The only return type supported by this syntax is `DATETIME`, with an optional precision specifier in the range of 0 to 6, inclusive.

`TIMESTAMP` values that use timezone offsets are also supported.

```
mysql> SELECT @@system_time_zone;
+-----+
| @@system_time_zone |
+-----+
| EDT |
+-----+
1 row in set (0.00 sec)

mysql> CREATE TABLE tz (c TIMESTAMP);
Query OK, 0 rows affected (0.41 sec)

mysql> INSERT INTO tz VALUES
-> ROW(CURRENT_TIMESTAMP),
-> ROW('2020-07-28 14:50:15+1:00');
Query OK, 1 row affected (0.08 sec)

mysql> TABLE tz;
+-----+
| c |
+-----+
| 2020-07-28 09:22:41 |
+-----+
```

```

| 2020-07-28 09:50:15 |
+-----+
2 rows in set (0.00 sec)

mysql> SELECT CAST(c AT TIME ZONE '+00:00' AS DATETIME) AS u FROM tz;
+-----+
| u |
+-----+
| 2020-07-28 13:22:41 |
| 2020-07-28 13:50:15 |
+-----+
2 rows in set (0.00 sec)

mysql> SELECT CAST(c AT TIME ZONE 'UTC' AS DATETIME(2)) AS u FROM tz;
+-----+
| u |
+-----+
| 2020-07-28 13:22:41.00 |
| 2020-07-28 13:50:15.00 |
+-----+
2 rows in set (0.00 sec)

```

If you use `'UTC'` as the time zone specifier with this form of `CAST()`, and the server raises an error such as `Unknown or incorrect time zone: 'UTC'`, you may need to install the MySQL time zone tables (see [Populating the Time Zone Tables](#)).

`AT TIME ZONE` does not support the `ARRAY` keyword, and is not supported by the `CONVERT()` function.

- `CONVERT(expr USING transcoding_name)`

`CONVERT(expr, type)`

`CONVERT(expr USING transcoding_name)` is standard SQL syntax. The non-`USING` form of `CONVERT()` is ODBC syntax. Regardless of the syntax used, the function returns `NULL` if `expr` is `NULL`.

`CONVERT(expr USING transcoding_name)` converts data between different character sets. In MySQL, transcoding names are the same as the corresponding character set names. For example, this statement converts the string `'abc'` in the default character set to the corresponding string in the `utf8mb4` character set:

```
SELECT CONVERT('abc' USING utf8mb4);
```

`CONVERT(expr, type)` syntax (without `USING`) takes an expression and a `type` value specifying a result type, and produces a result value of the specified type. This operation may also be expressed as `CAST(expr AS type)`, which is equivalent. For more information, see the description of `CAST()`.

## Character Set Conversions

`CONVERT()` with a `USING` clause converts data between character sets:

```
CONVERT(expr USING transcoding_name)
```

In MySQL, transcoding names are the same as the corresponding character set names.

Examples:

```

SELECT CONVERT('test' USING utf8mb4);
SELECT CONVERT(_latin1'Müller' USING utf8mb4);
INSERT INTO utf8mb4_table (utf8mb4_column)
 SELECT CONVERT(latin1_column USING utf8mb4) FROM latin1_table;

```

To convert strings between character sets, you can also use `CONVERT(expr, type)` syntax (without `USING`), or `CAST(expr AS type)`, which is equivalent:

```
CONVERT(string, CHAR[(N)] CHARACTER SET charset_name)
CAST(string AS CHAR[(N)] CHARACTER SET charset_name)
```

Examples:

```
SELECT CONVERT('test', CHAR CHARACTER SET utf8mb4);
SELECT CAST('test' AS CHAR CHARACTER SET utf8mb4);
```

If you specify `CHARACTER SET charset_name` as just shown, the character set and collation of the result are *charset\_name* and the default collation of *charset\_name*. If you omit `CHARACTER SET charset_name`, the character set and collation of the result are defined by the `character_set_connection` and `collation_connection` system variables that determine the default connection character set and collation (see [Section 12.4, “Connection Character Sets and Collations”](#)).

A `COLLATE` clause is not permitted within a `CONVERT()` or `CAST()` call, but you can apply it to the function result. For example, these are legal:

```
SELECT CONVERT('test' USING utf8mb4) COLLATE utf8mb4_bin;
SELECT CONVERT('test', CHAR CHARACTER SET utf8mb4) COLLATE utf8mb4_bin;
SELECT CAST('test' AS CHAR CHARACTER SET utf8mb4) COLLATE utf8mb4_bin;
```

But these are illegal:

```
SELECT CONVERT('test' USING utf8mb4 COLLATE utf8mb4_bin);
SELECT CONVERT('test', CHAR CHARACTER SET utf8mb4 COLLATE utf8mb4_bin);
SELECT CAST('test' AS CHAR CHARACTER SET utf8mb4 COLLATE utf8mb4_bin);
```

For string literals, another way to specify the character set is to use a character set introducer. `_latin1` and `_latin2` in the preceding example are instances of introducers. Unlike conversion functions such as `CAST()`, or `CONVERT()`, which convert a string from one character set to another, an introducer designates a string literal as having a particular character set, with no conversion involved. For more information, see [Section 12.3.8, “Character Set Introducers”](#).

## Character Set Conversions for String Comparisons

Normally, you cannot compare a `BLOB` value or other binary string in case-insensitive fashion because binary strings use the `binary` character set, which has no collation with the concept of lettercase. To perform a case-insensitive comparison, first use the `CONVERT()` or `CAST()` function to convert the value to a nonbinary string. Comparisons of the resulting string use its collation. For example, if the conversion result collation is not case-sensitive, a `LIKE` operation is not case-sensitive. That is true for the following operation because the default `utf8mb4` collation (`utf8mb4_0900_ai_ci`) is not case-sensitive:

```
SELECT 'A' LIKE CONVERT(blob_col USING utf8mb4)
FROM tbl_name;
```

To specify a particular collation for the converted string, use a `COLLATE` clause following the `CONVERT()` call:

```
SELECT 'A' LIKE CONVERT(blob_col USING utf8mb4) COLLATE utf8mb4_unicode_ci
FROM tbl_name;
```

To use a different character set, substitute its name for `utf8mb4` in the preceding statements (and similarly to use a different collation).

`CONVERT()` and `CAST()` can be used more generally for comparing strings represented in different character sets. For example, a comparison of these strings results in an error because they have different character sets:

```
mysql> SET @s1 = _latin1 'abc', @s2 = _latin2 'abc';
mysql> SELECT @s1 = @s2;
ERROR 1267 (HY000): Illegal mix of collations (latin1_swedish_ci,IMPLICIT)
and (latin2_general_ci,IMPLICIT) for operation '='

```

Converting one of the strings to a character set compatible with the other enables the comparison to occur without error:

```
mysql> SELECT @s1 = CONVERT(@s2 USING latin1);
+-----+
| @s1 = CONVERT(@s2 USING latin1) |
+-----+
| 1 |
+-----+

```

Character set conversion is also useful preceding lettercase conversion of binary strings. `LOWER()` and `UPPER()` are ineffective when applied directly to binary strings because the concept of lettercase does not apply. To perform lettercase conversion of a binary string, first convert it to a nonbinary string using a character set appropriate for the data stored in the string:

```
mysql> SET @str = BINARY 'New York';
mysql> SELECT LOWER(@str), LOWER(CONVERT(@str USING utf8mb4));
+-----+-----+
| LOWER(@str) | LOWER(CONVERT(@str USING utf8mb4)) |
+-----+-----+
| New York | new york |
+-----+-----+

```

Be aware that if you apply `BINARY`, `CAST()`, or `CONVERT()` to an indexed column, MySQL may not be able to use the index efficiently.

## Cast Operations on Spatial Types

`CAST()` and `CONVERT()` support casting geometry values from one spatial type to another, for certain combinations of spatial types. The following list shows the permitted type combinations, where “MySQL extension” designates casts implemented in MySQL beyond those defined in the [SQL/MM standard](#):

- From `Point` to:
  - `MultiPoint`
  - `GeometryCollection`
- From `LineString` to:
  - `Polygon` (MySQL extension)
  - `MultiPoint` (MySQL extension)
  - `MultiLineString`
  - `GeometryCollection`
- From `Polygon` to:
  - `LineString` (MySQL extension)
  - `MultiLineString` (MySQL extension)
  - `MultiPolygon`

- `GeometryCollection`
- From `MultiPoint` to:
  - `Point`
  - `LineString` (MySQL extension)
  - `GeometryCollection`
- From `MultiLineString` to:
  - `LineString`
  - `Polygon` (MySQL extension)
  - `MultiPolygon` (MySQL extension)
  - `GeometryCollection`
- From `MultiPolygon` to:
  - `Polygon`
  - `MultiLineString` (MySQL extension)
  - `GeometryCollection`
- From `GeometryCollection` to:
  - `Point`
  - `LineString`
  - `Polygon`
  - `MultiPoint`
  - `MultiLineString`
  - `MultiPolygon`

In spatial casts, `GeometryCollection` and `GeomCollection` are synonyms for the same result type.

Some conditions apply to all spatial type casts, and some conditions apply only when the cast result is to have a particular spatial type. For information about terms such as “well-formed geometry,” see [Section 13.4.4, “Geometry Well-Formedness and Validity”](#).

- [General Conditions for Spatial Casts](#)
- [Conditions for Casts to Point](#)
- [Conditions for Casts to LineString](#)
- [Conditions for Casts to Polygon](#)
- [Conditions for Casts to MultiPoint](#)
- [Conditions for Casts to MultiLineString](#)

- [Conditions for Casts to MultiPolygon](#)
- [Conditions for Casts to GeometryCollection](#)

## General Conditions for Spatial Casts

These conditions apply to all spatial casts regardless of the result type:

- The result of a cast is in the same SRS as that of the expression to cast.
- Casting between spatial types does not change coordinate values or order.
- If the expression to cast is `NULL`, the function result is `NULL`.
- Casting to spatial types using the `JSON_VALUE ( )` function with a `RETURNING` clause specifying a spatial type is not permitted.
- Casting to an `ARRAY` of spatial types is not permitted.
- If the spatial type combination is permitted but the expression to cast is not a syntactically well-formed geometry, an `ER_GIS_INVALID_DATA` error occurs.
- If the spatial type combination is permitted but the expression to cast is a syntactically well-formed geometry in an undefined spatial reference system (SRS), an `ER_SRS_NOT_FOUND` error occurs.
- If the expression to cast has a geographic SRS but has a longitude or latitude that is out of range, an error occurs:
  - If a longitude value is not in the range  $(-180, 180]$ , an `ER_GEOMETRY_PARAM_LONGITUDE_OUT_OF_RANGE` error occurs.
  - If a latitude value is not in the range  $[-90, 90]$ , an `ER_GEOMETRY_PARAM_LATITUDE_OUT_OF_RANGE` error occurs.

Ranges shown are in degrees. If an SRS uses another unit, the range uses the corresponding values in its unit. The exact range limits deviate slightly due to floating-point arithmetic.

## Conditions for Casts to Point

When the cast result type is `Point`, these conditions apply:

- If the expression to cast is a well-formed geometry of type `Point`, the function result is that `Point`.
- If the expression to cast is a well-formed geometry of type `MultiPoint` containing a single `Point`, the function result is that `Point`. If the expression contains more than one `Point`, an `ER_INVALID_CAST_TO_GEOMETRY` error occurs.
- If the expression to cast is a well-formed geometry of type `GeometryCollection` containing only a single `Point`, the function result is that `Point`. If the expression is empty, contains more than one `Point`, or contains other geometry types, an `ER_INVALID_CAST_TO_GEOMETRY` error occurs.
- If the expression to cast is a well-formed geometry of type other than `Point`, `MultiPoint`, `GeometryCollection`, an `ER_INVALID_CAST_TO_GEOMETRY` error occurs.

## Conditions for Casts to LineString

When the cast result type is `LineString`, these conditions apply:

- If the expression to cast is a well-formed geometry of type `LineString`, the function result is that `LineString`.

- If the expression to cast is a well-formed geometry of type `Polygon` that has no inner rings, the function result is a `LineString` containing the points of the outer ring in the same order. If the expression has inner rings, an `ER_INVALID_CAST_TO_GEOMETRY` error occurs.
- If the expression to cast is a well-formed geometry of type `MultiPoint` containing at least two points, the function result is a `LineString` containing the points of the `MultiPoint` in the order they appear in the expression. If the expression contains only one `Point`, an `ER_INVALID_CAST_TO_GEOMETRY` error occurs.
- If the expression to cast is a well-formed geometry of type `MultiLineString` containing a single `LineString`, the function result is that `LineString`. If the expression contains more than one `LineString`, an `ER_INVALID_CAST_TO_GEOMETRY` error occurs.
- If the expression to cast is a well-formed geometry of type `GeometryCollection`, containing only a single `LineString`, the function result is that `LineString`. If the expression is empty, contains more than one `LineString`, or contains other geometry types, an `ER_INVALID_CAST_TO_GEOMETRY` error occurs.
- If the expression to cast is a well-formed geometry of type other than `LineString`, `Polygon`, `MultiPoint`, `MultiLineString`, or `GeometryCollection`, an `ER_INVALID_CAST_TO_GEOMETRY` error occurs.

### Conditions for Casts to Polygon

When the cast result type is `Polygon`, these conditions apply:

- If the expression to cast is a well-formed geometry of type `LineString` that is a ring (that is, the start and end points are the same), the function result is a `Polygon` with an outer ring consisting of the points of the `LineString` in the same order. If the expression is not a ring, an `ER_INVALID_CAST_TO_GEOMETRY` error occurs. If the ring is not in the correct order (the exterior ring must be counter-clockwise), an `ER_INVALID_CAST_POLYGON_RING_DIRECTION` error occurs.
- If the expression to cast is a well-formed geometry of type `Polygon`, the function result is that `Polygon`.
- If the expression to cast is a well-formed geometry of type `MultiLineString` where all elements are rings, the function result is a `Polygon` with the first `LineString` as outer ring and any additional `LineString` values as inner rings. If any element of the expression is not a ring, an `ER_INVALID_CAST_TO_GEOMETRY` error occurs. If any ring is not in the correct order (the exterior ring must be counter-clockwise, interior rings must be clockwise), an `ER_INVALID_CAST_POLYGON_RING_DIRECTION` error occurs.
- If the expression to cast is a well-formed geometry of type `MultiPolygon` containing a single `Polygon`, the function result is that `Polygon`. If the expression contains more than one `Polygon`, an `ER_INVALID_CAST_TO_GEOMETRY` error occurs.
- If the expression to cast is a well-formed geometry of type `GeometryCollection` containing only a single `Polygon`, the function result is that `Polygon`. If the expression is empty, contains more than one `Polygon`, or contains other geometry types, an `ER_INVALID_CAST_TO_GEOMETRY` error occurs.
- If the expression to cast is a well-formed geometry of type other than `LineString`, `Polygon`, `MultiLineString`, `MultiPolygon`, or `GeometryCollection`, an `ER_INVALID_CAST_TO_GEOMETRY` error occurs.

### Conditions for Casts to MultiPoint

When the cast result type is `MultiPoint`, these conditions apply:

- If the expression to cast is a well-formed geometry of type `Point`, the function result is a `MultiPoint` containing that `Point` as its sole element.
- If the expression to cast is a well-formed geometry of type `LineString`, the function result is a `MultiPoint` containing the points of the `LineString` in the same order.
- If the expression to cast is a well-formed geometry of type `MultiPoint`, the function result is that `MultiPoint`.
- If the expression to cast is a well-formed geometry of type `GeometryCollection` containing only points, the function result is a `MultiPoint` containing those points. If the `GeometryCollection` is empty or contains other geometry types, an `ER_INVALID_CAST_TO_GEOMETRY` error occurs.
- If the expression to cast is a well-formed geometry of type other than `Point`, `LineString`, `MultiPoint`, or `GeometryCollection`, an `ER_INVALID_CAST_TO_GEOMETRY` error occurs.

## Conditions for Casts to MultiLineString

When the cast result type is `MultiLineString`, these conditions apply:

- If the expression to cast is a well-formed geometry of type `LineString`, the function result is a `MultiLineString` containing that `LineString` as its sole element.
- If the expression to cast is a well-formed geometry of type `Polygon`, the function result is a `MultiLineString` containing the outer ring of the `Polygon` as its first element and any inner rings as additional elements in the order they appear in the expression.
- If the expression to cast is a well-formed geometry of type `MultiLineString`, the function result is that `MultiLineString`.
- If the expression to cast is a well-formed geometry of type `MultiPolygon` containing only polygons without inner rings, the function result is a `MultiLineString` containing the polygon rings in the order they appear in the expression. If the expression contains any polygons with inner rings, an `ER_WRONG_PARAMETERS_TO_STORED_FCT` error occurs.
- If the expression to cast is a well-formed geometry of type `GeometryCollection` containing only linestrings, the function result is a `MultiLineString` containing those linestrings. If the expression is empty or contains other geometry types, an `ER_INVALID_CAST_TO_GEOMETRY` error occurs.
- If the expression to cast is a well-formed geometry of type other than `LineString`, `Polygon`, `MultiLineString`, `MultiPolygon`, or `GeometryCollection`, an `ER_INVALID_CAST_TO_GEOMETRY` error occurs.

## Conditions for Casts to MultiPolygon

When the cast result type is `MultiPolygon`, these conditions apply:

- If the expression to cast is a well-formed geometry of type `Polygon`, the function result is a `MultiPolygon` containing the `Polygon` as its sole element.
- If the expression to cast is a well-formed geometry of type `MultiLineString` where all elements are rings, the function result is a `MultiPolygon` containing a `Polygon` with only an outer ring for each element of the expression. If any element is not a ring, an `ER_INVALID_CAST_TO_GEOMETRY` error occurs. If any ring is not in the correct order (exterior ring must be counter-clockwise), an `ER_INVALID_CAST_POLYGON_RING_DIRECTION` error occurs.
- If the expression to cast is a well-formed geometry of type `MultiPolygon`, the function result is that `MultiPolygon`.

- If the expression to cast is a well-formed geometry of type `GeometryCollection` containing only polygons, the function result is a `MultiPolygon` containing those polygons. If the expression is empty or contains other geometry types, an `ER_INVALID_CAST_TO_GEOMETRY` error occurs.
- If the expression to cast is a well-formed geometry of type other than `Polygon`, `MultiLineString`, `MultiPolygon`, or `GeometryCollection`, an `ER_INVALID_CAST_TO_GEOMETRY` error occurs.

## Conditions for Casts to GeometryCollection

When the cast result type is `GeometryCollection`, these conditions apply:

- `GeometryCollection` and `GeomCollection` are synonyms for the same result type.
- If the expression to cast is a well-formed geometry of type `Point`, the function result is a `GeometryCollection` containing that `Point` as its sole element.
- If the expression to cast is a well-formed geometry of type `LineString`, the function result is a `GeometryCollection` containing that `LineString` as its sole element.
- If the expression to cast is a well-formed geometry of type `Polygon`, the function result is a `GeometryCollection` containing that `Polygon` as its sole element.
- If the expression to cast is a well-formed geometry of type `MultiPoint`, the function result is a `GeometryCollection` containing the points in the order they appear in the expression.
- If the expression to cast is a well-formed geometry of type `MultiLineString`, the function result is a `GeometryCollection` containing the linestrings in the order they appear in the expression.
- If the expression to cast is a well-formed geometry of type `MultiPolygon`, the function result is a `GeometryCollection` containing the elements of the `MultiPolygon` in the order they appear in the expression.
- If the expression to cast is a well-formed geometry of type `GeometryCollection`, the function result is that `GeometryCollection`.

## Other Uses for Cast Operations

The cast functions are useful for creating a column with a specific type in a `CREATE TABLE ... SELECT` statement:

```
mysql> CREATE TABLE new_table SELECT CAST('2000-01-01' AS DATE) AS c1;
mysql> SHOW CREATE TABLE new_table\G
***** 1. row *****
 Table: new_table
Create Table: CREATE TABLE `new_table` (
 `c1` date DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci
```

The cast functions are useful for sorting `ENUM` columns in lexical order. Normally, sorting of `ENUM` columns occurs using the internal numeric values. Casting the values to `CHAR` results in a lexical sort:

```
SELECT enum_col FROM tbl_name
ORDER BY CAST(enum_col AS CHAR);
```

`CAST()` also changes the result if you use it as part of a more complex expression such as `CONCAT('Date: ',CAST(NOW() AS DATE))`.

For temporal values, there is little need to use `CAST()` to extract data in different formats. Instead, use a function such as `EXTRACT()`, `DATE_FORMAT()`, or `TIME_FORMAT()`. See [Section 14.7, “Date and Time Functions”](#).

To cast a string to a number, it normally suffices to use the string value in numeric context:

```
mysql> SELECT 1+'1';
-> 2
```

That is also true for hexadecimal and bit literals, which are binary strings by default:

```
mysql> SELECT X'41', X'41'+0;
-> 'A', 65
mysql> SELECT b'1100001', b'1100001'+0;
-> 'a', 97
```

A string used in an arithmetic operation is converted to a floating-point number during expression evaluation.

A number used in string context is converted to a string:

```
mysql> SELECT CONCAT('hello you ',2);
-> 'hello you 2'
```

For information about implicit conversion of numbers to strings, see [Section 14.3, “Type Conversion in Expression Evaluation”](#).

MySQL supports arithmetic with both signed and unsigned 64-bit values. For numeric operators (such as `+` or `-`) where one of the operands is an unsigned integer, the result is unsigned by default (see [Section 14.6.1, “Arithmetic Operators”](#)). To override this, use the `SIGNED` or `UNSIGNED` cast operator to cast a value to a signed or unsigned 64-bit integer, respectively.

```
mysql> SELECT 1 - 2;
-> -1
mysql> SELECT CAST(1 - 2 AS UNSIGNED);
-> 18446744073709551615
mysql> SELECT CAST(CAST(1 - 2 AS UNSIGNED) AS SIGNED);
-> -1
```

If either operand is a floating-point value, the result is a floating-point value and is not affected by the preceding rule. (In this context, `DECIMAL` column values are regarded as floating-point values.)

```
mysql> SELECT CAST(1 AS UNSIGNED) - 2.0;
-> -1.0
```

The SQL mode affects the result of conversion operations (see [Section 7.1.11, “Server SQL Modes”](#)). Examples:

- For conversion of a “zero” date string to a date, `CONVERT( )` and `CAST( )` return `NULL` and produce a warning when the `NO_ZERO_DATE` SQL mode is enabled.
- For integer subtraction, if the `NO_UNSIGNED_SUBTRACTION` SQL mode is enabled, the subtraction result is signed even if any operand is unsigned.

## 14.11 XML Functions

**Table 14.16 XML Functions**

Name	Description
<code>ExtractValue( )</code>	Extract a value from an XML string using XPath notation
<code>UpdateXML( )</code>	Return replaced XML fragment

This section discusses XML and related functionality in MySQL.

**Note**

It is possible to obtain XML-formatted output from MySQL in the `mysql` and `mysqldump` clients by invoking them with the `--xml` option. See [Section 6.5.1, “mysql — The MySQL Command-Line Client”](#), and [Section 6.5.4, “mysqldump — A Database Backup Program”](#).

Two functions providing basic XPath 1.0 (XML Path Language, version 1.0) capabilities are available. Some basic information about XPath syntax and usage is provided later in this section; however, an in-depth discussion of these topics is beyond the scope of this manual, and you should refer to the [XML Path Language \(XPath\) 1.0 standard](#) for definitive information. A useful resource for those new to XPath or who desire a refresher in the basics is the [Zvon.org XPath Tutorial](#), which is available in several languages.

**Note**

These functions remain under development. We continue to improve these and other aspects of XML and XPath functionality in MySQL 9.1 and onwards. You may discuss these, ask questions about them, and obtain help from other users with them in the [MySQL XML User Forum](#).

XPath expressions used with these functions support user variables and local stored program variables. User variables are weakly checked; variables local to stored programs are strongly checked (see also Bug #26518):

- **User variables (weak checking).** Variables using the syntax `$_variable_name` (that is, user variables) are not checked. No warnings or errors are issued by the server if a variable has the wrong type or has previously not been assigned a value. This also means the user is fully responsible for any typographical errors, since no warnings are given if (for example) `$_myvairable` is used where `$_myvariable` was intended.

Example:

```
mysql> SET @xml = '<a>XY';
Query OK, 0 rows affected (0.00 sec)

mysql> SET @i =1, @j = 2;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @i, ExtractValue(@xml, '//b[$@i]');
+-----+-----+
| @i | ExtractValue(@xml, '//b[$@i]') |
+-----+-----+
| 1 | X |
+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT @j, ExtractValue(@xml, '//b[$@j]');
+-----+-----+
| @j | ExtractValue(@xml, '//b[$@j]') |
+-----+-----+
| 2 | Y |
+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT @k, ExtractValue(@xml, '//b[$@k]');
+-----+-----+
| @k | ExtractValue(@xml, '//b[$@k]') |
+-----+-----+
| NULL | |
+-----+-----+
1 row in set (0.00 sec)
```

- **Variables in stored programs (strong checking).** Variables using the syntax `$variable_name` can be declared and used with these functions when they are called inside stored programs. Such variables are local to the stored program in which they are defined, and are strongly checked for type and value.

Example:

```
mysql> DELIMITER |

mysql> CREATE PROCEDURE myproc ()
-> BEGIN
-> DECLARE i INT DEFAULT 1;
-> DECLARE xml VARCHAR(255) DEFAULT '<a>X<a>Y<a>Z';
->
-> WHILE i < 4 DO
-> SELECT xml, i, ExtractValue(xml, '//a[$i]');
-> SET i = i+1;
-> END WHILE;
-> END |
Query OK, 0 rows affected (0.01 sec)

mysql> DELIMITER ;

mysql> CALL myproc();
+-----+-----+-----+
| xml | i | ExtractValue(xml, '//a[$i]') |
+-----+-----+-----+
| <a>X<a>Y<a>Z | 1 | X |
+-----+-----+-----+
1 row in set (0.00 sec)

+-----+-----+-----+
| xml | i | ExtractValue(xml, '//a[$i]') |
+-----+-----+-----+
| <a>X<a>Y<a>Z | 2 | Y |
+-----+-----+-----+
1 row in set (0.01 sec)

+-----+-----+-----+
| xml | i | ExtractValue(xml, '//a[$i]') |
+-----+-----+-----+
| <a>X<a>Y<a>Z | 3 | Z |
+-----+-----+-----+
1 row in set (0.01 sec)
```

**Parameters.** Variables used in XPath expressions inside stored routines that are passed in as parameters are also subject to strong checking.

Expressions containing user variables or variables local to stored programs must otherwise (except for notation) conform to the rules for XPath expressions containing variables as given in the XPath 1.0 specification.

#### Note

A user variable used to store an XPath expression is treated as an empty string. Because of this, it is not possible to store an XPath expression as a user variable. (Bug #32911)

- `ExtractValue(xml_frag, xpath_expr)`

`ExtractValue()` takes two string arguments, a fragment of XML markup `xml_frag` and an XPath expression `xpath_expr` (also known as a *locator*); it returns the text (`CDATA`) of the first text node which is a child of the element or elements matched by the XPath expression.

Using this function is the equivalent of performing a match using the *xpath\_expr* after appending */text()*. In other words, `ExtractValue('<a><b>Sakila</b></a>', '/a/b')` and `ExtractValue('<a><b>Sakila</b></a>', '/a/b/text()')` produce the same result. If *xml\_frag* or *xpath\_expr* is `NULL`, the function returns `NULL`.

If multiple matches are found, the content of the first child text node of each matching element is returned (in the order matched) as a single, space-delimited string.

If no matching text node is found for the expression (including the implicit */text()*)—for whatever reason, as long as *xpath\_expr* is valid, and *xml\_frag* consists of elements which are properly nested and closed—an empty string is returned. No distinction is made between a match on an empty element and no match at all. This is by design.

If you need to determine whether no matching element was found in *xml\_frag* or such an element was found but contained no child text nodes, you should test the result of an expression that uses the XPath `count()` function. For example, both of these statements return an empty string, as shown here:

```
mysql> SELECT ExtractValue('<a>', '/a/b');
+-----+
| ExtractValue('<a>', '/a/b') |
+-----+
| |
+-----+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue('<a><c></c>', '/a/b');
+-----+
| ExtractValue('<a><c></c>', '/a/b') |
+-----+
| |
+-----+
1 row in set (0.00 sec)
```

However, you can determine whether there was actually a matching element using the following:

```
mysql> SELECT ExtractValue('<a>', 'count(/a/b)');
+-----+
| ExtractValue('<a>', 'count(/a/b)') |
+-----+
| 1 |
+-----+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue('<a><c></c>', 'count(/a/b)');
+-----+
| ExtractValue('<a><c></c>', 'count(/a/b)') |
+-----+
| 0 |
+-----+
1 row in set (0.01 sec)
```

### Important

`ExtractValue()` returns only `CDATA`, and does not return any tags that might be contained within a matching tag, nor any of their content (see the result returned as `val1` in the following example).

```
mysql> SELECT
-> ExtractValue('<a>cccddd', '/a') AS val1,
-> ExtractValue('<a>cccddd', '/a/b') AS val2,
-> ExtractValue('<a>cccddd', '//b') AS val3,
```

```

-> ExtractValue('<a>cccddd', '/b') AS val4,
-> ExtractValue('<a>cccdddeee', '//b') AS val5;

+-----+-----+-----+-----+-----+
| val1 | val2 | val3 | val4 | val5 |
+-----+-----+-----+-----+-----+
| ccc | ddd | ddd | | ddd eee |
+-----+-----+-----+-----+-----+

```

This function uses the current SQL collation for making comparisons with `contains()`, performing the same collation aggregation as other string functions (such as `CONCAT()`), in taking into account the collation coercibility of their arguments; see [Section 12.8.4, “Collation Coercibility in Expressions”](#), for an explanation of the rules governing this behavior.

(Previously, binary—that is, case-sensitive—comparison was always used.)

`NULL` is returned if `xml_frag` contains elements which are not properly nested or closed, and a warning is generated, as shown in this example:

```

mysql> SELECT ExtractValue('<a>c<b', '//a');
+-----+
| ExtractValue('<a>c<b', '//a') |
+-----+
| NULL |
+-----+
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Warning
Code: 1525
Message: Incorrect XML value: 'parse error at line 1 pos 11:
 END-OF-INPUT unexpected ('>' wanted)'
1 row in set (0.00 sec)

mysql> SELECT ExtractValue('<a>c', '//a');
+-----+
| ExtractValue('<a>c', '//a') |
+-----+
| c |
+-----+
1 row in set (0.00 sec)

```

- `UpdateXML(xml_target, xpath_expr, new_xml)`

This function replaces a single portion of a given fragment of XML markup `xml_target` with a new XML fragment `new_xml`, and then returns the changed XML. The portion of `xml_target` that is replaced matches an XPath expression `xpath_expr` supplied by the user.

If no expression matching `xpath_expr` is found, or if multiple matches are found, the function returns the original `xml_target` XML fragment. All three arguments should be strings. If any of the arguments to `UpdateXML()` are `NULL`, the function returns `NULL`.

```

mysql> SELECT
-> UpdateXML('<a>ccc<d></d>', '/a', '<e>fff</e>') AS val1,
-> UpdateXML('<a>ccc<d></d>', '/b', '<e>fff</e>') AS val2,
-> UpdateXML('<a>ccc<d></d>', '//b', '<e>fff</e>') AS val3,
-> UpdateXML('<a>ccc<d></d>', '/a/d', '<e>fff</e>') AS val4,
-> UpdateXML('<a><d></d>ccc<d></d>', '/a/d', '<e>fff</e>') AS val5
-> \G

***** 1. row *****
val1: <e>fff</e>

```

```
val2: <a>ccc<d></d>
val3: <a><e>fff</e><d></d>
val4: <a>ccc<e>fff</e>
val5: <a><d></d>ccc<d></d>
```

### Note

A discussion in depth of XPath syntax and usage are beyond the scope of this manual. Please see the [XML Path Language \(XPath\) 1.0 specification](#) for definitive information. A useful resource for those new to XPath or who are wishing a refresher in the basics is the [Zvon.org XPath Tutorial](#), which is available in several languages.

Descriptions and examples of some basic XPath expressions follow:

- `/tag`

Matches `<tag/>` if and only if `<tag/>` is the root element.

Example: `/a` has a match in `<a><b></b></a>` because it matches the outermost (root) tag. It does not match the inner `a` element in `<b><a></a></b>` because in this instance it is the child of another element.

- `/tag1/tag2`

Matches `<tag2/>` if and only if it is a child of `<tag1/>`, and `<tag1/>` is the root element.

Example: `/a/b` matches the `b` element in the XML fragment `<a><b></b></a>` because it is a child of the root element `a`. It does not have a match in `<b><a></a></b>` because in this case, `b` is the root element (and hence the child of no other element). Nor does the XPath expression have a match in `<a><c><b></b></c></a>`; here, `b` is a descendant of `a`, but not actually a child of `a`.

This construct is extendable to three or more elements. For example, the XPath expression `/a/b/c` matches the `c` element in the fragment `<a><b><c></c></b></a>`.

- `//tag`

Matches any instance of `<tag>`.

Example: `//a` matches the `a` element in any of the following: `<a><b><c></c></b></a>`; `<c><a><b></b></a></c>`; `<c><b><a></a></b></c>`.

`//` can be combined with `/`. For example, `//a/b` matches the `b` element in either of the fragments `<a><b></b></a>` or `<c><a><b></b></a></c>`.

### Note

`//tag` is the equivalent of `/descendant-or-self::*tag`. A common error is to confuse this with `/descendant-or-self::tag`, although the latter expression can actually lead to very different results, as can be seen here:

```
mysql> SET @xml = '<a><c>w</c>x<d>y</d>z';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @xml;
+-----+
| @xml |
+-----+
| <a><c>w</c>x<d>y</d>z |
+-----+
1 row in set (0.00 sec)
```

```

mysql> SELECT ExtractValue(@xml, '//b[1]');
+-----+
| ExtractValue(@xml, '//b[1]') |
+-----+
| x z |
+-----+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue(@xml, '//b[2]');
+-----+
| ExtractValue(@xml, '//b[2]') |
+-----+
| |
+-----+
1 row in set (0.01 sec)

mysql> SELECT ExtractValue(@xml, '/descendant-or-self::*b[1]');
+-----+
| ExtractValue(@xml, '/descendant-or-self::*b[1]') |
+-----+
| x z |
+-----+
1 row in set (0.06 sec)

mysql> SELECT ExtractValue(@xml, '/descendant-or-self::*b[2]');
+-----+
| ExtractValue(@xml, '/descendant-or-self::*b[2]') |
+-----+
| |
+-----+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue(@xml, '/descendant-or-self::b[1]');
+-----+
| ExtractValue(@xml, '/descendant-or-self::b[1]') |
+-----+
| z |
+-----+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue(@xml, '/descendant-or-self::b[2]');
+-----+
| ExtractValue(@xml, '/descendant-or-self::b[2]') |
+-----+
| x |
+-----+
1 row in set (0.00 sec)

```

- The `*` operator acts as a “wildcard” that matches any element. For example, the expression `*/b` matches the `b` element in either of the XML fragments `<a><b/></a>` or `<c><b/></c>`. However, the expression does not produce a match in the fragment `<b><a/></b>` because `b` must be a child of some other element. The wildcard may be used in any position: The expression `*/b/*` matches any child of a `b` element that is itself not the root element.
- You can match any of several locators using the `|` (UNION) operator. For example, the expression `//b|//c` matches all `b` and `c` elements in the XML target.
- It is also possible to match an element based on the value of one or more of its attributes. This done using the syntax `tag[@attribute="value"]`. For example, the expression `//b[@id="idB"]` matches the second `b` element in the fragment `<a><b id="idA"/><c/><b id="idB"/></a>`

`a>`. To match against *any* element having `attribute="value"`, use the XPath expression `//*[attribute="value"]`.

To filter multiple attribute values, simply use multiple attribute-comparison clauses in succession. For example, the expression `//b[@c="x"][@d="y"]` matches the element `<b c="x" d="y"/>` occurring anywhere in a given XML fragment.

To find elements for which the same attribute matches any of several values, you can use multiple locators joined by the `|` operator. For example, to match all `b` elements whose `c` attributes have either of the values 23 or 17, use the expression `//b[@c="23"]|//b[@c="17"]`. You can also use the logical `or` operator for this purpose: `//b[@c="23" or @c="17"]`.

#### Note

The difference between `or` and `|` is that `or` joins conditions, while `|` joins result sets.

**XPath Limitations.** The XPath syntax supported by these functions is currently subject to the following limitations:

- Nodeset-to-nodeset comparison (such as `'/a/b[@c=@d]'`) is not supported.
- All of the standard XPath comparison operators are supported. (Bug #22823)
- Relative locator expressions are resolved in the context of the root node. For example, consider the following query and result:

```
mysql> SELECT ExtractValue(
-> '<a><b c="1">X<b c="2">Y',
-> 'a/b'
->) AS result;
+-----+
| result |
+-----+
| X Y |
+-----+
1 row in set (0.03 sec)
```

In this case, the locator `a/b` resolves to `/a/b`.

Relative locators are also supported within predicates. In the following example, `d[../@c="1"]` is resolved as `/a/b[@c="1"]/d`:

```
mysql> SELECT ExtractValue(
-> '<a>
-> <b c="1"><d>X</d>
-> <b c="2"><d>X</d>
-> ',
-> 'a/b/d[../@c="1"]')
-> AS result;
+-----+
| result |
+-----+
| X |
+-----+
1 row in set (0.00 sec)
```

- Locators prefixed with expressions that evaluate as scalar values—including variable references, literals, numbers, and scalar function calls—are not permitted, and their use results in an error.
- The `::` operator is not supported in combination with node types such as the following:

- `axis::comment()`
- `axis::text()`
- `axis::processing-instructions()`
- `axis::node()`

However, name tests (such as `axis::name` and `axis::*`) are supported, as shown in these examples:

```
mysql> SELECT ExtractValue('<a>x<c>y</c>','/a/child::b');
+-----+
| ExtractValue('<a>x<c>y</c>','/a/child::b') |
+-----+
| x |
+-----+
1 row in set (0.02 sec)

mysql> SELECT ExtractValue('<a>x<c>y</c>','/a/child::*');
+-----+
| ExtractValue('<a>x<c>y</c>','/a/child::*') |
+-----+
| x y |
+-----+
1 row in set (0.01 sec)
```

- “Up-and-down” navigation is not supported in cases where the path would lead “above” the root element. That is, you cannot use expressions which match on descendants of ancestors of a given element, where one or more of the ancestors of the current element is also an ancestor of the root element (see Bug #16321).
- The following XPath functions are not supported, or have known issues as indicated:
  - `id()`
  - `lang()`
  - `local-name()`
  - `name()`
  - `namespace-uri()`
  - `normalize-space()`
  - `starts-with()`
  - `string()`
  - `substring-after()`
  - `substring-before()`
  - `translate()`
- The following axes are not supported:
  - `following-sibling`
  - `following`

- `preceding-sibling`
- `preceding`

XPath expressions passed as arguments to `ExtractValue()` and `UpdateXML()` may contain the colon character (:) in element selectors, which enables their use with markup employing XML namespaces notation. For example:

```
mysql> SET @xml = '<a>111<b:c>222<d>333</d><e:f>444</e:f></b:c>';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT ExtractValue(@xml, '//e:f');
+-----+
| ExtractValue(@xml, '//e:f') |
+-----+
| 444 |
+-----+
1 row in set (0.00 sec)

mysql> SELECT UpdateXML(@xml, '//b:c', '<g:h>555</g:h>');
+-----+
| UpdateXML(@xml, '//b:c', '<g:h>555</g:h>') |
+-----+
| <a>111<g:h>555</g:h> |
+-----+
1 row in set (0.00 sec)
```

This is similar in some respects to what is permitted by [Apache Xalan](#) and some other parsers, and is much simpler than requiring namespace declarations or the use of the `namespace-uri()` and `local-name()` functions.

**Error handling.** For both `ExtractValue()` and `UpdateXML()`, the XPath locator used must be valid and the XML to be searched must consist of elements which are properly nested and closed. If the locator is invalid, an error is generated:

```
mysql> SELECT ExtractValue('<a>c', '//*[@a]');
ERROR 1105 (HY000): XPATH syntax error: '//*[@a]'
```

If `xml_frag` does not consist of elements which are properly nested and closed, `NULL` is returned and a warning is generated, as shown in this example:

```
mysql> SELECT ExtractValue('<a>c<b', '//*[@a]');
+-----+
| ExtractValue('<a>c<b', '//*[@a]') |
+-----+
| NULL |
+-----+
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Warning
Code: 1525
Message: Incorrect XML value: 'parse error at line 1 pos 11:
 END-OF-INPUT unexpected ('>' wanted)'
1 row in set (0.00 sec)

mysql> SELECT ExtractValue('<a>c', '//*[@a]');
+-----+
| ExtractValue('<a>c', '//*[@a]') |
+-----+
| c |
+-----+
```

```
1 row in set (0.00 sec)
```

### Important

The replacement XML used as the third argument to `UpdateXML()` is *not* checked to determine whether it consists solely of elements which are properly nested and closed.

**XPath Injection.** *code injection* occurs when malicious code is introduced into the system to gain unauthorized access to privileges and data. It is based on exploiting assumptions made by developers about the type and content of data input from users. XPath is no exception in this regard.

A common scenario in which this can happen is the case of application which handles authorization by matching the combination of a login name and password with those found in an XML file, using an XPath expression like this one:

```
//user[login/text()='neapolitan' and password/text()='1c3cr34m']/attribute::id
```

This is the XPath equivalent of an SQL statement like this one:

```
SELECT id FROM users WHERE login='neapolitan' AND password='1c3cr34m';
```

A PHP application employing XPath might handle the login process like this:

```
<?php
 $file = "users.xml";

 $login = $_POST["login"];
 $password = $_POST["password"];

 $xpath = "//user[login/text()=$login and password/text()=$password]/attribute::id";

 if(file_exists($file))
 {
 $xml = simplexml_load_file($file);

 if($result = $xml->xpath($xpath))
 echo "You are now logged in as user $result[0].";
 else
 echo "Invalid login name or password.";
 }
 else
 exit("Failed to open $file.");
?>
```

No checks are performed on the input. This means that a malevolent user can “short-circuit” the test by entering ' or 1=1 for both the login name and password, resulting in `$xpath` being evaluated as shown here:

```
//user[login/text()=' ' or 1=1 and password/text()=' ' or 1=1]/attribute::id
```

Since the expression inside the square brackets always evaluates as `true`, it is effectively the same as this one, which matches the `id` attribute of every `user` element in the XML document:

```
//user/attribute::id
```

One way in which this particular attack can be circumvented is simply by quoting the variable names to be interpolated in the definition of `$xpath`, forcing the values passed from a Web form to be converted to strings:

```
$xpath = "//user[login/text()='$_login' and password/text()='$_password']/attribute::id";
```

This is the same strategy that is often recommended for preventing SQL injection attacks. In general, the practices you should follow for preventing XPath injection attacks are the same as for preventing SQL injection:

- Never accepted untested data from users in your application.
- Check all user-submitted data for type; reject or convert data that is of the wrong type
- Test numeric data for out of range values; truncate, round, or reject values that are out of range. Test strings for illegal characters and either strip them out or reject input containing them.
- Do not output explicit error messages that might provide an unauthorized user with clues that could be used to compromise the system; log these to a file or database table instead.

Just as SQL injection attacks can be used to obtain information about database schemas, so can XPath injection be used to traverse XML files to uncover their structure, as discussed in Amit Klein's paper [Blind XPath Injection](#) (PDF file, 46KB).

It is also important to check the output being sent back to the client. Consider what can happen when we use the MySQL `ExtractValue()` function:

```
mysql> SELECT ExtractValue(
-> LOAD_FILE('users.xml'),
-> '//user[login/text()="" or 1=1 and password/text()="" or 1=1]/attribute::id'
->) AS id;
+-----+
| id |
+-----+
| 00327 13579 02403 42354 28570 |
+-----+
1 row in set (0.01 sec)
```

Because `ExtractValue()` returns multiple matches as a single space-delimited string, this injection attack provides every valid ID contained within `users.xml` to the user as a single row of output. As an extra safeguard, you should also test output before returning it to the user. Here is a simple example:

```
mysql> SELECT @id = ExtractValue(
-> LOAD_FILE('users.xml'),
-> '//user[login/text()="" or 1=1 and password/text()="" or 1=1]/attribute::id'
->);
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT IF(
-> INSTR(@id, ' ') = 0,
-> @id,
-> 'Unable to retrieve user ID')
-> AS singleID;
+-----+
| singleID |
+-----+
| Unable to retrieve user ID |
+-----+
1 row in set (0.00 sec)
```

In general, the guidelines for returning data to users securely are the same as for accepting user input. These can be summed up as:

- Always test outgoing data for type and permissible values.
- Never permit unauthorized users to view error messages that might provide information about the application that could be used to exploit it.

## 14.12 Bit Functions and Operators

**Table 14.17 Bit Functions and Operators**

Name	Description
<code>&amp;</code>	Bitwise AND
<code>&gt;&gt;</code>	Right shift
<code>&lt;&lt;</code>	Left shift
<code>^</code>	Bitwise XOR
<code>BIT_COUNT()</code>	Return the number of bits that are set
<code> </code>	Bitwise OR
<code>~</code>	Bitwise inversion

The following list describes available bit functions and operators:

- `|`

Bitwise OR.

The result type depends on whether the arguments are evaluated as binary strings or numbers:

- Binary-string evaluation occurs when the arguments have a binary string type, and at least one of them is not a hexadecimal literal, bit literal, or `NULL` literal. Numeric evaluation occurs otherwise, with argument conversion to unsigned 64-bit integers as necessary.
- Binary-string evaluation produces a binary string of the same length as the arguments. If the arguments have unequal lengths, an `ER_INVALID_BITWISE_OPERANDS_SIZE` error occurs. Numeric evaluation produces an unsigned 64-bit integer.

For more information, see the introductory discussion in this section.

```
mysql> SELECT 29 | 15;
-> 31
mysql> SELECT _binary X'40404040' | X'01020304';
-> 'ABCD'
```

If bitwise OR is invoked from within the `mysql` client, binary string results display using hexadecimal notation, depending on the value of the `--binary-as-hex`. For more information about that option, see [Section 6.5.1, “mysql — The MySQL Command-Line Client”](#).

- `&`

Bitwise AND.

The result type depends on whether the arguments are evaluated as binary strings or numbers:

- Binary-string evaluation occurs when the arguments have a binary string type, and at least one of them is not a hexadecimal literal, bit literal, or `NULL` literal. Numeric evaluation occurs otherwise, with argument conversion to unsigned 64-bit integers as necessary.
- Binary-string evaluation produces a binary string of the same length as the arguments. If the arguments have unequal lengths, an `ER_INVALID_BITWISE_OPERANDS_SIZE` error occurs. Numeric evaluation produces an unsigned 64-bit integer.

For more information, see the introductory discussion in this section.

```
mysql> SELECT 29 & 15;
```

```
mysql> SELECT HEX(_binary X'FF' & b'11110000');
-> 'F0'
```

If bitwise AND is invoked from within the `mysql` client, binary string results display using hexadecimal notation, depending on the value of the `--binary-as-hex`. For more information about that option, see [Section 6.5.1, “mysql — The MySQL Command-Line Client”](#).

- ^

Bitwise XOR.

The result type depends on whether the arguments are evaluated as binary strings or numbers:

- Binary-string evaluation occurs when the arguments have a binary string type, and at least one of them is not a hexadecimal literal, bit literal, or `NULL` literal. Numeric evaluation occurs otherwise, with argument conversion to unsigned 64-bit integers as necessary.
- Binary-string evaluation produces a binary string of the same length as the arguments. If the arguments have unequal lengths, an `ER_INVALID_BITWISE_OPERANDS_SIZE` error occurs. Numeric evaluation produces an unsigned 64-bit integer.

For more information, see the introductory discussion in this section.

```
mysql> SELECT 1 ^ 1;
-> 0
mysql> SELECT 1 ^ 0;
-> 1
mysql> SELECT 11 ^ 3;
-> 8
mysql> SELECT HEX(_binary X'FEDC' ^ X'1111');
-> 'EFCB'
```

If bitwise XOR is invoked from within the `mysql` client, binary string results display using hexadecimal notation, depending on the value of the `--binary-as-hex`. For more information about that option, see [Section 6.5.1, “mysql — The MySQL Command-Line Client”](#).

- <<

Shifts a longlong (`BIGINT`) number or binary string to the left.

The result type depends on whether the bit argument is evaluated as a binary string or number:

- Binary-string evaluation occurs when the bit argument has a binary string type, and is not a hexadecimal literal, bit literal, or `NULL` literal. Numeric evaluation occurs otherwise, with argument conversion to an unsigned 64-bit integer as necessary.
- Binary-string evaluation produces a binary string of the same length as the bit argument. Numeric evaluation produces an unsigned 64-bit integer.

Bits shifted off the end of the value are lost without warning, regardless of the argument type. In particular, if the shift count is greater or equal to the number of bits in the bit argument, all bits in the result are 0.

For more information, see the introductory discussion in this section.

```
mysql> SELECT 1 << 2;
-> 4
mysql> SELECT HEX(_binary X'00FF00FF00FF' << 8);
-> 'FF00FF00FF00'
```

If a bit shift is invoked from within the `mysql` client, binary string results display using hexadecimal notation, depending on the value of the `--binary-as-hex`. For more information about that option, see [Section 6.5.1, “mysql — The MySQL Command-Line Client”](#).

- `>>`

Shifts a longlong (`BIGINT`) number or binary string to the right.

The result type depends on whether the bit argument is evaluated as a binary string or number:

- Binary-string evaluation occurs when the bit argument has a binary string type, and is not a hexadecimal literal, bit literal, or `NULL` literal. Numeric evaluation occurs otherwise, with argument conversion to an unsigned 64-bit integer as necessary.
- Binary-string evaluation produces a binary string of the same length as the bit argument. Numeric evaluation produces an unsigned 64-bit integer.

Bits shifted off the end of the value are lost without warning, regardless of the argument type. In particular, if the shift count is greater or equal to the number of bits in the bit argument, all bits in the result are 0.

For more information, see the introductory discussion in this section.

```
mysql> SELECT 4 >> 2;
-> 1
mysql> SELECT HEX(_binary X'00FF00FF00FF' >> 8);
-> '0000FF00FF00'
```

If a bit shift is invoked from within the `mysql` client, binary string results display using hexadecimal notation, depending on the value of the `--binary-as-hex`. For more information about that option, see [Section 6.5.1, “mysql — The MySQL Command-Line Client”](#).

- `~`

Invert all bits.

The result type depends on whether the bit argument is evaluated as a binary string or number:

- Binary-string evaluation occurs when the bit argument has a binary string type, and is not a hexadecimal literal, bit literal, or `NULL` literal. Numeric evaluation occurs otherwise, with argument conversion to an unsigned 64-bit integer as necessary.
- Binary-string evaluation produces a binary string of the same length as the bit argument. Numeric evaluation produces an unsigned 64-bit integer.

For more information, see the introductory discussion in this section.

```
mysql> SELECT 5 & ~1;
-> 4
mysql> SELECT HEX(~X'0000FFFF1111EEEE');
-> 'FFFF0000EEEE1111'
```

If bitwise inversion is invoked from within the `mysql` client, binary string results display using hexadecimal notation, depending on the value of the `--binary-as-hex`. For more information about that option, see [Section 6.5.1, “mysql — The MySQL Command-Line Client”](#).

- [BIT\\_COUNT\(N\)](#)

Returns the number of bits that are set in the argument *N* as an unsigned 64-bit integer, or [NULL](#) if the argument is [NULL](#).

```
mysql> SELECT BIT_COUNT(64), BIT_COUNT(BINARY 64);
-> 1, 7
mysql> SELECT BIT_COUNT('64'), BIT_COUNT(_binary '64');
-> 1, 7
mysql> SELECT BIT_COUNT(X'40'), BIT_COUNT(_binary X'40');
-> 1, 1
```

Bit functions and operators comprise [BIT\\_COUNT\(\)](#), [BIT\\_AND\(\)](#), [BIT\\_OR\(\)](#), [BIT\\_XOR\(\)](#), [&](#), [|](#), [^](#), [~](#), [<<](#), and [>>](#). (The [BIT\\_AND\(\)](#), [BIT\\_OR\(\)](#), and [BIT\\_XOR\(\)](#) aggregate functions are described in [Section 14.19.1, “Aggregate Function Descriptions”](#).)

Bit functions and operators permit binary string type arguments ([BINARY](#), [VARBINARY](#), and the [BLOB](#) types) and return a value of like type. Nonbinary string arguments are converted to [BIGINT](#).

## Bit Operations

MySQL 9.1 handles binary string arguments directly (without conversion) and produces binary string results. Arguments that are not integers or binary strings are converted to integers.

Arguments that count as binary strings include column values, routine parameters, local variables, and user-defined variables that have a binary string type: [BINARY](#), [VARBINARY](#), or one of the [BLOB](#) types.

You can specify arguments to bit operations using hexadecimal literals or bit literals with the intent that they represent numbers; MySQL evaluates bit operations in numeric context when all bit arguments are hexadecimal or bit literals. For evaluation as binary strings instead, use the [\\_binary](#) introducer for at least one of the literal values.

- These bit operations evaluate the hexadecimal literals and bit literals as integers:

```
mysql> SELECT X'40' | X'01', b'11110001' & b'01001111';
+-----+
| X'40' | X'01' | b'11110001' & b'01001111' |
+-----+
| 65 | 65 |
+-----+
```

- These bit operations evaluate the hexadecimal literals and bit literals as binary strings, due to the [\\_binary](#) introducer:

```
mysql> SELECT _binary X'40' | X'01', b'11110001' & _binary b'01001111';
+-----+
| _binary X'40' | X'01' | b'11110001' & _binary b'01001111' |
```

A	A
---	---

Although the bit operations in both statements produce a result with a numeric value of 65, the second statement operates in binary-string context, for which 65 is ASCII [A](#).

In numeric evaluation context, permitted values of hexadecimal literal and bit literal arguments have a maximum of 64 bits, as do results. By contrast, in binary-string evaluation context, permitted arguments (and results) can exceed 64 bits:

```
mysql> SELECT _binary X'4040404040404040' | X'0102030405060708';
```

_binary X'4040404040404040'   X'0102030405060708'
ABCDEFGH

There are several ways to refer to a hexadecimal literal or bit literal in a bit operation to cause binary-string evaluation:

```
_binary literal
BINARY literal
CAST(literal AS BINARY)
```

Another way to produce binary-string evaluation of hexadecimal literals or bit literals is to assign them to user-defined variables, which results in variables that have a binary string type:

```
mysql> SET @v1 = X'40', @v2 = X'01', @v3 = b'11110001', @v4 = b'01001111';
mysql> SELECT @v1 | @v2, @v3 & @v4;
```

@v1	@v2	@v3 & @v4
A	A	

In binary-string context, bitwise operation arguments must have the same length or an `ER_INVALID_BITWISE_OPERANDS_SIZE` error occurs:

```
mysql> SELECT _binary X'40' | X'0001';
ERROR 3513 (HY000): Binary operands of bitwise operators must be of equal length
```

To satisfy the equal-length requirement, pad the shorter value with leading zero digits or, if the longer value begins with leading zero digits and a shorter result value is acceptable, strip them:

```
mysql> SELECT _binary X'0040' | X'0001';
```

_binary X'0040'   X'0001'
A

```
mysql> SELECT _binary X'40' | X'01';
```

_binary X'40'   X'01'
A

Padding or stripping can also be accomplished using functions such as `LPAD()`, `RPAD()`, `SUBSTR()`, or `CAST()`. In such cases, the expression arguments are no longer all literals and `_binary` becomes unnecessary. Examples:

```
mysql> SELECT LPAD(X'40', 2, X'00') | X'0001';
```

```

+-----+
| LPAD(X'40', 2, X'00') | X'0001' |
+-----+
| A |
+-----+
mysql> SELECT X'40' | SUBSTR(X'0001', 2, 1);
+-----+
| X'40' | SUBSTR(X'0001', 2, 1) |
+-----+
| A |
+-----+

```

See also [Special Handling of Hexadecimal Literals, Bit Literals, and NULL Literals](#).

## Binary String Bit-Operation Examples

The following example illustrates use of bit operations to extract parts of a UUID value, in this case, the timestamp and IEEE 802 node number. This technique requires bitmasks for each extracted part.

Convert the text UUID to the corresponding 16-byte binary value so that it can be manipulated using bit operations in binary-string context:

```

mysql> SET @uuid = UUID_TO_BIN('6ccd780c-baba-1026-9564-5b8c656024db');
mysql> SELECT HEX(@uuid);
+-----+
| HEX(@uuid) |
+-----+
| 6CCD780CBABA102695645B8C656024DB |
+-----+

```

Construct bitmasks for the timestamp and node number parts of the value. The timestamp comprises the first three parts (64 bits, bits 0 to 63) and the node number is the last part (48 bits, bits 80 to 127):

```

mysql> SET @ts_mask = CAST(X'FFFFFFFFFFFFFFFF' AS BINARY(16));
mysql> SET @node_mask = CAST(X'FFFFFFFFFFFFFFFF' AS BINARY(16)) >> 80;
mysql> SELECT HEX(@ts_mask);
+-----+
| HEX(@ts_mask) |
+-----+
| FFFFFFFFFFFFFFFF0000000000000000 |
+-----+
mysql> SELECT HEX(@node_mask);
+-----+
| HEX(@node_mask) |
+-----+
| 000000000000000000000000FFFFFFFF |
+-----+

```

The `CAST(... AS BINARY(16))` function is used here because the masks must be the same length as the UUID value against which they are applied. The same result can be produced using other functions to pad the masks to the required length:

```

SET @ts_mask= RPAD(X'FFFFFFFFFFFFFFFF', 16, X'00');
SET @node_mask = LPAD(X'FFFFFFFFFFFFFFFF', 16, X'00') ;

```

Use the masks to extract the timestamp and node number parts:

```

mysql> SELECT HEX(@uuid & @ts_mask) AS 'timestamp part';
+-----+
| timestamp part |
+-----+
| 6CCD780CBABA10260000000000000000 |
+-----+
mysql> SELECT HEX(@uuid & @node_mask) AS 'node part';
+-----+

```

```

| node part |
+-----+
| 0000000000000000000000005B8C656024DB |
+-----+

```

The preceding example uses these bit operations: right shift (`>>`) and bitwise AND (`&`).

#### Note

`UUID_TO_BIN()` takes a flag that causes some bit rearrangement in the resulting binary UUID value. If you use that flag, modify the extraction masks accordingly.

The next example uses bit operations to extract the network and host parts of an IPv6 address. Suppose that the network part has a length of 80 bits. Then the host part has a length of  $128 - 80 = 48$  bits. To extract the network and host parts of the address, convert it to a binary string, then use bit operations in binary-string context.

Convert the text IPv6 address to the corresponding binary string:

```
mysql> SET @ip = INET6_ATON('fe80::219:d1ff:fe91:1a72');
```

Define the network length in bits:

```
mysql> SET @net_len = 80;
```

Construct network and host masks by shifting the all-ones address left or right. To do this, begin with the address `::`, which is shorthand for all zeros, as you can see by converting it to a binary string like this:

```
mysql> SELECT HEX(INET6_ATON('::')) AS 'all zeros';
+-----+
| all zeros |
+-----+
| 00000000000000000000000000000000 |
+-----+
```

To produce the complementary value (all ones), use the `~` operator to invert the bits:

```
mysql> SELECT HEX(~INET6_ATON('::')) AS 'all ones';
+-----+
| all ones |
+-----+
| FFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFF |
+-----+
```

Shift the all-ones value left or right to produce the network and host masks:

```
mysql> SET @net_mask = ~INET6_ATON('::') << (128 - @net_len);
mysql> SET @host_mask = ~INET6_ATON('::') >> @net_len;
```

Display the masks to verify that they cover the correct parts of the address:

```
mysql> SELECT INET6_NTOA(@net_mask) AS 'network mask';
+-----+
| network mask |
+-----+
| ffff:ffff:ffff:ffff:ffff:ffff:: |
+-----+
mysql> SELECT INET6_NTOA(@host_mask) AS 'host mask';
+-----+
| host mask |
+-----+
| ::ffff:255.255.255.255 |
+-----+
```

Extract and display the network and host parts of the address:

```
mysql> SET @net_part = @ip & @net_mask;
mysql> SET @host_part = @ip & @host_mask;
mysql> SELECT INET6_NTOA(@net_part) AS 'network part';
+-----+
| network part |
+-----+
| fe80::219:0:0:0 |
+-----+
mysql> SELECT INET6_NTOA(@host_part) AS 'host part';
+-----+
| host part |
+-----+
| ::d1ff:fe91:1a72 |
+-----+
```

The preceding example uses these bit operations: Complement (~), left shift (<<), and bitwise AND (&).

The remaining discussion provides details on argument handling for each group of bit operations, and more information about literal-value handling in bit operations.

## Bitwise AND, OR, and XOR Operations

For &, |, and ^ bit operations, the result type depends on whether the arguments are evaluated as binary strings or numbers:

- Binary-string evaluation occurs when the arguments have a binary string type, and at least one of them is not a hexadecimal literal, bit literal, or `NULL` literal. Numeric evaluation occurs otherwise, with argument conversion to unsigned 64-bit integers as necessary.
- Binary-string evaluation produces a binary string of the same length as the arguments. If the arguments have unequal lengths, an `ER_INVALID_BITWISE_OPERANDS_SIZE` error occurs. Numeric evaluation produces an unsigned 64-bit integer.

Examples of numeric evaluation:

```
mysql> SELECT 64 | 1, X'40' | X'01';
+-----+
| 64 | 1 | X'40' | X'01' |
+-----+
| 65 | 65 |
+-----+
```

Examples of binary-string evaluation:

```
mysql> SELECT _binary X'40' | X'01';
+-----+
| _binary X'40' | X'01' |
+-----+
| A |
+-----+
mysql> SET @var1 = X'40', @var2 = X'01';
mysql> SELECT @var1 | @var2;
+-----+
| @var1 | @var2 |
+-----+
| A |
+-----+
```

## Bitwise Complement and Shift Operations

For ~, <<, and >> bit operations, the result type depends on whether the bit argument is evaluated as a binary string or number:

- Binary-string evaluation occurs when the bit argument has a binary string type, and is not a hexadecimal literal, bit literal, or [NULL](#) literal. Numeric evaluation occurs otherwise, with argument conversion to an unsigned 64-bit integer as necessary.
- Binary-string evaluation produces a binary string of the same length as the bit argument. Numeric evaluation produces an unsigned 64-bit integer.

For shift operations, bits shifted off the end of the value are lost without warning, regardless of the argument type. In particular, if the shift count is greater or equal to the number of bits in the bit argument, all bits in the result are 0.

Examples of numeric evaluation:

```
mysql> SELECT ~0, 64 << 2, X'40' << 2;
+-----+-----+-----+
| ~0 | 64 << 2 | X'40' << 2 |
+-----+-----+-----+
| 18446744073709551615 | 256 | 256 |
+-----+-----+-----+
```

Examples of binary-string evaluation:

```
mysql> SELECT HEX(_binary X'1111000022220000' >> 16);
+-----+
| HEX(_binary X'1111000022220000' >> 16) |
+-----+
| 0000111100002222 |
+-----+
mysql> SELECT HEX(_binary X'1111000022220000' << 16);
+-----+
| HEX(_binary X'1111000022220000' << 16) |
+-----+
| 0000222200000000 |
+-----+
mysql> SET @var1 = X'F0F0F0F0';
mysql> SELECT HEX(~@var1);
+-----+
| HEX(~@var1) |
+-----+
| 0F0F0F0F |
+-----+
```

## BIT\_COUNT() Operations

The `BIT_COUNT()` function always returns an unsigned 64-bit integer, or [NULL](#) if the argument is [NULL](#).

```
mysql> SELECT BIT_COUNT(127);
+-----+
| BIT_COUNT(127) |
+-----+
| 7 |
+-----+
mysql> SELECT BIT_COUNT(b'010101'), BIT_COUNT(_binary b'010101');
+-----+-----+
| BIT_COUNT(b'010101') | BIT_COUNT(_binary b'010101') |
+-----+-----+
| 3 | 3 |
+-----+-----+
```

## BIT\_AND(), BIT\_OR(), and BIT\_XOR() Operations

For the `BIT_AND()`, `BIT_OR()`, and `BIT_XOR()` bit functions, the result type depends on whether the function argument values are evaluated as binary strings or numbers:

- Binary-string evaluation occurs when the argument values have a binary string type, and the argument is not a hexadecimal literal, bit literal, or `NULL` literal. Numeric evaluation occurs otherwise, with argument value conversion to unsigned 64-bit integers as necessary.
- Binary-string evaluation produces a binary string of the same length as the argument values. If argument values have unequal lengths, an `ER_INVALID_BITWISE_OPERANDS_SIZE` error occurs. If the argument size exceeds 511 bytes, an `ER_INVALID_BITWISEAggregate_OPERANDS_SIZE` error occurs. Numeric evaluation produces an unsigned 64-bit integer.

`NULL` values do not affect the result unless all values are `NULL`. In that case, the result is a neutral value having the same length as the length of the argument values (all bits 1 for `BIT_AND()`, all bits 0 for `BIT_OR()`, and `BIT_XOR()`).

Example:

```
mysql> CREATE TABLE t (group_id INT, a VARBINARY(6));
mysql> INSERT INTO t VALUES (1, NULL);
mysql> INSERT INTO t VALUES (1, NULL);
mysql> INSERT INTO t VALUES (2, NULL);
mysql> INSERT INTO t VALUES (2, X'1234');
mysql> INSERT INTO t VALUES (2, X'FF34');
mysql> SELECT HEX(BIT_AND(a)), HEX(BIT_OR(a)), HEX(BIT_XOR(a))
 FROM t GROUP BY group_id;
```

HEX(BIT_AND(a))	HEX(BIT_OR(a))	HEX(BIT_XOR(a))
FFFFFFFFFFFF	000000000000	000000000000
1234	FF34	ED00

## Special Handling of Hexadecimal Literals, Bit Literals, and NULL Literals

MySQL 9.1 evaluates bit operations in numeric context when all bit arguments are hexadecimal literals, bit literals, or `NULL` literals. That is, bit operations on binary-string bit arguments do not use binary-string evaluation if all bit arguments are unadorned hexadecimal literals, bit literals, or `NULL` literals. (This does not apply to such literals if they are written with a `_binary` introducer, `BINARY` operator, or other way of specifying them explicitly as binary strings.)

Examples:

- These bit operations evaluate the literals in numeric context and produce a `BIGINT` result:

```
b'0001' | b'0010'
X'0008' << 8
```

- These bit operations evaluate `NULL` in numeric context and produce a `BIGINT` result that has a `NULL` value:

```
NULL & NULL
NULL >> 4
```

You can cause those operations to evaluate the arguments in binary-string context by indicating explicitly that at least one argument is a binary string:

```
_binary b'0001' | b'0010'
_binary X'0008' << 8
BINARY NULL & NULL
BINARY NULL >> 4
```

The result of the last two expressions is `NULL`, just as without the `BINARY` operator, but the data type of the result is a binary string type rather than an integer type.

## 14.13 Encryption and Compression Functions

**Table 14.18 Encryption Functions**

Name	Description
<code>AES_DECRYPT()</code>	Decrypt using AES
<code>AES_ENCRYPT()</code>	Encrypt using AES
<code>COMPRESS()</code>	Return result as a binary string
<code>MD5()</code>	Calculate MD5 checksum
<code>RANDOM_BYTES()</code>	Return a random byte vector
<code>SHA1()</code> , <code>SHA()</code>	Calculate an SHA-1 160-bit checksum
<code>SHA2()</code>	Calculate an SHA-2 checksum
<code>STATEMENT_DIGEST()</code>	Compute statement digest hash value
<code>STATEMENT_DIGEST_TEXT()</code>	Compute normalized statement digest
<code>UNCOMPRESS()</code>	Uncompress a string compressed
<code>UNCOMPRESSED_LENGTH()</code>	Return the length of a string before compression
<code>VALIDATE_PASSWORD_STRENGTH()</code>	Determine strength of password

Many encryption and compression functions return strings for which the result might contain arbitrary byte values. If you want to store these results, use a column with a `VARBINARY` or `BLOB` binary string data type. This avoids potential problems with trailing space removal or character set conversion that would change data values, such as may occur if you use a nonbinary string data type (`CHAR`, `VARCHAR`, `TEXT`).

Some encryption functions return strings of ASCII characters: `MD5()`, `SHA()`, `SHA1()`, `SHA2()`, `STATEMENT_DIGEST()`, `STATEMENT_DIGEST_TEXT()`. Their return value is a string that has a character set and collation determined by the `character_set_connection` and `collation_connection` system variables. This is a nonbinary string unless the character set is `binary`.

If an application stores values from a function such as `MD5()` or `SHA1()` that returns a string of hex digits, more efficient storage and comparisons can be obtained by converting the hex representation to binary using `UNHEX()` and storing the result in a `BINARY(N)` column. Each pair of hexadecimal digits requires one byte in binary form, so the value of `N` depends on the length of the hex string. `N` is 16 for an `MD5()` value and 20 for a `SHA1()` value. For `SHA2()`, `N` ranges from 28 to 32 depending on the argument specifying the desired bit length of the result.

The size penalty for storing the hex string in a `CHAR` column is at least two times, up to eight times if the value is stored in a column that uses the `utf8mb4` character set (where each character uses 4 bytes). Storing the string also results in slower comparisons because of the larger values and the need to take character set collation rules into account.

Suppose that an application stores `MD5()` string values in a `CHAR(32)` column:

```
CREATE TABLE md5_tbl (md5_val CHAR(32), ...);
INSERT INTO md5_tbl (md5_val, ...) VALUES(MD5('abcdef'), ...);
```

To convert hex strings to more compact form, modify the application to use `UNHEX()` and `BINARY(16)` instead as follows:

```
CREATE TABLE md5_tbl (md5_val BINARY(16), ...);
INSERT INTO md5_tbl (md5_val, ...) VALUES(UNHEX(MD5('abcdef')), ...);
```

Applications should be prepared to handle the very rare case that a hashing function produces the same value for two different input values. One way to make collisions detectable is to make the hash column a primary key.

#### Note

Exploits for the MD5 and SHA-1 algorithms have become known. You may wish to consider using another one-way encryption function described in this section instead, such as [SHA2\(\)](#).

#### Caution

Passwords or other sensitive values supplied as arguments to encryption functions are sent as cleartext to the MySQL server unless an SSL connection is used. Also, such values appear in any MySQL logs to which they are written. To avoid these types of exposure, applications can encrypt sensitive values on the client side before sending them to the server. The same considerations apply to encryption keys. To avoid exposing these, applications can use stored procedures to encrypt and decrypt values on the server side.

- [AES\\_DECRYPT\(\)](#) (*crypt\_str*, *key\_str* [, *init\_vector*] [, *kdf\_name*] [, *salt*] [, *info* / *iterations*])

This function decrypts data using the official AES (Advanced Encryption Standard) algorithm. For more information, see the description of [AES\\_ENCRYPT\(\)](#).

Statements that use [AES\\_DECRYPT\(\)](#) are unsafe for statement-based replication.

- [AES\\_ENCRYPT\(\)](#) (*str*, *key\_str* [, *init\_vector*] [, *kdf\_name*] [, *salt*] [, *info* / *iterations*])

[AES\\_ENCRYPT\(\)](#) and [AES\\_DECRYPT\(\)](#) implement encryption and decryption of data using the official AES (Advanced Encryption Standard) algorithm, previously known as “Rijndael.” The AES standard permits various key lengths. By default these functions implement AES with a 128-bit key length. Key lengths of 196 or 256 bits can be used, as described later. The key length is a trade off between performance and security.

[AES\\_ENCRYPT\(\)](#) encrypts the string *str* using the key string *key\_str*, and returns a binary string containing the encrypted output. [AES\\_DECRYPT\(\)](#) decrypts the encrypted string *crypt\_str* using the key string *key\_str*, and returns the original (binary) string in hexadecimal format. (To obtain the string as plaintext, cast the result to [CHAR](#). Alternatively, start the `mysql` client with `--skip-binary-as-hex` to cause all binary values to be displayed as text.) If either function argument is [NULL](#), the function returns [NULL](#). If [AES\\_DECRYPT\(\)](#) detects invalid data or incorrect padding, it returns [NULL](#). However, it is possible for [AES\\_DECRYPT\(\)](#) to return a non-[NULL](#) value (possibly garbage) if the input data or the key is invalid.

These functions support the use of a key derivation function (KDF) to create a cryptographically strong secret key from the information passed in *key\_str*. The derived key is used to encrypt and decrypt the data, and it remains in the MySQL Server instance and is not accessible to users. Using a KDF is highly recommended, as it provides better security than specifying your own premade key or deriving it by a simpler method as you use the function. The functions support HKDF (available from OpenSSL 1.1.0), for which you can specify an optional salt and context-specific information to include in the keying material, and PBKDF2 (available from OpenSSL 1.0.2), for which you can specify an optional salt and set the number of iterations used to produce the key.

[AES\\_ENCRYPT\(\)](#) and [AES\\_DECRYPT\(\)](#) permit control of the block encryption mode. The [block\\_encryption\\_mode](#) system variable controls the mode for block-based encryption algorithms.

Its default value is `aes-128-ecb`, which signifies encryption using a key length of 128 bits and ECB mode. For a description of the permitted values of this variable, see [Section 7.1.8, “Server System Variables”](#). The optional `init_vector` argument is used to provide an initialization vector for block encryption modes that require it.

Statements that use `AES_ENCRYPT()` or `AES_DECRYPT()` are unsafe for statement-based replication.

If `AES_ENCRYPT()` is invoked from within the `mysql` client, binary strings display using hexadecimal notation, depending on the value of the `--binary-as-hex`. For more information about that option, see [Section 6.5.1, “mysql — The MySQL Command-Line Client”](#).

The arguments for the `AES_ENCRYPT()` and `AES_DECRYPT()` functions are as follows:

*str* The string for `AES_ENCRYPT()` to encrypt using the key string *key\_str*, or the key derived from it by the specified KDF. The string can be any length. Padding is automatically added to *str* so it is a multiple of a block as required by block-based algorithms such as AES. This padding is automatically removed by the `AES_DECRYPT()` function.

*crypt\_str* The encrypted string for `AES_DECRYPT()` to decrypt using the key string *key\_str*, or the key derived from it by the specified KDF. The string can be any length. The length of *crypt\_str* can be calculated from the length of the original string using this formula:

```
16 * (trunc(string_length / 16) + 1)
```

*key\_str* The encryption key, or the input keying material that is used as the basis for deriving a key using a key derivation function (KDF). For the same instance of data, use the same value of *key\_str* for encryption with `AES_ENCRYPT()` and decryption with `AES_DECRYPT()`.

If you are using a KDF, *key\_str* can be any arbitrary information such as a password or passphrase. In the further arguments for the function, you specify the KDF name, then add further options to increase the security as appropriate for the KDF.

When you use a KDF, the function creates a cryptographically strong secret key from the information passed in *key\_str* and any salt or additional information that you provide in the other arguments. The derived key is used to encrypt and decrypt the data, and it remains in the MySQL Server instance and is not accessible to users. Using a KDF is highly recommended, as it provides better security than specifying your own premade key or deriving it by a simpler method as you use the function.

If you are not using a KDF, for a key length of 128 bits, the most secure way to pass a key to the *key\_str* argument is to create a truly random 128-bit value and pass it as a binary value. For example:

```
INSERT INTO t
VALUES (1,AES_ENCRYPT('text',UNHEX('F3229A0B371ED2D9441B830D21A390C3')))
```

A passphrase can be used to generate an AES key by hashing the passphrase. For example:

```
INSERT INTO t
```

```
VALUES (1,AES_ENCRYPT('text', UNHEX(SHA2('My secret passphrase',512))));
```

If you exceed the maximum key length of 128 bits, a warning is returned. If you are not using a KDF, do not pass a password or passphrase directly to *key\_str*, hash it first. Previous versions of this documentation suggested the former approach, but it is no longer recommended as the examples shown here are more secure.

*init\_vector*

An initialization vector, for block encryption modes that require it. The *block\_encryption\_mode* system variable controls the mode. For the same instance of data, use the same value of *init\_vector* for encryption with *AES\_ENCRYPT()* and decryption with *AES\_DECRYPT()*.

#### Note

If you are using a KDF, you must specify an initialization vector or a null string for this argument, in order to access the later arguments to define the KDF.

For modes that require an initialization vector, it must be 16 bytes or longer (bytes in excess of 16 are ignored). An error occurs if *init\_vector* is missing. For modes that do not require an initialization vector, it is ignored and a warning is generated if *init\_vector* is specified, unless you are using a KDF.

The default value for the *block\_encryption\_mode* system variable is *aes-128-ecb*, or ECB mode, which does not require an initialization vector. The alternative permitted block encryption modes CBC, CFB1, CFB8, CFB128, and OFB all require an initialization vector.

A random string of bytes to use for the initialization vector can be produced by calling *RANDOM\_BYTES(16)*.

*kdf\_name*

The name of the key derivation function (KDF) to create a key from the input keying material passed in *key\_str*, and other arguments as appropriate for the KDF. Optional.

For the same instance of data, use the same value of *kdf\_name* for encryption with *AES\_ENCRYPT()* and decryption with *AES\_DECRYPT()*. When you specify *kdf\_name*, you must specify *init\_vector*, using either a valid initialization vector, or a null string if the encryption mode does not require an initialization vector.

The following values are supported:

*hkdf*

HKDF, which is available from OpenSSL 1.1.0. HKDF extracts a pseudorandom key from the keying material then expands it into additional keys. With HKDF, you can specify an optional salt (*salt*) and context-specific

information such as application details (*info*) to include in the keying material.

*pbkdf2\_hmac*

PBKDF2, which is available from OpenSSL 1.0.2. PBKDF2 applies a pseudorandom function to the keying material, and repeats this process a large number of times to produce the key. With PBKDF2, you can specify an optional salt (*salt*) to include in the keying material, and set the number of iterations used to produce the key (*iterations*).

In this example, HKDF is specified as the key derivation function, and a salt and context information are provided. The argument for the initialization vector is included but is the empty string:

```
SELECT AES_ENCRYPT('mytext','mykeystring', '', 'hkdf', 'salt', 'info');
```

In this example, PBKDF2 is specified as the key derivation function, a salt is provided, and the number of iterations is doubled from the recommended minimum:

```
SELECT AES_ENCRYPT('mytext','mykeystring', '', 'pbkdf2_hmac','salt', '20
```

*salt*

A salt to be passed to the key derivation function (KDF).

Optional. Both HKDF and PBKDF2 can use salts, and their use is recommended to help prevent attacks based on dictionaries of common passwords or rainbow tables.

A salt consists of random data, which for security must be different for each encryption operation. A random string of bytes to use for the salt can be produced by calling `RANDOM_BYTES()`. This example produces a 64-bit salt:

```
SET @salt = RANDOM_BYTES(8);
```

For the same instance of data, use the same value of *salt* for encryption with `AES_ENCRYPT()` and decryption with `AES_DECRYPT()`. The salt can safely be stored along with the encrypted data.

*info*

Context-specific information for HKDF to include in the keying material, such as information about the application. Optional; available when you specify *hkdf* as the KDF name. HKDF adds this information to the keying material specified in *key\_str* and the salt specified in *salt* to produce the key.

For the same instance of data, use the same value of *info* for encryption with `AES_ENCRYPT()` and decryption with `AES_DECRYPT()`.

*iterations*

The iteration count for PBKDF2 to use when producing the key. Optional; available when you specify `pbkdf2_hmac` as the KDF name. A higher count gives greater resistance to brute-force attacks because it has a greater computational cost for the attacker, but the same is necessarily true for the key derivation process. The default if you do not specify this argument is 1000, which is the minimum recommended by the OpenSSL standard.

For the same instance of data, use the same value of *iterations* for encryption with `AES_ENCRYPT()` and decryption with `AES_DECRYPT()`.

```
mysql> SET block_encryption_mode = 'aes-256-cbc';
mysql> SET @key_str = SHA2('My secret passphrase',512);
mysql> SET @init_vector = RANDOM_BYTES(16);
mysql> SET @crypt_str = AES_ENCRYPT('text',@key_str,@init_vector);
mysql> SELECT CAST(AES_DECRYPT(@crypt_str,@key_str,@init_vector) AS CHAR);
+-----+
| CAST(AES_DECRYPT(@crypt_str,@key_str,@init_vector) AS CHAR) |
+-----+
| text |
+-----+
```

- `COMPRESS(string_to_compress)`

Compresses a string and returns the result as a binary string. This function requires MySQL to have been compiled with a compression library such as `zlib`. Otherwise, the return value is always `NULL`. The return value is also `NULL` if *string\_to\_compress* is `NULL`. The compressed string can be uncompressed with `UNCOMPRESS()`.

```
mysql> SELECT LENGTH(COMPRESS(REPEAT('a',1000)));
-> 21
mysql> SELECT LENGTH(COMPRESS(''));
-> 0
mysql> SELECT LENGTH(COMPRESS('a'));
-> 13
mysql> SELECT LENGTH(COMPRESS(REPEAT('a',16)));
-> 15
```

The compressed string contents are stored the following way:

- Empty strings are stored as empty strings.
- Nonempty strings are stored as a 4-byte length of the uncompressed string (low byte first), followed by the compressed string. If the string ends with space, an extra `.` character is added to avoid problems with endspace trimming should the result be stored in a `CHAR` or `VARCHAR` column. (However, use of nonbinary string data types such as `CHAR` or `VARCHAR` to store compressed strings is not recommended anyway because character set conversion may occur. Use a `VARBINARY` or `BLOB` binary string column instead.)

If `COMPRESS()` is invoked from within the `mysql` client, binary strings display using hexadecimal notation, depending on the value of the `--binary-as-hex`. For more information about that option, see [Section 6.5.1, “mysql — The MySQL Command-Line Client”](#).

- `MD5(str)`

Calculates an MD5 128-bit checksum for the string. The value is returned as a string of 32 hexadecimal digits, or `NULL` if the argument was `NULL`. The return value can, for example, be used as a hash key. See the notes at the beginning of this section about storing hash values efficiently.

The return value is a string in the connection character set.

If FIPS mode is enabled, `MD5()` returns `NULL`. See [Section 8.8, “FIPS Support”](#).

```
mysql> SELECT MD5('testing');
-> 'ae2b1fca515949e5d54fb22b8ed95575'
```

This is the “RSA Data Security, Inc. MD5 Message-Digest Algorithm.”

See the note regarding the MD5 algorithm at the beginning this section.

- `RANDOM_BYTES(len)`

This function returns a binary string of *len* random bytes generated using the random number generator of the SSL library. Permitted values of *len* range from 1 to 1024. For values outside that range, an error occurs. Returns `NULL` if *len* is `NULL`.

`RANDOM_BYTES()` can be used to provide the initialization vector for the `AES_DECRYPT()` and `AES_ENCRYPT()` functions. For use in that context, *len* must be at least 16. Larger values are permitted, but bytes in excess of 16 are ignored.

`RANDOM_BYTES()` generates a random value, which makes its result nondeterministic. Consequently, statements that use this function are unsafe for statement-based replication.

If `RANDOM_BYTES()` is invoked from within the `mysql` client, binary strings display using hexadecimal notation, depending on the value of the `--binary-as-hex`. For more information about that option, see [Section 6.5.1, “mysql — The MySQL Command-Line Client”](#).

- `SHA1(str)`, `SHA(str)`

Calculates an SHA-1 160-bit checksum for the string, as described in RFC 3174 (Secure Hash Algorithm). The value is returned as a string of 40 hexadecimal digits, or `NULL` if the argument is `NULL`. One of the possible uses for this function is as a hash key. See the notes at the beginning of this section about storing hash values efficiently. `SHA()` is synonymous with `SHA1()`.

The return value is a string in the connection character set.

```
mysql> SELECT SHA1('abc');
-> 'a9993e364706816aba3e25717850c26c9cd0d89d'
```

`SHA1()` can be considered a cryptographically more secure equivalent of `MD5()`. However, see the note regarding the MD5 and SHA-1 algorithms at the beginning this section.

- `SHA2(str, hash_length)`

Calculates the SHA-2 family of hash functions (SHA-224, SHA-256, SHA-384, and SHA-512). The first argument is the plaintext string to be hashed. The second argument indicates the desired bit length of the result, which must have a value of 224, 256, 384, 512, or 0 (which is equivalent to 256). If either argument is `NULL` or the hash length is not one of the permitted values, the return value is `NULL`.

Otherwise, the function result is a hash value containing the desired number of bits. See the notes at the beginning of this section about storing hash values efficiently.

The return value is a string in the connection character set.

```
mysql> SELECT SHA2('abc', 224);
-> '23097d223405d8228642a477bda255b32aadbce4bda0b3f7e36c9da7'
```

This function works only if MySQL has been configured with SSL support. See [Section 8.3, “Using Encrypted Connections”](#).

`SHA2()` can be considered cryptographically more secure than `MD5()` or `SHA1()`.

- `STATEMENT_DIGEST(statement)`

Given an SQL statement as a string, returns the statement digest hash value as a string in the connection character set, or `NULL` if the argument is `NULL`. The related `STATEMENT_DIGEST_TEXT()` function returns the normalized statement digest. For information about statement digesting, see [Section 29.10, “Performance Schema Statement Digests and Sampling”](#).

Both functions use the MySQL parser to parse the statement. If parsing fails, an error occurs. The error message includes the parse error only if the statement is provided as a literal string.

The `max_digest_length` system variable determines the maximum number of bytes available to these functions for computing normalized statement digests.

```
mysql> SET @stmt = 'SELECT * FROM mytable WHERE cola = 10 AND colb = 20';
mysql> SELECT STATEMENT_DIGEST(@stmt);
+-----+
| STATEMENT_DIGEST(@stmt) |
+-----+
| 3bb95eeade896657c4526e74ff2a2862039d0a0fe8a9e7155b5fe492cbd78387 |
+-----+
mysql> SELECT STATEMENT_DIGEST_TEXT(@stmt);
+-----+
| STATEMENT_DIGEST_TEXT(@stmt) |
+-----+
| SELECT * FROM `mytable` WHERE `cola` = ? AND `colb` = ? |
+-----+
```

- `STATEMENT_DIGEST_TEXT(statement)`

Given an SQL statement as a string, returns the normalized statement digest as a string in the connection character set, or `NULL` if the argument is `NULL`. For additional discussion and examples, see the description of the related `STATEMENT_DIGEST()` function.

- `UNCOMPRESS(string_to_uncompress)`

Uncompresses a string compressed by the `COMPRESS()` function. If the argument is not a compressed value, the result is `NULL`; if `string_to_uncompress` is `NULL`, the result is also `NULL`. This function requires MySQL to have been compiled with a compression library such as `zlib`. Otherwise, the return value is always `NULL`.

```
mysql> SELECT UNCOMPRESS(COMPRESS('any string'));
-> 'any string'
mysql> SELECT UNCOMPRESS(NULL);
-> NULL
```

- `UNCOMPRESSED_LENGTH(compressed_string)`

Returns the length that the compressed string had before being compressed. Returns `NULL` if *compressed\_string* is `NULL`.

```
mysql> SELECT UNCOMPRESSED_LENGTH(COMPRESS(REPEAT('a',30)));
-> 30
```

- `VALIDATE_PASSWORD_STRENGTH(str)`

Given an argument representing a plaintext password, this function returns an integer to indicate how strong the password is, or `NULL` if the argument is `NULL`. The return value ranges from 0 (weak) to 100 (strong).

Password assessment by `VALIDATE_PASSWORD_STRENGTH()` is done by the `validate_password` component. If that component is not installed, the function always returns 0. For information about installing `validate_password`, see [Section 8.4.3, “The Password Validation Component”](#). To examine or configure the parameters that affect password testing, check or set the system variables implemented by `validate_password`. See [Section 8.4.3.2, “Password Validation Options and Variables”](#).

The password is subjected to increasingly strict tests and the return value reflects which tests were satisfied, as shown in the following table. In addition, if the `validate_password.check_user_name` system variable is enabled and the password matches the user name, `VALIDATE_PASSWORD_STRENGTH()` returns 0 regardless of how other `validate_password` system variables are set.

Password Test	Return Value
Length < 4	0
Length ≥ 4 and < <code>validate_password.length</code>	25
Satisfies policy 1 ( <code>LOW</code> )	50
Satisfies policy 2 ( <code>MEDIUM</code> )	75
Satisfies policy 3 ( <code>STRONG</code> )	100

## 14.14 Locking Functions

This section describes functions used to manipulate user-level locks.

**Table 14.19 Locking Functions**

Name	Description
<code>GET_LOCK()</code>	Get a named lock
<code>IS_FREE_LOCK()</code>	Whether the named lock is free
<code>IS_USED_LOCK()</code>	Whether the named lock is in use; return connection identifier if true
<code>RELEASE_ALL_LOCKS()</code>	Release all current named locks
<code>RELEASE_LOCK()</code>	Release the named lock

- `GET_LOCK(str,timeout)`

Tries to obtain a lock with a name given by the string *str*, using a timeout of *timeout* seconds. A negative *timeout* value means infinite timeout. The lock is exclusive. While held by one session, other sessions cannot obtain a lock of the same name.

Returns `1` if the lock was obtained successfully, `0` if the attempt timed out (for example, because another client has previously locked the name), or `NULL` if an error occurred (such as running out of memory or the thread was killed with `mysqladmin kill`).

A lock obtained with `GET_LOCK()` is released explicitly by executing `RELEASE_LOCK()` or implicitly when your session terminates (either normally or abnormally). Locks obtained with `GET_LOCK()` are not released when transactions commit or roll back.

`GET_LOCK()` is implemented using the metadata locking (MDL) subsystem. Multiple simultaneous locks can be acquired and `GET_LOCK()` does not release any existing locks. For example, suppose that you execute these statements:

```
SELECT GET_LOCK('lock1',10);
SELECT GET_LOCK('lock2',10);
SELECT RELEASE_LOCK('lock2');
SELECT RELEASE_LOCK('lock1');
```

The second `GET_LOCK()` acquires a second lock and both `RELEASE_LOCK()` calls return `1` (success).

It is even possible for a given session to acquire multiple locks for the same name. Other sessions cannot acquire a lock with that name until the acquiring session releases all its locks for the name.

Uniquely named locks acquired with `GET_LOCK()` appear in the Performance Schema `metadata_locks` table. The `OBJECT_TYPE` column says `USER LEVEL LOCK` and the `OBJECT_NAME` column indicates the lock name. In the case that multiple locks are acquired for the *same* name, only the first lock for the name registers a row in the `metadata_locks` table. Subsequent locks for the name increment a counter in the lock but do not acquire additional metadata locks. The `metadata_locks` row for the lock is deleted when the last lock instance on the name is released.

The capability of acquiring multiple locks means there is the possibility of deadlock among clients. When this happens, the server chooses a caller and terminates its lock-acquisition request with an `ER_USER_LOCK_DEADLOCK` error. This error does not cause transactions to roll back.

MySQL enforces a maximum length on lock names of 64 characters.

`GET_LOCK()` can be used to implement application locks or to simulate record locks. Names are locked on a server-wide basis. If a name has been locked within one session, `GET_LOCK()` blocks any request by another session for a lock with the same name. This enables clients that agree on a given lock name to use the name to perform cooperative advisory locking. But be aware that it also enables a client that is not among the set of cooperating clients to lock a name, either inadvertently or deliberately, and thus prevent any of the cooperating clients from locking that name. One way to reduce the likelihood of this is

to use lock names that are database-specific or application-specific. For example, use lock names of the form `db_name.str` or `app_name.str`.

If multiple clients are waiting for a lock, the order in which they acquire it is undefined. Applications should not assume that clients acquire the lock in the same order that they issued the lock requests.

`GET_LOCK()` is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

Since `GET_LOCK()` establishes a lock only on a single `mysqld`, it is not suitable for use with NDB Cluster, which has no way of enforcing an SQL lock across multiple MySQL servers. See [Section 25.2.7.10, “Limitations Relating to Multiple NDB Cluster Nodes”](#), for more information.

### Caution

With the capability of acquiring multiple named locks, it is possible for a single statement to acquire a large number of locks. For example:

```
INSERT INTO ... SELECT GET_LOCK(t1.col_name) FROM t1;
```

These types of statements may have certain adverse effects. For example, if the statement fails part way through and rolls back, locks acquired up to the point of failure still exist. If the intent is for there to be a correspondence between rows inserted and locks acquired, that intent is not satisfied. Also, if it is important that locks are granted in a certain order, be aware that result set order may differ depending on which execution plan the optimizer chooses. For these reasons, it may be best to limit applications to a single lock-acquisition call per statement.

A different locking interface is available as either a plugin service or a set of loadable functions. This interface provides lock namespaces and distinct read and write locks, unlike the interface provided by `GET_LOCK()` and related functions. For details, see [Section 7.6.9.1, “The Locking Service”](#).

- `IS_FREE_LOCK(str)`

Checks whether the lock named `str` is free to use (that is, not locked). Returns `1` if the lock is free (no one is using the lock), `0` if the lock is in use, and `NULL` if an error occurs (such as an incorrect argument).

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- `IS_USED_LOCK(str)`

Checks whether the lock named `str` is in use (that is, locked). If so, it returns the connection identifier of the client session that holds the lock. Otherwise, it returns `NULL`.

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- `RELEASE_ALL_LOCKS()`

Releases all named locks held by the current session and returns the number of locks released (0 if there were none)

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- `RELEASE_LOCK(str)`

Releases the lock named by the string *str* that was obtained with `GET_LOCK()`. Returns `1` if the lock was released, `0` if the lock was not established by this thread (in which case the lock is not released), and `NULL` if the named lock did not exist. The lock does not exist if it was never obtained by a call to `GET_LOCK()` or if it has previously been released.

The `DO` statement is convenient to use with `RELEASE_LOCK()`. See [Section 15.2.3, “DO Statement”](#).

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

## 14.15 Information Functions

**Table 14.20 Information Functions**

Name	Description
<code>BENCHMARK()</code>	Repeatedly execute an expression
<code>CHARSET()</code>	Return the character set of the argument
<code>COERCIBILITY()</code>	Return the collation coercibility value of the string argument
<code>COLLATION()</code>	Return the collation of the string argument
<code>CONNECTION_ID()</code>	Return the connection ID (thread ID) for the connection
<code>CURRENT_ROLE()</code>	Return the current active roles
<code>CURRENT_USER()</code> , <code>CURRENT_USER</code>	The authenticated user name and host name
<code>DATABASE()</code>	Return the default (current) database name
<code>FOUND_ROWS()</code>	For a <code>SELECT</code> with a <code>LIMIT</code> clause, the number of rows that would be returned were there no <code>LIMIT</code> clause
<code>ICU_VERSION()</code>	ICU library version
<code>LAST_INSERT_ID()</code>	Value of the <code>AUTOINCREMENT</code> column for the last <code>INSERT</code>
<code>ROLES_GRAPHML()</code>	Return a GraphML document representing memory role subgraphs
<code>ROW_COUNT()</code>	The number of rows updated
<code>SCHEMA()</code>	Synonym for <code>DATABASE()</code>
<code>SESSION_USER()</code>	Synonym for <code>USER()</code>
<code>SYSTEM_USER()</code>	Synonym for <code>USER()</code>
<code>USER()</code>	The user name and host name provided by the client
<code>VERSION()</code>	Return a string that indicates the MySQL server version

- `BENCHMARK(count,expr)`

The `BENCHMARK()` function executes the expression *expr* repeatedly *count* times. It may be used to time how quickly MySQL processes the expression. The result value is 0, or `NULL` for inappropriate arguments such as a `NULL` or negative repeat count.

The intended use is from within the `mysql` client, which reports query execution times:

```
mysql> SELECT BENCHMARK(1000000,AES_ENCRYPT('hello','goodbye'));
+-----+
| BENCHMARK(1000000,AES_ENCRYPT('hello','goodbye')) |
+-----+
| 0 |
+-----+
1 row in set (4.74 sec)
```

The time reported is elapsed time on the client end, not CPU time on the server end. It is advisable to execute `BENCHMARK()` several times, and to interpret the result with regard to how heavily loaded the server machine is.

`BENCHMARK()` is intended for measuring the runtime performance of scalar expressions, which has some significant implications for the way that you use it and interpret the results:

- Only scalar expressions can be used. Although the expression can be a subquery, it must return a single column and at most a single row. For example, `BENCHMARK(10, (SELECT * FROM t))` fails if the table `t` has more than one column or more than one row.
- Executing a `SELECT expr` statement *N* times differs from executing `SELECT BENCHMARK(N, expr)` in terms of the amount of overhead involved. The two have very different execution profiles and you should not expect them to take the same amount of time. The former involves the parser, optimizer, table locking, and runtime evaluation *N* times each. The latter involves only runtime evaluation *N* times, and all the other components just once. Memory structures already allocated are reused, and runtime optimizations such as local caching of results already evaluated for aggregate functions can alter the results. Use of `BENCHMARK()` thus measures performance of the runtime component by giving more weight to that component and removing the “noise” introduced by the network, parser, optimizer, and so forth.
- `CHARSET(str)`

Returns the character set of the string argument, or `NULL` if the argument is `NULL`.

```
mysql> SELECT CHARSET('abc');
-> 'utf8mb3'
mysql> SELECT CHARSET(CONVERT('abc' USING latin1));
-> 'latin1'
mysql> SELECT CHARSET(USER());
-> 'utf8mb3'
```

- `COERCIBILITY(str)`

Returns the collation coercibility value of the string argument.

```
mysql> SELECT COERCIBILITY('abc' COLLATE utf8mb4_swedish_ci);
-> 0
mysql> SELECT COERCIBILITY(USER());
-> 3
mysql> SELECT COERCIBILITY('abc');
-> 4
mysql> SELECT COERCIBILITY(1000);
```

-&gt; 5

The return values have the meanings shown in the following table. Lower values have higher precedence.

Coercibility	Meaning	Example
0	Explicit collation	Value with <code>COLLATE</code> clause
1	No collation	Concatenation of strings with different collations
2	Implicit collation	Column value, stored routine parameter or local variable
3	System constant	<code>USER()</code> return value
4	Coercible	Literal string
5	Numeric	Numeric or temporal value
6	Ignorable	<code>NULL</code> or an expression derived from <code>NULL</code>

For more information, see [Section 12.8.4, “Collation Coercibility in Expressions”](#).

- `COLLATION(str)`

Returns the collation of the string argument.

```
mysql> SELECT COLLATION('abc');
-> 'utf8mb4_0900_ai_ci'
mysql> SELECT COLLATION(_utf8mb4'abc');
-> 'utf8mb4_0900_ai_ci'
mysql> SELECT COLLATION(_latin1'abc');
-> 'latin1_swedish_ci'
```

- `CONNECTION_ID()`

Returns the connection ID (thread ID) for the connection. Every connection has an ID that is unique among the set of currently connected clients.

The value returned by `CONNECTION_ID()` is the same type of value as displayed in the `ID` column of the Information Schema `PROCESSLIST` table, the `Id` column of `SHOW PROCESSLIST` output, and the `PROCESSLIST_ID` column of the Performance Schema `threads` table.

```
mysql> SELECT CONNECTION_ID();
-> 23786
```

### Warning

Changing the session value of the `pseudo_thread_id` system variable changes the value returned by the `CONNECTION_ID()` function.

- `CURRENT_ROLE()`

Returns a `utf8mb3` string containing the current active roles for the current session, separated by commas, or `NONE` if there are none. The value reflects the setting of the `sql_quote_show_create` system variable.

Suppose that an account is granted roles as follows:

```
GRANT 'r1', 'r2' TO 'u1'@'localhost';
```

```
SET DEFAULT ROLE ALL TO 'u1'@'localhost';
```

In sessions for `u1`, the initial `CURRENT_ROLE()` value names the default account roles. Using `SET ROLE` changes that:

```
mysql> SELECT CURRENT_ROLE();
+-----+
| CURRENT_ROLE() |
+-----+
| `r1`@`%`,`r2`@`%` |
+-----+
mysql> SET ROLE 'r1'; SELECT CURRENT_ROLE();
+-----+
| CURRENT_ROLE() |
+-----+
| `r1`@`%` |
+-----+
```

- `CURRENT_USER`, `CURRENT_USER()`

Returns the user name and host name combination for the MySQL account that the server used to authenticate the current client. This account determines your access privileges. The return value is a string in the `utf8mb3` character set.

The value of `CURRENT_USER()` can differ from the value of `USER()`.

```
mysql> SELECT USER();
-> 'davida@localhost'
mysql> SELECT * FROM mysql.user;
ERROR 1044: Access denied for user ''@'localhost' to
database 'mysql'
mysql> SELECT CURRENT_USER();
-> '@localhost'
```

The example illustrates that although the client specified a user name of `davida` (as indicated by the value of the `USER()` function), the server authenticated the client using an anonymous user account (as

seen by the empty user name part of the `CURRENT_USER()` value). One way this might occur is that there is no account listed in the grant tables for `davida`.

Within a stored program or view, `CURRENT_USER()` returns the account for the user who defined the object (as given by its `DEFINER` value) unless defined with the `SQL SECURITY INVOKER` characteristic. In the latter case, `CURRENT_USER()` returns the object's invoker.

Triggers and events have no option to define the `SQL SECURITY` characteristic, so for these objects, `CURRENT_USER()` returns the account for the user who defined the object. To return the invoker, use `USER()` or `SESSION_USER()`.

The following statements support use of the `CURRENT_USER()` function to take the place of the name of (and, possibly, a host for) an affected user or a definer; in such cases, `CURRENT_USER()` is expanded where and as needed:

- `DROP USER`
- `RENAME USER`
- `GRANT`
- `REVOKE`
- `CREATE FUNCTION`
- `CREATE PROCEDURE`
- `CREATE TRIGGER`
- `CREATE EVENT`
- `CREATE VIEW`
- `ALTER EVENT`
- `ALTER VIEW`
- `SET PASSWORD`

For information about the implications that this expansion of `CURRENT_USER()` has for replication, see [Section 19.5.1.8, “Replication of `CURRENT\_USER\(\)`”](#).

This function can be used for the default value of a `VARCHAR` or `TEXT` column, as shown in the following `CREATE TABLE` statement:

```
CREATE TABLE t (c VARCHAR(288) DEFAULT (CURRENT_USER()));
```

- `DATABASE()`

Returns the default (current) database name as a string in the `utf8mb3` character set. If there is no default database, `DATABASE()` returns `NULL`. Within a stored routine, the default database is the database that the routine is associated with, which is not necessarily the same as the database that is the default in the calling context.

```
mysql> SELECT DATABASE();
-> 'test'
```

If there is no default database, `DATABASE()` returns `NULL`.

- `FOUND_ROWS()`

#### Note

The `SQL_CALC_FOUND_ROWS` query modifier and accompanying `FOUND_ROWS()` function are deprecated; expect them to be removed in a future version of MySQL. Execute the query with `LIMIT`, and then a second query with `COUNT(*)` and without `LIMIT` to determine whether there are additional rows. For example, instead of these queries:

```
SELECT SQL_CALC_FOUND_ROWS * FROM tbl_name WHERE id > 100 LIMIT 10;
SELECT FOUND_ROWS();
```

Use these queries instead:

```
SELECT * FROM tbl_name WHERE id > 100 LIMIT 10;
SELECT COUNT(*) FROM tbl_name WHERE id > 100;
```

`COUNT(*)` is subject to certain optimizations. `SQL_CALC_FOUND_ROWS` causes some optimizations to be disabled.

A `SELECT` statement may include a `LIMIT` clause to restrict the number of rows the server returns to the client. In some cases, it is desirable to know how many rows the statement would have returned without the `LIMIT`, but without running the statement again. To obtain this row count, include an `SQL_CALC_FOUND_ROWS` option in the `SELECT` statement, and then invoke `FOUND_ROWS()` afterward:

```
mysql> SELECT SQL_CALC_FOUND_ROWS * FROM tbl_name
-> WHERE id > 100 LIMIT 10;
mysql> SELECT FOUND_ROWS();
```

The second `SELECT` returns a number indicating how many rows the first `SELECT` would have returned had it been written without the `LIMIT` clause.

In the absence of the `SQL_CALC_FOUND_ROWS` option in the most recent successful `SELECT` statement, `FOUND_ROWS()` returns the number of rows in the result set returned by that statement. If the statement includes a `LIMIT` clause, `FOUND_ROWS()` returns the number of rows up to the limit. For example, `FOUND_ROWS()` returns 10 or 60, respectively, if the statement includes `LIMIT 10` or `LIMIT 50, 10`.

The row count available through `FOUND_ROWS()` is transient and not intended to be available past the statement following the `SELECT SQL_CALC_FOUND_ROWS` statement. If you need to refer to the value later, save it:

```
mysql> SELECT SQL_CALC_FOUND_ROWS * FROM ... ;
mysql> SET @rows = FOUND_ROWS();
```

If you are using `SELECT SQL_CALC_FOUND_ROWS`, MySQL must calculate how many rows are in the full result set. However, this is faster than running the query again without `LIMIT`, because the result set need not be sent to the client.

`SQL_CALC_FOUND_ROWS` and `FOUND_ROWS()` can be useful in situations when you want to restrict the number of rows that a query returns, but also determine the number of rows in the full result set without running the query again. An example is a Web script that presents a paged display containing links to

the pages that show other sections of a search result. Using `FOUND_ROWS()` enables you to determine how many other pages are needed for the rest of the result.

The use of `SQL_CALC_FOUND_ROWS` and `FOUND_ROWS()` is more complex for `UNION` statements than for simple `SELECT` statements, because `LIMIT` may occur at multiple places in a `UNION`. It may be applied to individual `SELECT` statements in the `UNION`, or global to the `UNION` result as a whole.

The intent of `SQL_CALC_FOUND_ROWS` for `UNION` is that it should return the row count that would be returned without a global `LIMIT`. The conditions for use of `SQL_CALC_FOUND_ROWS` with `UNION` are:

- The `SQL_CALC_FOUND_ROWS` keyword must appear in the first `SELECT` of the `UNION`.
- The value of `FOUND_ROWS()` is exact only if `UNION ALL` is used. If `UNION` without `ALL` is used, duplicate removal occurs and the value of `FOUND_ROWS()` is only approximate.
- If no `LIMIT` is present in the `UNION`, `SQL_CALC_FOUND_ROWS` is ignored and returns the number of rows in the temporary table that is created to process the `UNION`.

Beyond the cases described here, the behavior of `FOUND_ROWS()` is undefined (for example, its value following a `SELECT` statement that fails with an error).

### Important

`FOUND_ROWS()` is not replicated reliably using statement-based replication. This function is automatically replicated using row-based replication.

- `ICU_VERSION()`

The version of the International Components for Unicode (ICU) library used to support regular expression operations (see [Section 14.8.2, “Regular Expressions”](#)). This function is primarily intended for use in test cases.

- `LAST_INSERT_ID()`, `LAST_INSERT_ID(expr)`

With no argument, `LAST_INSERT_ID()` returns a `BIGINT UNSIGNED` (64-bit) value representing the first automatically generated value successfully inserted for an `AUTO_INCREMENT` column as a result of the most recently executed `INSERT` statement. The value of `LAST_INSERT_ID()` remains unchanged if no rows are successfully inserted.

With an argument, `LAST_INSERT_ID()` returns an unsigned integer, or `NULL` if the argument is `NULL`.

For example, after inserting a row that generates an `AUTO_INCREMENT` value, you can get the value like this:

```
mysql> SELECT LAST_INSERT_ID();
-> 195
```

The currently executing statement does not affect the value of `LAST_INSERT_ID()`. Suppose that you generate an `AUTO_INCREMENT` value with one statement, and then refer to `LAST_INSERT_ID()` in a multiple-row `INSERT` statement that inserts rows into a table with its own `AUTO_INCREMENT` column. The value of `LAST_INSERT_ID()` remains stable in the second statement; its value for the second and later rows is not affected by the earlier row insertions. (You should be aware that, if you mix references to `LAST_INSERT_ID()` and `LAST_INSERT_ID(expr)`, the effect is undefined.)

If the previous statement returned an error, the value of `LAST_INSERT_ID()` is undefined. For transactional tables, if the statement is rolled back due to an error, the value of `LAST_INSERT_ID()` is

left undefined. For manual [ROLLBACK](#), the value of [LAST\\_INSERT\\_ID\(\)](#) is not restored to that before the transaction; it remains as it was at the point of the [ROLLBACK](#).

Within the body of a stored routine (procedure or function) or a trigger, the value of [LAST\\_INSERT\\_ID\(\)](#) changes the same way as for statements executed outside the body of these kinds of objects. The effect of a stored routine or trigger upon the value of [LAST\\_INSERT\\_ID\(\)](#) that is seen by following statements depends on the kind of routine:

- If a stored procedure executes statements that change the value of [LAST\\_INSERT\\_ID\(\)](#), the changed value is seen by statements that follow the procedure call.
- For stored functions and triggers that change the value, the value is restored when the function or trigger ends, so statements coming after it do not see a changed value.

The ID that was generated is maintained in the server on a *per-connection basis*. This means that the value returned by the function to a given client is the first [AUTO\\_INCREMENT](#) value generated for most recent statement affecting an [AUTO\\_INCREMENT](#) column *by that client*. This value cannot be affected by other clients, even if they generate [AUTO\\_INCREMENT](#) values of their own. This behavior ensures that each client can retrieve its own ID without concern for the activity of other clients, and without the need for locks or transactions.

The value of [LAST\\_INSERT\\_ID\(\)](#) is not changed if you set the [AUTO\\_INCREMENT](#) column of a row to a non-“magic” value (that is, a value that is not [NULL](#) and not 0).

### Important

If you insert multiple rows using a single [INSERT](#) statement, [LAST\\_INSERT\\_ID\(\)](#) returns the value generated for the *first* inserted row *only*. The reason for this is to make it possible to reproduce easily the same [INSERT](#) statement against some other server.

For example:

```
mysql> USE test;

mysql> CREATE TABLE t (
 id INT AUTO_INCREMENT NOT NULL PRIMARY KEY,
 name VARCHAR(10) NOT NULL
);

mysql> INSERT INTO t VALUES (NULL, 'Bob');

mysql> SELECT * FROM t;
+----+-----+
| id | name |
+----+-----+
| 1 | Bob |
+----+-----+

mysql> SELECT LAST_INSERT_ID();
+-----+
| LAST_INSERT_ID() |
+-----+
| 1 |
+-----+

mysql> INSERT INTO t VALUES
 (NULL, 'Mary'), (NULL, 'Jane'), (NULL, 'Lisa');

mysql> SELECT * FROM t;
+----+-----+
| id | name |
+----+-----+
| 1 | Mary |
| 2 | Jane |
| 3 | Lisa |
+----+-----+
```

id	name
1	Bob
2	Mary
3	Jane
4	Lisa

```
mysql> SELECT LAST_INSERT_ID();
+-----+
| LAST_INSERT_ID() |
+-----+
| 2 |
+-----+
```

Although the second `INSERT` statement inserted three new rows into `t`, the ID generated for the first of these rows was `2`, and it is this value that is returned by `LAST_INSERT_ID()` for the following `SELECT` statement.

If you use `INSERT IGNORE` and the row is ignored, the `LAST_INSERT_ID()` remains unchanged from the current value (or 0 is returned if the connection has not yet performed a successful `INSERT`) and, for non-transactional tables, the `AUTO_INCREMENT` counter is not incremented. For `InnoDB` tables, the `AUTO_INCREMENT` counter is incremented if `innodb_autoinc_lock_mode` is set to 1 or 2, as demonstrated in the following example:

```
mysql> USE test;

mysql> SELECT @@innodb_autoinc_lock_mode;
+-----+
| @@innodb_autoinc_lock_mode |
+-----+
| 1 |
+-----+

mysql> CREATE TABLE `t` (
 `id` INT(11) NOT NULL AUTO_INCREMENT,
 `val` INT(11) DEFAULT NULL,
 PRIMARY KEY (`id`),
 UNIQUE KEY `i1` (`val`)
) ENGINE=InnoDB;

Insert two rows

mysql> INSERT INTO t (val) VALUES (1),(2);

With auto_increment_offset=1, the inserted rows
result in an AUTO_INCREMENT value of 3

mysql> SHOW CREATE TABLE t\G
***** 1. row *****
 Table: t
Create Table: CREATE TABLE `t` (
 `id` int(11) NOT NULL AUTO_INCREMENT,
 `val` int(11) DEFAULT NULL,
 PRIMARY KEY (`id`),
 UNIQUE KEY `i1` (`val`)
) ENGINE=InnoDB AUTO_INCREMENT=3 DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci

LAST_INSERT_ID() returns the first automatically generated
value that is successfully inserted for the AUTO_INCREMENT column

mysql> SELECT LAST_INSERT_ID();
+-----+
| LAST_INSERT_ID() |
+-----+
```

```

| 1 |
+-----+

The attempted insertion of duplicate rows fail but errors are ignored

mysql> INSERT IGNORE INTO t (val) VALUES (1),(2);
Query OK, 0 rows affected (0.00 sec)
Records: 2 Duplicates: 2 Warnings: 0

With innodb_autoinc_lock_mode=1, the AUTO_INCREMENT counter
is incremented for the ignored rows

mysql> SHOW CREATE TABLE t\G
***** 1. row *****
 Table: t
Create Table: CREATE TABLE `t` (
 `id` int(11) NOT NULL AUTO_INCREMENT,
 `val` int(11) DEFAULT NULL,
 PRIMARY KEY (`id`),
 UNIQUE KEY `i1` (`val`)
) ENGINE=InnoDB AUTO_INCREMENT=5 DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci

The LAST_INSERT_ID is unchanged because the previous insert was unsuccessful

mysql> SELECT LAST_INSERT_ID();
+-----+
| LAST_INSERT_ID() |
+-----+
| 1 |
+-----+

```

For more information, see [Section 17.6.1.6, “AUTO\\_INCREMENT Handling in InnoDB”](#).

If *expr* is given as an argument to `LAST_INSERT_ID()`, the value of the argument is returned by the function and is remembered as the next value to be returned by `LAST_INSERT_ID()`. This can be used to simulate sequences:

1. Create a table to hold the sequence counter and initialize it:

```

mysql> CREATE TABLE sequence (id INT NOT NULL);
mysql> INSERT INTO sequence VALUES (0);

```

2. Use the table to generate sequence numbers like this:

```

mysql> UPDATE sequence SET id=LAST_INSERT_ID(id+1);
mysql> SELECT LAST_INSERT_ID();

```

The `UPDATE` statement increments the sequence counter and causes the next call to `LAST_INSERT_ID()` to return the updated value. The `SELECT` statement retrieves that value. The `mysql_insert_id()` C API function can also be used to get the value. See [mysql\\_insert\\_id\(\)](#).

You can generate sequences without calling `LAST_INSERT_ID()`, but the utility of using the function this way is that the ID value is maintained in the server as the last automatically generated value. It is multi-user safe because multiple clients can issue the `UPDATE` statement and get their own sequence value with the `SELECT` statement (or `mysql_insert_id()`), without affecting or being affected by other clients that generate their own sequence values.

Note that `mysql_insert_id()` is only updated after `INSERT` and `UPDATE` statements, so you cannot use the C API function to retrieve the value for `LAST_INSERT_ID(expr)` after executing other SQL statements like `SELECT` or `SET`.

- `ROLES_GRAPHML()`

Returns a `utf8mb3` string containing a GraphML document representing memory role subgraphs. The `ROLE_ADMIN` privilege (or the deprecated `SUPER` privilege) is required to see content in the `<graphml>` element. Otherwise, the result shows only an empty element:

```
mysql> SELECT ROLES_GRAPHML();
+-----+
| ROLES_GRAPHML() |
+-----+
| <?xml version="1.0" encoding="UTF-8"?><graphml /> |
+-----+
```

- `ROW_COUNT()`

`ROW_COUNT()` returns a value as follows:

- DDL statements: 0. This applies to statements such as `CREATE TABLE` or `DROP TABLE`.
- DML statements other than `SELECT`: The number of affected rows. This applies to statements such as `UPDATE`, `INSERT`, or `DELETE` (as before), but now also to statements such as `ALTER TABLE` and `LOAD DATA`.
- `SELECT`: -1 if the statement returns a result set, or the number of rows “affected” if it does not. For example, for `SELECT * FROM t1`, `ROW_COUNT()` returns -1. For `SELECT * FROM t1 INTO OUTFILE 'file_name'`, `ROW_COUNT()` returns the number of rows written to the file.
- `SIGNAL` statements: 0.

For `UPDATE` statements, the affected-rows value by default is the number of rows actually changed. If you specify the `CLIENT_FOUND_ROWS` flag to `mysql_real_connect()` when connecting to `mysqld`, the affected-rows value is the number of rows “found”; that is, matched by the `WHERE` clause.

For `REPLACE` statements, the affected-rows value is 2 if the new row replaced an old row, because in this case, one row was inserted after the duplicate was deleted.

For `INSERT ... ON DUPLICATE KEY UPDATE` statements, the affected-rows value per row is 1 if the row is inserted as a new row, 2 if an existing row is updated, and 0 if an existing row is set to its current values. If you specify the `CLIENT_FOUND_ROWS` flag, the affected-rows value is 1 (not 0) if an existing row is set to its current values.

The `ROW_COUNT()` value is similar to the value from the `mysql_affected_rows()` C API function and the row count that the `mysql` client displays following statement execution.

```
mysql> INSERT INTO t VALUES(1),(2),(3);
Query OK, 3 rows affected (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 0

mysql> SELECT ROW_COUNT();
+-----+
| ROW_COUNT() |
+-----+
| 3 |
+-----+
1 row in set (0.00 sec)

mysql> DELETE FROM t WHERE i IN(1,2);
Query OK, 2 rows affected (0.00 sec)

mysql> SELECT ROW_COUNT();
+-----+
```

```
| ROW_COUNT() |
+-----+
| 2 |
+-----+
1 row in set (0.00 sec)
```

**Important**

`ROW_COUNT()` is not replicated reliably using statement-based replication. This function is automatically replicated using row-based replication.

- `SCHEMA()`

This function is a synonym for `DATABASE()`.

- `SESSION_USER()`

`SESSION_USER()` is a synonym for `USER()`.

Like `USER()`, this function can be used for the default value of a `VARCHAR` or `TEXT` column, as shown in the following `CREATE TABLE` statement:

```
CREATE TABLE t (c VARCHAR(288) DEFAULT (SESSION_USER()));
```

- `SYSTEM_USER()`

`SYSTEM_USER()` is a synonym for `USER()`.

**Note**

The `SYSTEM_USER()` function is distinct from the `SYSTEM_USER` privilege. The former returns the current MySQL account name. The latter distinguishes the system user and regular user account categories (see [Section 8.2.11, “Account Categories”](#)).

Like `USER()`, this function can be used for the default value of a `VARCHAR` or `TEXT` column, as shown in the following `CREATE TABLE` statement:

```
CREATE TABLE t (c VARCHAR(288) DEFAULT (SYSTEM_USER()));
```

- `USER()`

Returns the current MySQL user name and host name as a string in the `utf8mb3` character set.

```
mysql> SELECT USER();
-> 'david@localhost'
```

The value indicates the user name you specified when connecting to the server, and the client host from which you connected. The value can be different from that of `CURRENT_USER()`.

This function can be used for the default value of a `VARCHAR` or `TEXT` column, as shown in the following `CREATE TABLE` statement:

```
CREATE TABLE t (c VARCHAR(288) DEFAULT (USER()));
```

- `VERSION()`

Returns a string that indicates the MySQL server version. The string uses the `utf8mb3` character set. The value might have a suffix in addition to the version number. See the description of the `version` system variable in [Section 7.1.8, “Server System Variables”](#).

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

```
mysql> SELECT VERSION();
-> '9.1.0-standard'
```

## 14.16 Spatial Analysis Functions

MySQL provides functions to perform various operations on spatial data. These functions can be grouped into several major categories according to the type of operation they perform:

- Functions that create geometries in various formats (WKT, WKB, internal)
- Functions that convert geometries between formats
- Functions that access qualitative or quantitative properties of a geometry
- Functions that describe relations between two geometries
- Functions that create new geometries from existing ones

For general background about MySQL support for using spatial data, see [Section 13.4, “Spatial Data Types”](#).

### 14.16.1 Spatial Function Reference

The following table lists each spatial function and provides a short description of each one.

**Table 14.21 Spatial Functions**

Name	Description
<code>GeomCollection()</code>	Construct geometry collection from geometries
<code>GeometryCollection()</code>	Construct geometry collection from geometries
<code>LineString()</code>	Construct LineString from Point values
<code>MBRContains()</code>	Whether MBR of one geometry contains MBR of another
<code>MBRCoveredBy()</code>	Whether one MBR is covered by another
<code>MBRCovers()</code>	Whether one MBR covers another
<code>MBRDisjoint()</code>	Whether MBRs of two geometries are disjoint
<code>MBREquals()</code>	Whether MBRs of two geometries are equal
<code>MBRIntersects()</code>	Whether MBRs of two geometries intersect
<code>MBROverlaps()</code>	Whether MBRs of two geometries overlap
<code>MBRTouches()</code>	Whether MBRs of two geometries touch
<code>MBRWithin()</code>	Whether MBR of one geometry is within MBR of another
<code>MultiLineString()</code>	Construct MultiLineString from LineString values
<code>MultiPoint()</code>	Construct MultiPoint from Point values
<code>MultiPolygon()</code>	Construct MultiPolygon from Polygon values
<code>Point()</code>	Construct Point from coordinates
<code>Polygon()</code>	Construct Polygon from LineString arguments

Name	Description
<code>ST_Area()</code>	Return Polygon or MultiPolygon area
<code>ST_AsBinary()</code> , <code>ST_AsWKB()</code>	Convert from internal geometry format to WKB
<code>ST_AsGeoJSON()</code>	Generate GeoJSON object from geometry
<code>ST_AsText()</code> , <code>ST_AsWKT()</code>	Convert from internal geometry format to WKT
<code>ST_Buffer()</code>	Return geometry of points within given distance from geometry
<code>ST_Buffer_Strategy()</code>	Produce strategy option for <code>ST_Buffer()</code>
<code>ST_Centroid()</code>	Return centroid as a point
<code>ST_Collect()</code>	Aggregate spatial values into collection
<code>ST_Contains()</code>	Whether one geometry contains another
<code>ST_ConvexHull()</code>	Return convex hull of geometry
<code>ST_Crosses()</code>	Whether one geometry crosses another
<code>ST_Difference()</code>	Return point set difference of two geometries
<code>ST_Dimension()</code>	Dimension of geometry
<code>ST_Disjoint()</code>	Whether one geometry is disjoint from another
<code>ST_Distance()</code>	The distance of one geometry from another
<code>ST_Distance_Sphere()</code>	Minimum distance on earth between two geometries
<code>ST_EndPoint()</code>	End Point of LineString
<code>ST_Envelope()</code>	Return MBR of geometry
<code>ST_Equals()</code>	Whether one geometry is equal to another
<code>ST_ExteriorRing()</code>	Return exterior ring of Polygon
<code>ST_FrechetDistance()</code>	The discrete Fréchet distance of one geometry from another
<code>ST_GeoHash()</code>	Produce a geohash value
<code>ST_GeomCollFromText()</code> , <code>ST_GeometryCollectionFromText()</code> , <code>ST_GeomCollFromTxt()</code>	Return geometry collection from WKT
<code>ST_GeomCollFromWKB()</code> , <code>ST_GeometryCollectionFromWKB()</code>	Return geometry collection from WKB
<code>ST_GeometryN()</code>	Return N-th geometry from geometry collection
<code>ST_GeometryType()</code>	Return name of geometry type
<code>ST_GeomFromGeoJSON()</code>	Generate geometry from GeoJSON object
<code>ST_GeomFromText()</code> , <code>ST_GeometryFromText()</code>	Return geometry from WKT
<code>ST_GeomFromWKB()</code> , <code>ST_GeometryFromWKB()</code>	Return geometry from WKB
<code>ST_HausdorffDistance()</code>	The discrete Hausdorff distance of one geometry from another
<code>ST_InteriorRingN()</code>	Return N-th interior ring of Polygon
<code>ST_Intersection()</code>	Return point set intersection of two geometries
<code>ST_Intersects()</code>	Whether one geometry intersects another

Name	Description
<code>ST_IsClosed()</code>	Whether a geometry is closed and simple
<code>ST_IsEmpty()</code>	Whether a geometry is empty
<code>ST_IsSimple()</code>	Whether a geometry is simple
<code>ST_IsValid()</code>	Whether a geometry is valid
<code>ST_LatFromGeoHash()</code>	Return latitude from geohash value
<code>ST_Latitude()</code>	Return latitude of Point
<code>ST_Length()</code>	Return length of LineString
<code>ST_LineFromText()</code> , <code>ST_LineStringFromText()</code>	Construct LineString from WKT
<code>ST_LineFromWKB()</code> , <code>ST_LineStringFromWKB()</code>	Construct LineString from WKB
<code>ST_LineInterpolatePoint()</code>	The point a given percentage along a LineString
<code>ST_LineInterpolatePoints()</code>	The points a given percentage along a LineString
<code>ST_LongFromGeoHash()</code>	Return longitude from geohash value
<code>ST_Longitude()</code>	Return longitude of Point
<code>ST_MakeEnvelope()</code>	Rectangle around two points
<code>ST_MLineFromText()</code> , <code>ST_MultiLineStringFromText()</code>	Construct MultiLineString from WKT
<code>ST_MLineFromWKB()</code> , <code>ST_MultiLineStringFromWKB()</code>	Construct MultiLineString from WKB
<code>ST_MPointFromText()</code> , <code>ST_MultiPointFromText()</code>	Construct MultiPoint from WKT
<code>ST_MPointFromWKB()</code> , <code>ST_MultiPointFromWKB()</code>	Construct MultiPoint from WKB
<code>ST_MPolyFromText()</code> , <code>ST_MultiPolygonFromText()</code>	Construct MultiPolygon from WKT
<code>ST_MPolyFromWKB()</code> , <code>ST_MultiPolygonFromWKB()</code>	Construct MultiPolygon from WKB
<code>ST_NumGeometries()</code>	Return number of geometries in geometry collection
<code>ST_NumInteriorRing()</code> , <code>ST_NumInteriorRings()</code>	Return number of interior rings in Polygon
<code>ST_NumPoints()</code>	Return number of points in LineString
<code>ST_Overlaps()</code>	Whether one geometry overlaps another
<code>ST_PointAtDistance()</code>	The point a given distance along a LineString
<code>ST_PointFromGeoHash()</code>	Convert geohash value to POINT value
<code>ST_PointFromText()</code>	Construct Point from WKT
<code>ST_PointFromWKB()</code>	Construct Point from WKB
<code>ST_PointN()</code>	Return N-th point from LineString
<code>ST_PolyFromText()</code> , <code>ST_PolygonFromText()</code>	Construct Polygon from WKT
<code>ST_PolyFromWKB()</code> , <code>ST_PolygonFromWKB()</code>	Construct Polygon from WKB

Name	Description
<code>ST_Simplify()</code>	Return simplified geometry
<code>ST_SRID()</code>	Return spatial reference system ID for geometry
<code>ST_StartPoint()</code>	Start Point of LineString
<code>ST_SwapXY()</code>	Return argument with X/Y coordinates swapped
<code>ST_SymDifference()</code>	Return point set symmetric difference of two geometries
<code>ST_Touches()</code>	Whether one geometry touches another
<code>ST_Transform()</code>	Transform coordinates of geometry
<code>ST_Union()</code>	Return point set union of two geometries
<code>ST_Validate()</code>	Return validated geometry
<code>ST_Within()</code>	Whether one geometry is within another
<code>ST_X()</code>	Return X coordinate of Point
<code>ST_Y()</code>	Return Y coordinate of Point

## 14.16.2 Argument Handling by Spatial Functions

Spatial values, or geometries, have the properties described in [Section 13.4.2.2, “Geometry Class”](#). The following discussion lists general spatial function argument-handling characteristics. Specific functions or groups of functions may have additional or different argument-handling characteristics, as discussed in the sections where those function descriptions occur. Where that is true, those descriptions take precedence over the general discussion here.

Spatial functions are defined only for valid geometry values. See [Section 13.4.4, “Geometry Well-Formedness and Validity”](#).

Each geometry value is associated with a spatial reference system (SRS), which is a coordinate-based system for geographic locations. See [Section 13.4.5, “Spatial Reference System Support”](#).

The spatial reference identifier (SRID) of a geometry identifies the SRS in which the geometry is defined. In MySQL, the SRID value is an integer associated with the geometry value. The maximum usable SRID value is  $2^{32}-1$ . If a larger value is given, only the lower 32 bits are used.

SRID 0 represents an infinite flat Cartesian plane with no units assigned to its axes. To ensure SRID 0 behavior, create geometry values using SRID 0. SRID 0 is the default for new geometry values if no SRID is specified.

For computations on multiple geometry values, all values must be in the same SRS or an error occurs. Thus, spatial functions that take multiple geometry arguments require those arguments to be in the same SRS. If a spatial function returns `ER_GIS_DIFFERENT_SRIDS`, it means that the geometry arguments were not all in the same SRS. You must modify them to have the same SRS.

A geometry returned by a spatial function is in the SRS of the geometry arguments because geometry values produced by any spatial function inherit the SRID of the geometry arguments.

The [Open Geospatial Consortium](#) guidelines require that input polygons already be closed, so unclosed polygons are rejected as invalid rather than being closed.

In MySQL, the only valid empty geometry is represented in the form of an empty geometry collection. Empty geometry collection handling is as follows: An empty WKT input geometry collection may be

specified as `'GEOMETRYCOLLECTION()'` . This is also the output WKT resulting from a spatial operation that produces an empty geometry collection.

During parsing of a nested geometry collection, the collection is flattened and its basic components are used in various GIS operations to compute results. This provides additional flexibility to users because it is unnecessary to be concerned about the uniqueness of geometry data. Nested geometry collections may be produced from nested GIS function calls without having to be explicitly flattened first.

### 14.16.3 Functions That Create Geometry Values from WKT Values

These functions take as arguments a Well-Known Text (WKT) representation and, optionally, a spatial reference system identifier (SRID). They return the corresponding geometry. For a description of WKT format, see [Well-Known Text \(WKT\) Format](#).

Functions in this section detect arguments in either Cartesian or geographic spatial reference systems (SRSS), and return results appropriate to the SRS.

`ST_GeomFromText()` accepts a WKT value of any geometry type as its first argument. Other functions provide type-specific construction functions for construction of geometry values of each geometry type.

Functions such as `ST_MPointFromText()` and `ST_GeomFromText()` that accept WKT-format representations of `MultiPoint` values permit individual points within values to be surrounded by parentheses. For example, both of the following function calls are valid:

```
ST_MPointFromText('MULTIPOINT (1 1, 2 2, 3 3)')
ST_MPointFromText('MULTIPOINT ((1 1), (2 2), (3 3))')
```

Functions such as `ST_GeomFromText()` that accept WKT geometry collection arguments understand both OpenGIS `'GEOMETRYCOLLECTION EMPTY'` standard syntax and MySQL `'GEOMETRYCOLLECTION()'`  nonstandard syntax. Functions such as `ST_AsWKT()` that produce WKT values produce `'GEOMETRYCOLLECTION EMPTY'` standard syntax:

```
mysql> SET @s1 = ST_GeomFromText('GEOMETRYCOLLECTION()');
mysql> SET @s2 = ST_GeomFromText('GEOMETRYCOLLECTION EMPTY');
mysql> SELECT ST_AsWKT(@s1), ST_AsWKT(@s2);
+-----+-----+
| ST_AsWKT(@s1) | ST_AsWKT(@s2) |
+-----+-----+
| GEOMETRYCOLLECTION EMPTY | GEOMETRYCOLLECTION EMPTY |
+-----+-----+
```

Unless otherwise specified, functions in this section handle their geometry arguments as follows:

- If any geometry argument is `NULL` or is not a syntactically well-formed geometry, or if the SRID argument is `NULL`, the return value is `NULL`.
- By default, geographic coordinates (latitude, longitude) are interpreted as in the order specified by the spatial reference system of geometry arguments. An optional `options` argument may be given to override the default axis order. `options` consists of a list of comma-separated `key=value`. The only permitted `key` value is `axis-order`, with permitted values of `lat-long`, `long-lat` and `srid-defined` (the default).

If the `options` argument is `NULL`, the return value is `NULL`. If the `options` argument is invalid, an error occurs to indicate why.

- If an SRID argument refers to an undefined spatial reference system (SRS), an `ER_SRS_NOT_FOUND` error occurs.
- For geographic SRS geometry arguments, if any argument has a longitude or latitude that is out of range, an error occurs:

- If a longitude value is not in the range  $(-180, 180]$ , an `ER_LONGITUDE_OUT_OF_RANGE` error occurs.
- If a latitude value is not in the range  $[-90, 90]$ , an `ER_LATITUDE_OUT_OF_RANGE` error occurs.

Ranges shown are in degrees. If an SRS uses another unit, the range uses the corresponding values in its unit. The exact range limits deviate slightly due to floating-point arithmetic.

These functions are available for creating geometries from WKT values:

- `ST_GeomCollFromText(wkt [, srid [, options]])`,  
`ST_GeometryCollectionFromText(wkt [, srid [, options]])`,  
`ST_GeomCollFromText(wkt [, srid [, options]])`

Constructs a `GeometryCollection` value using its WKT representation and SRID.

These functions handle their arguments as described in the introduction to this section.

```
mysql> SET @g = "MULTILINESTRING((10 10, 11 11), (9 9, 10 10));"
mysql> SELECT ST_AsText(ST_GeomCollFromText(@g));
+-----+
| ST_AsText(ST_GeomCollFromText(@g)) |
+-----+
| MULTILINESTRING((10 10,11 11),(9 9,10 10)) |
+-----+
```

- `ST_GeomFromText(wkt [, srid [, options]])`, `ST_GeometryFromText(wkt [, srid [, options]])`

Constructs a geometry value of any type using its WKT representation and SRID.

These functions handle their arguments as described in the introduction to this section.

- `ST_LineFromText(wkt [, srid [, options]])`, `ST_LineStringFromText(wkt [, srid [, options]])`

Constructs a `LineString` value using its WKT representation and SRID.

These functions handle their arguments as described in the introduction to this section.

- `ST_MLineFromText(wkt [, srid [, options]])`, `ST_MultiLineStringFromText(wkt [, srid [, options]])`

Constructs a `MultiLineString` value using its WKT representation and SRID.

These functions handle their arguments as described in the introduction to this section.

- `ST_MPointFromText(wkt [, srid [, options]])`, `ST_MultiPointFromText(wkt [, srid [, options]])`

Constructs a `MultiPoint` value using its WKT representation and SRID.

These functions handle their arguments as described in the introduction to this section.

- `ST_MPolyFromText(wkt [, srid [, options]])`, `ST_MultiPolygonFromText(wkt [, srid [, options]])`

Constructs a `MultiPolygon` value using its WKT representation and SRID.

These functions handle their arguments as described in the introduction to this section.

- `ST_PointFromText(wkt [, srid [, options]])`

Constructs a `Point` value using its WKT representation and SRID.

`ST_PointFromText()` handles its arguments as described in the introduction to this section.

- `ST_PolyFromText(wkt [, srid [, options]]), ST_PolygonFromText(wkt [, srid [, options]])`

Constructs a `Polygon` value using its WKT representation and SRID.

These functions handle their arguments as described in the introduction to this section.

## 14.16.4 Functions That Create Geometry Values from WKB Values

These functions take as arguments a `BLOB` containing a Well-Known Binary (WKB) representation and, optionally, a spatial reference system identifier (SRID). They return the corresponding geometry. For a description of WKB format, see [Well-Known Binary \(WKB\) Format](#).

Functions in this section detect arguments in either Cartesian or geographic spatial reference systems (SRSS), and return results appropriate to the SRS.

`ST_GeomFromWKB()` accepts a WKB value of any geometry type as its first argument. Other functions provide type-specific construction functions for construction of geometry values of each geometry type.

Prior to MySQL 9.1, these functions also accepted geometry objects as returned by the functions in [Section 14.16.5, “MySQL-Specific Functions That Create Geometry Values”](#). Geometry arguments are no longer permitted and produce an error. To migrate calls from using geometry arguments to using WKB arguments, follow these guidelines:

- Rewrite constructs such as `ST_GeomFromWKB(Point(0, 0))` as `Point(0, 0)`.
- Rewrite constructs such as `ST_GeomFromWKB(Point(0, 0), 4326)` as `ST_SRID(Point(0, 0), 4326)` or `ST_GeomFromWKB(ST_AsWKB(Point(0, 0)), 4326)`.

Unless otherwise specified, functions in this section handle their geometry arguments as follows:

- If the WKB or SRID argument is `NULL`, the return value is `NULL`.
- By default, geographic coordinates (latitude, longitude) are interpreted as in the order specified by the spatial reference system of geometry arguments. An optional `options` argument may be given to override the default axis order. `options` consists of a list of comma-separated `key=value`. The only permitted `key` value is `axis-order`, with permitted values of `lat-long`, `long-lat` and `srid-defined` (the default).

If the `options` argument is `NULL`, the return value is `NULL`. If the `options` argument is invalid, an error occurs to indicate why.

- If an SRID argument refers to an undefined spatial reference system (SRS), an `ER_SRS_NOT_FOUND` error occurs.
- For geographic SRS geometry arguments, if any argument has a longitude or latitude that is out of range, an error occurs:
  - If a longitude value is not in the range  $(-180, 180]$ , an `ER_LONGITUDE_OUT_OF_RANGE` error occurs.
  - If a latitude value is not in the range  $[-90, 90]$ , an `ER_LATITUDE_OUT_OF_RANGE` error occurs.

Ranges shown are in degrees. If an SRS uses another unit, the range uses the corresponding values in its unit. The exact range limits deviate slightly due to floating-point arithmetic.

These functions are available for creating geometries from WKB values:

- `ST_GeomCollFromWKB(wkb [, srid [, options]]), ST_GeometryCollectionFromWKB(wkb [, srid [, options]])`

Constructs a `GeometryCollection` value using its WKB representation and SRID.

These functions handle their arguments as described in the introduction to this section.

- `ST_GeomFromWKB(wkb [, srid [, options]]), ST_GeometryFromWKB(wkb [, srid [, options]])`

Constructs a geometry value of any type using its WKB representation and SRID.

These functions handle their arguments as described in the introduction to this section.

- `ST_LineFromWKB(wkb [, srid [, options]]), ST_LineStringFromWKB(wkb [, srid [, options]])`

Constructs a `LineString` value using its WKB representation and SRID.

These functions handle their arguments as described in the introduction to this section.

- `ST_MLineFromWKB(wkb [, srid [, options]]), ST_MultiLineStringFromWKB(wkb [, srid [, options]])`

Constructs a `MultiLineString` value using its WKB representation and SRID.

These functions handle their arguments as described in the introduction to this section.

- `ST_MPointFromWKB(wkb [, srid [, options]]), ST_MultiPointFromWKB(wkb [, srid [, options]])`

Constructs a `MultiPoint` value using its WKB representation and SRID.

These functions handle their arguments as described in the introduction to this section.

- `ST_MPolyFromWKB(wkb [, srid [, options]]), ST_MultiPolygonFromWKB(wkb [, srid [, options]])`

Constructs a `MultiPolygon` value using its WKB representation and SRID.

These functions handle their arguments as described in the introduction to this section.

- `ST_PointFromWKB(wkb [, srid [, options]])`

Constructs a `Point` value using its WKB representation and SRID.

`ST_PointFromWKB()` handles its arguments as described in the introduction to this section.

- `ST_PolyFromWKB(wkb [, srid [, options]]), ST_PolygonFromWKB(wkb [, srid [, options]])`

Constructs a `Polygon` value using its WKB representation and SRID.

These functions handle their arguments as described in the introduction to this section.

## 14.16.5 MySQL-Specific Functions That Create Geometry Values

MySQL provides a set of useful nonstandard functions for creating geometry values. The functions described in this section are MySQL extensions to the OpenGIS specification.

These functions produce geometry objects from either WKB values or geometry objects as arguments. If any argument is not a proper WKB or geometry representation of the proper object type, the return value is `NULL`.

For example, you can insert the geometry return value from `Point()` directly into a `POINT` column:

```
INSERT INTO t1 (pt_col) VALUES(Point(1,2));
```

- `GeomCollection(g [, g] ...)`

Constructs a `GeomCollection` value from the geometry arguments.

`GeomCollection()` returns all the proper geometries contained in the arguments even if a nonsupported geometry is present.

`GeomCollection()` with no arguments is permitted as a way to create an empty geometry. Also, functions such as `ST_GeomFromText()` that accept WKT geometry collection arguments understand both OpenGIS '`GEOMETRYCOLLECTION EMPTY`' standard syntax and MySQL '`GEOMETRYCOLLECTION()`' nonstandard syntax.

`GeomCollection()` and `GeometryCollection()` are synonymous, with `GeomCollection()` the preferred function.

- `GeometryCollection(g [, g] ...)`

Constructs a `GeomCollection` value from the geometry arguments.

`GeometryCollection()` returns all the proper geometries contained in the arguments even if a nonsupported geometry is present.

`GeometryCollection()` with no arguments is permitted as a way to create an empty geometry. Also, functions such as `ST_GeomFromText()` that accept WKT geometry collection arguments understand both OpenGIS '`GEOMETRYCOLLECTION EMPTY`' standard syntax and MySQL '`GEOMETRYCOLLECTION()`' nonstandard syntax.

`GeomCollection()` and `GeometryCollection()` are synonymous, with `GeomCollection()` the preferred function.

- `LineString(pt [, pt] ...)`

Constructs a `LineString` value from a number of `Point` or WKB `Point` arguments. If the number of arguments is less than two, the return value is `NULL`.

- `MultiLineString(ls [, ls] ...)`

Constructs a `MultiLineString` value using `LineString` or WKB `LineString` arguments.

- `MultiPoint(pt [, pt2] ...)`

Constructs a `MultiPoint` value using `Point` or WKB `Point` arguments.

- `MultiPolygon(poly [, poly] ...)`

Constructs a `MultiPolygon` value from a set of `Polygon` or WKB `Polygon` arguments.

- `Point(x, y)`

Constructs a `Point` using its coordinates.

- `Polygon(ls [, ls] ...)`

Constructs a `Polygon` value from a number of `LineString` or WKB `LineString` arguments. If any argument does not represent a `LinearRing` (that is, not a closed and simple `LineString`), the return value is `NULL`.

## 14.16.6 Geometry Format Conversion Functions

MySQL supports the functions listed in this section for converting geometry values from internal geometry format to WKT or WKB format, or for swapping the order of X and Y coordinates.

There are also functions to convert a string from WKT or WKB format to internal geometry format. See [Section 14.16.3, “Functions That Create Geometry Values from WKT Values”](#), and [Section 14.16.4, “Functions That Create Geometry Values from WKB Values”](#).

Functions such as `ST_GeomFromText()` that accept WKT geometry collection arguments understand both OpenGIS `'GEOMETRYCOLLECTION EMPTY'` standard syntax and MySQL `'GEOMETRYCOLLECTION()'` nonstandard syntax. Another way to produce an empty geometry collection is by calling `GeometryCollection()` with no arguments. Functions such as `ST_AsWKT()` that produce WKT values produce `'GEOMETRYCOLLECTION EMPTY'` standard syntax:

```
mysql> SET @s1 = ST_GeomFromText('GEOMETRYCOLLECTION()');
mysql> SET @s2 = ST_GeomFromText('GEOMETRYCOLLECTION EMPTY');
mysql> SELECT ST_AsWKT(@s1), ST_AsWKT(@s2);
+-----+-----+
| ST_AsWKT(@s1) | ST_AsWKT(@s2) |
+-----+-----+
| GEOMETRYCOLLECTION EMPTY | GEOMETRYCOLLECTION EMPTY |
+-----+-----+
mysql> SELECT ST_AsWKT(GeomCollection());
+-----+
| ST_AsWKT(GeomCollection()) |
+-----+
| GEOMETRYCOLLECTION EMPTY |
+-----+
```

Unless otherwise specified, functions in this section handle their geometry arguments as follows:

- If any argument is `NULL`, the return value is `NULL`.
- If any geometry argument is not a syntactically well-formed geometry, an `ER_GIS_INVALID_DATA` error occurs.
- If any geometry argument is in an undefined spatial reference system, the axes are output in the order they appear in the geometry and an `ER_WARN_SRS_NOT_FOUND_AXIS_ORDER` warning occurs.
- By default, geographic coordinates (latitude, longitude) are interpreted as in the order specified by the spatial reference system of geometry arguments. An optional `options` argument may be given to override the default axis order. `options` consists of a list of comma-separated `key=value`. The only permitted `key` value is `axis-order`, with permitted values of `lat-long`, `long-lat` and `srid-defined` (the default).

If the *options* argument is `NULL`, the return value is `NULL`. If the *options* argument is invalid, an error occurs to indicate why.

- Otherwise, the return value is non-`NULL`.

These functions are available for format conversions or coordinate swapping:

- `ST_AsBinary(g [, options]), ST_AsWKB(g [, options])`

Converts a value in internal geometry format to its WKB representation and returns the binary result.

The function return value has geographic coordinates (latitude, longitude) in the order specified by the spatial reference system that applies to the geometry argument. An optional *options* argument may be given to override the default axis order.

`ST_AsBinary()` and `ST_AsWKB()` handle their arguments as described in the introduction to this section.

```
mysql> SET @g = ST_LineFromText('LINESTRING(0 5,5 10,10 15)', 4326);
mysql> SELECT ST_AsText(ST_GeomFromWKB(ST_AsWKB(@g)));
+-----+
| ST_AsText(ST_GeomFromWKB(ST_AsWKB(@g))) |
+-----+
| LINESTRING(5 0,10 5,15 10) |
+-----+
mysql> SELECT ST_AsText(ST_GeomFromWKB(ST_AsWKB(@g, 'axis-order=long-lat')));
+-----+
| ST_AsText(ST_GeomFromWKB(ST_AsWKB(@g, 'axis-order=long-lat'))) |
+-----+
| LINESTRING(0 5,5 10,10 15) |
+-----+
mysql> SELECT ST_AsText(ST_GeomFromWKB(ST_AsWKB(@g, 'axis-order=lat-long')));
+-----+
| ST_AsText(ST_GeomFromWKB(ST_AsWKB(@g, 'axis-order=lat-long'))) |
+-----+
| LINESTRING(5 0,10 5,15 10) |
+-----+
```

- `ST_AsText(g [, options]), ST_AsWKT(g [, options])`

Converts a value in internal geometry format to its WKT representation and returns the string result.

The function return value has geographic coordinates (latitude, longitude) in the order specified by the spatial reference system that applies to the geometry argument. An optional *options* argument may be given to override the default axis order.

`ST_AsText()` and `ST_AsWKT()` handle their arguments as described in the introduction to this section.

```
mysql> SET @g = 'LineString(1 1,2 2,3 3)';
mysql> SELECT ST_AsText(ST_GeomFromText(@g));
+-----+
| ST_AsText(ST_GeomFromText(@g)) |
+-----+
| LINESTRING(1 1,2 2,3 3) |
+-----+
```

Output for `MultiPoint` values includes parentheses around each point. For example:

```
mysql> SELECT ST_AsText(ST_GeomFromText(@mp));
+-----+
| ST_AsText(ST_GeomFromText(@mp)) |
+-----+
```

```
+-----+
| MULTIPOINT((1 1),(2 2),(3 3)) |
+-----+
```

- [ST\\_SwapXY\(\*g\*\)](#)

Accepts an argument in internal geometry format, swaps the X and Y values of each coordinate pair within the geometry, and returns the result.

[ST\\_SwapXY\(\)](#) handles its arguments as described in the introduction to this section.

```
mysql> SET @g = ST_LineFromText('LINESTRING(0 5,5 10,10 15)');
mysql> SELECT ST_AsText(@g);
+-----+
| ST_AsText(@g) |
+-----+
| LINESTRING(0 5,5 10,10 15) |
+-----+
mysql> SELECT ST_AsText(ST_SwapXY(@g));
+-----+
| ST_AsText(ST_SwapXY(@g)) |
+-----+
| LINESTRING(5 0,10 5,15 10) |
+-----+
```

## 14.16.7 Geometry Property Functions

Each function that belongs to this group takes a geometry value as its argument and returns some quantitative or qualitative property of the geometry. Some functions restrict their argument type. Such functions return [NULL](#) if the argument is of an incorrect geometry type. For example, the [ST\\_Area\(\)](#) polygon function returns [NULL](#) if the object type is neither [Polygon](#) nor [MultiPolygon](#).

### 14.16.7.1 General Geometry Property Functions

The functions listed in this section do not restrict their argument and accept a geometry value of any type.

Unless otherwise specified, functions in this section handle their geometry arguments as follows:

- If any argument is [NULL](#), the return value is [NULL](#).
- If any geometry argument is not a syntactically well-formed geometry, an [ER\\_GIS\\_INVALID\\_DATA](#) error occurs.
- If any geometry argument is a syntactically well-formed geometry in an undefined spatial reference system (SRS), an [ER\\_SRS\\_NOT\\_FOUND](#) error occurs.
- If any SRID argument is not within the range of a 32-bit unsigned integer, an [ER\\_DATA\\_OUT\\_OF\\_RANGE](#) error occurs.
- If any SRID argument refers to an undefined SRS, an [ER\\_SRS\\_NOT\\_FOUND](#) error occurs.
- Otherwise, the return value is non-[NULL](#).

These functions are available for obtaining geometry properties:

- [ST\\_Dimension\(\*g\*\)](#)

Returns the inherent dimension of the geometry value *g*. The dimension can be -1, 0, 1, or 2. The meaning of these values is given in [Section 13.4.2.2, “Geometry Class”](#).

[ST\\_Dimension\(\)](#) handles its arguments as described in the introduction to this section.

```
mysql> SELECT ST_Dimension(ST_GeomFromText('LineString(1 1,2 2)'));
+-----+
| ST_Dimension(ST_GeomFromText('LineString(1 1,2 2)')) |
+-----+
| 1 |
+-----+
```

- `ST_Envelope(g)`

Returns the minimum bounding rectangle (MBR) for the geometry value *g*. The result is returned as a `Polygon` value that is defined by the corner points of the bounding box:

```
POLYGON((MINX MINY, MAXX MINY, MAXX MAXY, MINX MAXY, MINX MINY))
```

```
mysql> SELECT ST_AsText(ST_Envelope(ST_GeomFromText('LineString(1 1,2 2)')));
+-----+
| ST_AsText(ST_Envelope(ST_GeomFromText('LineString(1 1,2 2)')) |
+-----+
| POLYGON((1 1,2 1,2 2,1 2,1 1)) |
+-----+
```

If the argument is a point or a vertical or horizontal line segment, `ST_Envelope()` returns the point or the line segment as its MBR rather than returning an invalid polygon:

```
mysql> SELECT ST_AsText(ST_Envelope(ST_GeomFromText('LineString(1 1,1 2)')));
+-----+
| ST_AsText(ST_Envelope(ST_GeomFromText('LineString(1 1,1 2)')) |
+-----+
| LINESTRING(1 1,1 2) |
+-----+
```

`ST_Envelope()` handles its arguments as described in the introduction to this section, with this exception:

- If the geometry has an SRID value for a geographic spatial reference system (SRS), an `ER_NOT_IMPLEMENTED_FOR_GEOGRAPHIC_SRS` error occurs.
- `ST_GeometryType(g)`

Returns a binary string indicating the name of the geometry type of which the geometry instance *g* is a member. The name corresponds to one of the instantiable `Geometry` subclasses.

`ST_GeometryType()` handles its arguments as described in the introduction to this section.

```
mysql> SELECT ST_GeometryType(ST_GeomFromText('POINT(1 1)'));
+-----+
| ST_GeometryType(ST_GeomFromText('POINT(1 1)')) |
+-----+
| POINT |
+-----+
```

- `ST_IsEmpty(g)`

This function is a placeholder that returns 1 for an empty geometry collection value or 0 otherwise.

The only valid empty geometry is represented in the form of an empty geometry collection value. MySQL does not support GIS `EMPTY` values such as `POINT EMPTY`.

`ST_IsEmpty()` handles its arguments as described in the introduction to this section.

- `ST_IsSimple(g)`

Returns 1 if the geometry value *g* is simple according to the ISO *SQL/MM Part 3: Spatial* standard. `ST_IsSimple()` returns 0 if the argument is not simple.

The descriptions of the instantiable geometric classes given under [Section 13.4.2, “The OpenGIS Geometry Model”](#) include the specific conditions that cause class instances to be classified as not simple.

`ST_IsSimple()` handles its arguments as described in the introduction to this section, with this exception:

- If the geometry has a geographic SRS with a longitude or latitude that is out of range, an error occurs:
  - If a longitude value is not in the range  $(-180, 180]$ , an `ER_GEOMETRY_PARAM_LONGITUDE_OUT_OF_RANGE` error occurs.
  - If a latitude value is not in the range  $[-90, 90]$ , an `ER_GEOMETRY_PARAM_LATITUDE_OUT_OF_RANGE` error occurs.

Ranges shown are in degrees. The exact range limits deviate slightly due to floating-point arithmetic.

- `ST_SRID(g [, srid])`

With a single argument representing a valid geometry object *g*, `ST_SRID()` returns an integer indicating the ID of the spatial reference system (SRS) associated with *g*.

With the optional second argument representing a valid SRID value, `ST_SRID()` returns an object with the same type as its first argument with an SRID value equal to the second argument. This only sets the SRID value of the object; it does not perform any transformation of coordinate values.

`ST_SRID()` handles its arguments as described in the introduction to this section, with this exception:

- For the single-argument syntax, `ST_SRID()` returns the geometry SRID even if it refers to an undefined SRS. An `ER_SRS_NOT_FOUND` error does not occur.

`ST_SRID(g, target_srid)` and `ST_Transform(g, target_srid)` differ as follows:

- `ST_SRID()` changes the geometry SRID value without transforming its coordinates.
- `ST_Transform()` transforms the geometry coordinates in addition to changing its SRID value.

```
mysql> SET @g = ST_GeomFromText('LineString(1 1,2 2)', 0);
mysql> SELECT ST_SRID(@g);
+-----+
| ST_SRID(@g) |
+-----+
| 0 |
+-----+
mysql> SET @g = ST_SRID(@g, 4326);
mysql> SELECT ST_SRID(@g);
+-----+
| ST_SRID(@g) |
+-----+
| 4326 |
+-----+
```

It is possible to create a geometry in a particular SRID by passing to `ST_SRID()` the result of one of the MySQL-specific functions for creating spatial values, along with an SRID value. For example:

```
SET @g1 = ST_SRID(Point(1, 1), 4326);
```

However, that method creates the geometry in SRID 0, then casts it to SRID 4326 (WGS 84). A preferable alternative is to create the geometry with the correct spatial reference system to begin with. For example:

```
SET @g1 = ST_PointFromText('POINT(1 1)', 4326);
SET @g1 = ST_GeomFromText('POINT(1 1)', 4326);
```

The two-argument form of `ST_SRID()` is useful for tasks such as correcting or changing the SRS of geometries that have an incorrect SRID.

### 14.16.7.2 Point Property Functions

A `Point` consists of X and Y coordinates, which may be obtained using the `ST_X()` and `ST_Y()` functions, respectively. These functions also permit an optional second argument that specifies an X or Y coordinate value, in which case the function result is the `Point` object from the first argument with the appropriate coordinate modified to be equal to the second argument.

For `Point` objects that have a geographic spatial reference system (SRS), the longitude and latitude may be obtained using the `ST_Longitude()` and `ST_Latitude()` functions, respectively. These functions also permit an optional second argument that specifies a longitude or latitude value, in which case the function result is the `Point` object from the first argument with the longitude or latitude modified to be equal to the second argument.

Unless otherwise specified, functions in this section handle their geometry arguments as follows:

- If any argument is `NULL`, the return value is `NULL`.
- If any geometry argument is a valid geometry but not a `Point` object, an `ER_UNEXPECTED_GEOMETRY_TYPE` error occurs.
- If any geometry argument is not a syntactically well-formed geometry, an `ER_GIS_INVALID_DATA` error occurs.
- If any geometry argument is a syntactically well-formed geometry in an undefined spatial reference system (SRS), an `ER_SRS_NOT_FOUND` error occurs.
- If an X or Y coordinate argument is provided and the value is `-inf`, `+inf`, or `NaN`, an `ER_DATA_OUT_OF_RANGE` error occurs.
- If a longitude or latitude value is out of range, an error occurs:
  - If a longitude value is not in the range  $(-180, 180]$ , an `ER_LONGITUDE_OUT_OF_RANGE` error occurs.
  - If a latitude value is not in the range  $[-90, 90]$ , an `ER_LATITUDE_OUT_OF_RANGE` error occurs.

Ranges shown are in degrees. The exact range limits deviate slightly due to floating-point arithmetic.

- Otherwise, the return value is non-`NULL`.

These functions are available for obtaining point properties:

- `ST_Latitude(p [, new_latitude_val])`

With a single argument representing a valid `Point` object `p` that has a geographic spatial reference system (SRS), `ST_Latitude()` returns the latitude value of `p` as a double-precision number.

With the optional second argument representing a valid latitude value, `ST_Latitude()` returns a `Point` object like the first argument with its latitude equal to the second argument.

`ST_Latitude()` handles its arguments as described in the introduction to this section, with the addition that if the `Point` object is valid but does not have a geographic SRS, an `ER_SRS_NOT_GEOGRAPHIC` error occurs.

```
mysql> SET @pt = ST_GeomFromText('POINT(45 90)', 4326);
mysql> SELECT ST_Latitude(@pt);
+-----+
| ST_Latitude(@pt) |
+-----+
| 45 |
+-----+
mysql> SELECT ST_AsText(ST_Latitude(@pt, 10));
+-----+
| ST_AsText(ST_Latitude(@pt, 10)) |
+-----+
| POINT(10 90) |
+-----+
```

- `ST_Longitude(p [, new_longitude_val])`

With a single argument representing a valid `Point` object `p` that has a geographic spatial reference system (SRS), `ST_Longitude()` returns the longitude value of `p` as a double-precision number.

With the optional second argument representing a valid longitude value, `ST_Longitude()` returns a `Point` object like the first argument with its longitude equal to the second argument.

`ST_Longitude()` handles its arguments as described in the introduction to this section, with the addition that if the `Point` object is valid but does not have a geographic SRS, an `ER_SRS_NOT_GEOGRAPHIC` error occurs.

```
mysql> SET @pt = ST_GeomFromText('POINT(45 90)', 4326);
mysql> SELECT ST_Longitude(@pt);
+-----+
| ST_Longitude(@pt) |
+-----+
| 90 |
+-----+
mysql> SELECT ST_AsText(ST_Longitude(@pt, 10));
+-----+
| ST_AsText(ST_Longitude(@pt, 10)) |
+-----+
| POINT(45 10) |
+-----+
```

- `ST_X(p [, new_x_val])`

With a single argument representing a valid `Point` object `p`, `ST_X()` returns the X-coordinate value of `p` as a double-precision number. The X coordinate is considered to refer to the axis that appears first in the `Point` spatial reference system (SRS) definition.

With the optional second argument, `ST_X()` returns a `Point` object like the first argument with its X coordinate equal to the second argument. If the `Point` object has a geographic SRS, the second argument must be in the proper range for longitude or latitude values.

`ST_X()` handles its arguments as described in the introduction to this section.

```
mysql> SELECT ST_X(Point(56.7, 53.34));
+-----+
| ST_X(Point(56.7, 53.34)) |
+-----+
| 56.7 |
+-----+
```

```
+-----+
mysql> SELECT ST_AsText(ST_X(Point(56.7, 53.34), 10.5));
+-----+
| ST_AsText(ST_X(Point(56.7, 53.34), 10.5)) |
+-----+
| POINT(10.5 53.34) |
+-----+
```

- `ST_Y(p [, new_y_val])`

With a single argument representing a valid `Point` object `p`, `ST_Y()` returns the Y-coordinate value of `p` as a double-precision number. The Y coordinate is considered to refer to the axis that appears second in the `Point` spatial reference system (SRS) definition.

With the optional second argument, `ST_Y()` returns a `Point` object like the first argument with its Y coordinate equal to the second argument. If the `Point` object has a geographic SRS, the second argument must be in the proper range for longitude or latitude values.

`ST_Y()` handles its arguments as described in the introduction to this section.

```
mysql> SELECT ST_Y(Point(56.7, 53.34));
+-----+
| ST_Y(Point(56.7, 53.34)) |
+-----+
| 53.34 |
+-----+
mysql> SELECT ST_AsText(ST_Y(Point(56.7, 53.34), 10.5));
+-----+
| ST_AsText(ST_Y(Point(56.7, 53.34), 10.5)) |
+-----+
| POINT(56.7 10.5) |
+-----+
```

## 14.16.7.3 LineString and MultiLineString Property Functions

A `LineString` consists of `Point` values. You can extract particular points of a `LineString`, count the number of points that it contains, or obtain its length.

Some functions in this section also work for `MultiLineString` values.

Unless otherwise specified, functions in this section handle their geometry arguments as follows:

- If any argument is `NULL` or any geometry argument is an empty geometry, the return value is `NULL`.
- If any geometry argument is not a syntactically well-formed geometry, an `ER_GIS_INVALID_DATA` error occurs.
- If any geometry argument is a syntactically well-formed geometry in an undefined spatial reference system (SRS), an `ER_SRS_NOT_FOUND` error occurs.
- Otherwise, the return value is non-`NULL`.

These functions are available for obtaining linestring properties:

- `ST_EndPoint(ls)`

Returns the `Point` that is the endpoint of the `LineString` value `ls`.

`ST_EndPoint()` handles its arguments as described in the introduction to this section.

```
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT ST_AsText(ST_EndPoint(ST_GeomFromText(@ls)));
+-----+
```

```
| ST_AsText(ST_EndPoint(ST_GeomFromText(@ls))) |
+-----+
| POINT(3 3) |
+-----+
```

- `ST_IsClosed(ls)`

For a `LineString` value `ls`, `ST_IsClosed()` returns 1 if `ls` is closed (that is, its `ST_StartPoint()` and `ST_EndPoint()` values are the same).

For a `MultiLineString` value `ls`, `ST_IsClosed()` returns 1 if `ls` is closed (that is, the `ST_StartPoint()` and `ST_EndPoint()` values are the same for each `LineString` in `ls`).

`ST_IsClosed()` returns 0 if `ls` is not closed, and `NULL` if `ls` is `NULL`.

`ST_IsClosed()` handles its arguments as described in the introduction to this section, with this exception:

- If the geometry has an SRID value for a geographic spatial reference system (SRS), an `ER_NOT_IMPLEMENTED_FOR_GEOGRAPHIC_SRS` error occurs.

```
mysql> SET @ls1 = 'LineString(1 1,2 2,3 3,2 2)';
mysql> SET @ls2 = 'LineString(1 1,2 2,3 3,1 1)';

mysql> SELECT ST_IsClosed(ST_GeomFromText(@ls1));
+-----+
| ST_IsClosed(ST_GeomFromText(@ls1)) |
+-----+
| 0 |
+-----+

mysql> SELECT ST_IsClosed(ST_GeomFromText(@ls2));
+-----+
| ST_IsClosed(ST_GeomFromText(@ls2)) |
+-----+
| 1 |
+-----+

mysql> SET @ls3 = 'MultiLineString((1 1,2 2,3 3),(4 4,5 5))';
mysql> SELECT ST_IsClosed(ST_GeomFromText(@ls3));
+-----+
| ST_IsClosed(ST_GeomFromText(@ls3)) |
+-----+
| 0 |
+-----+
```

- `ST_Length(ls [, unit])`

Returns a double-precision number indicating the length of the `LineString` or `MultiLineString` value `ls` in its associated spatial reference system. The length of a `MultiLineString` value is equal to the sum of the lengths of its elements.

`ST_Length()` computes a result as follows:

- If the geometry is a valid `LineString` in a Cartesian SRS, the return value is the Cartesian length of the geometry.
- If the geometry is a valid `MultiLineString` in a Cartesian SRS, the return value is the sum of the Cartesian lengths of its elements.
- If the geometry is a valid `LineString` in a geographic SRS, the return value is the geodetic length of the geometry in that SRS, in meters.
