Similar to the system tablespace, truncating or dropping tables stored in a general tablespace creates free space internally in the general tablespace [.ibd data file](#) which can only be used for new [InnoDB](#) data. Space is not released back to the operating system as it is when a file-per-table tablespace is deleted during a `DROP TABLE` operation.

This example demonstrates how to drop an [InnoDB](#) general tablespace. The general tablespace `ts1` is created with a single table. The table must be dropped before dropping the tablespace.

```
mysql> CREATE TABLESPACE `ts1` ADD DATAFILE 'ts1.ibd' Engine=InnoDB;
mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY) TABLESPACE ts1 Engine=InnoDB;
mysql> DROP TABLE t1;
mysql> DROP TABLESPACE ts1;
```

#### Note

`tablespace_name` is a case-sensitive identifier in MySQL.

## General Tablespace Limitations

- A generated or existing tablespace cannot be changed to a general tablespace.
- Creation of temporary general tablespaces is not supported.
- General tablespaces do not support temporary tables.
- Similar to the system tablespace, truncating or dropping tables stored in a general tablespace creates free space internally in the general tablespace [.ibd data file](#) which can only be used for new [InnoDB](#) data. Space is not released back to the operating system as it is for [file-per-table](#) tablespaces.

Additionally, a table-copying `ALTER TABLE` operation on table that resides in a shared tablespace (a general tablespace or the system tablespace) can increase the amount of space used by the tablespace. Such operations require as much additional space as the data in the table plus indexes. The additional space required for the table-copying `ALTER TABLE` operation is not released back to the operating system as it is for file-per-table tablespaces.

- `ALTER TABLE ... DISCARD TABLESPACE` and `ALTER TABLE ... IMPORT TABLESPACE` are not supported for tables that belong to a general tablespace.
- Placing table partitions in general tablespaces is not supported.
- The `ADD DATAFILE` clause is not supported in a replication environment where the source and replica reside on the same host, as it would cause the source and replica to create a tablespace of the same

name in the same location, which is not supported. However, if the `ADD DATAFILE` clause is omitted, the tablespace is created in the data directory with a generated file name that is unique, which is permitted.

- General tablespaces cannot be created in the undo tablespace directory (`innodb_undo_directory`) unless that directly is known to `InnoDB`. Known directories are those defined by the `datadir`, `innodb_data_home_dir`, and `innodb_directories` variables.

### 17.6.3.4 Undo Tablespaces

Undo tablespaces contain undo logs, which are collections of records containing information about how to undo the latest change by a transaction to a clustered index record.

Undo tablespaces are described under the following topics in this section:

- [Default Undo Tablespaces](#)
- [Undo Tablespace Size](#)
- [Adding Undo Tablespaces](#)
- [Dropping Undo Tablespaces](#)
- [Moving Undo Tablespaces](#)
- [Configuring the Number of Rollback Segments](#)
- [Truncating Undo Tablespaces](#)
- [Undo Tablespace Status Variables](#)

#### Default Undo Tablespaces

Two default undo tablespaces are created when the MySQL instance is initialized. Default undo tablespaces are created at initialization time to provide a location for rollback segments that must exist before SQL statements can be accepted. A minimum of two undo tablespaces is required to support automated truncation of undo tablespaces. See [Truncating Undo Tablespaces](#).

Default undo tablespaces are created in the location defined by the `innodb_undo_directory` variable. If the `innodb_undo_directory` variable is undefined, default undo tablespaces are created in the data directory. Default undo tablespace data files are named `undo_001` and `undo_002`. The corresponding undo tablespace names defined in the data dictionary are `innodb_undo_001` and `innodb_undo_002`.

Additional undo tablespaces can be created at runtime using SQL statements. See [Adding Undo Tablespaces](#).

#### Undo Tablespace Size

The initial undo tablespace size is normally 16MiB. The initial size may differ when a new undo tablespace is created by a truncate operation. In this case, if the file extension size is larger than 16MB, and the previous file extension occurred within the last second, the new undo tablespace is created at a quarter of the size defined by the `innodb_max_undo_log_size` variable.

An undo tablespace is extended by a minimum of 16MB. To handle aggressive growth, the file extension size is doubled if the previous file extension happened less than 0.1 seconds earlier. Doubling of the extension size can occur multiple times to a maximum of 256MB. If the previous file extension occurred more than 0.1 seconds earlier, the extension size is reduced by half, which can also occur multiple times, to a minimum of 16MB. If the `AUTOEXTEND_SIZE` option is defined for an undo tablespace, it is

extended by the greater of the `AUTOEXTEND_SIZE` setting and the extension size determined by the logic described above. For information about the `AUTOEXTEND_SIZE` option, see [Section 17.6.3.9, “Tablespace AUTOEXTEND\\_SIZE Configuration”](#).

## Adding Undo Tablespaces

Because undo logs can become large during long-running transactions, creating additional undo tablespaces can help prevent individual undo tablespaces from becoming too large. Additional undo tablespaces can be created at runtime using `CREATE UNDO TABLESPACE` syntax.

```
CREATE UNDO TABLESPACE tablespace_name ADD DATAFILE 'file_name.ibu';
```

The undo tablespace file name must have an `.ibu` extension. It is not permitted to specify a relative path when defining the undo tablespace file name. A fully qualified path is permitted, but the path must be known to InnoDB. Known paths are those defined by the `innodb_directories` variable. Unique undo tablespace file names are recommended to avoid potential file name conflicts when moving or cloning data.

### Note

In a replication environment, the source and each replica must have its own undo tablespace file directory. Replicating the creation of an undo tablespace file to a common directory would cause a file name conflict.

At startup, directories defined by the `innodb_directories` variable are scanned for undo tablespace files. (The scan also traverses subdirectories.) Directories defined by the `innodb_data_home_dir`, `innodb_undo_directory`, and `datadir` variables are automatically appended to the `innodb_directories` value regardless of whether the `innodb_directories` variable is defined explicitly. An undo tablespace can therefore reside in paths defined by any of those variables.

If the undo tablespace file name does not include a path, the undo tablespace is created in the directory defined by the `innodb_undo_directory` variable. If that variable is undefined, the undo tablespace is created in the data directory.

### Note

The InnoDB recovery process requires that undo tablespace files reside in known directories. Undo tablespace files must be discovered and opened before redo recovery and before other data files are opened to permit uncommitted transactions and data dictionary changes to be rolled back. An undo tablespace not found before recovery cannot be used, which can lead to database inconsistencies. An error message is reported at startup if an undo tablespace known to the data dictionary is not found. The known directory requirement also supports undo tablespace portability. See [Moving Undo Tablespaces](#).

To create undo tablespaces in a path relative to the data directory, set the `innodb_undo_directory` variable to the relative path, and specify the file name only when creating an undo tablespace.

To view undo tablespace names and paths, query `INFORMATION_SCHEMA.FILES`:

```
SELECT TABLESPACE_NAME, FILE_NAME FROM INFORMATION_SCHEMA.FILES
WHERE FILE_TYPE LIKE 'UNDO LOG';
```

A MySQL instance supports up to 127 undo tablespaces including the two default undo tablespaces created when the MySQL instance is initialized.

Undo tablespaces can be dropped using `DROP UNDO TABALESPACE` syntax. See [Dropping Undo Tablespaces](#).

## Dropping Undo Tablespaces

Undo tablespaces created using `CREATE UNDO TABLESPACE` syntax can be dropped at runtime using `DROP UNDO TABALESSPACE` syntax.

An undo tablespace must be empty before it can be dropped. To empty an undo tablespace, the undo tablespace must first be marked as inactive using `ALTER UNDO TABLESPACE` syntax so that the tablespace is no longer used for assigning rollback segments to new transactions.

```
ALTER UNDO TABLESPACE tablespace_name SET INACTIVE;
```

After an undo tablespace is marked as inactive, transactions currently using rollback segments in the undo tablespace are permitted to finish, as are any transactions started before those transactions are completed. After transactions are completed, the purge system frees the rollback segments in the undo tablespace, and the undo tablespace is truncated to its initial size. (The same process is used when truncating undo tablespaces. See [Truncating Undo Tablespaces](#).) Once the undo tablespace is empty, it can be dropped.

```
DROP UNDO TABLESPACE tablespace_name;
```

### Note

Alternatively, the undo tablespace can be left in an empty state and reactivated later, if needed, by issuing an `ALTER UNDO TABLESPACE tablespace_name SET ACTIVE` statement.

The state of an undo tablespace can be monitored by querying the Information Schema `INNODB_TABLESPACES` table.

```
SELECT NAME, STATE FROM INFORMATION_SCHEMA.INNODB_TABLESPACES
WHERE NAME LIKE 'tablespace_name';
```

An `inactive` state indicates that rollback segments in an undo tablespace are no longer used by new transactions. An `empty` state indicates that an undo tablespace is empty and ready to be dropped, or ready to be made active again using an `ALTER UNDO TABLESPACE tablespace_name SET ACTIVE` statement. Attempting to drop an undo tablespace that is not empty returns an error.

The default undo tablespaces (`innodb_undo_001` and `innodb_undo_002`) created when the MySQL instance is initialized cannot be dropped. They can, however, be made inactive using an `ALTER UNDO TABLESPACE tablespace_name SET INACTIVE` statement. Before a default undo tablespace can be made inactive, there must be an undo tablespace to take its place. A minimum of two active undo tablespaces are required at all times to support automated truncation of undo tablespaces.

## Moving Undo Tablespaces

Undo tablespaces created with `CREATE UNDO TABLESPACE` syntax can be moved while the server is offline to any known directory. Known directories are those defined by the `innodb_directories` variable. Directories defined by `innodb_data_home_dir`, `innodb_undo_directory`, and `datadir` are automatically appended to the `innodb_directories` value regardless of whether the `innodb_directories` variable is defined explicitly. Those directories and their subdirectories are scanned at startup for undo tablespaces files. An undo tablespace file moved to any of those directories is discovered at startup and assumed to be the undo tablespace that was moved.

The default undo tablespaces (`innodb_undo_001` and `innodb_undo_002`) created when the MySQL instance is initialized must reside in the directory defined by the `innodb_undo_directory` variable. If the `innodb_undo_directory` variable is undefined, default undo tablespaces reside in the data directory. If default undo tablespaces are moved while the server is offline, the server must be started with the `innodb_undo_directory` variable configured to the new directory.

The I/O patterns for undo logs make undo tablespaces good candidates for [SSD](#) storage.

## Configuring the Number of Rollback Segments

The `innodb_rollback_segments` variable defines the number of [rollback segments](#) allocated to each undo tablespace and to the global temporary tablespace. The `innodb_rollback_segments` variable can be configured at startup or while the server is running.

The default setting for `innodb_rollback_segments` is 128, which is also the maximum value. For information about the number of transactions that a rollback segment supports, see [Section 17.6.6, “Undo Logs”](#).

## Truncating Undo Tablespaces

There are two methods of truncating undo tablespaces, which can be used individually or in combination to manage undo tablespace size. One method is automated, enabled using configuration variables. The other method is manual, performed using SQL statements.

The automated method does not require monitoring undo tablespace size and, once enabled, it performs deactivation, truncation, and reactivation of undo tablespaces without manual intervention. The manual truncation method may be preferable if you want to control when undo tablespaces are taken offline for truncation. For example, you may want to avoid truncating undo tablespaces during peak workload times.

### Automated Truncation

Automated truncation of undo tablespaces requires a minimum of two active undo tablespaces, which ensures that one undo tablespace remains active while the other is taken offline to be truncated. By default, two undo tablespaces are created when the MySQL instance is initialized.

To have undo tablespaces automatically truncated, enable the `innodb_undo_log_truncate` variable. For example:

```
mysql> SET GLOBAL innodb_undo_log_truncate=ON;
```

When the `innodb_undo_log_truncate` variable is enabled, undo tablespaces that exceed the size limit defined by the `innodb_max_undo_log_size` variable are subject to truncation. The `innodb_max_undo_log_size` variable is dynamic and has a default value of 1073741824 bytes (1024 MiB).

```
mysql> SELECT @@innodb_max_undo_log_size;
+-----+
| @@innodb_max_undo_log_size |
+-----+
| 1073741824 |
+-----+
```

When the `innodb_undo_log_truncate` variable is enabled:

1. Default and user-defined undo tablespaces that exceed the `innodb_max_undo_log_size` setting are marked for truncation. Selection of an undo tablespace for truncation is performed in a circular fashion to avoid truncating the same undo tablespace each time.
2. Rollback segments residing in the selected undo tablespace are made inactive so that they are not assigned to new transactions. Existing transactions that are currently using rollback segments are permitted to finish.
3. The [purge](#) system empties rollback segments by freeing undo logs that are no longer in use.

- After all rollback segments in the undo tablespace are freed, the truncate operation runs and truncates the undo tablespace to its initial size.

The size of an undo tablespace after a truncate operation may be larger than the initial size due to immediate use following the completion of the operation.

The `innodb_undo_directory` variable defines the location of default undo tablespace files. If the `innodb_undo_directory` variable is undefined, default undo tablespaces reside in the data directory. The location of all undo tablespace files including user-defined undo tablespaces created using `CREATE UNDO TABLESPACE` syntax can be determined by querying the Information Schema `FILES` table:

```
SELECT TABLESPACE_NAME, FILE_NAME FROM INFORMATION_SCHEMA.FILES WHERE FILE_TYPE LIKE 'UNDO LOG';
```

- Rollback segments are reactivated so that they can be assigned to new transactions.

## Manual Truncation

Manual truncation of undo tablespaces requires a minimum of three active undo tablespaces. Two active undo tablespaces are required at all times to support the possibility that automated truncation is enabled. A minimum of three undo tablespaces satisfies this requirement while permitting an undo tablespace to be taken offline manually.

To manually initiate truncation of an undo tablespace, deactivate the undo tablespace by issuing the following statement:

```
ALTER UNDO TABLESPACE tablespace_name SET INACTIVE;
```

After the undo tablespace is marked as inactive, transactions currently using rollback segments in the undo tablespace are permitted to finish, as are any transactions started before those transactions are completed. After transactions are completed, the purge system frees the rollback segments in the undo tablespace, the undo tablespace is truncated to its initial size, and the undo tablespace state changes from `inactive` to `empty`.

### Note

When an `ALTER UNDO TABLESPACE tablespace_name SET INACTIVE` statement deactivates an undo tablespace, the purge thread looks for that undo tablespace at the next opportunity. Once the undo tablespace is found and marked for truncation, the purge thread returns with increased frequency to quickly empty and truncate the undo tablespace.

To check the state of an undo tablespace, query the Information Schema `INNODB_TABLESPACES` table.

```
SELECT NAME, STATE FROM INFORMATION_SCHEMA.INNODB_TABLESPACES
WHERE NAME LIKE 'tablespace_name';
```

Once the undo tablespace is in an `empty` state, it can be reactivated by issuing the following statement:

```
ALTER UNDO TABLESPACE tablespace_name SET ACTIVE;
```

An undo tablespace in an `empty` state can also be dropped. See [Dropping Undo Tablespaces](#).

## Expediting Automated Truncation of Undo Tablespaces

The purge thread is responsible for emptying and truncating undo tablespaces. By default, the purge thread looks for undo tablespaces to truncate once every 128 times that purge is invoked. The frequency with which the purge thread looks for undo tablespaces to truncate is controlled by the `innodb_purge_rseg_truncate_frequency` variable, which has a default setting of 128.

```
mysql> SELECT @@innodb_purge_rseg_truncate_frequency;
+-----+
| @@innodb_purge_rseg_truncate_frequency |
+-----+
| 128 |
+-----+
```

To increase the frequency, decrease the `innodb_purge_rseg_truncate_frequency` setting. For example, to have the purge thread look for undo tablespaces once every 32 times that purge is invoked, set `innodb_purge_rseg_truncate_frequency` to 32.

```
mysql> SET GLOBAL innodb_purge_rseg_truncate_frequency=32;
```

## Performance Impact of Truncating Undo Tablespace Files

When an undo tablespace is truncated, the rollback segments in the undo tablespace are deactivated. The active rollback segments in other undo tablespaces assume responsibility for the entire system load, which may result in a slight performance degradation. The extent to which performance is affected depends on a number of factors:

- Number of undo tablespaces
- Number of undo logs
- Undo tablespace size
- Speed of the I/O subsystem
- Existing long running transactions
- System load

The easiest way to avoid the potential performance impact is to increase the number of undo tablespaces.

## Monitoring Undo Tablespace Truncation

`undo` and `purge` subsystem counters are provided for monitoring background activities associated with undo log truncation. For counter names and descriptions, query the Information Schema `INNODB_METRICS` table.

```
SELECT NAME, SUBSYSTEM, COMMENT FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME LIKE '%truncate%';
```

For information about enabling counters and querying counter data, see [Section 17.15.6, “InnoDB INFORMATION\\_SCHEMA Metrics Table”](#).

## Undo Tablespace Truncation Limit

The number of truncate operations on the same undo tablespace between checkpoints is limited to 64. The limit prevents potential issues caused by an excessive number of undo tablespace truncate operations, which can occur if `innodb_max_undo_log_size` is set too low on a busy system, for example. If the limit is exceeded, an undo tablespace can still be made inactive, but it is not truncated until after the next checkpoint. In MySQL 9.1 the limit is 50000.

## Undo Tablespace Truncation Recovery

An undo tablespace truncate operation creates a temporary `undo_space_number_trunc.log` file in the server log directory. That log directory is defined by `innodb_log_group_home_dir`. If a system failure occurs during the truncate operation, the temporary log file permits the startup process to identify undo tablespaces that were being truncated and to continue the operation.

## Undo Tablespace Status Variables

The following status variables permit tracking the total number of undo tablespaces, implicit ([InnoDB](#)-created) undo tablespaces, explicit (user-created) undo tablespaces, and the number of active undo tablespaces:

```
mysql> SHOW STATUS LIKE 'Innodb_undo_tablespaces%';
```

Variable_name	Value
Innodb_undo_tablespaces_total	2
Innodb_undo_tablespaces_implicit	2
Innodb_undo_tablespaces_explicit	0
Innodb_undo_tablespaces_active	2

For status variable descriptions, see [Section 7.1.10, “Server Status Variables”](#).

## 17.6.3.5 Temporary Tablespaces

[InnoDB](#) uses session temporary tablespaces and a global temporary tablespace.

### Session Temporary Tablespaces

Session temporary tablespaces store user-created temporary tables and internal temporary tables created by the optimizer when [InnoDB](#) is configured as the storage engine for on-disk internal temporary tables. On-disk internal temporary tables use the [InnoDB](#) storage engine.

Session temporary tablespaces are allocated to a session from a pool of temporary tablespaces on the first request to create an on-disk temporary table. A maximum of two tablespaces is allocated to a session, one for user-created temporary tables and the other for internal temporary tables created by the optimizer. The temporary tablespaces allocated to a session are used for all on-disk temporary tables created by the session. When a session disconnects, its temporary tablespaces are truncated and released back to the pool. A pool of 10 temporary tablespaces is created when the server is started. The size of the pool never shrinks and tablespaces are added to the pool automatically as necessary. The pool of temporary tablespaces is removed on normal shutdown or on an aborted initialization. Session temporary tablespace files are five pages in size when created and have an `.ibt` file name extension.

A range of 400 thousand space IDs is reserved for session temporary tablespaces. Because the pool of session temporary tablespaces is recreated each time the server is started, space IDs for session temporary tablespaces are not persisted when the server is shut down, and may be reused.

The `innodb_temp_tablespaces_dir` variable defines the location where session temporary tablespaces are created. The default location is the `#innodb_temp` directory in the data directory. Startup is refused if the pool of temporary tablespaces cannot be created.

```
$> cd BASEDIR/data/#innodb_temp
$> ls
temp_10.ibt temp_2.ibt temp_4.ibt temp_6.ibt temp_8.ibt
temp_1.ibt temp_3.ibt temp_5.ibt temp_7.ibt temp_9.ibt
```

In statement based replication (SBR) mode, temporary tables created on a replica reside in a single session temporary tablespace that is truncated only when the MySQL server is shut down.

The `INNODB_SESSION_TEMP_TABLESPACES` table provides metadata about session temporary tablespaces.

The Information Schema `INNODB_TEMP_TABLE_INFO` table provides metadata about user-created temporary tables that are active in an [InnoDB](#) instance.

## Global Temporary Tablespace

The global temporary tablespace (`ibtmp1`) stores rollback segments for changes made to user-created temporary tables.

The `innodb_temp_data_file_path` variable defines the relative path, name, size, and attributes for global temporary tablespace data files. If no value is specified for `innodb_temp_data_file_path`, the default behavior is to create a single auto-extending data file named `ibtmp1` in the `innodb_data_home_dir` directory. The initial file size is slightly larger than 12MB.

The global temporary tablespace is removed on normal shutdown or on an aborted initialization, and recreated each time the server is started. The global temporary tablespace receives a dynamically generated space ID when it is created. Startup is refused if the global temporary tablespace cannot be created. The global temporary tablespace is not removed if the server halts unexpectedly. In this case, a database administrator can remove the global temporary tablespace manually or restart the MySQL server. Restarting the MySQL server removes and recreates the global temporary tablespace automatically.

The global temporary tablespace cannot reside on a raw device.

The Information Schema `FILES` table provides metadata about the global temporary tablespace. Issue a query similar to this one to view global temporary tablespace metadata:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.FILES WHERE TABLESPACE_NAME='innodb_temporary'\G
```

By default, the global temporary tablespace data file is autoextending and increases in size as necessary.

To determine if a global temporary tablespace data file is autoextending, check the `innodb_temp_data_file_path` setting:

```
mysql> SELECT @@innodb_temp_data_file_path;
+-----+
| @@innodb_temp_data_file_path |
+-----+
| ibtmp1:12M:autoextend |
+-----+
```

To check the size of global temporary tablespace data files, examine the Information Schema `FILES` table using a query similar to this one:

```
mysql> SELECT FILE_NAME, TABLESPACE_NAME, ENGINE, INITIAL_SIZE, TOTAL_EXTENTS*EXTENT_SIZE
 AS TotalSizeBytes, DATA_FREE, MAXIMUM_SIZE FROM INFORMATION_SCHEMA.FILES
 WHERE TABLESPACE_NAME = 'innodb_temporary'\G
***** 1. row *****
FILE_NAME: ./ibtmp1
TABLESPACE_NAME: innodb_temporary
ENGINE: InnoDB
INITIAL_SIZE: 12582912
TotalSizeBytes: 12582912
DATA_FREE: 6291456
MAXIMUM_SIZE: NULL
```

`TotalSizeBytes` shows the current size of the global temporary tablespace data file. For information about other field values, see [Section 28.3.15, “The INFORMATION\\_SCHEMA FILES Table”](#).

Alternatively, check the global temporary tablespace data file size on your operating system. The global temporary tablespace data file is located in the directory defined by the `innodb_temp_data_file_path` variable.

To reclaim disk space occupied by a global temporary tablespace data file, restart the MySQL server. Restarting the server removes and recreates the global temporary tablespace data file according to the attributes defined by `innodb_temp_data_file_path`.

To limit the size of the global temporary tablespace data file, configure `innodb_temp_data_file_path` to specify a maximum file size. For example:

```
[mysqld]
innodb_temp_data_file_path=ibtmp1:12M:autoextend:max:500M
```

Configuring `innodb_temp_data_file_path` requires restarting the server.

### 17.6.3.6 Moving Tablespace Files While the Server is Offline

The `innodb_directories` variable, which defines directories to scan at startup for tablespace files, supports moving or restoring tablespace files to a new location while the server is offline. During startup, discovered tablespace files are used instead those referenced in the data dictionary, and the data dictionary is updated to reference the relocated files. If duplicate tablespace files are discovered by the scan, startup fails with an error indicating that multiple files were found for the same tablespace ID.

The directories defined by the `innodb_data_home_dir`, `innodb_undo_directory`, and `datadir` variables are automatically appended to the `innodb_directories` argument value. These directories are scanned at startup regardless of whether an `innodb_directories` setting is specified explicitly. The implicit addition of these directories permits moving system tablespace files, the data directory, or undo tablespace files without configuring the `innodb_directories` setting. However, settings must be updated when directories change. For example, after relocating the data directory, you must update the `--datadir` setting before restarting the server.

The `innodb_directories` variable can be specified in a startup command or MySQL option file. Quotes are used around the argument value because a semicolon (;) is interpreted as a special character by some command interpreters. (Unix shells treat it as a command terminator, for example.)

Startup command:

```
mysqld --innodb-directories="directory_path_1;directory_path_2"
```

MySQL option file:

```
[mysqld]
innodb_directories="directory_path_1;directory_path_2"
```

The following procedure is applicable to moving individual [file-per-table](#) and [general tablespace](#) files, [system tablespace](#) files, [undo tablespace](#) files, or the data directory. Before moving files or directories, review the usage notes that follow.

1. Stop the server.
2. Move the tablespace files or directories to the desired location.
3. Make the new directory known to [InnoDB](#).
  - If moving individual [file-per-table](#) or [general tablespace](#) files, add unknown directories to the `innodb_directories` value.
  - The directories defined by the `innodb_data_home_dir`, `innodb_undo_directory`, and `datadir` variables are automatically appended to the `innodb_directories` argument value, so you need not specify these.
  - A file-per-table tablespace file can only be moved to a directory with same name as the schema. For example, if the `actor` table belongs to the `sakila` schema, then the `actor.ibd` data file can only be moved to a directory named `sakila`.

- General tablespace files cannot be moved to the data directory or a subdirectory of the data directory.
  - If moving system tablespace files, undo tablespaces, or the data directory, update the `innodb_data_home_dir`, `innodb_undo_directory`, and `datadir` settings, as necessary.
4. Restart the server.

## Usage Notes

- Wildcard expressions cannot be used in the `innodb_directories` argument value.
- The `innodb_directories` scan also traverses subdirectories of specified directories. Duplicate directories and subdirectories are discarded from the list of directories to be scanned.
- `innodb_directories` supports moving InnoDB tablespace files. Moving files that belong to a storage engine other than InnoDB is not supported. This restriction also applies when moving the entire data directory.
- `innodb_directories` supports renaming of tablespace files when moving files to a scanned directory. It also supports moving tablespaces files to other supported operating systems.
- When moving tablespace files to a different operating system, ensure that tablespace file names do not include prohibited characters or characters with a special meaning on the destination system.
- When moving a data directory from a Windows operating system to a Linux operating system, modify the binary log file paths in the binary log index file to use backward slashes instead of forward slashes. By default, the binary log index file has the same base name as the binary log file, with the extension `'.index'`. The location of the binary log index file is defined by `--log-bin`. The default location is the data directory.
- If moving tablespace files to a different operating system introduces cross-platform replication, it is the database administrator's responsibility to ensure proper replication of DDL statements that contain platform-specific directories. Statements that permit specifying directories include `CREATE TABLE ... DATA DIRECTORY` and `CREATE TABLESPACE ... ADD DATAFILE`.
- Add the directories of file-per-table and general tablespaces created with an absolute path or in a location outside of the data directory to the `innodb_directories` setting. Otherwise, InnoDB is not able to locate the files during recovery. For related information, see [Tablespace Discovery During Crash Recovery](#).

To view tablespace file locations, query the Information Schema `FILES` table:

```
mysql> SELECT TABLESPACE_NAME, FILE_NAME FROM INFORMATION_SCHEMA.FILES \G
```

### 17.6.3.7 Disabling Tablespace Path Validation

At startup, InnoDB scans directories defined by the `innodb_directories` variable for tablespace files. The paths of discovered tablespace files are validated against the paths recorded in the data dictionary. If the paths do not match, the paths in the data dictionary are updated.

The `innodb_validate_tablespace_paths` variable permits disabling tablespace path validation. This feature is intended for environments where tablespaces files are not moved. Disabling path validation improves startup time on systems with a large number of tablespace files. If `log_error_verbosity` is set to 3, the following message is printed at startup when tablespace path validation is disabled:

```
[InnoDB] Skipping InnoDB tablespace path validation.
```

Manually moved tablespace files will not be detected!

### Warning

Starting the server with tablespace path validation disabled after moving tablespace files can lead to undefined behavior.

## 17.6.3.8 Optimizing Tablespace Space Allocation on Linux

You can optimize how [InnoDB](#) allocates space to file-per-table and general tablespaces on Linux. By default, when additional space is required, [InnoDB](#) allocates pages to the tablespace and physically writes NULLs to those pages. This behavior can affect performance if new pages are allocated frequently. You can disable [innodb\\_extend\\_and\\_initialize](#) on Linux systems to avoid physically writing NULLs to newly allocated tablespace pages. When [innodb\\_extend\\_and\\_initialize](#) is disabled, space is allocated to tablespace files using [posix\\_fallocate\(\)](#) calls, which reserve space without physically writing NULLs.

When pages are allocated using [posix\\_fallocate\(\)](#) calls, the extension size is small by default and pages are often allocated only a few at a time, which can cause fragmentation and increase random I/O. To avoid this issue, increase the tablespace extension size when enabling [posix\\_fallocate\(\)](#) calls. Tablespace extension size can be increased up to 4GB using the [AUTOEXTEND\\_SIZE](#) option. For more information, see [Section 17.6.3.9, “Tablespace AUTOEXTEND\\_SIZE Configuration”](#).

[InnoDB](#) writes a redo log record before allocating a new tablespace page. If a page allocation operation is interrupted, the operation is replayed from the redo log record during recovery. (A page allocation operation replayed from a redo log record physically writes NULLs to the newly allocated page.) A redo log record is written before allocating a page regardless of the [innodb\\_extend\\_and\\_initialize](#) setting.

On non-Linux systems and Windows, [InnoDB](#) allocates new pages to the tablespace and physically writes NULLs to those pages, which is the default behavior. Attempting to disable [innodb\\_extend\\_and\\_initialize](#) on those systems returns the following error:

Changing innodb\_extend\_and\_initialize not supported on this platform. Falling back to the default.

## 17.6.3.9 Tablespace AUTOEXTEND\_SIZE Configuration

By default, when a file-per-table or general tablespace requires additional space, the tablespace is extended incrementally according to the following rules:

- If the tablespace is less than an extent in size, it is extended one page at a time.
- If the tablespace is greater than 1 extent but smaller than 32 extents in size, it is extended one extent at a time.
- If the tablespace is more than 32 extents in size, it is extended four extents at a time.

For information about extent size, see [Section 17.11.2, “File Space Management”](#).

The amount by which a file-per-table or general tablespace is extended is configurable by specifying the [AUTOEXTEND\\_SIZE](#) option. Configuring a larger extension size can help avoid fragmentation and facilitate ingestion of large amounts of data.

To configure the extension size for a file-per-table tablespace, specify the [AUTOEXTEND\\_SIZE](#) size in a [CREATE TABLE](#) or [ALTER TABLE](#) statement:

```
CREATE TABLE t1 (c1 INT) AUTOEXTEND_SIZE = 4M;

ALTER TABLE t1 AUTOEXTEND_SIZE = 8M;
```

To configure the extension size for a general tablespace, specify the `AUTOEXTEND_SIZE` size in a `CREATE TABLESPACE` or `ALTER TABLESPACE` statement:

```
CREATE TABLESPACE ts1 AUTOEXTEND_SIZE = 4M;

ALTER TABLESPACE ts1 AUTOEXTEND_SIZE = 8M;
```

#### Note

The `AUTOEXTEND_SIZE` option can also be used when creating an undo tablespace, but the extension behavior for undo tablespaces differs. For more information, see [Section 17.6.3.4, “Undo Tablespaces”](#).

The `AUTOEXTEND_SIZE` setting must be a multiple of 4M. Specifying an `AUTOEXTEND_SIZE` setting that is not a multiple of 4M returns an error.

The `AUTOEXTEND_SIZE` default setting is 0, which causes the tablespace to be extended according to the default behavior described above.

The maximum allowed `AUTOEXTEND_SIZE` is 4GB. The maximum tablespace size is described at [Section 17.21, “InnoDB Limits”](#).

The minimum `AUTOEXTEND_SIZE` setting depends on the `InnoDB` page size, as shown in the following table:

InnoDB Page Size	Minimum AUTOEXTEND_SIZE
4K	4M
8K	4M
16K	4M
32K	8M
64K	16M

The default `InnoDB` page size is 16K (16384 bytes). To determine the `InnoDB` page size for your MySQL instance, query the `innodb_page_size` setting:

```
mysql> SELECT @@GLOBAL.innodb_page_size;
+-----+
| @@GLOBAL.innodb_page_size |
+-----+
| 16384 |
+-----+
```

When the `AUTOEXTEND_SIZE` setting for a tablespace is altered, the first extension that occurs afterward increases the tablespace size to a multiple of the `AUTOEXTEND_SIZE` setting. Subsequent extensions are of the configured size.

When a file-per-table or general tablespace is created with a non-zero `AUTOEXTEND_SIZE` setting, the tablespace is initialized at the specified `AUTOEXTEND_SIZE` size.

`ALTER TABLESPACE` cannot be used to configure the `AUTOEXTEND_SIZE` of a file-per-table tablespace. `ALTER TABLE` must be used.

For tables created in file-per-table tablespaces, `SHOW CREATE TABLE` shows the `AUTOEXTEND_SIZE` option only when it is configured to a non-zero value.

To determine the `AUTOEXTEND_SIZE` for any `InnoDB` tablespace, query the Information Schema `INNODB_TABLESPACES` table. For example:

```
mysql> SELECT NAME, AUTOEXTEND_SIZE FROM INFORMATION_SCHEMA.INNODB_TABLESPACES
WHERE NAME LIKE 'test/t1';
+-----+-----+
| NAME | AUTOEXTEND_SIZE |
+-----+-----+
| test/t1 | 4194304 |
+-----+-----+

mysql> SELECT NAME, AUTOEXTEND_SIZE FROM INFORMATION_SCHEMA.INNODB_TABLESPACES
WHERE NAME LIKE 'ts1';
+-----+-----+
| NAME | AUTOEXTEND_SIZE |
+-----+-----+
| ts1 | 4194304 |
+-----+-----+
```

### Note

An `AUTOEXTEND_SIZE` of 0, which is the default setting, means that the tablespace is extended according to the default tablespace extension behavior described above.

## 17.6.4 Doublewrite Buffer

The doublewrite buffer is a storage area where `InnoDB` writes pages flushed from the buffer pool before writing the pages to their proper positions in the `InnoDB` data files. If there is an operating system, storage subsystem, or unexpected `mysqld` process exit in the middle of a page write, `InnoDB` can find a good copy of the page from the doublewrite buffer during crash recovery.

Although data is written twice, the doublewrite buffer does not require twice as much I/O overhead or twice as many I/O operations. Data is written to the doublewrite buffer in a large sequential chunk, with a single `fsync()` call to the operating system (except in the case that `innodb_flush_method` is set to `O_DIRECT_NO_FSYNC`).

The doublewrite buffer storage area is located in doublewrite files.

The following variables are provided for doublewrite buffer configuration:

- `innodb_doublewrite`

The `innodb_doublewrite` variable controls whether the doublewrite buffer is enabled. It is enabled by default in most cases. To disable the doublewrite buffer, set `innodb_doublewrite` to `OFF`. Consider disabling the doublewrite buffer if you are more concerned with performance than data integrity, as may be the case when performing benchmarks, for example.

`innodb_doublewrite` supports `DETECT_AND_RECOVER` and `DETECT_ONLY` settings.

The `DETECT_AND_RECOVER` setting is the same as the `ON` setting. With this setting, the doublewrite buffer is fully enabled, with database page content written to the doublewrite buffer where it is accessed during recovery to fix incomplete page writes.

With the `DETECT_ONLY` setting, only metadata is written to the doublewrite buffer. Database page content is not written to the doublewrite buffer, and recovery does not use the doublewrite buffer to fix incomplete page writes. This lightweight setting is intended for detecting incomplete page writes only.

MySQL supports dynamic changes to the `innodb_doublewrite` setting that enables the doublewrite buffer, between `ON`, `DETECT_AND_RECOVER`, and `DETECT_ONLY`. MySQL does not support dynamic changes between a setting that enables the doublewrite buffer and `OFF` or vice versa.

If the doublewrite buffer is located on a Fusion-io device that supports atomic writes, the doublewrite buffer is automatically disabled and data file writes are performed using Fusion-io atomic writes instead. However, be aware that the `innodb_doublewrite` setting is global. When the doublewrite buffer is disabled, it is disabled for all data files including those that do not reside on Fusion-io hardware. This feature is only supported on Fusion-io hardware and is only enabled for Fusion-io NVMFS on Linux. To take full advantage of this feature, an `innodb_flush_method` setting of `O_DIRECT` is recommended.

- `innodb_doublewrite_dir`

The `innodb_doublewrite_dir` variable defines the directory where InnoDB creates doublewrite files. If no directory is specified, doublewrite files are created in the `innodb_data_home_dir` directory, which defaults to the data directory if unspecified.

A hash symbol '#' is automatically prefixed to the specified directory name to avoid conflicts with schema names. However, if a '.', '#', or '/' prefix is specified explicitly in the directory name, the hash symbol '#' is not prefixed to the directory name.

Ideally, the doublewrite directory should be placed on the fastest storage media available.

- `innodb_doublewrite_files`

The `innodb_doublewrite_files` variable defines the number of doublewrite files, which defaults to 2. By default, two doublewrite files are created for each buffer pool instance: A flush list doublewrite file and an LRU list doublewrite file.

The flush list doublewrite file is for pages flushed from the buffer pool flush list. The default size of a flush list doublewrite file is the InnoDB page size \* doublewrite page bytes.

The LRU list doublewrite file is for pages flushed from the buffer pool LRU list. It also contains slots for single page flushes. The default size of an LRU list doublewrite file is the InnoDB page size \* (doublewrite pages + (512 / the number of buffer pool instances)) where 512 is the total number of slots reserved for single page flushes.

At a minimum, there are two doublewrite files. The maximum number of doublewrite files is two times the number of buffer pool instances. (The number of buffer pool instances is controlled by the `innodb_buffer_pool_instances` variable.)

Doublewrite file names have the following format: `#ib_page_size_file_number.dblwr` (or `.bdblwr` with the `DETECT_ONLY` setting). For example, the following doublewrite files are created for a MySQL instance with an InnoDB pages size of 16KB and a single buffer pool:

```
#ib_16384_0.dblwr
#ib_16384_1.dblwr
```

The `innodb_doublewrite_files` variable is intended for advanced performance tuning. The default setting should be suitable for most users.

- `innodb_doublewrite_pages`

The `innodb_doublewrite_pages` variable controls the maximum number of doublewrite pages per thread. This variable is intended for advanced performance tuning. The default value should be suitable for most users.

InnoDB automatically encrypts doublewrite file pages that belong to encrypted tablespaces (see [Section 17.13, “InnoDB Data-at-Rest Encryption”](#)). Likewise, doublewrite file pages belonging to page-compressed tablespaces are compressed. As a result, doublewrite files can contain different page types

including unencrypted and uncompressed pages, encrypted pages, compressed pages, and pages that are both encrypted and compressed.

## 17.6.5 Redo Log

The redo log is a disk-based data structure used during crash recovery to correct data written by incomplete transactions. During normal operations, the redo log encodes requests to change table data that result from SQL statements or low-level API calls. Modifications that did not finish updating data files before an unexpected shutdown are replayed automatically during initialization and before connections are accepted. For information about the role of the redo log in crash recovery, see [Section 17.18.2, “InnoDB Recovery”](#).

The redo log is physically represented on disk by redo log files. Data that is written to redo log files is encoded in terms of records affected, and this data is collectively referred to as redo. The passage of data through redo log files is represented by an ever-increasing [LSN](#) value. Redo log data is appended as data modifications occur, and the oldest data is truncated as the checkpoint progresses.

Information and procedures related to redo logs are described under the following topics in the section:

- [Configuring Redo Log Capacity](#)
- [Automatic Redo Log Capacity Configuration](#)
- [Redo Log Archiving](#)
- [Disabling Redo Logging](#)
- [Related Topics](#)

### Configuring Redo Log Capacity

The `innodb_redo_log_capacity` system variable controls the amount of disk space occupied by redo log files. You can set this variable in an option file at startup or at runtime using a `SET GLOBAL` statement; for example, the following statement sets the redo log capacity to 8GB:

```
SET GLOBAL innodb_redo_log_capacity = 8589934592;
```

When set at runtime, the configuration change occurs immediately but it may take some time for the new limit to be fully implemented. If the redo log files occupy less space than the specified value, dirty pages are flushed from the buffer pool to tablespace data files less aggressively, eventually increasing the disk space occupied by the redo log files. If the redo log files occupy more space than the specified value, dirty pages are flushed more aggressively, eventually decreasing the disk space occupied by redo log files.

If `innodb_redo_log_capacity` is not defined, and if neither `innodb_log_file_size` or `innodb_log_files_in_group` are defined, then the default `innodb_redo_log_capacity` value is used.

If `innodb_redo_log_capacity` is not defined, and if `innodb_log_file_size` and/or `innodb_log_files_in_group` is defined, then the InnoDB redo log capacity is calculated as  $(\text{innodb\_log\_files\_in\_group} * \text{innodb\_log\_file\_size})$ . This calculation does not modify the unused `innodb_redo_log_capacity` setting's value.

The `Innodb_redo_log_capacity_resized` server status variable indicates the total redo log capacity for all redo log files.

Redo log files reside in the `#innodb_redo` directory in the data directory unless a different directory was specified by the `innodb_log_group_home_dir` variable. If `innodb_log_group_home_dir` was

defined, the redo log files reside in the `#innodb_redo` directory in that directory. There are two types of redo log files, ordinary and spare. Ordinary redo log files are those being used. Spare redo log files are those waiting to be used. InnoDB tries to maintain 32 redo log files in total, with each file equal in size to  $1/32 * \text{innodb\_redo\_log\_capacity}$ ; however, file sizes may differ for a time after modifying the `innodb\_redo\_log\_capacity` setting.

Redo log files use an `#ib_redoN` naming convention, where `N` is the redo log file number. Spare redo log files are denoted by a `_tmp` suffix. The following example shows the redo log files in an `#innodb_redo` directory, where there are 21 active redo log files and 11 spare redo log files, numbered sequentially.

```
'#ib_redo582' '#ib_redo590' '#ib_redo598' '#ib_redo606_tmp'
'#ib_redo583' '#ib_redo591' '#ib_redo599' '#ib_redo607_tmp'
'#ib_redo584' '#ib_redo592' '#ib_redo600' '#ib_redo608_tmp'
'#ib_redo585' '#ib_redo593' '#ib_redo601' '#ib_redo609_tmp'
'#ib_redo586' '#ib_redo594' '#ib_redo602' '#ib_redo610_tmp'
'#ib_redo587' '#ib_redo595' '#ib_redo603_tmp' '#ib_redo611_tmp'
'#ib_redo588' '#ib_redo596' '#ib_redo604_tmp' '#ib_redo612_tmp'
'#ib_redo589' '#ib_redo597' '#ib_redo605_tmp' '#ib_redo613_tmp'
```

Each ordinary redo log file is associated with a particular range of LSN values; for example, the following query shows the `START_LSN` and `END_LSN` values for the active redo log files listed in the previous example:

```
mysql> SELECT FILE_NAME, START_LSN, END_LSN FROM performance_schema.innodb_redo_log_files;
+-----+-----+-----+
| FILE_NAME | START_LSN | END_LSN |
+-----+-----+-----+
| ./#innodb_redo/#ib_redo582 | 117654982144 | 117658256896 |
| ./#innodb_redo/#ib_redo583 | 117658256896 | 117661531648 |
| ./#innodb_redo/#ib_redo584 | 117661531648 | 117664806400 |
| ./#innodb_redo/#ib_redo585 | 117664806400 | 117668081152 |
| ./#innodb_redo/#ib_redo586 | 117668081152 | 117671355904 |
| ./#innodb_redo/#ib_redo587 | 117671355904 | 117674630656 |
| ./#innodb_redo/#ib_redo588 | 117674630656 | 117677905408 |
| ./#innodb_redo/#ib_redo589 | 117677905408 | 117681180160 |
| ./#innodb_redo/#ib_redo590 | 117681180160 | 117684454912 |
| ./#innodb_redo/#ib_redo591 | 117684454912 | 117687729664 |
| ./#innodb_redo/#ib_redo592 | 117687729664 | 117691004416 |
| ./#innodb_redo/#ib_redo593 | 117691004416 | 117694279168 |
| ./#innodb_redo/#ib_redo594 | 117694279168 | 117697553920 |
| ./#innodb_redo/#ib_redo595 | 117697553920 | 117700828672 |
| ./#innodb_redo/#ib_redo596 | 117700828672 | 117704103424 |
| ./#innodb_redo/#ib_redo597 | 117704103424 | 117707378176 |
| ./#innodb_redo/#ib_redo598 | 117707378176 | 117710652928 |
| ./#innodb_redo/#ib_redo599 | 117710652928 | 117713927680 |
| ./#innodb_redo/#ib_redo600 | 117713927680 | 117717202432 |
| ./#innodb_redo/#ib_redo601 | 117717202432 | 117720477184 |
| ./#innodb_redo/#ib_redo602 | 117720477184 | 117723751936 |
+-----+-----+-----+
```

When doing a checkpoint, InnoDB stores the checkpoint LSN in the header of the file which contains this LSN. During recovery, all redo log files are checked and recovery starts at the latest checkpoint LSN.

Several status variables are provided for monitoring the redo log and redo log capacity resize operations; for example, you can query `Innodb_redo_log_resize_status` to view the status of a resize operation:

```
mysql> SHOW STATUS LIKE 'Innodb_redo_log_resize_status';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Innodb_redo_log_resize_status | OK |
+-----+-----+
```

The `Innodb_redo_log_capacity_resized` status variable shows the current redo log capacity limit:

```
mysql> SHOW STATUS LIKE 'Innodb_redo_log_capacity_resized';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Innodb_redo_log_capacity_resized | 104857600 |
+-----+-----+
```

Other applicable status variables include:

- `Innodb_redo_log_checkpoint_lsn`
- `Innodb_redo_log_current_lsn`
- `Innodb_redo_log_flushed_to_disk_lsn`
- `Innodb_redo_log_logical_size`
- `Innodb_redo_log_physical_size`
- `Innodb_redo_log_read_only`
- `Innodb_redo_log_uuid`

Refer to the status variable descriptions for more information.

You can view information about active redo log files by querying the `innodb_redo_log_files` Performance Schema table. The following query retrieves data from all of the table's columns:

```
SELECT FILE_ID, START_LSN, END_LSN, SIZE_IN_BYTES, IS_FULL, CONSUMER_LEVEL
FROM performance_schema.innodb_redo_log_files;
```

## Automatic Redo Log Capacity Configuration

When the server is started with `--innodb-dedicated-server`, InnoDB automatically calculates and sets the values for certain InnoDB parameters, including redo log capacity. Automated configuration is intended for MySQL instances that reside on a server dedicated to MySQL, where the MySQL server can use all available system resources. For more information, see [Section 17.8.12, “Enabling Automatic InnoDB Configuration for a Dedicated MySQL Server”](#).

## Redo Log Archiving

Backup utilities that copy redo log records may sometimes fail to keep pace with redo log generation while a backup operation is in progress, resulting in lost redo log records due to those records being overwritten. This issue most often occurs when there is significant MySQL server activity during the backup operation, and the redo log file storage media operates at a faster speed than the backup storage media. The redo log archiving feature addresses this issue by sequentially writing redo log records to an archive file in addition to the redo log files. Backup utilities can copy redo log records from the archive file as necessary, thereby avoiding the potential loss of data.

If redo log archiving is configured on the server, [MySQL Enterprise Backup](#), available with [MySQL Enterprise Edition](#), uses the redo log archiving feature when backing up a MySQL server.

Enabling redo log archiving on the server requires setting a value for the `innodb_redo_log_archive_dirs` system variable. The value is specified as a semicolon-separated list of labeled redo log archive directories. The `label:directory` pair is separated by a colon (:). For example:

```
mysql> SET GLOBAL innodb_redo_log_archive_dirs='label1:directory_path1[:label2:directory_path2;...];'
```

The `label` is an arbitrary identifier for the archive directory. It can be any string of characters, with the exception of colons (:), which are not permitted. An empty label is also permitted, but the colon (:) is still

required in this case. A `directory_path` must be specified. The directory selected for the redo log archive file must exist when redo log archiving is activated, or an error is returned. The path can contain colons (':'), but semicolons (;) are not permitted.

The `innodb_redo_log_archive_dirs` variable must be configured before redo log archiving can be activated. The default value is `NULL`, which does not permit activating redo log archiving.

### Notes

The archive directories that you specify must satisfy the following requirements. (The requirements are enforced when redo log archiving is activated.):

- Directories must exist. Directories are not created by the redo log archive process. Otherwise, the following error is returned:

```
ERROR 3844 (HY000): Redo log archive directory
'directory_path1' does not exist or is not a directory
```

- Directories must not be world-accessible. This is to prevent the redo log data from being exposed to unauthorized users on the system. Otherwise, the following error is returned:

```
ERROR 3846 (HY000): Redo log archive directory
'directory_path1' is accessible to all OS users
```

- Directories cannot be those defined by `datadir`, `innodb_data_home_dir`, `innodb_directories`, `innodb_log_group_home_dir`, `innodb_temp_tablespaces_dir`, `innodb_tmpdir`, `innodb_undo_directory`, or `secure_file_priv`, nor can they be parent directories or subdirectories of those directories. Otherwise, an error similar to the following is returned:

```
ERROR 3845 (HY000): Redo log archive directory
'directory_path1' is in, under, or over server directory
'datadir' - '/path/to/data_directory'
```

When a backup utility that supports redo log archiving initiates a backup, the backup utility activates redo log archiving by invoking the `innodb_redo_log_archive_start()` function.

If you are not using a backup utility that supports redo log archiving, redo log archiving can also be activated manually, as shown:

```
mysql> SELECT innodb_redo_log_archive_start('label', 'subdir');
+-----+
| innodb_redo_log_archive_start('label') |
+-----+
| 0 |
+-----+
```

Or:

```
mysql> DO innodb_redo_log_archive_start('label', 'subdir');
Query OK, 0 rows affected (0.09 sec)
```

### Note

The MySQL session that activates redo log archiving (using `innodb_redo_log_archive_start()`) must remain open for the duration

of the archiving. The same session must deactivate redo log archiving (using `innodb_redo_log_archive_stop()`). If the session is terminated before the redo log archiving is explicitly deactivated, the server deactivates redo log archiving implicitly and removes the redo log archive file.

where *label* is a label defined by `innodb_redo_log_archive_dirs`; *subdir* is an optional argument for specifying a subdirectory of the directory identified by *label* for saving the archive file; it must be a simple directory name (no slash (/), backslash (\), or colon (:)) is permitted). *subdir* can be empty, null, or it can be left out.

Only users with the `INNODB_REDO_LOG_ARCHIVE` privilege can activate redo log archiving by invoking `innodb_redo_log_archive_start()`, or deactivate it using `innodb_redo_log_archive_stop()`. The MySQL user running the backup utility or the MySQL user activating and deactivating redo log archiving manually must have this privilege.

The redo log archive file path is *directory\_identified\_by\_label*/[*subdir*/]archive.serverUUID.000001.log, where *directory\_identified\_by\_label* is the archive directory identified by the *label* argument for `innodb_redo_log_archive_start()`. *subdir* is the optional argument used for `innodb_redo_log_archive_start()`.

For example, the full path and name for a redo log archive file appears similar to the following:

```
/directory_path/subdirectory/archive.e71a47dc-61f8-11e9-a3cb-080027154b4d.000001.log
```

After the backup utility finishes copying InnoDB data files, it deactivates redo log archiving by calling the `innodb_redo_log_archive_stop()` function.

If you are not using a backup utility that supports redo log archiving, redo log archiving can also be deactivated manually, as shown:

```
mysql> SELECT innodb_redo_log_archive_stop();
+-----+
| innodb_redo_log_archive_stop() |
+-----+
| 0 |
+-----+
```

Or:

```
mysql> DO innodb_redo_log_archive_stop();
Query OK, 0 rows affected (0.01 sec)
```

After the stop function completes successfully, the backup utility looks for the relevant section of redo log data from the archive file and copies it into the backup.

After the backup utility finishes copying the redo log data and no longer needs the redo log archive file, it deletes the archive file.

Removal of the archive file is the responsibility of the backup utility in normal situations. However, if the redo log archiving operation quits unexpectedly before `innodb_redo_log_archive_stop()` is called, the MySQL server removes the file.

## Performance Considerations

Activating redo log archiving typically has a minor performance cost due to the additional write activity.

On Unix and Unix-like operating systems, the performance impact is typically minor, assuming there is not a sustained high rate of updates. On Windows, the performance impact is typically a bit higher, assuming the same.

If there is a sustained high rate of updates and the redo log archive file is on the same storage media as the redo log files, the performance impact may be more significant due to compounded write activity.

If there is a sustained high rate of updates and the redo log archive file is on slower storage media than the redo log files, performance is impacted arbitrarily.

Writing to the redo log archive file does not impede normal transactional logging except in the case that the redo log archive file storage media operates at a much slower rate than the redo log file storage media, and there is a large backlog of persisted redo log blocks waiting to be written to the redo log archive file. In this case, the transactional logging rate is reduced to a level that can be managed by the slower storage media where the redo log archive file resides.

## Disabling Redo Logging

You can disable redo logging using the `ALTER INSTANCE DISABLE INNODB REDO_LOG` statement. This functionality is intended for loading data into a new MySQL instance. Disabling redo logging speeds up data loading by avoiding redo log writes and doublewrite buffering.

### Warning

This feature is intended only for loading data into a new MySQL instance. *Do not disable redo logging on a production system.* It is permitted to shutdown and restart the server while redo logging is disabled, but an unexpected server stoppage while redo logging is disabled can cause data loss and instance corruption.

Attempting to restart the server after an unexpected server stoppage while redo logging is disabled is refused with the following error:

```
[ERROR] [MY-013598] [InnoDB] Server was killed when InnoDB Redo logging was disabled. Data files could be corrupt. You can try to restart the database with innodb_force_recovery=6
```

In this case, initialize a new MySQL instance and start the data loading procedure again.

The `INNODB_REDO_LOG_ENABLE` privilege is required to enable and disable redo logging.

The `InnoDB_redo_log_enabled` status variable permits monitoring redo logging status.

Cloning operations and redo log archiving are not permitted while redo logging is disabled and vice versa.

An `ALTER INSTANCE [ENABLE|DISABLE] INNODB REDO_LOG` operation requires an exclusive backup metadata lock, which prevents other `ALTER INSTANCE` operations from executing concurrently. Other `ALTER INSTANCE` operations must wait for the lock to be released before executing.

The following procedure demonstrates how to disable redo logging when loading data into a new MySQL instance.

1. On the new MySQL instance, grant the `INNODB_REDO_LOG_ENABLE` privilege to the user account responsible for disabling redo logging.

```
mysql> GRANT INNODB_REDO_LOG_ENABLE ON *.* to 'data_load_admin';
```

2. As the `data_load_admin` user, disable redo logging:

```
mysql> ALTER INSTANCE DISABLE INNODB REDO_LOG;
```

3. Check the `InnoDB_redo_log_enabled` status variable to ensure that redo logging is disabled.

```
mysql> SHOW GLOBAL STATUS LIKE 'Innodb_redo_log_enabled';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Innodb_redo_log_enabled | OFF |
+-----+-----+
```

4. Run the data load operation.
5. As the `data_load_admin` user, enable redo logging after the data load operation finishes:

```
mysql> ALTER INSTANCE ENABLE INNODB REDO_LOG;
```

6. Check the `Innodb_redo_log_enabled` status variable to ensure that redo logging is enabled.

```
mysql> SHOW GLOBAL STATUS LIKE 'Innodb_redo_log_enabled';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Innodb_redo_log_enabled | ON |
+-----+-----+
```

## 17.6.6 Undo Logs

An undo log is a collection of undo log records associated with a single read-write transaction. An undo log record contains information about how to undo the latest change by a transaction to a [clustered index](#) record. If another transaction needs to see the original data as part of a consistent read operation, the unmodified data is retrieved from undo log records. Undo logs exist within [undo log segments](#), which are contained within [rollback segments](#). Rollback segments reside in [undo tablespaces](#) and in the [global temporary tablespace](#).

Undo logs that reside in the global temporary tablespace are used for transactions that modify data in user-defined temporary tables. These undo logs are not redo-logged, as they are not required for crash recovery. They are used only for rollback while the server is running. This type of undo log benefits performance by avoiding redo logging I/O.

For information about data-at-rest encryption for undo logs, see [Undo Log Encryption](#).

Each undo tablespace and the global temporary tablespace individually support a maximum of 128 rollback segments. The `innodb_rollback_segments` variable defines the number of rollback segments.

The number of transactions that a rollback segment supports depends on the number of undo slots in the rollback segment and the number of undo logs required by each transaction. The number of undo slots in a rollback segment differs according to [InnoDB](#) page size.

InnoDB Page Size	Number of Undo Slots in a Rollback Segment (InnoDB Page Size / 16)
4096 (4KB)	256

InnoDB Page Size	Number of Undo Slots in a Rollback Segment (InnoDB Page Size / 16)
8192 (8KB)	512
16384 (16KB)	1024
32768 (32KB)	2048
65536 (64KB)	4096

A transaction is assigned up to four undo logs, one for each of the following operation types:

1. **INSERT** operations on user-defined tables
2. **UPDATE** and **DELETE** operations on user-defined tables
3. **INSERT** operations on user-defined temporary tables
4. **UPDATE** and **DELETE** operations on user-defined temporary tables

Undo logs are assigned as needed. For example, a transaction that performs **INSERT**, **UPDATE**, and **DELETE** operations on regular and temporary tables requires a full assignment of four undo logs. A transaction that performs only **INSERT** operations on regular tables requires a single undo log.

A transaction that performs operations on regular tables is assigned undo logs from an assigned undo tablespace rollback segment. A transaction that performs operations on temporary tables is assigned undo logs from an assigned global temporary tablespace rollback segment.

An undo log assigned to a transaction remains attached to the transaction for its duration. For example, an undo log assigned to a transaction for an **INSERT** operation on a regular table is used for all **INSERT** operations on regular tables performed by that transaction.

Given the factors described above, the following formulas can be used to estimate the number of concurrent read-write transactions that **InnoDB** is capable of supporting.

#### Note

It is possible to encounter a concurrent transaction limit error before reaching the number of concurrent read-write transactions that **InnoDB** is capable of supporting. This occurs when a rollback segment assigned to a transaction runs out of undo slots. In such cases, try rerunning the transaction.

When transactions perform operations on temporary tables, the number of concurrent read-write transactions that **InnoDB** is capable of supporting is constrained by the number of rollback segments allocated to the global temporary tablespace, which is 128 by default.

- If each transaction performs either an **INSERT** or an **UPDATE** or **DELETE** operation, the number of concurrent read-write transactions that **InnoDB** is capable of supporting is:

```
(innodb_page_size / 16) * innodb_rollback_segments * number of undo tablespaces
```

- If each transaction performs an **INSERT** and an **UPDATE** or **DELETE** operation, the number of concurrent read-write transactions that **InnoDB** is capable of supporting is:

```
(innodb_page_size / 16 / 2) * innodb_rollback_segments * number of undo tablespaces
```

- If each transaction performs an **INSERT** operation on a temporary table, the number of concurrent read-write transactions that **InnoDB** is capable of supporting is:

```
(innodb_page_size / 16) * innodb_rollback_segments
```

- If each transaction performs an **INSERT** and an **UPDATE** or **DELETE** operation on a temporary table, the number of concurrent read-write transactions that **InnoDB** is capable of supporting is:

```
(innodb_page_size / 16 / 2) * innodb_rollback_segments
```

## 17.7 InnoDB Locking and Transaction Model

To implement a large-scale, busy, or highly reliable database application, to port substantial code from a different database system, or to tune MySQL performance, it is important to understand **InnoDB** locking and the **InnoDB** transaction model.

This section discusses several topics related to **InnoDB** locking and the **InnoDB** transaction model with which you should be familiar.

- [Section 17.7.1, “InnoDB Locking”](#) describes lock types used by **InnoDB**.
- [Section 17.7.2, “InnoDB Transaction Model”](#) describes transaction isolation levels and the locking strategies used by each. It also discusses the use of `autocommit`, consistent non-locking reads, and locking reads.
- [Section 17.7.3, “Locks Set by Different SQL Statements in InnoDB”](#) discusses specific types of locks set in **InnoDB** for various statements.
- [Section 17.7.4, “Phantom Rows”](#) describes how **InnoDB** uses next-key locking to avoid phantom rows.
- [Section 17.7.5, “Deadlocks in InnoDB”](#) provides a deadlock example, discusses deadlock detection, and provides tips for minimizing and handling deadlocks in **InnoDB**.

### 17.7.1 InnoDB Locking

This section describes lock types used by **InnoDB**.

- [Shared and Exclusive Locks](#)
- [Intention Locks](#)
- [Record Locks](#)
- [Gap Locks](#)
- [Next-Key Locks](#)
- [Insert Intention Locks](#)
- [AUTO-INC Locks](#)
- [Predicate Locks for Spatial Indexes](#)

#### Shared and Exclusive Locks

**InnoDB** implements standard row-level locking where there are two types of locks, [shared \(S\) locks](#) and [exclusive \(X\) locks](#).

- A [shared \(S\) lock](#) permits the transaction that holds the lock to read a row.
- An [exclusive \(X\) lock](#) permits the transaction that holds the lock to update or delete a row.

If transaction **T1** holds a shared (**S**) lock on row **r**, then requests from some distinct transaction **T2** for a lock on row **r** are handled as follows:

- A request by **T2** for an **S** lock can be granted immediately. As a result, both **T1** and **T2** hold an **S** lock on **r**.
- A request by **T2** for an **X** lock cannot be granted immediately.

If a transaction **T1** holds an exclusive (**X**) lock on row **r**, a request from some distinct transaction **T2** for a lock of either type on **r** cannot be granted immediately. Instead, transaction **T2** has to wait for transaction **T1** to release its lock on row **r**.

## Intention Locks

InnoDB supports *multiple granularity locking* which permits coexistence of row locks and table locks. For example, a statement such as `LOCK TABLES ... WRITE` takes an exclusive lock (an **X** lock) on the specified table. To make locking at multiple granularity levels practical, InnoDB uses **intention locks**. Intention locks are table-level locks that indicate which type of lock (shared or exclusive) a transaction requires later for a row in a table. There are two types of intention locks:

- An **intention shared lock** (**IS**) indicates that a transaction intends to set a *shared* lock on individual rows in a table.
- An **intention exclusive lock** (**IX**) indicates that a transaction intends to set an exclusive lock on individual rows in a table.

For example, `SELECT ... FOR SHARE` sets an **IS** lock, and `SELECT ... FOR UPDATE` sets an **IX** lock.

The intention locking protocol is as follows:

- Before a transaction can acquire a shared lock on a row in a table, it must first acquire an **IS** lock or stronger on the table.
- Before a transaction can acquire an exclusive lock on a row in a table, it must first acquire an **IX** lock on the table.

Table-level lock type compatibility is summarized in the following matrix.

	<b>X</b>	<b>IX</b>	<b>S</b>	<b>IS</b>
<b>X</b>	Conflict	Conflict	Conflict	Conflict
<b>IX</b>	Conflict	Compatible	Conflict	Compatible
<b>S</b>	Conflict	Conflict	Compatible	Compatible
<b>IS</b>	Conflict	Compatible	Compatible	Compatible

A lock is granted to a requesting transaction if it is compatible with existing locks, but not if it conflicts with existing locks. A transaction waits until the conflicting existing lock is released. If a lock request conflicts with an existing lock and cannot be granted because it would cause **deadlock**, an error occurs.

Intention locks do not block anything except full table requests (for example, `LOCK TABLES ... WRITE`). The main purpose of intention locks is to show that someone is locking a row, or going to lock a row in the table.

Transaction data for an intention lock appears similar to the following in `SHOW ENGINE INNODB STATUS` and **InnoDB monitor** output:

```
TABLE LOCK table `test`.`t` trx id 10080 lock mode IX
```

## Record Locks

A record lock is a lock on an index record. For example, `SELECT c1 FROM t WHERE c1 = 10 FOR UPDATE;` prevents any other transaction from inserting, updating, or deleting rows where the value of `t.c1` is 10.

Record locks always lock index records, even if a table is defined with no indexes. For such cases, InnoDB creates a hidden clustered index and uses this index for record locking. See [Section 17.6.2.1, “Clustered and Secondary Indexes”](#).

Transaction data for a record lock appears similar to the following in `SHOW ENGINE INNODB STATUS` and InnoDB monitor output:

```
RECORD LOCKS space id 58 page no 3 n bits 72 index `PRIMARY` of table `test`.`t`
trx id 10078 lock_mode X locks rec but not gap
Record lock, heap no 2 PHYSICAL RECORD: n_fields 3; compact format; info bits 0
 0: len 4; hex 8000000a; asc ;;
 1: len 6; hex 00000000274f; asc 'O';
 2: len 7; hex b60000019d0110; asc ;;
```

## Gap Locks

A gap lock is a lock on a gap between index records, or a lock on the gap before the first or after the last index record. For example, `SELECT c1 FROM t WHERE c1 BETWEEN 10 and 20 FOR UPDATE;` prevents other transactions from inserting a value of 15 into column `t.c1`, whether or not there was already any such value in the column, because the gaps between all existing values in the range are locked.

A gap might span a single index value, multiple index values, or even be empty.

Gap locks are part of the tradeoff between performance and concurrency, and are used in some transaction isolation levels and not others.

Gap locking is not needed for statements that lock rows using a unique index to search for a unique row. (This does not include the case that the search condition includes only some columns of a multiple-column unique index; in that case, gap locking does occur.) For example, if the `id` column has a unique index, the following statement uses only an index-record lock for the row having `id` value 100 and it does not matter whether other sessions insert rows in the preceding gap:

```
SELECT * FROM child WHERE id = 100;
```

If `id` is not indexed or has a nonunique index, the statement does lock the preceding gap.

It is also worth noting here that conflicting locks can be held on a gap by different transactions. For example, transaction A can hold a shared gap lock (gap S-lock) on a gap while transaction B holds an exclusive gap lock (gap X-lock) on the same gap. The reason conflicting gap locks are allowed is that if a record is purged from an index, the gap locks held on the record by different transactions must be merged.

Gap locks in InnoDB are “purely inhibitive”, which means that their only purpose is to prevent other transactions from inserting to the gap. Gap locks can co-exist. A gap lock taken by one transaction does not prevent another transaction from taking a gap lock on the same gap. There is no difference between shared and exclusive gap locks. They do not conflict with each other, and they perform the same function.

Gap locking can be disabled explicitly. This occurs if you change the transaction isolation level to `READ COMMITTED`. In this case, gap locking is disabled for searches and index scans and is used only for foreign-key constraint checking and duplicate-key checking.

There are also other effects of using the [READ COMMITTED](#) isolation level. Record locks for nonmatching rows are released after MySQL has evaluated the [WHERE](#) condition. For [UPDATE](#) statements, InnoDB does a “semi-consistent” read, such that it returns the latest committed version to MySQL so that MySQL can determine whether the row matches the [WHERE](#) condition of the [UPDATE](#).

## Next-Key Locks

A next-key lock is a combination of a record lock on the index record and a gap lock on the gap before the index record.

InnoDB performs row-level locking in such a way that when it searches or scans a table index, it sets shared or exclusive locks on the index records it encounters. Thus, the row-level locks are actually index-record locks. A next-key lock on an index record also affects the “gap” before that index record. That is, a next-key lock is an index-record lock plus a gap lock on the gap preceding the index record. If one session has a shared or exclusive lock on record [R](#) in an index, another session cannot insert a new index record in the gap immediately before [R](#) in the index order.

Suppose that an index contains the values 10, 11, 13, and 20. The possible next-key locks for this index cover the following intervals, where a round bracket denotes exclusion of the interval endpoint and a square bracket denotes inclusion of the endpoint:

```
(negative infinity, 10]
(10, 11]
(11, 13]
(13, 20]
(20, positive infinity)
```

For the last interval, the next-key lock locks the gap above the largest value in the index and the “supremum” pseudo-record having a value higher than any value actually in the index. The supremum is not a real index record, so, in effect, this next-key lock locks only the gap following the largest index value.

By default, InnoDB operates in [REPEATABLE READ](#) transaction isolation level. In this case, InnoDB uses next-key locks for searches and index scans, which prevents phantom rows (see [Section 17.7.4, “Phantom Rows”](#)).

Transaction data for a next-key lock appears similar to the following in [SHOW ENGINE INNODB STATUS](#) and [InnoDB monitor](#) output:

```
RECORD LOCKS space id 58 page no 3 n bits 72 index `PRIMARY` of table `test`.`t`
trx id 10080 lock_mode X
Record lock, heap no 1 PHYSICAL RECORD: n_fields 1; compact format; info bits 0
 0: len 8; hex 73757072656d756d; asc supremum;;

Record lock, heap no 2 PHYSICAL RECORD: n_fields 3; compact format; info bits 0
 0: len 4; hex 8000000a; asc ;;
 1: len 6; hex 00000000274f; asc 'O';
 2: len 7; hex b60000019d0110; asc ;;
```

## Insert Intention Locks

An insert intention lock is a type of gap lock set by [INSERT](#) operations prior to row insertion. This lock signals the intent to insert in such a way that multiple transactions inserting into the same index gap need not wait for each other if they are not inserting at the same position within the gap. Suppose that there are index records with values of 4 and 7. Separate transactions that attempt to insert values of 5 and 6, respectively, each lock the gap between 4 and 7 with insert intention locks prior to obtaining the exclusive lock on the inserted row, but do not block each other because the rows are nonconflicting.

The following example demonstrates a transaction taking an insert intention lock prior to obtaining an exclusive lock on the inserted record. The example involves two clients, A and B.

Client A creates a table containing two index records (90 and 102) and then starts a transaction that places an exclusive lock on index records with an ID greater than 100. The exclusive lock includes a gap lock before record 102:

```
mysql> CREATE TABLE child (id int(11) NOT NULL, PRIMARY KEY(id)) ENGINE=InnoDB;
mysql> INSERT INTO child (id) values (90),(102);

mysql> START TRANSACTION;
mysql> SELECT * FROM child WHERE id > 100 FOR UPDATE;
+-----+
| id |
+-----+
| 102 |
+-----+
```

Client B begins a transaction to insert a record into the gap. The transaction takes an insert intention lock while it waits to obtain an exclusive lock.

```
mysql> START TRANSACTION;
mysql> INSERT INTO child (id) VALUES (101);
```

Transaction data for an insert intention lock appears similar to the following in `SHOW ENGINE INNODB STATUS` and [InnoDB monitor](#) output:

```
RECORD LOCKS space id 31 page no 3 n bits 72 index `PRIMARY` of table `test`.`child`
trx id 8731 lock_mode X locks gap before rec insert intention waiting
Record lock, heap no 3 PHYSICAL RECORD: n_fields 3; compact format; info bits 0
 0: len 4; hex 80000066; asc f;;
 1: len 6; hex 000000002215; asc " ";
 2: len 7; hex 9000000172011c; asc r ;;...
```

## AUTO-INC Locks

An [AUTO-INC](#) lock is a special table-level lock taken by transactions inserting into tables with [AUTO\\_INCREMENT](#) columns. In the simplest case, if one transaction is inserting values into the table, any other transactions must wait to do their own inserts into that table, so that rows inserted by the first transaction receive consecutive primary key values.

The `innodb_autoinc_lock_mode` variable controls the algorithm used for auto-increment locking. It allows you to choose how to trade off between predictable sequences of auto-increment values and maximum concurrency for insert operations.

For more information, see [Section 17.6.1.6, “AUTO\\_INCREMENT Handling in InnoDB”](#).

## Predicate Locks for Spatial Indexes

[InnoDB](#) supports [SPATIAL](#) indexing of columns containing spatial data (see [Section 13.4.9, “Optimizing Spatial Analysis”](#)).

To handle locking for operations involving [SPATIAL](#) indexes, next-key locking does not work well to support [REPEATABLE READ](#) or [SERIALIZABLE](#) transaction isolation levels. There is no absolute ordering concept in multidimensional data, so it is not clear which is the “next” key.

To enable support of isolation levels for tables with [SPATIAL](#) indexes, [InnoDB](#) uses predicate locks. A [SPATIAL](#) index contains minimum bounding rectangle (MBR) values, so [InnoDB](#) enforces consistent read on the index by setting a predicate lock on the MBR value used for a query. Other transactions cannot insert or modify a row that would match the query condition.

## 17.7.2 InnoDB Transaction Model

The InnoDB transaction model aims to combine the best properties of a multi-versioning database with traditional two-phase locking. InnoDB performs locking at the row level and runs queries as nonlocking consistent reads by default, in the style of Oracle. The lock information in InnoDB is stored space-efficiently so that lock escalation is not needed. Typically, several users are permitted to lock every row in InnoDB tables, or any random subset of the rows, without causing InnoDB memory exhaustion.

### 17.7.2.1 Transaction Isolation Levels

Transaction isolation is one of the foundations of database processing. Isolation is the I in the acronym ACID; the isolation level is the setting that fine-tunes the balance between performance and reliability, consistency, and reproducibility of results when multiple transactions are making changes and performing queries at the same time.

InnoDB offers all four transaction isolation levels described by the SQL:1992 standard: READ UNCOMMITTED, READ COMMITTED, REPEATABLE READ, and SERIALIZABLE. The default isolation level for InnoDB is REPEATABLE READ.

A user can change the isolation level for a single session or for all subsequent connections with the SET TRANSACTION statement. To set the server's default isolation level for all connections, use the --transaction-isolation option on the command line or in an option file. For detailed information about isolation levels and level-setting syntax, see [Section 15.3.7, “SET TRANSACTION Statement”](#).

InnoDB supports each of the transaction isolation levels described here using different locking strategies. You can enforce a high degree of consistency with the default REPEATABLE READ level, for operations on crucial data where ACID compliance is important. Or you can relax the consistency rules with READ COMMITTED or even READ UNCOMMITTED, in situations such as bulk reporting where precise consistency and repeatable results are less important than minimizing the amount of overhead for locking. SERIALIZABLE enforces even stricter rules than REPEATABLE READ, and is used mainly in specialized situations, such as with XA transactions and for troubleshooting issues with concurrency and deadlocks.

The following list describes how MySQL supports the different transaction levels. The list goes from the most commonly used level to the least used.

- REPEATABLE READ

This is the default isolation level for InnoDB. Consistent reads within the same transaction read the snapshot established by the first read. This means that if you issue several plain (nonlocking) SELECT statements within the same transaction, these SELECT statements are consistent also with respect to each other. See [Section 17.7.2.3, “Consistent Nonlocking Reads”](#).

For locking reads (SELECT with FOR UPDATE or FOR SHARE), UPDATE, and DELETE statements, locking depends on whether the statement uses a unique index with a unique search condition, or a range-type search condition.

- For a unique index with a unique search condition, InnoDB locks only the index record found, not the gap before it.
- For other search conditions, InnoDB locks the index range scanned, using gap locks or next-key locks to block insertions by other sessions into the gaps covered by the range. For information about gap locks and next-key locks, see [Section 17.7.1, “InnoDB Locking”](#).

It is not recommended to mix locking statements (UPDATE, INSERT, DELETE, or SELECT ... FOR ...) with non-locking SELECT statements in a single REPEATABLE READ transaction, because typically in such cases you want SERIALIZABLE. This is because a non-locking SELECT statement presents the state of the database from a read view which consists of transactions committed before the read view was created, and before the current transaction's own writes, while the locking statements

use the most recent state of the database to use locking. In general, these two different table states are inconsistent with each other and difficult to parse.

- **READ COMMITTED**

Each consistent read, even within the same transaction, sets and reads its own fresh snapshot. For information about consistent reads, see [Section 17.7.2.3, “Consistent Nonlocking Reads”](#).

For locking reads (**SELECT** with **FOR UPDATE** or **FOR SHARE**), **UPDATE** statements, and **DELETE** statements, **InnoDB** locks only index records, not the gaps before them, and thus permits the free insertion of new records next to locked records. Gap locking is only used for foreign-key constraint checking and duplicate-key checking.

Because gap locking is disabled, phantom row problems may occur, as other sessions can insert new rows into the gaps. For information about phantom rows, see [Section 17.7.4, “Phantom Rows”](#).

Only row-based binary logging is supported with the **READ COMMITTED** isolation level. If you use **READ COMMITTED** with **binlog\_format=MIXED**, the server automatically uses row-based logging.

Using **READ COMMITTED** has additional effects:

- For **UPDATE** or **DELETE** statements, **InnoDB** holds locks only for rows that it updates or deletes. Record locks for nonmatching rows are released after MySQL has evaluated the **WHERE** condition. This greatly reduces the probability of deadlocks, but they can still happen.
- For **UPDATE** statements, if a row is already locked, **InnoDB** performs a “semi-consistent” read, returning the latest committed version to MySQL so that MySQL can determine whether the row matches the **WHERE** condition of the **UPDATE**. If the row matches (must be updated), MySQL reads the row again and this time **InnoDB** either locks it or waits for a lock on it.

Consider the table created and populated like this:

```
CREATE TABLE t (a INT NOT NULL, b INT) ENGINE = InnoDB;
INSERT INTO t VALUES (1,2),(2,3),(3,2),(4,3),(5,2);
COMMIT;
```

In this case, the table has no indexes, so searches and index scans use the hidden clustered index for record locking (see [Section 17.6.2.1, “Clustered and Secondary Indexes”](#)) rather than indexed columns.

Suppose that one session performs an **UPDATE** using these statements:

```
Session A
START TRANSACTION;
UPDATE t SET b = 5 WHERE b = 3;
```

Suppose also that a second session performs an **UPDATE** by executing these statements following those of the first session:

```
Session B
UPDATE t SET b = 4 WHERE b = 2;
```

As **InnoDB** executes each **UPDATE**, it first acquires an exclusive lock for each row, and then determines whether to modify it. If **InnoDB** does not modify the row, it releases the lock. Otherwise, **InnoDB** retains the lock until the end of the transaction. This affects transaction processing as follows.

When using the default **REPEATABLE READ** isolation level, the first **UPDATE** acquires an x-lock on each row that it reads and does not release any of them:

```
x-lock(1,2); retain x-lock
```

```
x-lock(2,3); update(2,3) to (2,5); retain x-lock
x-lock(3,2); retain x-lock
x-lock(4,3); update(4,3) to (4,5); retain x-lock
x-lock(5,2); retain x-lock
```

The second **UPDATE** blocks as soon as it tries to acquire any locks (because first update has retained locks on all rows), and does not proceed until the first **UPDATE** commits or rolls back:

```
x-lock(1,2); block and wait for first UPDATE to commit or roll back
```

If **READ COMMITTED** is used instead, the first **UPDATE** acquires an x-lock on each row that it reads and releases those for rows that it does not modify:

```
x-lock(1,2); unlock(1,2)
x-lock(2,3); update(2,3) to (2,5); retain x-lock
x-lock(3,2); unlock(3,2)
x-lock(4,3); update(4,3) to (4,5); retain x-lock
x-lock(5,2); unlock(5,2)
```

For the second **UPDATE**, InnoDB does a “semi-consistent” read, returning the latest committed version of each row that it reads to MySQL so that MySQL can determine whether the row matches the **WHERE** condition of the **UPDATE**:

```
x-lock(1,2); update(1,2) to (1,4); retain x-lock
x-lock(2,3); unlock(2,3)
x-lock(3,2); update(3,2) to (3,4); retain x-lock
x-lock(4,3); unlock(4,3)
x-lock(5,2); update(5,2) to (5,4); retain x-lock
```

However, if the **WHERE** condition includes an indexed column, and InnoDB uses the index, only the indexed column is considered when taking and retaining record locks. In the following example, the first **UPDATE** takes and retains an x-lock on each row where  $b = 2$ . The second **UPDATE** blocks when it tries to acquire x-locks on the same records, as it also uses the index defined on column  $b$ .

```
CREATE TABLE t (a INT NOT NULL, b INT, c INT, INDEX (b)) ENGINE = InnoDB;
INSERT INTO t VALUES (1,2,3),(2,2,4);
COMMIT;

Session A
START TRANSACTION;
UPDATE t SET b = 3 WHERE b = 2 AND c = 3;

Session B
UPDATE t SET b = 4 WHERE b = 2 AND c = 4;
```

The **READ COMMITTED** isolation level can be set at startup or changed at runtime. At runtime, it can be set globally for all sessions, or individually per session.

- **READ UNCOMMITTED**

**SELECT** statements are performed in a nonlocking fashion, but a possible earlier version of a row might be used. Thus, using this isolation level, such reads are not consistent. This is also called a **dirty read**. Otherwise, this isolation level works like **READ COMMITTED**.

- **SERIALIZABLE**

This level is like **REPEATABLE READ**, but InnoDB implicitly converts all plain **SELECT** statements to **SELECT ... FOR SHARE** if **autocommit** is disabled. If **autocommit** is enabled, the **SELECT** is its own transaction. It therefore is known to be read only and can be serialized if performed as a consistent

(nonlocking) read and need not block for other transactions. (To force a plain `SELECT` to block if other transactions have modified the selected rows, disable `autocommit`.)

DML operations that read data from MySQL grant tables (through a join list or subquery) but do not modify them do not acquire read locks on the MySQL grant tables, regardless of the isolation level. For more information, see [Grant Table Concurrency](#).

### 17.7.2.2 autocommit, Commit, and Rollback

In `InnoDB`, all user activity occurs inside a transaction. If `autocommit` mode is enabled, each SQL statement forms a single transaction on its own. By default, MySQL starts the session for each new connection with `autocommit` enabled, so MySQL does a commit after each SQL statement if that statement did not return an error. If a statement returns an error, the commit or rollback behavior depends on the error. See [Section 17.20.5, “InnoDB Error Handling”](#).

A session that has `autocommit` enabled can perform a multiple-statement transaction by starting it with an explicit `START TRANSACTION` or `BEGIN` statement and ending it with a `COMMIT` or `ROLLBACK` statement. See [Section 15.3.1, “START TRANSACTION, COMMIT, and ROLLBACK Statements”](#).

If `autocommit` mode is disabled within a session with `SET autocommit = 0`, the session always has a transaction open. A `COMMIT` or `ROLLBACK` statement ends the current transaction and a new one starts.

If a session that has `autocommit` disabled ends without explicitly committing the final transaction, MySQL rolls back that transaction.

Some statements implicitly end a transaction, as if you had done a `COMMIT` before executing the statement. For details, see [Section 15.3.3, “Statements That Cause an Implicit Commit”](#).

A `COMMIT` means that the changes made in the current transaction are made permanent and become visible to other sessions. A `ROLLBACK` statement, on the other hand, cancels all modifications made by the current transaction. Both `COMMIT` and `ROLLBACK` release all `InnoDB` locks that were set during the current transaction.

### Grouping DML Operations with Transactions

By default, connection to the MySQL server begins with `autocommit` mode enabled, which automatically commits every SQL statement as you execute it. This mode of operation might be unfamiliar if you have experience with other database systems, where it is standard practice to issue a sequence of `DML` statements and commit them or roll them back all together.

To use multiple-statement [transactions](#), switch `autocommit` off with the SQL statement `SET autocommit = 0` and end each transaction with `COMMIT` or `ROLLBACK` as appropriate. To leave `autocommit` on, begin each transaction with `START TRANSACTION` and end it with `COMMIT` or `ROLLBACK`. The following example shows two transactions. The first is committed; the second is rolled back.

```
$> mysql test

mysql> CREATE TABLE customer (a INT, b CHAR (20), INDEX (a));
Query OK, 0 rows affected (0.00 sec)
mysql> -- Do a transaction with autocommit turned on.
mysql> START TRANSACTION;
Query OK, 0 rows affected (0.00 sec)
mysql> INSERT INTO customer VALUES (10, 'Heikki');
Query OK, 1 row affected (0.00 sec)
mysql> COMMIT;
Query OK, 0 rows affected (0.00 sec)
mysql> -- Do another transaction with autocommit turned off.
mysql> SET autocommit=0;
Query OK, 0 rows affected (0.00 sec)
```

```

mysql> INSERT INTO customer VALUES (15, 'John');
Query OK, 1 row affected (0.00 sec)
mysql> INSERT INTO customer VALUES (20, 'Paul');
Query OK, 1 row affected (0.00 sec)
mysql> DELETE FROM customer WHERE b = 'Heikki';
Query OK, 1 row affected (0.00 sec)
mysql> -- Now we undo those last 2 inserts and the delete.
mysql> ROLLBACK;
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT * FROM customer;
+-----+-----+
| a | b |
+-----+-----+
| 10 | Heikki |
+-----+-----+
1 row in set (0.00 sec)
mysql>

```

## Transactions in Client-Side Languages

In APIs such as PHP, Perl DBI, JDBC, ODBC, or the standard C call interface of MySQL, you can send transaction control statements such as `COMMIT` to the MySQL server as strings just like any other SQL statements such as `SELECT` or `INSERT`. Some APIs also offer separate special transaction commit and rollback functions or methods.

### 17.7.2.3 Consistent Nonlocking Reads

A **consistent read** means that InnoDB uses multi-versioning to present to a query a snapshot of the database at a point in time. The query sees the changes made by transactions that committed before that point in time, and no changes made by later or uncommitted transactions. The exception to this rule is that the query sees the changes made by earlier statements within the same transaction. This exception causes the following anomaly: If you update some rows in a table, a `SELECT` sees the latest version of the updated rows, but it might also see older versions of any rows. If other sessions simultaneously update the same table, the anomaly means that you might see the table in a state that never existed in the database.

If the transaction **isolation level** is `REPEATABLE READ` (the default level), all consistent reads within the same transaction read the snapshot established by the first such read in that transaction. You can get a fresher snapshot for your queries by committing the current transaction and after that issuing new queries.

With `READ COMMITTED` isolation level, each consistent read within a transaction sets and reads its own fresh snapshot.

Consistent read is the default mode in which InnoDB processes `SELECT` statements in `READ COMMITTED` and `REPEATABLE READ` isolation levels. A consistent read does not set any locks on the tables it accesses, and therefore other sessions are free to modify those tables at the same time a consistent read is being performed on the table.

Suppose that you are running in the default `REPEATABLE READ` isolation level. When you issue a consistent read (that is, an ordinary `SELECT` statement), InnoDB gives your transaction a timepoint according to which your query sees the database. If another transaction deletes a row and commits after your timepoint was assigned, you do not see the row as having been deleted. Inserts and updates are treated similarly.

#### Note

The snapshot of the database state applies to `SELECT` statements within a transaction, not necessarily to `DML` statements. If you insert or modify some rows and then commit that transaction, a `DELETE` or `UPDATE` statement issued from another concurrent `REPEATABLE READ` transaction could affect those just-

committed rows, even though the session could not query them. If a transaction does update or delete rows committed by a different transaction, those changes do become visible to the current transaction. For example, you might encounter a situation like the following:

```
SELECT COUNT(c1) FROM t1 WHERE c1 = 'xyz';
-- Returns 0: no rows match.
DELETE FROM t1 WHERE c1 = 'xyz';
-- Deletes several rows recently committed by other transaction.

SELECT COUNT(c2) FROM t1 WHERE c2 = 'abc';
-- Returns 0: no rows match.
UPDATE t1 SET c2 = 'cba' WHERE c2 = 'abc';
-- Affects 10 rows: another txn just committed 10 rows with 'abc' values.
SELECT COUNT(c2) FROM t1 WHERE c2 = 'cba';
-- Returns 10: this txn can now see the rows it just updated.
```

You can advance your timepoint by committing your transaction and then doing another [SELECT](#) or [START TRANSACTION WITH CONSISTENT SNAPSHOT](#).

This is called *multi-versioned concurrency control*.

In the following example, session A sees the row inserted by B only when B has committed the insert and A has committed as well, so that the timepoint is advanced past the commit of B.

	Session A	Session B
time	SET autocommit=0;	SET autocommit=0;
	SELECT * FROM t;	
	empty set	
		INSERT INTO t VALUES (1, 2);
v	SELECT * FROM t;	
	empty set	COMMIT;
	SELECT * FROM t;	
	empty set	
	COMMIT;	
	SELECT * FROM t;	
	-----	
	1   2	
	-----	

If you want to see the “freshest” state of the database, use either the [READ COMMITTED](#) isolation level or a [locking read](#):

```
SELECT * FROM t FOR SHARE;
```

With [READ COMMITTED](#) isolation level, each consistent read within a transaction sets and reads its own fresh snapshot. With [FOR SHARE](#), a locking read occurs instead: A [SELECT](#) blocks until the transaction containing the freshest rows ends (see [Section 17.7.2.4, “Locking Reads”](#)).

Consistent read does not work over certain DDL statements:

- Consistent read does not work over [DROP TABLE](#), because MySQL cannot use a table that has been dropped and [InnoDB](#) destroys the table.
- Consistent read does not work over [ALTER TABLE](#) operations that make a temporary copy of the original table and delete the original table when the temporary copy is built. When you reissue a

consistent read within a transaction, rows in the new table are not visible because those rows did not exist when the transaction's snapshot was taken. In this case, the transaction returns an error: `ER_TABLE_DEF_CHANGED`, "Table definition has changed, please retry transaction".

The type of read varies for selects in clauses like `INSERT INTO ... SELECT`, `UPDATE ... (SELECT)`, and `CREATE TABLE ... SELECT` that do not specify `FOR UPDATE` or `FOR SHARE`:

- By default, InnoDB uses stronger locks for those statements and the `SELECT` part acts like `READ COMMITTED`, where each consistent read, even within the same transaction, sets and reads its own fresh snapshot.
- To perform a nonlocking read in such cases, set the isolation level of the transaction to `READ UNCOMMITTED` or `READ COMMITTED` to avoid setting locks on rows read from the selected table.

### 17.7.2.4 Locking Reads

If you query data and then insert or update related data within the same transaction, the regular `SELECT` statement does not give enough protection. Other transactions can update or delete the same rows you just queried. InnoDB supports two types of [locking reads](#) that offer extra safety:

- `SELECT ... FOR SHARE`

Sets a shared mode lock on any rows that are read. Other sessions can read the rows, but cannot modify them until your transaction commits. If any of these rows were changed by another transaction that has not yet committed, your query waits until that transaction ends and then uses the latest values.

#### Note

`SELECT ... FOR SHARE` is a replacement for `SELECT ... LOCK IN SHARE MODE`, but `LOCK IN SHARE MODE` remains available for backward compatibility. The statements are equivalent. However, `FOR SHARE` supports `OF table_name`, `NOWAIT`, and `SKIP LOCKED` options. See [Locking Read Concurrency with NOWAIT and SKIP LOCKED](#).

`SELECT ... FOR SHARE` requires the `SELECT` privilege.

`SELECT ... FOR SHARE` statements do not acquire read locks on MySQL grant tables. For more information, see [Grant Table Concurrency](#).

- `SELECT ... FOR UPDATE`

For index records the search encounters, locks the rows and any associated index entries, the same as if you issued an `UPDATE` statement for those rows. Other transactions are blocked from updating those rows, from doing `SELECT ... FOR SHARE`, or from reading the data in certain transaction isolation levels. Consistent reads ignore any locks set on the records that exist in the read view. (Old versions of a record cannot be locked; they are reconstructed by applying [undo logs](#) on an in-memory copy of the record.)

`SELECT ... FOR UPDATE` requires the `SELECT` privilege and at least one of the `DELETE`, `LOCK TABLES`, or `UPDATE` privileges.

These clauses are primarily useful when dealing with tree-structured or graph-structured data, either in a single table or split across multiple tables. You traverse edges or tree branches from one place to another, while reserving the right to come back and change any of these "pointer" values.

All locks set by `FOR SHARE` and `FOR UPDATE` queries are released when the transaction is committed or rolled back.

**Note**

Locking reads are only possible when autocommit is disabled (either by beginning transaction with `START TRANSACTION` or by setting `autocommit` to 0).

A locking read clause in an outer statement does not lock the rows of a table in a nested subquery unless a locking read clause is also specified in the subquery. For example, the following statement does not lock rows in table `t2`.

```
SELECT * FROM t1 WHERE c1 = (SELECT c1 FROM t2) FOR UPDATE;
```

To lock rows in table `t2`, add a locking read clause to the subquery:

```
SELECT * FROM t1 WHERE c1 = (SELECT c1 FROM t2 FOR UPDATE) FOR UPDATE;
```

**Locking Read Examples**

Suppose that you want to insert a new row into a table `child`, and make sure that the child row has a parent row in table `parent`. Your application code can ensure referential integrity throughout this sequence of operations.

First, use a consistent read to query the table `PARENT` and verify that the parent row exists. Can you safely insert the child row to table `CHILD`? No, because some other session could delete the parent row in the moment between your `SELECT` and your `INSERT`, without you being aware of it.

To avoid this potential issue, perform the `SELECT` using `FOR SHARE`:

```
SELECT * FROM parent WHERE NAME = 'Jones' FOR SHARE;
```

After the `FOR SHARE` query returns the parent `'Jones'`, you can safely add the child record to the `CHILD` table and commit the transaction. Any transaction that tries to acquire an exclusive lock in the applicable row in the `PARENT` table waits until you are finished, that is, until the data in all tables is in a consistent state.

For another example, consider an integer counter field in a table `CHILD_CODES`, used to assign a unique identifier to each child added to table `CHILD`. Do not use either consistent read or a shared mode read to read the present value of the counter, because two users of the database could see the same value for the counter, and a duplicate-key error occurs if two transactions attempt to add rows with the same identifier to the `CHILD` table.

Here, `FOR SHARE` is not a good solution because if two users read the counter at the same time, at least one of them ends up in deadlock when it attempts to update the counter.

To implement reading and incrementing the counter, first perform a locking read of the counter using `FOR UPDATE`, and then increment the counter. For example:

```
SELECT counter_field FROM child_codes FOR UPDATE;
UPDATE child_codes SET counter_field = counter_field + 1;
```

A `SELECT ... FOR UPDATE` reads the latest available data, setting exclusive locks on each row it reads. Thus, it sets the same locks a searched SQL `UPDATE` would set on the rows.

The preceding description is merely an example of how `SELECT ... FOR UPDATE` works. In MySQL, the specific task of generating a unique identifier actually can be accomplished using only a single access to the table:

```
UPDATE child_codes SET counter_field = LAST_INSERT_ID(counter_field + 1);
SELECT LAST_INSERT_ID();
```

The `SELECT` statement merely retrieves the identifier information (specific to the current connection). It does not access any table.

## Locking Read Concurrency with `NOWAIT` and `SKIP LOCKED`

If a row is locked by a transaction, a `SELECT ... FOR UPDATE` or `SELECT ... FOR SHARE` transaction that requests the same locked row must wait until the blocking transaction releases the row lock. This behavior prevents transactions from updating or deleting rows that are queried for updates by other transactions. However, waiting for a row lock to be released is not necessary if you want the query to return immediately when a requested row is locked, or if excluding locked rows from the result set is acceptable.

To avoid waiting for other transactions to release row locks, `NOWAIT` and `SKIP LOCKED` options may be used with `SELECT ... FOR UPDATE` or `SELECT ... FOR SHARE` locking read statements.

- `NOWAIT`

A locking read that uses `NOWAIT` never waits to acquire a row lock. The query executes immediately, failing with an error if a requested row is locked.

- `SKIP LOCKED`

A locking read that uses `SKIP LOCKED` never waits to acquire a row lock. The query executes immediately, removing locked rows from the result set.

### Note

Queries that skip locked rows return an inconsistent view of the data. `SKIP LOCKED` is therefore not suitable for general transactional work. However, it may be used to avoid lock contention when multiple sessions access the same queue-like table.

`NOWAIT` and `SKIP LOCKED` only apply to row-level locks.

Statements that use `NOWAIT` or `SKIP LOCKED` are unsafe for statement based replication.

The following example demonstrates `NOWAIT` and `SKIP LOCKED`. Session 1 starts a transaction that takes a row lock on a single record. Session 2 attempts a locking read on the same record using the `NOWAIT` option. Because the requested row is locked by Session 1, the locking read returns immediately with an error. In Session 3, the locking read with `SKIP LOCKED` returns the requested rows except for the row that is locked by Session 1.

```
Session 1:

mysql> CREATE TABLE t (i INT, PRIMARY KEY (i)) ENGINE = InnoDB;

mysql> INSERT INTO t (i) VALUES(1),(2),(3);

mysql> START TRANSACTION;

mysql> SELECT * FROM t WHERE i = 2 FOR UPDATE;
+----+
| i |
+----+
| 2 |
+----+

Session 2:

mysql> START TRANSACTION;
```

```
mysql> SELECT * FROM t WHERE i = 2 FOR UPDATE NOWAIT;
ERROR 3572 (HY000): Do not wait for lock.

Session 3:

mysql> START TRANSACTION;

mysql> SELECT * FROM t FOR UPDATE SKIP LOCKED;
+----+
| i |
+----+
| 1 |
| 3 |
+----+
```

### 17.7.3 Locks Set by Different SQL Statements in InnoDB

A [locking read](#), an [UPDATE](#), or a [DELETE](#) generally set record locks on every index record that is scanned in the processing of an SQL statement. It does not matter whether there are [WHERE](#) conditions in the statement that would exclude the row. [InnoDB](#) does not remember the exact [WHERE](#) condition, but only knows which index ranges were scanned. The locks are normally [next-key locks](#) that also block inserts into the “gap” immediately before the record. However, [gap locking](#) can be disabled explicitly, which causes next-key locking not to be used. For more information, see [Section 17.7.1, “InnoDB Locking”](#). The transaction isolation level can also affect which locks are set; see [Section 17.7.2.1, “Transaction Isolation Levels”](#).

If a secondary index is used in a search and the index record locks to be set are exclusive, [InnoDB](#) also retrieves the corresponding clustered index records and sets locks on them.

If you have no indexes suitable for your statement and MySQL must scan the entire table to process the statement, every row of the table becomes locked, which in turn blocks all inserts by other users to the table. It is important to create good indexes so that your queries do not scan more rows than necessary.

[InnoDB](#) sets specific types of locks as follows.

- [SELECT ... FROM](#) is a consistent read, reading a snapshot of the database and setting no locks unless the transaction isolation level is set to [SERIALIZABLE](#). For [SERIALIZABLE](#) level, the search sets shared next-key locks on the index records it encounters. However, only an index record lock is required for statements that lock rows using a unique index to search for a unique row.
- [SELECT ... FOR UPDATE](#) and [SELECT ... FOR SHARE](#) statements that use a unique index acquire locks for scanned rows, and release the locks for rows that do not qualify for inclusion in the result set (for example, if they do not meet the criteria given in the [WHERE](#) clause). However, in some cases, rows might not be unlocked immediately because the relationship between a result row and its original source is lost during query execution. For example, in a [UNION](#), scanned (and locked) rows from a table might be inserted into a temporary table before evaluating whether they qualify for the result set. In this circumstance, the relationship of the rows in the temporary table to the rows in the original table is lost and the latter rows are not unlocked until the end of query execution.
- For [locking reads](#) ([SELECT](#) with [FOR UPDATE](#) or [FOR SHARE](#)), [UPDATE](#), and [DELETE](#) statements, the locks that are taken depend on whether the statement uses a unique index with a unique search condition or a range-type search condition.
  - For a unique index with a unique search condition, [InnoDB](#) locks only the index record found, not the [gap](#) before it.
  - For other search conditions, and for non-unique indexes, [InnoDB](#) locks the index range scanned, using [gap locks](#) or [next-key locks](#) to block insertions by other sessions into the gaps covered by the range. For information about gap locks and next-key locks, see [Section 17.7.1, “InnoDB Locking”](#).

- For index records the search encounters, `SELECT ... FOR UPDATE` blocks other sessions from doing `SELECT ... FOR SHARE` or from reading in certain transaction isolation levels. Consistent reads ignore any locks set on the records that exist in the read view.
- `UPDATE ... WHERE ...` sets an exclusive next-key lock on every record the search encounters. However, only an index record lock is required for statements that lock rows using a unique index to search for a unique row.
- When `UPDATE` modifies a clustered index record, implicit locks are taken on affected secondary index records. The `UPDATE` operation also takes shared locks on affected secondary index records when performing duplicate check scans prior to inserting new secondary index records, and when inserting new secondary index records.
- `DELETE FROM ... WHERE ...` sets an exclusive next-key lock on every record the search encounters. However, only an index record lock is required for statements that lock rows using a unique index to search for a unique row.
- `INSERT` sets an exclusive lock on the inserted row. This lock is an index-record lock, not a next-key lock (that is, there is no gap lock) and does not prevent other sessions from inserting into the gap before the inserted row.

Prior to inserting the row, a type of gap lock called an insert intention gap lock is set. This lock signals the intent to insert in such a way that multiple transactions inserting into the same index gap need not wait for each other if they are not inserting at the same position within the gap. Suppose that there are index records with values of 4 and 7. Separate transactions that attempt to insert values of 5 and 6 each lock the gap between 4 and 7 with insert intention locks prior to obtaining the exclusive lock on the inserted row, but do not block each other because the rows are nonconflicting.

If a duplicate-key error occurs, a shared lock on the duplicate index record is set. This use of a shared lock can result in deadlock should there be multiple sessions trying to insert the same row if another session already has an exclusive lock. This can occur if another session deletes the row. Suppose that an InnoDB table `t1` has the following structure:

```
CREATE TABLE t1 (i INT, PRIMARY KEY (i)) ENGINE = InnoDB;
```

Now suppose that three sessions perform the following operations in order:

Session 1:

```
START TRANSACTION;
INSERT INTO t1 VALUES(1);
```

Session 2:

```
START TRANSACTION;
INSERT INTO t1 VALUES(1);
```

Session 3:

```
START TRANSACTION;
INSERT INTO t1 VALUES(1);
```

Session 1:

```
ROLLBACK;
```

The first operation by session 1 acquires an exclusive lock for the row. The operations by sessions 2 and 3 both result in a duplicate-key error and they both request a shared lock for the row. When session 1 rolls back, it releases its exclusive lock on the row and the queued shared lock requests for sessions 2

and 3 are granted. At this point, sessions 2 and 3 deadlock: Neither can acquire an exclusive lock for the row because of the shared lock held by the other.

A similar situation occurs if the table already contains a row with key value 1 and three sessions perform the following operations in order:

Session 1:

```
START TRANSACTION;
DELETE FROM t1 WHERE i = 1;
```

Session 2:

```
START TRANSACTION;
INSERT INTO t1 VALUES(1);
```

Session 3:

```
START TRANSACTION;
INSERT INTO t1 VALUES(1);
```

Session 1:

```
COMMIT;
```

The first operation by session 1 acquires an exclusive lock for the row. The operations by sessions 2 and 3 both result in a duplicate-key error and they both request a shared lock for the row. When session 1 commits, it releases its exclusive lock on the row and the queued shared lock requests for sessions 2 and 3 are granted. At this point, sessions 2 and 3 deadlock: Neither can acquire an exclusive lock for the row because of the shared lock held by the other.

- `INSERT ... ON DUPLICATE KEY UPDATE` differs from a simple `INSERT` in that an exclusive lock rather than a shared lock is placed on the row to be updated when a duplicate-key error occurs. An exclusive index-record lock is taken for a duplicate primary key value. An exclusive next-key lock is taken for a duplicate unique key value.
- `REPLACE` is done like an `INSERT` if there is no collision on a unique key. Otherwise, an exclusive next-key lock is placed on the row to be replaced.
- `INSERT INTO T SELECT ... FROM S WHERE ...` sets an exclusive index record lock (without a gap lock) on each row inserted into `T`. If the transaction isolation level is `READ COMMITTED`, InnoDB does the search on `S` as a consistent read (no locks). Otherwise, InnoDB sets shared next-key locks on rows from `S`. InnoDB has to set locks in the latter case: During roll-forward recovery using a statement-based binary log, every SQL statement must be executed in exactly the same way it was done originally.

`CREATE TABLE ... SELECT ...` performs the `SELECT` with shared next-key locks or as a consistent read, as for `INSERT ... SELECT`.

When a `SELECT` is used in the constructs `REPLACE INTO t SELECT ... FROM s WHERE ...` or `UPDATE t ... WHERE col IN (SELECT ... FROM s ...)`, InnoDB sets shared next-key locks on rows from table `s`.

- InnoDB sets an exclusive lock on the end of the index associated with the `AUTO_INCREMENT` column while initializing a previously specified `AUTO_INCREMENT` column on a table.

With `innodb_autoinc_lock_mode=0`, InnoDB uses a special `AUTO-INC` table lock mode where the lock is obtained and held to the end of the current SQL statement (not to the end of the entire transaction) while accessing the auto-increment counter. Other clients cannot

insert into the table while the `AUTO-INC` table lock is held. The same behavior occurs for “bulk inserts” with `innodb_autoinc_lock_mode=1`. Table-level `AUTO-INC` locks are not used with `innodb_autoinc_lock_mode=2`. For more information, See [Section 17.6.1.6, “AUTO\\_INCREMENT Handling in InnoDB”](#).

`InnoDB` fetches the value of a previously initialized `AUTO_INCREMENT` column without setting any locks.

- If a `FOREIGN KEY` constraint is defined on a table, any insert, update, or delete that requires the constraint condition to be checked sets shared record-level locks on the records that it looks at to check the constraint. `InnoDB` also sets these locks in the case where the constraint fails.
- `LOCK TABLES` sets table locks, but it is the higher MySQL layer above the `InnoDB` layer that sets these locks. `InnoDB` is aware of table locks if `innodb_table_locks = 1` (the default) and `autocommit = 0`, and the MySQL layer above `InnoDB` knows about row-level locks.

Otherwise, `InnoDB`'s automatic deadlock detection cannot detect deadlocks where such table locks are involved. Also, because in this case the higher MySQL layer does not know about row-level locks, it is possible to get a table lock on a table where another session currently has row-level locks. However, this does not endanger transaction integrity, as discussed in [Section 17.7.5.2, “Deadlock Detection”](#).

- `LOCK TABLES` acquires two locks on each table if `innodb_table_locks=1` (the default). In addition to a table lock on the MySQL layer, it also acquires an `InnoDB` table lock. To avoid acquiring `InnoDB` table locks, set `innodb_table_locks=0`. If no `InnoDB` table lock is acquired, `LOCK TABLES` completes even if some records of the tables are being locked by other transactions.

In MySQL 9.1, `innodb_table_locks=0` has no effect for tables locked explicitly with `LOCK TABLES ... WRITE`. It does have an effect for tables locked for read or write by `LOCK TABLES ... WRITE` implicitly (for example, through triggers) or by `LOCK TABLES ... READ`.

- All `InnoDB` locks held by a transaction are released when the transaction is committed or aborted. Thus, it does not make much sense to invoke `LOCK TABLES` on `InnoDB` tables in `autocommit=1` mode because the acquired `InnoDB` table locks would be released immediately.
- You cannot lock additional tables in the middle of a transaction because `LOCK TABLES` performs an implicit `COMMIT` and `UNLOCK TABLES`.

## 17.7.4 Phantom Rows

The so-called *phantom* problem occurs within a transaction when the same query produces different sets of rows at different times. For example, if a `SELECT` is executed twice, but returns a row the second time that was not returned the first time, the row is a “phantom” row.

Suppose that there is an index on the `id` column of the `child` table and that you want to read and lock all rows from the table having an identifier value larger than 100, with the intention of updating some column in the selected rows later:

```
SELECT * FROM child WHERE id > 100 FOR UPDATE;
```

The query scans the index starting from the first record where `id` is bigger than 100. Let the table contain rows having `id` values of 90 and 102. If the locks set on the index records in the scanned range do not lock out inserts made in the gaps (in this case, the gap between 90 and 102), another session can insert a new row into the table with an `id` of 101. If you were to execute the same `SELECT` within the same transaction, you would see a new row with an `id` of 101 (a “phantom”) in the result set returned by the query. If we regard a set of rows as a data item, the new phantom child would violate the isolation principle of transactions that a transaction should be able to run so that the data it has read does not change during the transaction.

To prevent phantoms, InnoDB uses an algorithm called *next-key locking* that combines index-row locking with gap locking. InnoDB performs row-level locking in such a way that when it searches or scans a table index, it sets shared or exclusive locks on the index records it encounters. Thus, the row-level locks are actually index-record locks. In addition, a next-key lock on an index record also affects the “gap” before the index record. That is, a next-key lock is an index-record lock plus a gap lock on the gap preceding the index record. If one session has a shared or exclusive lock on record *R* in an index, another session cannot insert a new index record in the gap immediately before *R* in the index order.

When InnoDB scans an index, it can also lock the gap after the last record in the index. Just that happens in the preceding example: To prevent any insert into the table where *id* would be bigger than 100, the locks set by InnoDB include a lock on the gap following *id* value 102.

You can use next-key locking to implement a uniqueness check in your application: If you read your data in share mode and do not see a duplicate for a row you are going to insert, then you can safely insert your row and know that the next-key lock set on the successor of your row during the read prevents anyone meanwhile inserting a duplicate for your row. Thus, the next-key locking enables you to “lock” the nonexistence of something in your table.

Gap locking can be disabled as discussed in [Section 17.7.1, “InnoDB Locking”](#). This may cause phantom problems because other sessions can insert new rows into the gaps when gap locking is disabled.

## 17.7.5 Deadlocks in InnoDB

A deadlock is a situation in which multiple transactions are unable to proceed because each transaction holds a lock that is needed by another one. Because all transactions involved are waiting for the same resource to become available, none of them ever releases the lock it holds.

A deadlock can occur when transactions lock rows in multiple tables (through statements such as `UPDATE` or `SELECT ... FOR UPDATE`), but in the opposite order. A deadlock can also occur when such statements lock ranges of index records and gaps, with each transaction acquiring some locks but not others due to a timing issue. For a deadlock example, see [Section 17.7.5.1, “An InnoDB Deadlock Example”](#).

To reduce the possibility of deadlocks, use transactions rather than `LOCK TABLES` statements; keep transactions that insert or update data small enough that they do not stay open for long periods of time; when different transactions update multiple tables or large ranges of rows, use the same order of operations (such as `SELECT ... FOR UPDATE`) in each transaction; create indexes on the columns used in `SELECT ... FOR UPDATE` and `UPDATE ... WHERE` statements. The possibility of deadlocks is not affected by the isolation level, because the isolation level changes the behavior of read operations, while deadlocks occur because of write operations. For more information about avoiding and recovering from deadlock conditions, see [Section 17.7.5.3, “How to Minimize and Handle Deadlocks”](#).

When deadlock detection is enabled (the default) and a deadlock does occur, InnoDB detects the condition and rolls back one of the transactions (the victim). If deadlock detection is disabled using the `innodb_deadlock_detect` variable, InnoDB relies on the `innodb_lock_wait_timeout` setting to roll back transactions in case of a deadlock. Thus, even if your application logic is correct, you must still handle the case where a transaction must be retried. To view the last deadlock in an InnoDB user transaction, use `SHOW ENGINE INNODB STATUS`. If frequent deadlocks highlight a problem with transaction structure or application error handling, enable `innodb_print_all_deadlocks` to print information about all deadlocks to the `mysqld` error log. For more information about how deadlocks are automatically detected and handled, see [Section 17.7.5.2, “Deadlock Detection”](#).

### 17.7.5.1 An InnoDB Deadlock Example

The following example illustrates how an error can occur when a lock request causes a deadlock. The example involves two clients, A and B.

InnoDB status contains details of the last deadlock. For frequent deadlocks, enable global variable `innodb_print_all_deadlocks`. This adds deadlock information to the error log.

Client A enables `innodb_print_all_deadlocks`, creates two tables, 'Animals' and 'Birds', and inserts data into each. Client A begins a transaction, and selects a row in Animals in share mode:

```
mysql> SET GLOBAL innodb_print_all_deadlocks = ON;
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE Animals (name VARCHAR(10) PRIMARY KEY, value INT) ENGINE = InnoDB;
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE Birds (name VARCHAR(10) PRIMARY KEY, value INT) ENGINE = InnoDB;
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO Animals (name,value) VALUES ("Aardvark",10);
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO Birds (name,value) VALUES ("Buzzard",20);
Query OK, 1 row affected (0.00 sec)

mysql> START TRANSACTION;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT value FROM Animals WHERE name='Aardvark' FOR SHARE;
+-----+
| value |
+-----+
| 10 |
+-----+
1 row in set (0.00 sec)
```

Next, client B begins a transaction, and selects a row in Birds in share mode:

```
mysql> START TRANSACTION;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT value FROM Birds WHERE name='Buzzard' FOR SHARE;
+-----+
| value |
+-----+
| 20 |
+-----+
1 row in set (0.00 sec)
```

The Performance Schema shows the locks after the two select statements:

```
mysql> SELECT ENGINE_TRANSACTION_ID as Trx_Id,
-> OBJECT_NAME as `Table`,
-> INDEX_NAME as `Index`,
-> LOCK_DATA as Data,
-> LOCK_MODE as Mode,
-> LOCK_STATUS as Status,
-> LOCK_TYPE as Type
-> FROM performance_schema.data_locks;
+-----+-----+-----+-----+-----+-----+-----+
| Trx_Id | Table | Index | Data | Mode | Status | Type |
+-----+-----+-----+-----+-----+-----+-----+
| 421291106147544 | Animals | NULL | NULL | IS | GRANTED | TABLE |
| 421291106147544 | Animals | PRIMARY | 'Aardvark' | S,REC_NOT_GAP | GRANTED | RECORD |
| 421291106148352 | Birds | NULL | NULL | IS | GRANTED | TABLE |
| 421291106148352 | Birds | PRIMARY | 'Buzzard' | S,REC_NOT_GAP | GRANTED | RECORD |
+-----+-----+-----+-----+-----+-----+-----+
4 rows in set (0.00 sec)
```

Client B then updates a row in Animals:

```
mysql> UPDATE Animals SET value=30 WHERE name='Aardvark';
```

Client B has to wait. The Performance Schema shows the wait for a lock:

```
mysql> SELECT REQUESTING_ENGINE_LOCK_ID as Req_Lock_Id,
-> REQUESTING_ENGINE_TRANSACTION_ID as Req_Trx_Id,
-> BLOCKING_ENGINE_LOCK_ID as Blk_Lock_Id,
-> BLOCKING_ENGINE_TRANSACTION_ID as Blk_Trx_Id
-> FROM performance_schema.data_lock_waits;
```

Req_Lock_Id	Req_Trx_Id	Blk_Lock_Id	Blk_Trx_Id
139816129437696:27:4:2:139816016601240	43260	139816129436888:27:4:2:139816016594720	4212911061475

1 row in set (0.00 sec)

```
mysql> SELECT ENGINE_LOCK_ID as Lock_Id,
-> ENGINE_TRANSACTION_ID as Trx_id,
-> OBJECT_NAME as `Table`,
-> INDEX_NAME as `Index`,
-> LOCK_DATA as Data,
-> LOCK_MODE as Mode,
-> LOCK_STATUS as Status,
-> LOCK_TYPE as Type
-> FROM performance_schema.data_locks;
```

Lock_Id	Trx_Id	Table	Index	Data	Mode
139816129437696:1187:139816016603896	43260	Animals	NULL	NULL	IX
139816129437696:1188:139816016603808	43260	Birds	NULL	NULL	IS
139816129437696:28:4:2:139816016600896	43260	Birds	PRIMARY	'Buzzard'	S,REC_NOT_GAP
139816129437696:27:4:2:139816016601240	43260	Animals	PRIMARY	'Aardvark'	X,REC_NOT_GAP
139816129436888:1187:139816016597712	421291106147544	Animals	NULL	NULL	IS
139816129436888:27:4:2:139816016594720	421291106147544	Animals	PRIMARY	'Aardvark'	S,REC_NOT_GAP

6 rows in set (0.00 sec)

InnoDB only uses sequential transaction ids when a transaction attempts to modify the database. Therefore, the previous read-only transaction id changes from 421291106148352 to 43260.

If client A attempts to update a row in Birds at the same time, this will lead to a deadlock:

```
mysql> UPDATE Birds SET value=40 WHERE name='Buzzard';
ERROR 1213 (40001): Deadlock found when trying to get lock; try restarting transaction
```

InnoDB rolls back the transaction that caused the deadlock. The first update, from Client B, can now proceed.

The Information Schema contains the number of deadlocks:

```
mysql> SELECT `count` FROM INFORMATION_SCHEMA.INNODB_METRICS
WHERE NAME="lock_deadlocks";
```

count
1

1 row in set (0.00 sec)

The InnoDB status contains the following information about the deadlock and transactions. It also shows that the read-only transaction id 421291106147544 changes to sequential transaction id 43261.

```
mysql> SHOW ENGINE INNODB STATUS;
```

```

LATEST DETECTED DEADLOCK

```

```

### 17.7.5.2 Deadlock Detection

When [deadlock detection](#) is enabled (the default), [InnoDB](#) automatically detects transaction [deadlocks](#) and rolls back a transaction or transactions to break the deadlock. [InnoDB](#) tries to pick small transactions to roll back, where the size of a transaction is determined by the number of rows inserted, updated, or deleted.

[InnoDB](#) is aware of table locks if `innodb_table_locks = 1` (the default) and `autocommit = 0`, and the MySQL layer above it knows about row-level locks. Otherwise, [InnoDB](#) cannot detect deadlocks where a table lock set by a MySQL `LOCK TABLES` statement or a lock set by a storage engine other than [InnoDB](#) is involved. Resolve these situations by setting the value of the `innodb_lock_wait_timeout` system variable.

If the `LATEST DETECTED DEADLOCK` section of [InnoDB](#) Monitor output includes a message stating `TOO DEEP OR LONG SEARCH IN THE LOCK TABLE WAITS-FOR GRAPH, WE WILL ROLL BACK FOLLOWING TRANSACTION`, this indicates that the number of transactions on the wait-for list has reached a limit of 200. A wait-for list that exceeds 200 transactions is treated as a deadlock and the transaction

attempting to check the wait-for list is rolled back. The same error may also occur if the locking thread must look at more than 1,000,000 locks owned by transactions on the wait-for list.

For techniques to organize database operations to avoid deadlocks, see [Section 17.7.5, “Deadlocks in InnoDB”](#).

## Disabling Deadlock Detection

On high concurrency systems, deadlock detection can cause a slowdown when numerous threads wait for the same lock. At times, it may be more efficient to disable deadlock detection and rely on the `innodb_lock_wait_timeout` setting for transaction rollback when a deadlock occurs. Deadlock detection can be disabled using the `innodb_deadlock_detect` variable.

### 17.7.5.3 How to Minimize and Handle Deadlocks

This section builds on the conceptual information about deadlocks in [Section 17.7.5.2, “Deadlock Detection”](#). It explains how to organize database operations to minimize deadlocks and the subsequent error handling required in applications.

**Deadlocks** are a classic problem in transactional databases, but they are not dangerous unless they are so frequent that you cannot run certain transactions at all. Normally, you must write your applications so that they are always prepared to re-issue a transaction if it gets rolled back because of a deadlock.

**InnoDB** uses automatic row-level locking. You can get deadlocks even in the case of transactions that just insert or delete a single row. That is because these operations are not really “atomic”; they automatically set locks on the (possibly several) index records of the row inserted or deleted.

You can cope with deadlocks and reduce the likelihood of their occurrence with the following techniques:

- At any time, issue `SHOW ENGINE INNODB STATUS` to determine the cause of the most recent deadlock. That can help you to tune your application to avoid deadlocks.
- If frequent deadlock warnings cause concern, collect more extensive debugging information by enabling the `innodb_print_all_deadlocks` variable. Information about each deadlock, not just the latest one, is recorded in the MySQL [error log](#). Disable this option when you are finished debugging.
- Always be prepared to re-issue a transaction if it fails due to deadlock. Deadlocks are not dangerous. Just try again.
- Keep transactions small and short in duration to make them less prone to collision.
- Commit transactions immediately after making a set of related changes to make them less prone to collision. In particular, do not leave an interactive `mysql` session open for a long time with an uncommitted transaction.
- If you use **locking reads** (`SELECT ... FOR UPDATE` or `SELECT ... FOR SHARE`), try using a lower isolation level such as `READ COMMITTED`.
- When modifying multiple tables within a transaction, or different sets of rows in the same table, do those operations in a consistent order each time. Then transactions form well-defined queues and do not deadlock. For example, organize database operations into functions within your application, or call stored routines, rather than coding multiple similar sequences of `INSERT`, `UPDATE`, and `DELETE` statements in different places.
- Add well-chosen indexes to your tables so that your queries scan fewer index records and set fewer locks. Use `EXPLAIN SELECT` to determine which indexes the MySQL server regards as the most appropriate for your queries.

- Use less locking. If you can afford to permit a `SELECT` to return data from an old snapshot, do not add a `FOR UPDATE` or `FOR SHARE` clause to it. Using the `READ COMMITTED` isolation level is good here, because each consistent read within the same transaction reads from its own fresh snapshot.
- If nothing else helps, serialize your transactions with table-level locks. The correct way to use `LOCK TABLES` with transactional tables, such as InnoDB tables, is to begin a transaction with `SET autocommit = 0` (not `START TRANSACTION`) followed by `LOCK TABLES`, and to not call `UNLOCK TABLES` until you commit the transaction explicitly. For example, if you need to write to table `t1` and read from table `t2`, you can do this:

```
SET autocommit=0;
LOCK TABLES t1 WRITE, t2 READ, ...;
... do something with tables t1 and t2 here ...
COMMIT;
UNLOCK TABLES;
```

Table-level locks prevent concurrent updates to the table, avoiding deadlocks at the expense of less responsiveness for a busy system.

- Another way to serialize transactions is to create an auxiliary “semaphore” table that contains just a single row. Have each transaction update that row before accessing other tables. In that way, all transactions happen in a serial fashion. Note that the InnoDB instant deadlock detection algorithm also works in this case, because the serializing lock is a row-level lock. With MySQL table-level locks, the timeout method must be used to resolve deadlocks.

## 17.7.6 Transaction Scheduling

InnoDB uses the Contention-Aware Transaction Scheduling (CATS) algorithm to prioritize transactions that are waiting for locks. When multiple transactions are waiting for a lock on the same object, the CATS algorithm determines which transaction receives the lock first.

The CATS algorithm prioritizes waiting transactions by assigning a scheduling weight, which is computed based on the number of transactions that a transaction blocks. For example, if two transactions are waiting for a lock on the same object, the transaction that blocks the most transactions is assigned a greater scheduling weight. If weights are equal, priority is given to the longest waiting transaction.

You can view transaction scheduling weights by querying the `TRX_SCHEDULE_WEIGHT` column in the Information Schema `INNODB_TRX` table. Weights are computed for waiting transactions only. Waiting transactions are those in a `LOCK WAIT` transaction execution state, as reported by the `TRX_STATE` column. A transaction that is not waiting for a lock reports a NULL `TRX_SCHEDULE_WEIGHT` value.

`INNODB_METRICS` counters are provided for monitoring of code-level transaction scheduling events. For information about using `INNODB_METRICS` counters, see [Section 17.15.6, “InnoDB INFORMATION\\_SCHEMA Metrics Table”](#).

- `lock_rec_release_attempts`

The number of attempts to release record locks. A single attempt may lead to zero or more record locks being released, as there may be zero or more record locks in a single structure.

- `lock_rec_grant_attempts`

The number of attempts to grant record locks. A single attempt may result in zero or more record locks being granted.

- `lock_schedule_refreshes`

The number of times the wait-for graph was analyzed to update the scheduled transaction weights.

## 17.8 InnoDB Configuration

This section provides configuration information and procedures for [InnoDB](#) initialization, startup, and various components and features of the [InnoDB](#) storage engine. For information about optimizing database operations for [InnoDB](#) tables, see [Section 10.5, “Optimizing for InnoDB Tables”](#).

### 17.8.1 InnoDB Startup Configuration

The first decisions to make about [InnoDB](#) configuration involve the configuration of data files, log files, page size, and memory buffers, which should be configured before initializing [InnoDB](#). Modifying the configuration after [InnoDB](#) is initialized may involve non-trivial procedures.

This section provides information about specifying [InnoDB](#) settings in a configuration file, viewing [InnoDB](#) initialization information, and important storage considerations.

- [Specifying Options in a MySQL Option File](#)
- [Viewing InnoDB Initialization Information](#)
- [Important Storage Considerations](#)
- [System Tablespace Data File Configuration](#)
- [InnoDB Doublewrite Buffer File Configuration](#)
- [Redo Log Configuration](#)
- [Undo Tablespace Configuration](#)
- [Global Temporary Tablespace Configuration](#)
- [Session Temporary Tablespace Configuration](#)
- [Page Size Configuration](#)
- [Memory Configuration](#)

#### Specifying Options in a MySQL Option File

Because MySQL uses data file, log file, and page size settings to initialize [InnoDB](#), it is recommended that you define these settings in an option file that MySQL reads at startup, prior to initializing [InnoDB](#). Normally, [InnoDB](#) is initialized when the MySQL server is started for the first time.

You can place [InnoDB](#) options in the `[mysqld]` group of any option file that your server reads when it starts. The locations of MySQL option files are described in [Section 6.2.2.2, “Using Option Files”](#).

To make sure that `mysqld` reads options only from a specific file (and `mysqld-auto.cnf`), use the `--defaults-file` option as the first option on the command line when starting the server:

```
mysqld --defaults-file=path_to_option_file
```

#### Viewing InnoDB Initialization Information

To view [InnoDB](#) initialization information during startup, start `mysqld` from a command prompt, which prints initialization information to the console.

For example, on Windows, if `mysqld` is located in `C:\Program Files\MySQL\MySQL Server 9.1\bin`, start the MySQL server like this:

```
C:\> "C:\Program Files\MySQL\MySQL Server 9.1\bin\mysqld" --console
```

On Unix-like systems, `mysqld` is located in the `bin` directory of your MySQL installation:

```
$> bin/mysqld --user=mysql &
```

If you do not send server output to the console, check the error log after startup to see the initialization information `InnoDB` printed during the startup process.

For information about starting MySQL using other methods, see [Section 2.9.5, “Starting and Stopping MySQL Automatically”](#).

#### Note

`InnoDB` does not open all user tables and associated data files at startup. However, `InnoDB` does check for the existence of tablespace files referenced in the data dictionary. If a tablespace file is not found, `InnoDB` logs an error and continues the startup sequence. Tablespace files referenced in the redo log may be opened during crash recovery for redo application.

## Important Storage Considerations

Review the following storage-related considerations before proceeding with your startup configuration.

- In some cases, you can improve database performance by placing data and log files on separate physical disks. You can also use raw disk partitions (raw devices) for `InnoDB` data files, which may speed up I/O. See [Using Raw Disk Partitions for the System Tablespace](#).
- `InnoDB` is a transaction-safe (ACID compliant) storage engine with commit, rollback, and crash-recovery capabilities to protect user data. **However, it cannot do so** if the underlying operating system or hardware does not work as advertised. Many operating systems or disk subsystems may delay or reorder write operations to improve performance. On some operating systems, the very `fsync()` system call that should wait until all unwritten data for a file has been flushed might actually return before the data has been flushed to stable storage. Because of this, an operating system crash or a power outage may destroy recently committed data, or in the worst case, even corrupt the database because write operations have been reordered. If data integrity is important to you, perform “pull-the-plug” tests before using anything in production. On macOS, `InnoDB` uses a special `fcntl()` file flush method. Under Linux, it is advisable to **disable the write-back cache**.

On ATA/SATA disk drives, a command such `hdparm -W0 /dev/hda` may work to disable the write-back cache. **Beware that some drives or disk controllers may be unable to disable the write-back cache.**

- With regard to `InnoDB` recovery capabilities that protect user data, `InnoDB` uses a file flush technique involving a structure called the [doublewrite buffer](#), which is enabled by default (`innodb_doublewrite=ON`). The doublewrite buffer adds safety to recovery following an unexpected exit or power outage, and improves performance on most varieties of Unix by reducing the need for `fsync()` operations. It is recommended that the `innodb_doublewrite` option remains enabled if you are concerned with data integrity or possible failures. For information about the doublewrite buffer, see [Section 17.11.1, “InnoDB Disk I/O”](#).
- Before using NFS with `InnoDB`, review potential issues outlined in [Using NFS with MySQL](#).

## System Tablespace Data File Configuration

The `innodb_data_file_path` option defines the name, size, and attributes of `InnoDB` system tablespace data files. If you do not configure this option prior to initializing the MySQL server, the default behavior is to create a single auto-extending data file, slightly larger than 12MB, named `ibdata1`:

```
mysql> SHOW VARIABLES LIKE 'innodb_data_file_path';
```

Variable_name	Value
innodb_data_file_path	ibdata1:12M:autoextend

The full data file specification syntax includes the file name, file size, [autoextend](#) attribute, and [max](#) attribute:

```
file_name:file_size[:autoextend[:max:max_file_size]]
```

File sizes are specified in kilobytes, megabytes, or gigabytes by appending [K](#), [M](#) or [G](#) to the size value. If specifying the data file size in kilobytes, do so in multiples of 1024. Otherwise, kilobyte values are rounded to nearest megabyte (MB) boundary. The sum of file sizes must be, at a minimum, slightly larger than 12MB.

You can specify more than one data file using a semicolon-separated list. For example:

```
[mysqld]
innodb_data_file_path=ibdata1:50M;ibdata2:50M:autoextend
```

The [autoextend](#) and [max](#) attributes can be used only for the data file that is specified last.

When the [autoextend](#) attribute is specified, the data file automatically increases in size by 64MB increments as space is required. The [innodb\\_autoextend\\_increment](#) variable controls the increment size.

To specify a maximum size for an auto-extending data file, use the [max](#) attribute following the [autoextend](#) attribute. Use the [max](#) attribute only in cases where constraining disk usage is of critical importance. The following configuration permits [ibdata1](#) to grow to a limit of 500MB:

```
[mysqld]
innodb_data_file_path=ibdata1:12M:autoextend:max:500M
```

A minimum file size is enforced for the *first* system tablespace data file to ensure that there is enough space for doublewrite buffer pages. The following table shows minimum file sizes for each [InnoDB](#) page size. The default [InnoDB](#) page size is 16384 (16KB).

Page Size (innodb_page_size)	Minimum File Size
16384 (16KB) or less	5MB
32768 (32KB)	6MB
65536 (64KB)	12MB

If your disk becomes full, you can add a data file on another disk. For instructions, see [Resizing the System Tablespace](#).

The size limit for individual files is determined by your operating system. You can set the file size to more than 4GB on operating systems that support large files. You can also use raw disk partitions as data files. See [Using Raw Disk Partitions for the System Tablespace](#).

[InnoDB](#) is not aware of the file system maximum file size, so be cautious on file systems where the maximum file size is a small value such as 2GB.

System tablespace files are created in the data directory by default ([datadir](#)). To specify an alternate location, use the [innodb\\_data\\_home\\_dir](#) option. For example, to create a system tablespace data file in a directory named [myibdata](#), use this configuration:

```
[mysqld]
innodb_data_home_dir = /myibdata/
innodb_data_file_path=ibdata1:50M:autoextend
```

A trailing slash is required when specifying a value for `innodb_data_home_dir`. InnoDB does not create directories, so ensure that the specified directory exists before you start the server. Also, ensure sure that the MySQL server has the proper access rights to create files in the directory.

InnoDB forms the directory path for each data file by textually concatenating the value of `innodb_data_home_dir` to the data file name. If `innodb_data_home_dir` is not defined, the default value is `./`, which is the data directory. (The MySQL server changes its current working directory to the data directory when it begins executing.)

Alternatively, you can specify an absolute path for system tablespace data files. The following configuration is equivalent to the preceding one:

```
[mysqld]
innodb_data_file_path=/myibdata/ibdata1:50M:autoextend
```

When you specify an absolute path for `innodb_data_file_path`, the setting is not concatenated with the `innodb_data_home_dir` setting. System tablespace files are created in the specified absolute path. The specified directory must exist before you start the server.

## InnoDB Doublewrite Buffer File Configuration

The InnoDB doublewrite buffer storage area resides in doublewrite files, which provides flexibility with respect to the storage location of doublewrite pages. In previous releases, the doublewrite buffer storage area resided in the system tablespace. The `innodb_doublewrite_dir` variable defines the directory where InnoDB creates doublewrite files at startup. If no directory is specified, doublewrite files are created in the `innodb_data_home_dir` directory, which defaults to the data directory if unspecified.

To have doublewrite files created in a location other than the `innodb_data_home_dir` directory, configure `innodb_doublewrite_dir` variable. For example:

```
innodb_doublewrite_dir=/path/to/doublewrite_directory
```

Other doublewrite buffer variables permit defining the number of doublewrite files, the number of pages per thread, and the doublewrite batch size. For more information about doublewrite buffer configuration, see [Section 17.6.4, “Doublewrite Buffer”](#).

## Redo Log Configuration

The amount of disk space occupied by redo log files is controlled by the `innodb_redo_log_capacity` variable, which can be set at startup or runtime; for example, to set the variable to 8GiB in an option file, add the following entry:

```
[mysqld]
innodb_redo_log_capacity = 8589934592
```

For information about configuring redo log capacity at runtime, see [Configuring Redo Log Capacity](#).

The `innodb_redo_log_capacity` variable supersedes the `innodb_log_file_size` and `innodb_log_files_in_group` variables, which are deprecated. When the `innodb_redo_log_capacity` setting is defined, the `innodb_log_file_size` and `innodb_log_files_in_group` settings are ignored; otherwise, if one or both of these deprecated settings are defined then they are used to compute `InnoDB_redo_log_capacity_resized` as  $(\text{innodb\_log\_files\_in\_group} * \text{innodb\_log\_file\_size})$ . If none of those variables are set, then the default `innodb_redo_log_capacity` value is used.

InnoDB attempts to maintain 32 redo log files, with each file equal to  $1/32 * \text{innodb\_redo\_log\_capacity}$ . The redo log files reside in the `#innodb_redo` directory in the data directory unless a different directory was specified by the `innodb_log_group_home_dir` variable. If

`innodb_log_group_home_dir` was defined, the redo log files reside in the `#innodb_redo` directory in that directory. For more information, see [Section 17.6.5, “Redo Log”](#).

You can define a different number of redo log files and different redo log file size when initializing the MySQL Server instance by configuring the `innodb_log_files_in_group` and `innodb_log_file_size` variables.

`innodb_log_files_in_group` defines the number of log files in the log group. The default and recommended value is 2.

`innodb_log_file_size` defines the size in bytes of each log file in the log group. The combined log file size (`innodb_log_file_size * innodb_log_files_in_group`) cannot exceed the maximum value, which is slightly less than 512GB. A pair of 255 GB log files, for example, approaches the limit but does not exceed it. The default log file size is 48MB. Generally, the combined size of the log files should be large enough that the server can smooth out peaks and troughs in workload activity, which often means that there is enough redo log space to handle more than an hour of write activity. A larger log file size means less checkpoint flush activity in the buffer pool, which reduces disk I/O. For additional information, see [Section 10.5.4, “Optimizing InnoDB Redo Logging”](#).

The `innodb_log_group_home_dir` defines the directory path to the InnoDB log files. You might use this option to place InnoDB redo log files in a different physical storage location than InnoDB data files to avoid potential I/O resource conflicts; for example:

```
[mysqld]
innodb_log_group_home_dir = /dr3/iblogs
```

#### Note

InnoDB does not create directories, so make sure that the log directory exists before you start the server. Use the Unix or DOS `mkdir` command to create any necessary directories.

Make sure that the MySQL server has the proper access rights to create files in the log directory. More generally, the server must have access rights in any directory where it needs to create files.

## Undo Tablespace Configuration

Undo logs, by default, reside in two undo tablespaces created when the MySQL instance is initialized.

The `innodb_undo_directory` variable defines the path where InnoDB creates default undo tablespaces. If that variable is undefined, default undo tablespaces are created in the data directory. The `innodb_undo_directory` variable is not dynamic. Configuring it requires restarting the server.

The I/O patterns for undo logs make undo tablespaces good candidates for [SSD](#) storage.

For information about configuring additional undo tablespaces, see [Section 17.6.3.4, “Undo Tablespaces”](#).

## Global Temporary Tablespace Configuration

The global temporary tablespace stores rollback segments for changes made to user-created temporary tables.

A single auto-extending global temporary tablespace data file named `ibtmp1` in the `innodb_data_home_dir` directory by default. The initial file size is slightly larger than 12MB.

The `innodb_temp_data_file_path` option specifies the path, file name, and file size for global temporary tablespace data files. File size is specified in KB, MB, or GB by appending K, M, or G to the size value. The file size or combined file size must be slightly larger than 12MB.

To specify an alternate location for global temporary tablespace data files, configure the `innodb_temp_data_file_path` option at startup.

## Session Temporary Tablespace Configuration

In MySQL 9.1, `InnoDB` is always used as the on-disk storage engine for internal temporary tables.

The `innodb_temp_tablespaces_dir` variable defines the location where `InnoDB` creates session temporary tablespaces. The default location is the `#innodb_temp` directory in the data directory.

To specify an alternate location for session temporary tablespaces, configure the `innodb_temp_tablespaces_dir` variable at startup. A fully qualified path or path relative to the data directory is permitted.

## Page Size Configuration

The `innodb_page_size` option specifies the page size for all `InnoDB` tablespaces in a MySQL instance. This value is set when the instance is created and remains constant afterward. Valid values are 64KB, 32KB, 16KB (the default), 8KB, and 4KB. Alternatively, you can specify page size in bytes (65536, 32768, 16384, 8192, 4096).

The default 16KB page size is appropriate for a wide range of workloads, particularly for queries involving table scans and DML operations involving bulk updates. Smaller page sizes might be more efficient for OLTP workloads involving many small writes, where contention can be an issue when a single page contains many rows. Smaller pages can also be more efficient for SSD storage devices, which typically use small block sizes. Keeping the `InnoDB` page size close to the storage device block size minimizes the amount of unchanged data that is rewritten to disk.

### Important

`innodb_page_size` can be set only when initializing the data directory. See the description of this variable for more information.

## Memory Configuration

MySQL allocates memory to various caches and buffers to improve performance of database operations. When allocating memory for `InnoDB`, always consider memory required by the operating system, memory allocated to other applications, and memory allocated for other MySQL buffers and caches. For example, if you use `MyISAM` tables, consider the amount of memory allocated for the key buffer (`key_buffer_size`). For an overview of MySQL buffers and caches, see [Section 10.12.3.1, “How MySQL Uses Memory”](#).

Buffers specific to `InnoDB` are configured using the following parameters:

- `innodb_buffer_pool_size` defines size of the buffer pool, which is the memory area that holds cached data for `InnoDB` tables, indexes, and other auxiliary buffers. The size of the buffer pool is important for system performance, and it is typically recommended that `innodb_buffer_pool_size` is configured to 50 to 75 percent of system memory. The default buffer pool size is 128MB. For additional guidance, see [Section 10.12.3.1, “How MySQL Uses Memory”](#). For information about how to configure `InnoDB` buffer pool size, see [Section 17.8.3.1, “Configuring InnoDB Buffer Pool Size”](#). Buffer pool size can be configured at startup or dynamically.

On systems with a large amount of memory, you can improve concurrency by dividing the buffer pool into multiple buffer pool instances. The number of buffer pool instances is controlled by the `innodb_buffer_pool_instances` option. By default, `InnoDB` creates one buffer pool instance. The number of buffer pool instances can be configured at startup. For more information, see [Section 17.8.3.2, “Configuring Multiple Buffer Pool Instances”](#).

- `innodb_log_buffer_size` defines the size of the buffer that InnoDB uses to write to the log files on disk. The default size is 64MB. A large log buffer enables large transactions to run without writing the log to disk before the transactions commit. If you have transactions that update, insert, or delete many rows, you might consider increasing the size of the log buffer to save disk I/O. `innodb_log_buffer_size` can be configured at startup. For related information, see [Section 10.5.4, “Optimizing InnoDB Redo Logging”](#).

### Warning

On 32-bit GNU/Linux x86, if memory usage is set too high, `glibc` may permit the process heap to grow over the thread stacks, causing a server failure. It is a risk if the memory allocated to the `mysqld` process for global and per-thread buffers and caches is close to or exceeds 2GB.

A formula similar to the following that calculates global and per-thread memory allocation for MySQL can be used to estimate MySQL memory usage. You may need to modify the formula to account for buffers and caches in your MySQL version and configuration. For an overview of MySQL buffers and caches, see [Section 10.12.3.1, “How MySQL Uses Memory”](#).

```
innodb_buffer_pool_size
+ key_buffer_size
+ max_connections*(sort_buffer_size+read_buffer_size+binlog_cache_size)
+ max_connections*2MB
```

Each thread uses a stack (often 2MB, but only 256KB in MySQL binaries provided by Oracle Corporation.) and in the worst case also uses `sort_buffer_size` + `read_buffer_size` additional memory.

On Linux, if the kernel is enabled for large page support, InnoDB can use large pages to allocate memory for its buffer pool. See [Section 10.12.3.3, “Enabling Large Page Support”](#).

## 17.8.2 Configuring InnoDB for Read-Only Operation

You can query InnoDB tables where the MySQL data directory is on read-only media by enabling the `--innodb-read-only` configuration option at server startup.

### How to Enable

To prepare an instance for read-only operation, make sure all the necessary information is [flushed](#) to the data files before storing it on the read-only medium. Run the server with change buffering disabled (`innodb_change_buffering=0`) and do a [slow shutdown](#).

To enable read-only mode for an entire MySQL instance, specify the following configuration options at server startup:

- `--innodb-read-only=1`
- If the instance is on read-only media such as a DVD or CD, or the `/var` directory is not writeable by all: `--pid-file=path_on_writeable_media` and `--event-scheduler=disabled`
- `--innodb-temp-data-file-path`. This option specifies the path, file name, and file size for InnoDB temporary tablespace data files. The default setting is `ibtmp1:12M:autoextend`, which creates the `ibtmp1` temporary tablespace data file in the data directory. To prepare an instance for read-only operation, set `innodb_temp_data_file_path` to a location outside of the data directory. The path must be relative to the data directory. For example:

```
--innodb-temp-data-file-path=../../tmp/ibtmp1:12M:autoextend
```

Enabling `innodb_read_only` prevents table creation and drop operations for all storage engines. These operations modify data dictionary tables in the `mysql` system database, but those tables use the `InnoDB` storage engine and cannot be modified when `innodb_read_only` is enabled. The same restriction applies to any operation that modifies data dictionary tables, such as `ANALYZE TABLE` and `ALTER TABLE tbl_name ENGINE=engine_name`.

In addition, other tables in the `mysql` system database use the `InnoDB` storage engine in MySQL 9.1. Making those tables read only results in restrictions on operations that modify them. For example, `CREATE USER`, `GRANT`, `REVOKE`, and `INSTALL PLUGIN` operations are not permitted in read-only mode.

## Usage Scenarios

This mode of operation is appropriate in situations such as:

- Distributing a MySQL application, or a set of MySQL data, on a read-only storage medium such as a DVD or CD.
- Multiple MySQL instances querying the same data directory simultaneously, typically in a data warehousing configuration. You might use this technique to avoid [bottlenecks](#) that can occur with a heavily loaded MySQL instance, or you might use different configuration options for the various instances to tune each one for particular kinds of queries.
- Querying data that has been put into a read-only state for security or data integrity reasons, such as archived backup data.

### Note

This feature is mainly intended for flexibility in distribution and deployment, rather than raw performance based on the read-only aspect. See [Section 10.5.3, “Optimizing InnoDB Read-Only Transactions”](#) for ways to tune the performance of read-only queries, which do not require making the entire server read-only.

## How It Works

When the server is run in read-only mode through the `--innodb-read-only` option, certain `InnoDB` features and components are reduced or turned off entirely:

- No [change buffering](#) is done, in particular no merges from the change buffer. To make sure the change buffer is empty when you prepare the instance for read-only operation, disable change buffering (`innodb_change_buffering=0`) and do a [slow shutdown](#) first.
- There is no [crash recovery](#) phase at startup. The instance must have performed a [slow shutdown](#) before being put into the read-only state.
- Because the [redo log](#) is not used in read-only operation, you can set `innodb_log_file_size` to the smallest size possible (1 MB) before making the instance read-only.
- Most background threads are turned off. I/O read threads remain, as well as I/O write threads and a page flush coordinator thread for writes to temporary files, which are permitted in read-only mode. A buffer pool resize thread also remains active to enable online resizing of the buffer pool.
- Information about deadlocks, monitor output, and so on is not written to temporary files. As a consequence, `SHOW ENGINE INNODB STATUS` does not produce any output.
- Changes to configuration option settings that would normally change the behavior of write operations, have no effect when the server is in read-only mode.
- The [MVCC](#) processing to enforce [isolation levels](#) is turned off. All queries read the latest version of a record, because update and deletes are not possible.

- The [undo log](#) is not used. Disable any settings for the `innodb_undo_tablespaces` and `innodb_undo_directory` configuration options.

## 17.8.3 InnoDB Buffer Pool Configuration

This section provides configuration and tuning information for the [InnoDB](#) buffer pool.

### 17.8.3.1 Configuring InnoDB Buffer Pool Size

You can configure [InnoDB](#) buffer pool size offline or while the server is running. Behavior described in this section applies to both methods. For additional information about configuring buffer pool size online, see [Configuring InnoDB Buffer Pool Size Online](#).

When increasing or decreasing `innodb_buffer_pool_size`, the operation is performed in chunks. Chunk size is defined by the `innodb_buffer_pool_chunk_size` configuration option, which has a default of `128M`. For more information, see [Configuring InnoDB Buffer Pool Chunk Size](#).

Buffer pool size must always be equal to or a multiple of `innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances`. If you configure `innodb_buffer_pool_size` to a value that is not equal to or a multiple of `innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances`, buffer pool size is automatically adjusted to a value that is equal to or a multiple of `innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances`.

In the following example, `innodb_buffer_pool_size` is set to `8G`, and `innodb_buffer_pool_instances` is set to `16`. `innodb_buffer_pool_chunk_size` is `128M`, which is the default value.

`8G` is a valid `innodb_buffer_pool_size` value because `8G` is a multiple of `innodb_buffer_pool_instances=16 * innodb_buffer_pool_chunk_size=128M`, which is `2G`.

```
$> mysqld --innodb-buffer-pool-size=8G --innodb-buffer-pool-instances=16
```

```
mysql> SELECT @@innodb_buffer_pool_size/1024/1024/1024;
+-----+
| @@innodb_buffer_pool_size/1024/1024/1024 |
+-----+
| 8.000000000000000 |
+-----+
```

In this example, `innodb_buffer_pool_size` is set to `9G`, and `innodb_buffer_pool_instances` is set to `16`. `innodb_buffer_pool_chunk_size` is `128M`, which is the default value. In this case, `9G` is not a multiple of `innodb_buffer_pool_instances=16 * innodb_buffer_pool_chunk_size=128M`, so `innodb_buffer_pool_size` is adjusted to `10G`, which is a multiple of `innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances`.

```
$> mysqld --innodb-buffer-pool-size=9G --innodb-buffer-pool-instances=16
```

```
mysql> SELECT @@innodb_buffer_pool_size/1024/1024/1024;
+-----+
| @@innodb_buffer_pool_size/1024/1024/1024 |
+-----+
| 10.000000000000000 |
+-----+
```

### Configuring InnoDB Buffer Pool Chunk Size

`innodb_buffer_pool_chunk_size` can be increased or decreased in `1MB` (`1048576` byte) units but can only be modified at startup, in a command line string or in a MySQL configuration file.

Command line:

```
$> mysql --innodb-buffer-pool-chunk-size=134217728
```

Configuration file:

```
[mysqld]
innodb_buffer_pool_chunk_size=134217728
```

The following conditions apply when altering `innodb_buffer_pool_chunk_size`:

- If the new `innodb_buffer_pool_chunk_size` value \* `innodb_buffer_pool_instances` is larger than the current buffer pool size when the buffer pool is initialized, `innodb_buffer_pool_chunk_size` is truncated to `innodb_buffer_pool_size / innodb_buffer_pool_instances`.

For example, if the buffer pool is initialized with a size of **2GB** (2147483648 bytes), **4** buffer pool instances, and a chunk size of **1GB** (1073741824 bytes), chunk size is truncated to a value equal to `innodb_buffer_pool_size / innodb_buffer_pool_instances`, as shown below:

```
$> mysql --innodb-buffer-pool-size=2147483648 --innodb-buffer-pool-instances=4
--innodb-buffer-pool-chunk-size=1073741824;
```

```
mysql> SELECT @@innodb_buffer_pool_size;
+-----+
| @@innodb_buffer_pool_size |
+-----+
| 2147483648 |
+-----+

mysql> SELECT @@innodb_buffer_pool_instances;
+-----+
| @@innodb_buffer_pool_instances |
+-----+
| 4 |
+-----+

Chunk size was set to 1GB (1073741824 bytes) on startup but was
truncated to innodb_buffer_pool_size / innodb_buffer_pool_instances

mysql> SELECT @@innodb_buffer_pool_chunk_size;
+-----+
| @@innodb_buffer_pool_chunk_size |
+-----+
| 536870912 |
+-----+
```

- Buffer pool size must always be equal to or a multiple of `innodb_buffer_pool_chunk_size` \* `innodb_buffer_pool_instances`. If you alter `innodb_buffer_pool_chunk_size`, `innodb_buffer_pool_size` is automatically adjusted to a value that is equal to or a multiple of `innodb_buffer_pool_chunk_size` \* `innodb_buffer_pool_instances`. The adjustment occurs when the buffer pool is initialized. This behavior is demonstrated in the following example:

```
The buffer pool has a default size of 128MB (134217728 bytes)
```

```
mysql> SELECT @@innodb_buffer_pool_size;
+-----+
| @@innodb_buffer_pool_size |
+-----+
| 134217728 |
+-----+

The chunk size is also 128MB (134217728 bytes)

mysql> SELECT @@innodb_buffer_pool_chunk_size;
+-----+
```

```

| @@innodb_buffer_pool_chunk_size |
+-----+
| 134217728 |
+-----+

There is a single buffer pool instance

mysql> SELECT @@innodb_buffer_pool_instances;
+-----+
| @@innodb_buffer_pool_instances |
+-----+
| 1 |
+-----+

Chunk size is decreased by 1MB (1048576 bytes) at startup
(134217728 - 1048576 = 133169152):

$> mysqld --innodb-buffer-pool-chunk-size=133169152

mysql> SELECT @@innodb_buffer_pool_chunk_size;
+-----+
| @@innodb_buffer_pool_chunk_size |
+-----+
| 133169152 |
+-----+

Buffer pool size increases from 134217728 to 266338304
Buffer pool size is automatically adjusted to a value that is equal to
or a multiple of innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances

mysql> SELECT @@innodb_buffer_pool_size;
+-----+
| @@innodb_buffer_pool_size |
+-----+
| 266338304 |
+-----+

```

This example demonstrates the same behavior but with multiple buffer pool instances:

```

The buffer pool has a default size of 2GB (2147483648 bytes)

mysql> SELECT @@innodb_buffer_pool_size;
+-----+
| @@innodb_buffer_pool_size |
+-----+
| 2147483648 |
+-----+

The chunk size is .5 GB (536870912 bytes)

mysql> SELECT @@innodb_buffer_pool_chunk_size;
+-----+
| @@innodb_buffer_pool_chunk_size |
+-----+
| 536870912 |
+-----+

There are 4 buffer pool instances

mysql> SELECT @@innodb_buffer_pool_instances;
+-----+
| @@innodb_buffer_pool_instances |
+-----+
| 4 |
+-----+

Chunk size is decreased by 1MB (1048576 bytes) at startup

```

```
(536870912 - 1048576 = 535822336):

$> mysqld --innodb-buffer-pool-chunk-size=535822336

mysql> SELECT @@innodb_buffer_pool_chunk_size;
+-----+
| @@innodb_buffer_pool_chunk_size |
+-----+
| 535822336 |
+-----+

Buffer pool size increases from 2147483648 to 4286578688
Buffer pool size is automatically adjusted to a value that is equal to
or a multiple of innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances

mysql> SELECT @@innodb_buffer_pool_size;
+-----+
| @@innodb_buffer_pool_size |
+-----+
| 4286578688 |
+-----+
```

Care should be taken when changing `innodb_buffer_pool_chunk_size`, as changing this value can increase the size of the buffer pool, as shown in the examples above. Before you change `innodb_buffer_pool_chunk_size`, calculate the effect on `innodb_buffer_pool_size` to ensure that the resulting buffer pool size is acceptable.

#### Note

To avoid potential performance issues, the number of chunks (`innodb_buffer_pool_size / innodb_buffer_pool_chunk_size`) should not exceed 1000.

## Configuring InnoDB Buffer Pool Size Online

The `innodb_buffer_pool_size` configuration option can be set dynamically using a `SET` statement, allowing you to resize the buffer pool without restarting the server. For example:

```
mysql> SET GLOBAL innodb_buffer_pool_size=402653184;
```

#### Note

The buffer pool size must be equal to or a multiple of `innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances`. Changing those variable settings requires restarting the server.

Active transactions and operations performed through InnoDB APIs should be completed before resizing the buffer pool. When initiating a resizing operation, the operation does not start until all active transactions are completed. Once the resizing operation is in progress, new transactions and operations that require access to the buffer pool must wait until the resizing operation finishes. The exception to the rule is that concurrent access to the buffer pool is permitted while the buffer pool is defragmented and pages are withdrawn when buffer pool size is decreased. A drawback of allowing concurrent access is that it could result in a temporary shortage of available pages while pages are being withdrawn.

#### Note

Nested transactions could fail if initiated after the buffer pool resizing operation begins.

## Monitoring Online Buffer Pool Resizing Progress

The `Innodb_buffer_pool_resize_status` variable reports a string value indicating buffer pool resizing progress; for example:

```
mysql> SHOW STATUS WHERE Variable_name='InnoDB_buffer_pool_resize_status';
```

Variable_name	Value
Innodb_buffer_pool_resize_status	Resizing also other hash tables.

You can also monitor an online buffer pool resizing operation using the `Innodb_buffer_pool_resize_status_code` and `Innodb_buffer_pool_resize_status_progress` status variables, which report numeric values, preferable for programmatic monitoring.

The `Innodb_buffer_pool_resize_status_code` status variable reports a status code indicating the stage of an online buffer pool resizing operation. Status codes include:

- 0: No Resize operation in progress
- 1: Starting Resize
- 2: Disabling AHI (Adaptive Hash Index)
- 3: Withdrawing Blocks
- 4: Acquiring Global Lock
- 5: Resizing Pool
- 6: Resizing Hash
- 7: Resizing Failed

The `Innodb_buffer_pool_resize_status_progress` status variable reports a percentage value indicating the progress of each stage. The percentage value is updated after each buffer pool instance is processed. As the status (reported by `Innodb_buffer_pool_resize_status_code`) changes from one status to another, the percentage value is reset to 0.

The following query returns a string value indicating the buffer pool resizing progress, a code indicating the current stage of the operation, and the current progress of that stage, expressed as a percentage value:

```
SELECT variable_name, variable_value
FROM performance_schema.global_status
WHERE LOWER(variable_name) LIKE "innodb_buffer_pool_resize%";
```

Buffer pool resizing progress is also visible in the server error log. This example shows notes that are logged when increasing the size of the buffer pool:

```
[Note] InnoDB: Resizing buffer pool from 134217728 to 4294967296. (unit=134217728)
[Note] InnoDB: disabled adaptive hash index.
[Note] InnoDB: buffer pool 0 : 31 chunks (253952 blocks) was added.
[Note] InnoDB: buffer pool 0 : hash tables were resized.
[Note] InnoDB: Resized hash tables at lock_sys, adaptive hash index, dictionary.
[Note] InnoDB: completed to resize buffer pool from 134217728 to 4294967296.
[Note] InnoDB: re-enabled adaptive hash index.
```

This example shows notes that are logged when decreasing the size of the buffer pool:

```
[Note] InnoDB: Resizing buffer pool from 4294967296 to 134217728. (unit=134217728)
[Note] InnoDB: disabled adaptive hash index.
```

```
[Note] InnoDB: buffer pool 0 : start to withdraw the last 253952 blocks.
[Note] InnoDB: buffer pool 0 : withdrew 253952 blocks from free list. tried to relocate
0 pages. (253952/253952)
[Note] InnoDB: buffer pool 0 : withdrawn target 253952 blocks.
[Note] InnoDB: buffer pool 0 : 31 chunks (253952 blocks) was freed.
[Note] InnoDB: buffer pool 0 : hash tables were resized.
[Note] InnoDB: Resized hash tables at lock_sys, adaptive hash index, dictionary.
[Note] InnoDB: completed to resize buffer pool from 4294967296 to 134217728.
[Note] InnoDB: re-enabled adaptive hash index.
```

Starting the server with `--log-error-verbosity=3` logs additional information to the error log during an online buffer pool resizing operation. Additional information includes the status codes reported by [InnoDB\\_buffer\\_pool\\_resize\\_status\\_code](#) and the percentage progress value reported by [InnoDB\\_buffer\\_pool\\_resize\\_status\\_progress](#).

```
[Note] [MY-012398] [InnoDB] Requested to resize buffer pool. (new size: 1073741824 bytes)
[Note] [MY-013954] [InnoDB] Status code 1: Resizing buffer pool from 134217728 to 1073741824
(unit=134217728).

## Online Buffer Pool Resizing Internals

The resizing operation is performed by a background thread. When increasing the size of the buffer pool, the resizing operation:

- Adds pages in [chunks](#) (chunk size is defined by [innodb\\_buffer\\_pool\\_chunk\\_size](#))
- Converts hash tables, lists, and pointers to use new addresses in memory
- Adds new pages to the free list

While these operations are in progress, other threads are blocked from accessing the buffer pool.

When decreasing the size of the buffer pool, the resizing operation:

- Defragments the buffer pool and withdraws (frees) pages
- Removes pages in `chunks` (chunk size is defined by `innodb_buffer_pool_chunk_size`)
- Converts hash tables, lists, and pointers to use new addresses in memory

Of these operations, only defragmenting the buffer pool and withdrawing pages allow other threads to access to the buffer pool concurrently.

### 17.8.3.2 Configuring Multiple Buffer Pool Instances

For systems with buffer pools in the multi-gigabyte range, dividing the buffer pool into separate instances can improve concurrency, by reducing contention as different threads read and write to cached pages. This feature is typically intended for systems with a `buffer pool` size in the multi-gigabyte range. Multiple buffer pool instances are configured using the `innodb_buffer_pool_instances` configuration option, and you might also adjust the `innodb_buffer_pool_size` value.

When the `InnoDB` buffer pool is large, many data requests can be satisfied by retrieving from memory. You might encounter bottlenecks from multiple threads trying to access the buffer pool at once. You can enable multiple buffer pools to minimize this contention. Each page that is stored in or read from the buffer pool is assigned to one of the buffer pools randomly, using a hashing function. Each buffer pool manages its own free lists, flush lists, LRUs, and all other data structures connected to a buffer pool.

To enable multiple buffer pool instances, set the `innodb_buffer_pool_instances` configuration option to a value greater than 1 (the default) up to 64 (the maximum). This option takes effect only when you set `innodb_buffer_pool_size` to a size of 1GB or more. The total size you specify is divided among all the buffer pools. For best efficiency, specify a combination of `innodb_buffer_pool_instances` and `innodb_buffer_pool_size` so that each buffer pool instance is at least 1GB.

For information about modifying `InnoDB` buffer pool size, see [Section 17.8.3.1, “Configuring InnoDB Buffer Pool Size”](#).

### 17.8.3.3 Making the Buffer Pool Scan Resistant

Rather than using a strict `LRU` algorithm, `InnoDB` uses a technique to minimize the amount of data that is brought into the `buffer pool` and never accessed again. The goal is to make sure that frequently accessed (“hot”) pages remain in the buffer pool, even as `read-ahead` and `full table scans` bring in new blocks that might or might not be accessed afterward.

Newly read blocks are inserted into the middle of the LRU list. All newly read pages are inserted at a location that by default is  $3/8$  from the tail of the LRU list. The pages are moved to the front of the list (the most-recently used end) when they are accessed in the buffer pool for the first time. Thus, pages that are never accessed never make it to the front portion of the LRU list, and “age out” sooner than with a strict LRU approach. This arrangement divides the LRU list into two segments, where the pages downstream of the insertion point are considered “old” and are desirable victims for LRU eviction.

For an explanation of the inner workings of the `InnoDB` buffer pool and specifics about the LRU algorithm, see [Section 17.5.1, “Buffer Pool”](#).

You can control the insertion point in the LRU list and choose whether `InnoDB` applies the same optimization to blocks brought into the buffer pool by table or index scans. The configuration parameter `innodb_old_blocks_pct` controls the percentage of “old” blocks in the LRU list. The default value of `innodb_old_blocks_pct` is 37, corresponding to the original fixed ratio of  $3/8$ . The value range is 5 (new pages in the buffer pool age out very quickly) to 95 (only 5% of the buffer pool is reserved for hot pages, making the algorithm close to the familiar LRU strategy).

The optimization that keeps the buffer pool from being churned by read-ahead can avoid similar problems due to table or index scans. In these scans, a data page is typically accessed a few times in quick succession and is never touched again. The configuration parameter `innodb_old_blocks_time` specifies the time window (in milliseconds) after the first access to a page during which it can be accessed without being moved to the front (most-recently used end) of the LRU list. The default value of `innodb_old_blocks_time` is 1000. Increasing this value makes more and more blocks likely to age out faster from the buffer pool.

Both `innodb_old_blocks_pct` and `innodb_old_blocks_time` can be specified in the MySQL option file (`my.cnf` or `my.ini`) or changed at runtime with the `SET GLOBAL` statement. Changing the value at runtime requires privileges sufficient to set global system variables. See [Section 7.1.9.1, “System Variable Privileges”](#).

To help you gauge the effect of setting these parameters, the `SHOW ENGINE INNODB STATUS` statement reports buffer pool statistics. For details, see [Monitoring the Buffer Pool Using the InnoDB Standard Monitor](#).

Because the effects of these parameters can vary widely based on your hardware configuration, your data, and the details of your workload, always benchmark to verify the effectiveness before changing these settings in any performance-critical or production environment.

In mixed workloads where most of the activity is OLTP type with periodic batch reporting queries which result in large scans, setting the value of `innodb_old_blocks_time` during the batch runs can help keep the working set of the normal workload in the buffer pool.

When scanning large tables that cannot fit entirely in the buffer pool, setting `innodb_old_blocks_pct` to a small value keeps the data that is only read once from consuming a significant portion of the buffer pool. For example, setting `innodb_old_blocks_pct=5` restricts this data that is only read once to 5% of the buffer pool.

When scanning small tables that do fit into memory, there is less overhead for moving pages around within the buffer pool, so you can leave `innodb_old_blocks_pct` at its default value, or even higher, such as `innodb_old_blocks_pct=50`.

The effect of the `innodb_old_blocks_time` parameter is harder to predict than the `innodb_old_blocks_pct` parameter, is relatively small, and varies more with the workload. To arrive at an optimal value, conduct your own benchmarks if the performance improvement from adjusting `innodb_old_blocks_pct` is not sufficient.

### 17.8.3.4 Configuring InnoDB Buffer Pool Prefetching (Read-Ahead)

A [read-ahead](#) request is an I/O request to prefetch multiple pages in the [buffer pool](#) asynchronously, in anticipation of impending need for these pages. The requests bring in all the pages in one [extent](#). InnoDB uses two read-ahead algorithms to improve I/O performance:

**Linear** read-ahead is a technique that predicts what pages might be needed soon based on pages in the buffer pool being accessed sequentially. You control when InnoDB performs a read-ahead operation by adjusting the number of sequential page accesses required to trigger an asynchronous read request, using the configuration parameter `innodb_read_ahead_threshold`. Before this parameter was added, InnoDB would only calculate whether to issue an asynchronous prefetch request for the entire next extent when it read the last page of the current extent.

The configuration parameter `innodb_read_ahead_threshold` controls how sensitive InnoDB is in detecting patterns of sequential page access. If the number of pages read sequentially from an extent is greater than or equal to `innodb_read_ahead_threshold`, InnoDB initiates an asynchronous read-ahead operation of the entire following extent. `innodb_read_ahead_threshold` can be set to any value from 0-64. The default value is 56. The higher the value, the more strict the access pattern check. For

example, if you set the value to 48, **InnoDB** triggers a linear read-ahead request only when 48 pages in the current extent have been accessed sequentially. If the value is 8, **InnoDB** triggers an asynchronous read-ahead even if as few as 8 pages in the extent are accessed sequentially. You can set the value of this parameter in the MySQL [configuration file](#), or change it dynamically with the `SET GLOBAL` statement, which requires privileges sufficient to set global system variables. See [Section 7.1.9.1, “System Variable Privileges”](#).

**Random** read-ahead is a technique that predicts when pages might be needed soon based on pages already in the buffer pool, regardless of the order in which those pages were read. If 13 consecutive pages from the same extent are found in the buffer pool, **InnoDB** asynchronously issues a request to prefetch the remaining pages of the extent. To enable this feature, set the configuration variable `innodb_random_read_ahead` to `ON`.

The `SHOW ENGINE INNODB STATUS` statement displays statistics to help you evaluate the effectiveness of the read-ahead algorithm. Statistics include counter information for the following global status variables:

- `Innodb_buffer_pool_read_ahead`
- `Innodb_buffer_pool_read_ahead_evicted`
- `Innodb_buffer_pool_read_ahead_rnd`

This information can be useful when fine-tuning the `innodb_random_read_ahead` setting.

For more information about I/O performance, see [Section 10.5.8, “Optimizing InnoDB Disk I/O”](#) and [Section 10.12.1, “Optimizing Disk I/O”](#).

### 17.8.3.5 Configuring Buffer Pool Flushing

**InnoDB** performs certain tasks in the background, including flushing of dirty pages from the buffer pool. Dirty pages are those that have been modified but are not yet written to the data files on disk.

Buffer pool flushing is performed by page cleaner threads. The number of page cleaner threads is controlled by the `innodb_page_cleaners` variable, which has a default value set to the same value as `innodb_buffer_pool_instances`.

Buffer pool flushing is initiated when the percentage of dirty pages reaches the low water mark value defined by the `innodb_max_dirty_pages_pct_lwm` variable. The default low water mark is 10% of buffer pool pages. A `innodb_max_dirty_pages_pct_lwm` value of 0 disables this early flushing behaviour.

The purpose of the `innodb_max_dirty_pages_pct_lwm` threshold is to control the percentage dirty pages in the buffer pool and to prevent the amount of dirty pages from reaching the threshold defined by the `innodb_max_dirty_pages_pct` variable, which has a default value of 90. **InnoDB** aggressively flushes buffer pool pages if the percentage of dirty pages in the buffer pool reaches the `innodb_max_dirty_pages_pct` threshold.

When configuring `innodb_max_dirty_pages_pct_lwm`, the value should always be lower than the `innodb_max_dirty_pages_pct` value.

Additional variables permit fine-tuning of buffer pool flushing behavior:

- The `innodb_flush_neighbors` variable defines whether flushing a page from the buffer pool also flushes other dirty pages in the same extent.
  - The default setting of 0 disables `innodb_flush_neighbors`. Dirty pages in the same extent are not flushed. This setting is recommended for non-rotational storage (SSD) devices where seek time is not a significant factor.

- A setting of 1 flushes contiguous dirty pages in the same extent.
- A setting of 2 flushes dirty pages in the same extent.

When table data is stored on a traditional [HDD](#) storage device, flushing neighbor pages in one operation reduces I/O overhead (primarily for disk seek operations) compared to flushing individual pages at different times. For table data stored on [SSD](#), seek time is not a significant factor and you can disable this setting to spread out write operations.

- The [innodb\\_lru\\_scan\\_depth](#) variable specifies, per buffer pool instance, how far down the buffer pool LRU list the page cleaner thread scans looking for dirty pages to flush. This is a background operation performed by a page cleaner thread once per second.

A setting smaller than the default is generally suitable for most workloads. A value that is significantly higher than necessary may impact performance. Only consider increasing the value if you have spare I/O capacity under a typical workload. Conversely, if a write-intensive workload saturates your I/O capacity, decrease the value, especially in the case of a large buffer pool.

When tuning [innodb\\_lru\\_scan\\_depth](#), start with a low value and configure the setting upward with the goal of rarely seeing zero free pages. Also, consider adjusting [innodb\\_lru\\_scan\\_depth](#) when changing the number of buffer pool instances, since [innodb\\_lru\\_scan\\_depth](#) \* [innodb\\_buffer\\_pool\\_instances](#) defines the amount of work performed by the page cleaner thread each second.

The [innodb\\_flush\\_neighbors](#) and [innodb\\_lru\\_scan\\_depth](#) variables are primarily intended for write-intensive workloads. With heavy DML activity, flushing can fall behind if it is not aggressive enough, or disk writes can saturate I/O capacity if flushing is too aggressive. The ideal settings depend on your workload, data access patterns, and storage configuration (for example, whether data is stored on HDD or SSD devices).

## Adaptive Flushing

[InnoDB](#) uses an adaptive flushing algorithm to dynamically adjust the rate of flushing based on the speed of redo log generation and the current rate of flushing. The intent is to smooth overall performance by ensuring that flushing activity keeps pace with the current workload. Automatically adjusting the flushing rate helps avoid sudden dips in throughput that can occur when bursts of I/O activity due to buffer pool flushing affects the I/O capacity available for ordinary read and write activity.

Sharp checkpoints, which are typically associated with write-intensive workloads that generate a lot of redo entries, can cause a sudden change in throughput, for example. A sharp checkpoint occurs when [InnoDB](#) wants to reuse a portion of a log file. Before doing so, all dirty pages with redo entries in that portion of the log file must be flushed. If log files become full, a sharp checkpoint occurs, causing a temporary reduction in throughput. This scenario can occur even if [innodb\\_max\\_dirty\\_pages\\_pct](#) threshold is not reached.

The adaptive flushing algorithm helps avoid such scenarios by tracking the number of dirty pages in the buffer pool and the rate at which redo log records are being generated. Based on this information, it decides how many dirty pages to flush from the buffer pool each second, which permits it to manage sudden changes in workload.

The [innodb\\_adaptive\\_flushing\\_lwm](#) variable defines a low water mark for redo log capacity. When that threshold is crossed, adaptive flushing is enabled, even if the [innodb\\_adaptive\\_flushing](#) variable is disabled.

Internal benchmarking has shown that the algorithm not only maintains throughput over time, but can also improve overall throughput significantly. However, adaptive flushing can affect the I/O pattern of a

workload significantly and may not be appropriate in all cases. It gives the most benefit when the redo log is in danger of filling up. If adaptive flushing is not appropriate to the characteristics of your workload, you can disable it. Adaptive flushing controlled by the `innodb_adaptive_flushing` variable, which is enabled by default.

`innodb_flushing_avg_loops` defines the number of iterations that InnoDB keeps the previously calculated snapshot of the flushing state, controlling how quickly adaptive flushing responds to foreground workload changes. A high `innodb_flushing_avg_loops` value means that InnoDB keeps the previously calculated snapshot longer, so adaptive flushing responds more slowly. When setting a high value it is important to ensure that redo log utilization does not reach 75% (the hardcoded limit at which asynchronous flushing starts), and that the `innodb_max_dirty_pages_pct` threshold keeps the number of dirty pages to a level that is appropriate for the workload.

Systems with consistent workloads, a large log file size (`innodb_log_file_size`), and small spikes that do not reach 75% log space utilization should use a high `innodb_flushing_avg_loops` value to keep flushing as smooth as possible. For systems with extreme load spikes or log files that do not provide a lot of space, a smaller value allows flushing to closely track workload changes, and helps to avoid reaching 75% log space utilization.

Be aware that if flushing falls behind, the rate of buffer pool flushing can exceed the I/O capacity available to InnoDB, as defined by `innodb_io_capacity` setting. The `innodb_io_capacity_max` value defines an upper limit on I/O capacity in such situations, so that a spike in I/O activity does not consume the entire I/O capacity of the server.

The `innodb_io_capacity` setting is applicable to all buffer pool instances. When dirty pages are flushed, I/O capacity is divided equally among buffer pool instances.

## Limiting Buffer Flushing During Idle Periods

The `innodb_idle_flush_pct` variable limits the rate of buffer pool flushing during idle periods, which are periods of time that database pages are not modified. Its value is interpreted as a percentage of `innodb_io_capacity` (which defines the number of I/O operations per second available to InnoDB). The default value is 100, or 100 percent of the value of `innodb_io_capacity`. To limit flushing during idle periods, set `innodb_idle_flush_pct` to less than 100.

Limiting page flushing during idle periods can help extend the life of solid state storage devices. Side effects of limiting page flushing during idle periods may include a longer shutdown time following a lengthy idle period, and a longer recovery period should a server failure occur.

### 17.8.3.6 Saving and Restoring the Buffer Pool State

To reduce the `warmup` period after restarting the server, InnoDB saves a percentage of the most recently used pages for each buffer pool at server shutdown and restores these pages at server startup. The percentage of recently used pages that is stored is defined by the `innodb_buffer_pool_dump_pct` configuration option.

After restarting a busy server, there is typically a warmup period with steadily increasing throughput, as disk pages that were in the buffer pool are brought back into memory (as the same data is queried, updated, and so on). The ability to restore the buffer pool at startup shortens the warmup period by reloading disk pages that were in the buffer pool before the restart rather than waiting for DML operations to access corresponding rows. Also, I/O requests can be performed in large batches, making the overall I/O faster. Page loading happens in the background, and does not delay database startup.

In addition to saving the buffer pool state at shutdown and restoring it at startup, you can save and restore the buffer pool state at any time, while the server is running. For example, you can save the state of the buffer pool after reaching a stable throughput under a steady workload. You could also restore the previous

buffer pool state after running reports or maintenance jobs that bring data pages into the buffer pool that are only required for those operations, or after running some other non-typical workload.

Even though a buffer pool can be many gigabytes in size, the buffer pool data that InnoDB saves to disk is tiny by comparison. Only tablespace IDs and page IDs necessary to locate the appropriate pages are saved to disk. This information is derived from the `INNODB_BUFFER_PAGE_LRU INFORMATION_SCHEMA` table. By default, tablespace ID and page ID data is saved in a file named `ib_buffer_pool`, which is saved to the InnoDB data directory. The file name and location can be modified using the `innodb_buffer_pool_filename` configuration parameter.

Because data is cached in and aged out of the buffer pool as it is with regular database operations, there is no problem if the disk pages are recently updated, or if a DML operation involves data that has not yet been loaded. The loading mechanism skips requested pages that no longer exist.

The underlying mechanism involves a background thread that is dispatched to perform the dump and load operations.

Disk pages from compressed tables are loaded into the buffer pool in their compressed form. Pages are uncompressed as usual when page contents are accessed during DML operations. Because uncompressing pages is a CPU-intensive process, it is more efficient for concurrency to perform the operation in a connection thread rather than in the single thread that performs the buffer pool restore operation.

Operations related to saving and restoring the buffer pool state are described in the following topics:

- [Configuring the Dump Percentage for Buffer Pool Pages](#)
- [Saving the Buffer Pool State at Shutdown and Restoring it at Startup](#)
- [Saving and Restoring the Buffer Pool State Online](#)
- [Displaying Buffer Pool Dump Progress](#)
- [Displaying Buffer Pool Load Progress](#)
- [Aborting a Buffer Pool Load Operation](#)
- [Monitoring Buffer Pool Load Progress Using Performance Schema](#)

## Configuring the Dump Percentage for Buffer Pool Pages

Before dumping pages from the buffer pool, you can configure the percentage of most-recently-used buffer pool pages that you want to dump by setting the `innodb_buffer_pool_dump_pct` option. If you plan to dump buffer pool pages while the server is running, you can configure the option dynamically:

```
SET GLOBAL innodb_buffer_pool_dump_pct=40;
```

If you plan to dump buffer pool pages at server shutdown, set `innodb_buffer_pool_dump_pct` in your configuration file.

```
[mysqld]
innodb_buffer_pool_dump_pct=40
```

The `innodb_buffer_pool_dump_pct` default value is 25 (dump 25% of most-recently-used pages).

## Saving the Buffer Pool State at Shutdown and Restoring it at Startup

To save the state of the buffer pool at server shutdown, issue the following statement prior to shutting down the server:

```
SET GLOBAL innodb_buffer_pool_dump_at_shutdown=ON;
```

`innodb_buffer_pool_dump_at_shutdown` is enabled by default.

To restore the buffer pool state at server startup, specify the `--innodb-buffer-pool-load-at-startup` option when starting the server:

```
mysqld --innodb-buffer-pool-load-at-startup=ON;
```

`innodb_buffer_pool_load_at_startup` is enabled by default.

## Saving and Restoring the Buffer Pool State Online

To save the state of the buffer pool while MySQL server is running, issue the following statement:

```
SET GLOBAL innodb_buffer_pool_dump_now=ON;
```

To restore the buffer pool state while MySQL is running, issue the following statement:

```
SET GLOBAL innodb_buffer_pool_load_now=ON;
```

## Displaying Buffer Pool Dump Progress

To display progress when saving the buffer pool state to disk, issue the following statement:

```
SHOW STATUS LIKE 'Innodb_buffer_pool_dump_status';
```

If the operation has not yet started, “not started” is returned. If the operation is complete, the completion time is printed (e.g. Finished at 110505 12:18:02). If the operation is in progress, status information is provided (e.g. Dumping buffer pool 5/7, page 237/2873).

## Displaying Buffer Pool Load Progress

To display progress when loading the buffer pool, issue the following statement:

```
SHOW STATUS LIKE 'Innodb_buffer_pool_load_status';
```

If the operation has not yet started, “not started” is returned. If the operation is complete, the completion time is printed (e.g. Finished at 110505 12:23:24). If the operation is in progress, status information is provided (e.g. Loaded 123/22301 pages).

## Aborting a Buffer Pool Load Operation

To abort a buffer pool load operation, issue the following statement:

```
SET GLOBAL innodb_buffer_pool_load_abort=ON;
```

## Monitoring Buffer Pool Load Progress Using Performance Schema

You can monitor buffer pool load progress using [Performance Schema](#).

The following example demonstrates how to enable the `stage/innodb/buffer pool load` stage event instrument and related consumer tables to monitor buffer pool load progress.

For information about buffer pool dump and load procedures used in this example, see [Section 17.8.3.6, “Saving and Restoring the Buffer Pool State”](#). For information about Performance Schema stage event instruments and related consumers, see [Section 29.12.5, “Performance Schema Stage Event Tables”](#).

1. Enable the `stage/innodb/buffer pool load` instrument:

```
mysql> UPDATE performance_schema.setup_instruments SET ENABLED = 'YES'
```

```
WHERE NAME LIKE 'stage/innodb/buffer%';
```

2. Enable the stage event consumer tables, which include `events_stages_current`, `events_stages_history`, and `events_stages_history_long`.

```
mysql> UPDATE performance_schema.setup_consumers SET ENABLED = 'YES'
 WHERE NAME LIKE '%stages%';
```

3. Dump the current buffer pool state by enabling `innodb_buffer_pool_dump_now`.

```
mysql> SET GLOBAL innodb_buffer_pool_dump_now=ON;
```

4. Check the buffer pool dump status to ensure that the operation has completed.

```
mysql> SHOW STATUS LIKE 'Innodb_buffer_pool_dump_status'\G
***** 1. row *****
Variable_name: Innodb_buffer_pool_dump_status
Value: Buffer pool(s) dump completed at 150202 16:38:58
```

5. Load the buffer pool by enabling `innodb_buffer_pool_load_now`:

```
mysql> SET GLOBAL innodb_buffer_pool_load_now=ON;
```

6. Check the current status of the buffer pool load operation by querying the Performance Schema `events_stages_current` table. The `WORK_COMPLETED` column shows the number of buffer pool pages loaded. The `WORK_ESTIMATED` column provides an estimate of the remaining work, in pages.

```
mysql> SELECT EVENT_NAME, WORK_COMPLETED, WORK_ESTIMATED
 FROM performance_schema.events_stages_current;
+-----+-----+-----+
| EVENT_NAME | WORK_COMPLETED | WORK_ESTIMATED |
+-----+-----+-----+
| stage/innodb/buffer pool load | 5353 | 7167 |
+-----+-----+-----+
```

The `events_stages_current` table returns an empty set if the buffer pool load operation has completed. In this case, you can check the `events_stages_history` table to view data for the completed event. For example:

```
mysql> SELECT EVENT_NAME, WORK_COMPLETED, WORK_ESTIMATED
 FROM performance_schema.events_stages_history;
+-----+-----+-----+
| EVENT_NAME | WORK_COMPLETED | WORK_ESTIMATED |
+-----+-----+-----+
| stage/innodb/buffer pool load | 7167 | 7167 |
+-----+-----+-----+
```

#### Note

You can also monitor buffer pool load progress using Performance Schema when loading the buffer pool at startup using `innodb_buffer_pool_load_at_startup`. In this case, the `stage/innodb/buffer pool load` instrument and related consumers must be enabled at startup. For more information, see [Section 29.3, “Performance Schema Startup Configuration”](#).

### 17.8.3.7 Excluding or Including Buffer Pool Pages from Core Files

A core file records the status and memory image of a running process. Because the buffer pool resides in main memory, and the memory image of a running process is dumped to the core file, systems with large buffer pools can produce large core files when the `mysqld` process dies.

Large core files can be problematic for a number of reasons including the time it takes to write them, the amount of disk space they consume, and the challenges associated with transferring large files.

Excluding buffer pool pages may also be desirable from a security perspective if you have concerns about dumping database pages to core files that may be shared inside or outside of your organization for debugging purposes.

#### Note

Access to the data present in buffer pool pages at the time the `mysqld` process died may be beneficial in some debugging scenarios. If in doubt whether to include or exclude buffer pool pages, consult MySQL Support.

The `innodb_buffer_pool_in_core_file` option is only relevant if the `core_file` variable is enabled and the operating system supports the `MADV_DONTDUMP` non-POSIX extension to the `madvise()` system call, which is supported in Linux 3.4 and later. The `MADV_DONTDUMP` extension causes pages in a specified range to be excluded from core dumps. The `innodb_buffer_pool_in_core_file` option is disabled by default on systems that support `MADV_DONTDUMP`, otherwise it defaults to ON.

To generate core files with buffer pool pages, start the server with the `--core-file` and `--innodb-buffer-pool-in-core-file=ON` options.

```
$> mysqld --core-file --innodb-buffer-pool-in-core-file=ON
```

The `core_file` variable is read-only and disabled by default. It is enabled by specifying the `--core-file` option at startup. The `innodb_buffer_pool_in_core_file` variable is dynamic. It can be specified at startup or configured at runtime using a `SET` statement.

```
mysql> SET GLOBAL innodb_buffer_pool_in_core_file=OFF;
```

If the `innodb_buffer_pool_in_core_file` variable is disabled but `MADV_DONTDUMP` is not supported by the operating system, or an `madvise()` failure occurs, a warning is written to the MySQL server error log and the `core_file` variable is disabled to prevent writing core files that unintentionally include buffer pool pages. If the read-only `core_file` variable becomes disabled, the server must be restarted to enable it again.

The following table shows configuration and `MADV_DONTDUMP` support scenarios that determine whether core files are generated and whether they include buffer pool pages.

**Table 17.4 Core File Configuration Scenarios**

<code>core_file</code> variable	<code>innodb_buffer_pool_in_core_file</code> variable	<code>madvise()</code> File <code>MADV_DONTDUMP</code> Support	Outcome
OFF (default)	Not relevant to outcome	Not relevant to outcome	Core file is not generated
ON	ON (default on systems without <code>MADV_DONTDUMP</code> support)	Not relevant to outcome	Core file is generated with buffer pool pages
ON	OFF (default on systems with <code>MADV_DONTDUMP</code> support)	Yes	Core file is generated without buffer pool pages
ON	OFF	No	Core file is not generated, <code>core_file</code> is disabled, and a warning is written to the server error log

The reduction in core file size achieved by disabling the `innodb_buffer_pool_in_core_file` variable depends on the size of the buffer pool, but it is also affected by the InnoDB page size. A smaller page size means more pages are required for the same amount of data, and more pages means more page metadata. The following table provides size reduction examples that you might see for a 1GB buffer pool with different pages sizes.

**Table 17.5 Core File Size with Buffer Pool Pages Included and Excluded**

<code>innodb_page_size</code> Setting	Buffer Pool Pages Included ( <code>innodb_buffer_pool_in_core_file=ON</code> )	Buffer Pool Pages Excluded ( <code>innodb_buffer_pool_in_core_file=OFF</code> )
4KB	2.1GB	0.9GB
64KB	1.7GB	0.7GB

## 17.8.4 Configuring Thread Concurrency for InnoDB

InnoDB uses operating system threads to process requests from user transactions. (Transactions may issue many requests to InnoDB before they commit or roll back.) On modern operating systems and servers with multi-core processors, where context switching is efficient, most workloads run well without any limit on the number of concurrent threads.

In situations where it is helpful to minimize context switching between threads, InnoDB can use a number of techniques to limit the number of concurrently executing operating system threads (and thus the number of requests that are processed at any one time). When InnoDB receives a new request from a user session, if the number of threads concurrently executing is at a pre-defined limit, the new request sleeps for a short time before it tries again. Threads waiting for locks are not counted in the number of concurrently executing threads.

You can limit the number of concurrent threads by setting the configuration parameter `innodb_thread_concurrency`. Once the number of executing threads reaches this limit, additional threads sleep for a number of microseconds, set by the configuration parameter `innodb_thread_sleep_delay`, before being placed into the queue.

You can set the configuration option `innodb_adaptive_max_sleep_delay` to the highest value you would allow for `innodb_thread_sleep_delay`, and InnoDB automatically adjusts `innodb_thread_sleep_delay` up or down depending on the current thread-scheduling activity. This dynamic adjustment helps the thread scheduling mechanism to work smoothly during times when the system is lightly loaded and when it is operating near full capacity.

The default value for `innodb_thread_concurrency` and the implied default limit on the number of concurrent threads has been changed in various releases of MySQL and InnoDB. The default value of `innodb_thread_concurrency` is 0, so that by default there is no limit on the number of concurrently executing threads.

InnoDB causes threads to sleep only when the number of concurrent threads is limited. When there is no limit on the number of threads, all contend equally to be scheduled. That is, if `innodb_thread_concurrency` is 0, the value of `innodb_thread_sleep_delay` is ignored.

When there is a limit on the number of threads (when `innodb_thread_concurrency` is > 0), InnoDB reduces context switching overhead by permitting multiple requests made during the execution of a *single SQL statement* to enter InnoDB without observing the limit set by `innodb_thread_concurrency`. Since an SQL statement (such as a join) may comprise multiple row operations within InnoDB, InnoDB assigns a specified number of “tickets” that allow a thread to be scheduled repeatedly with minimal overhead.

When a new SQL statement starts, a thread has no tickets, and it must observe `innodb_thread_concurrency`. Once the thread is entitled to enter InnoDB, it is assigned a number

of tickets that it can use for subsequently entering [InnoDB](#) to perform row operations. If the tickets run out, the thread is evicted, and [innodb\\_thread\\_concurrency](#) is observed again which may place the thread back into the first-in/first-out queue of waiting threads. When the thread is once again entitled to enter [InnoDB](#), tickets are assigned again. The number of tickets assigned is specified by the global option [innodb\\_concurrency\\_tickets](#), which is 5000 by default. A thread that is waiting for a lock is given one ticket once the lock becomes available.

The correct values of these variables depend on your environment and workload. Try a range of different values to determine what value works for your applications. Before limiting the number of concurrently executing threads, review configuration options that may improve the performance of [InnoDB](#) on multi-core and multi-processor computers, such as [innodb\\_adaptive\\_hash\\_index](#).

For general performance information about MySQL thread handling, see [Section 7.1.12.1, “Connection Interfaces”](#).

## 17.8.5 Configuring the Number of Background InnoDB I/O Threads

[InnoDB](#) uses background [threads](#) to service various types of I/O requests. You can configure the number of background threads that service read and write I/O on data pages using the [innodb\\_read\\_io\\_threads](#) and [innodb\\_write\\_io\\_threads](#) configuration parameters. These parameters signify the number of background threads used for read and write requests, respectively. They are effective on all supported platforms. You can set values for these parameters in the MySQL option file ([my.cnf](#) or [my.ini](#)); you cannot change values dynamically. The default value for [innodb\\_read\\_io\\_threads](#) is the number of available logical processors on the system divided by 2, with a minimum default value of 4. The default value for [innodb\\_write\\_io\\_threads](#) is 4. The permissible values range from 1–64 for both options.

The purpose of these configuration options to make [InnoDB](#) more scalable on high end systems. Each background thread can handle up to 256 pending I/O requests. A major source of background I/O is [read-ahead](#) requests. [InnoDB](#) tries to balance the load of incoming requests in such way that most background threads share work equally. [InnoDB](#) also attempts to allocate read requests from the same extent to the same thread, to increase the chances of coalescing the requests. If you have a high end I/O subsystem and you see more than  $64 \times \text{innodb\_read\_io\_threads}$  pending read requests in [SHOW ENGINE INNODB STATUS](#) output, you might improve performance by increasing the value of [innodb\\_read\\_io\\_threads](#).

On Linux systems, [InnoDB](#) uses the asynchronous I/O subsystem by default to perform read-ahead and write requests for data file pages, which changes the way that [InnoDB](#) background threads service these types of I/O requests. For more information, see [Section 17.8.6, “Using Asynchronous I/O on Linux”](#).

For more information about [InnoDB](#) I/O performance, see [Section 10.5.8, “Optimizing InnoDB Disk I/O”](#).

## 17.8.6 Using Asynchronous I/O on Linux

[InnoDB](#) uses the asynchronous I/O subsystem (native AIO) on Linux to perform read-ahead and write requests for data file pages. This behavior is controlled by the [innodb\\_use\\_native\\_aio](#) configuration option, which applies to Linux systems only and is enabled by default. On other Unix-like systems, [InnoDB](#) uses synchronous I/O only. Historically, [InnoDB](#) only used asynchronous I/O on Windows systems. Using the asynchronous I/O subsystem on Linux requires the [libaio](#) library.

With synchronous I/O, query threads queue I/O requests, and [InnoDB](#) background threads retrieve the queued requests one at a time, issuing a synchronous I/O call for each. When an I/O request is completed and the I/O call returns, the [InnoDB](#) background thread that is handling the request calls an I/O completion routine and returns to process the next request. The number of requests that can be processed in parallel is  $n$ , where  $n$  is the number of [InnoDB](#) background threads. The number of [InnoDB](#) background threads

is controlled by `innodb_read_io_threads` and `innodb_write_io_threads`. See [Section 17.8.5, “Configuring the Number of Background InnoDB I/O Threads”](#).

With native AIO, query threads dispatch I/O requests directly to the operating system, thereby removing the limit imposed by the number of background threads. InnoDB background threads wait for I/O events to signal completed requests. When a request is completed, a background thread calls an I/O completion routine and resumes waiting for I/O events.

The advantage of native AIO is scalability for heavily I/O-bound systems that typically show many pending reads and writes in `SHOW ENGINE INNODB STATUS` output. The increase in parallel processing when using native AIO means that the type of I/O scheduler or properties of the disk array controller have a greater influence on I/O performance.

A potential disadvantage of native AIO for heavily I/O-bound systems is lack of control over the number of I/O write requests dispatched to the operating system at once. Too many I/O write requests dispatched to the operating system for parallel processing could, in some cases, result in I/O read starvation, depending on the amount of I/O activity and system capabilities.

If a problem with the asynchronous I/O subsystem in the OS prevents InnoDB from starting, you can start the server with `innodb_use_native_aio=0`. This option may also be disabled automatically during startup if InnoDB detects a potential problem such as a combination of `tmpdir` location, `tmpfs` file system, and Linux kernel that does not support asynchronous I/O on `tmpfs`.

## 17.8.7 Configuring InnoDB I/O Capacity

The InnoDB master thread and other threads perform various tasks in the background, most of which are I/O related, such as flushing dirty pages from the buffer pool and writing changes from the change buffer to the appropriate secondary indexes. InnoDB attempts to perform these tasks in a way that does not adversely affect the normal working of the server. It tries to estimate the available I/O bandwidth and tune its activities to take advantage of available capacity.

The `innodb_io_capacity` variable defines the overall I/O capacity available to InnoDB. It should be set to approximately the number of I/O operations that the system can perform per second (IOPS). When `innodb_io_capacity` is set, InnoDB estimates the I/O bandwidth available for background tasks based on the set value.

You can set `innodb_io_capacity` to a value of 100 or greater. The default value is `10000`. Typically, faster hard drives, RAID configurations, and solid state drives (SSDs) benefit from higher values than do lower-end storage devices, such as hard drives up to 7200 RPMs.

Ideally, keep the setting as low as practical, but not so low that background activities fall behind. If the value is too high, data is removed from the buffer pool and change buffer too quickly for caching to provide a significant benefit. For busy systems capable of higher I/O rates, you can set a higher value to help the server handle the background maintenance work associated with a high rate of row changes. Generally, you can increase the value as a function of the number of drives used for InnoDB I/O. For example, you can increase the value on systems that use multiple disks or SSDs.

Although you can specify a high value such as a million, in practice such large values have little benefit. Generally, a value higher than 20000 is not recommended unless you are certain that lower values are insufficient for your workload. See also the `innodb_io_capacity_max` option that automatically increases this value when flushing falls behind.

Consider write workload when tuning `innodb_io_capacity`. Systems with large write workloads are likely to benefit from a higher setting. A lower setting may be sufficient for systems with a small write workload.

The `innodb_io_capacity` setting is not a per buffer pool instance setting. Available I/O capacity is distributed equally among buffer pool instances for flushing activities.

You can set the `innodb_io_capacity` value in the MySQL option file (`my.cnf` or `my.ini`) or modify it at runtime using a `SET GLOBAL` statement, which requires privileges sufficient to set global system variables. See [Section 7.1.9.1, “System Variable Privileges”](#).

## Ignoring I/O Capacity at Checkpoints

The `innodb_flush_sync` variable, which is enabled by default, causes the `innodb_io_capacity` setting to be ignored during bursts of I/O activity that occur at [checkpoints](#). To adhere to the I/O rate defined by the `innodb_io_capacity` and `innodb_io_capacity_max` settings, disable `innodb_flush_sync`.

You can set the `innodb_flush_sync` value in the MySQL option file (`my.cnf` or `my.ini`) or modify it at runtime using a `SET GLOBAL` statement, which requires privileges sufficient to set global system variables. See [Section 7.1.9.1, “System Variable Privileges”](#).

## Configuring an I/O Capacity Maximum

If flushing activity falls behind, InnoDB can flush more aggressively, at a higher rate of I/O operations per second (IOPS) than defined by the `innodb_io_capacity` variable. The `innodb_io_capacity_max` variable defines a maximum number of IOPS performed by InnoDB background tasks in such situations.

If you specify an `innodb_io_capacity` setting at startup but do not specify a value for `innodb_io_capacity_max`, `innodb_io_capacity_max` defaults to twice the value of `innodb_io_capacity`.

When configuring `innodb_io_capacity_max`, twice the `innodb_io_capacity` is often a good starting point. As with the `innodb_io_capacity` setting, keep the setting as low as practical, but not so low that InnoDB cannot sufficiently extend rate of IOPS beyond the `innodb_io_capacity` setting.

Consider write workload when tuning `innodb_io_capacity_max`. Systems with large write workloads may benefit from a higher setting. A lower setting may be sufficient for systems with a small write workload.

`innodb_io_capacity_max` cannot be set to a value lower than the `innodb_io_capacity` value.

Setting `innodb_io_capacity_max` to `DEFAULT` using a `SET` statement (`SET GLOBAL innodb_io_capacity_max=DEFAULT`) sets `innodb_io_capacity_max` to the default value.

The `innodb_io_capacity_max` limit applies to all buffer pool instances. It is not a per buffer pool instance setting.

## 17.8.8 Configuring Spin Lock Polling

InnoDB [mutexes](#) and [rw-locks](#) are typically reserved for short intervals. On a multi-core system, it can be more efficient for a thread to continuously check if it can acquire a mutex or rw-lock for a period of time before it sleeps. If the mutex or rw-lock becomes available during this period, the thread can continue immediately, in the same time slice. However, too-frequent polling of a shared object such as a mutex or rw-lock by multiple threads can cause “cache ping pong”, which results in processors invalidating portions of each other's cache. InnoDB minimizes this issue by forcing a random delay between polls to desynchronize polling activity. The random delay is implemented as a spin-wait loop.

The duration of a spin-wait loop is determined by the number of `PAUSE` instructions that occur in the loop. That number is generated by randomly selecting an integer ranging from 0 up to but not including the `innodb_spin_wait_delay` value, and multiplying that value by 50. For example, an integer is randomly selected from the following range for an `innodb_spin_wait_delay` setting of 6:

```
{0,1,2,3,4,5}
```

The selected integer is multiplied by 50, resulting in one of six possible PAUSE instruction values:

```
{0,50,100,150,200,250}
```

For that set of values, 250 is the maximum number of PAUSE instructions that can occur in a spin-wait loop. An `innodb_spin_wait_delay` setting of 5 results in a set of five possible values `{0,50,100,150,200}`, where 200 is the maximum number of PAUSE instructions, and so on. In this way, the `innodb_spin_wait_delay` setting controls the maximum delay between spin lock polls.

On a system where all processor cores share a fast cache memory, you might reduce the maximum delay or disable the busy loop altogether by setting `innodb_spin_wait_delay=0`. On a system with multiple processor chips, the effect of cache invalidation can be more significant and you might increase the maximum delay.

In the 100MHz Pentium era, an `innodb_spin_wait_delay` unit was calibrated to be equivalent to one microsecond. That time equivalence did not hold, but PAUSE instruction duration remained fairly constant in terms of processor cycles relative to other CPU instructions until the introduction of the Skylake generation of processors, which have a comparatively longer PAUSE instruction. The `innodb_spin_wait_pause_multiplier` variable provides a way to account for differences in PAUSE instruction duration.

The `innodb_spin_wait_pause_multiplier` variable controls the size of PAUSE instruction values. For example, assuming an `innodb_spin_wait_delay` setting of 6, decreasing the `innodb_spin_wait_pause_multiplier` value from 50 (the default and previously hardcoded value) to 5 generates a set of smaller PAUSE instruction values:

```
{0,5,10,15,20,25}
```

The ability to increase or decrease PAUSE instruction values permits fine tuning `InnoDB` for different processor architectures. Smaller PAUSE instruction values would be appropriate for processor architectures with a comparatively longer PAUSE instruction, for example.

The `innodb_spin_wait_delay` and `innodb_spin_wait_pause_multiplier` variables are dynamic. They can be specified in a MySQL option file or modified at runtime using a `SET GLOBAL` statement. Modifying the variables at runtime requires privileges sufficient to set global system variables. See [Section 7.1.9.1, “System Variable Privileges”](#).

## 17.8.9 Purge Configuration

`InnoDB` does not physically remove a row from the database immediately when you delete it with an SQL statement. A row and its index records are only physically removed when `InnoDB` discards the undo log record written for the deletion. This removal operation, which only occurs after the row is no longer required for multi-version concurrency control (MVCC) or rollback, is called a purge.

Purge runs on a periodic schedule. It parses and processes undo log pages from the history list, which is a list of undo log pages for committed transactions that is maintained by the `InnoDB` transaction system. Purge frees the undo log pages from the history list after processing them.

### Configuring Purge Threads

Purge operations are performed in the background by one or more purge threads. The number of purge threads is controlled by the `innodb_purge_threads` variable. The default value is 1 if the number of available logical processors is  $\leq 16$ , otherwise the default is 4.

If DML action is concentrated on a single table, purge operations for the table are performed by a single purge thread, which can result in slowed purge operations, increased purge lag, and increased tablespace file size if the DML operations involve large object values. If the `innodb_max_purge_lag` setting is exceeded, purge work is automatically redistributed among available purge threads. Too many active purge threads in this scenario can cause contention with user threads, so manage the `innodb_purge_threads` setting accordingly. The `innodb_max_purge_lag` variable is set to 0 by default, which means that there is no maximum purge lag by default.

If DML action is concentrated on few tables, keep the `innodb_purge_threads` setting low so that the threads do not contend with each other for access to the busy tables. If DML operations are spread across many tables, consider a higher `innodb_purge_threads` setting. The maximum number of purge threads is 32.

The `innodb_purge_threads` setting is the maximum number of purge threads permitted. The purge system automatically adjusts the number of purge threads that are used.

## Configuring Purge Batch Size

The `innodb_purge_batch_size` variable defines the number of undo log pages that purge parses and processes in one batch from the history list. The default value is 300. In a multithreaded purge configuration, the coordinator purge thread divides `innodb_purge_batch_size` by `innodb_purge_threads` and assigns that number of pages to each purge thread.

The purge system also frees the undo log pages that are no longer required. It does so every 128 iterations through the undo logs. In addition to defining the number of undo log pages parsed and processed in a batch, the `innodb_purge_batch_size` variable defines the number of undo log pages that purge frees every 128 iterations through the undo logs.

The `innodb_purge_batch_size` variable is intended for advanced performance tuning and experimentation. Most users need not change `innodb_purge_batch_size` from its default value.

## Configuring the Maximum Purge Lag

The `innodb_max_purge_lag` variable defines the desired maximum purge lag. When the purge lag exceeds the `innodb_max_purge_lag` threshold, a delay is imposed on `INSERT`, `UPDATE`, and `DELETE` operations to allow time for purge operations to catch up. The default value is 0, which means there is no maximum purge lag and no delay.

The InnoDB transaction system maintains a list of transactions that have index records delete-marked by `UPDATE` or `DELETE` operations. The length of the list is the purge lag.

The purge lag delay is calculated by the following formula:

```
(purge_lag/innodb_max_purge_lag - 0.9995) * 10000
```

The delay is calculated at the beginning of a purge batch.

A typical `innodb_max_purge_lag` setting for a problematic workload might be 1000000 (1 million), assuming that transactions are small, only 100 bytes in size, and it is permissible to have 100MB of unpurged table rows.

The purge lag is presented as the `History list length` value in the `TRANSACTIONS` section of `SHOW ENGINE INNODB STATUS` output.

```
mysql> SHOW ENGINE INNODB STATUS;
...

TRANSACTIONS
```

```

Trx id counter 0 290328385
Purge done for trx's n:o < 0 290315608 undo n:o < 0 17
History list length 20
```

The `History list length` is typically a low value, usually less than a few thousand, but a write-heavy workload or long running transactions can cause it to increase, even for transactions that are read only. The reason that a long running transaction can cause the `History list length` to increase is that under a consistent read transaction isolation level such as `REPEATABLE READ`, a transaction must return the same result as when the read view for that transaction was created. Consequently, the InnoDB multi-version concurrency control (MVCC) system must keep a copy of the data in the undo log until all transactions that depend on that data have completed. The following are examples of long running transactions that could cause the `History list length` to increase:

- A `mysqldump` operation that uses the `--single-transaction` option while there is a significant amount of concurrent DML.
- Running a `SELECT` query after disabling `autocommit`, and forgetting to issue an explicit `COMMIT` or `ROLLBACK`.

To prevent excessive delays in extreme situations where the purge lag becomes huge, you can limit the delay by setting the `innodb_max_purge_lag_delay` variable. The `innodb_max_purge_lag_delay` variable specifies the maximum delay in microseconds for the delay imposed when the `innodb_max_purge_lag` threshold is exceeded. The specified `innodb_max_purge_lag_delay` value is an upper limit on the delay period calculated by the `innodb_max_purge_lag` formula.

## Purge and Undo Tablespace Truncation

The purge system is also responsible for truncating undo tablespaces. You can configure the `innodb_purge_rseg_truncate_frequency` variable to control the frequency with which the purge system looks for undo tablespaces to truncate. For more information, see [Truncating Undo Tablespaces](#).

## 17.8.10 Configuring Optimizer Statistics for InnoDB

This section describes how to configure persistent and non-persistent optimizer statistics for InnoDB tables.

Persistent optimizer statistics are persisted across server restarts, allowing for greater [plan stability](#) and more consistent query performance. Persistent optimizer statistics also provide control and flexibility with these additional benefits:

- You can use the `innodb_stats_auto_recalc` configuration option to control whether statistics are updated automatically after substantial changes to a table.
- You can use the `STATS_PERSISTENT`, `STATS_AUTO_RECALC`, and `STATS_SAMPLE_PAGES` clauses with `CREATE TABLE` and `ALTER TABLE` statements to configure optimizer statistics for individual tables.
- You can query optimizer statistics data in the `mysql.innodb_table_stats` and `mysql.innodb_index_stats` tables.
- You can view the `last_update` column of the `mysql.innodb_table_stats` and `mysql.innodb_index_stats` tables to see when statistics were last updated.
- You can manually modify the `mysql.innodb_table_stats` and `mysql.innodb_index_stats` tables to force a specific query optimization plan or to test alternative plans without modifying the database.

The persistent optimizer statistics feature is enabled by default (`innodb_stats_persistent=ON`).

Non-persistent optimizer statistics are cleared on each server restart and after some other operations, and recomputed on the next table access. As a result, different estimates could be produced when recomputing statistics, leading to different choices in execution plans and variations in query performance.

This section also provides information about estimating `ANALYZE TABLE` complexity, which may be useful when attempting to achieve a balance between accurate statistics and `ANALYZE TABLE` execution time.

### 17.8.10.1 Configuring Persistent Optimizer Statistics Parameters

The persistent optimizer statistics feature improves [plan stability](#) by storing statistics to disk and making them persistent across server restarts so that the [optimizer](#) is more likely to make consistent choices each time for a given query.

Optimizer statistics are persisted to disk when `innodb_stats_persistent=ON` or when individual tables are defined with `STATS_PERSISTENT=1`. `innodb_stats_persistent` is enabled by default.

Formerly, optimizer statistics were cleared when restarting the server and after some other types of operations, and recomputed on the next table access. Consequently, different estimates could be produced when recalculating statistics leading to different choices in query execution plans and variation in query performance.

Persistent statistics are stored in the `mysql.innodb_table_stats` and `mysql.innodb_index_stats` tables. See [InnoDB Persistent Statistics Tables](#).

If you prefer not to persist optimizer statistics to disk, see [Section 17.8.10.2, “Configuring Non-Persistent Optimizer Statistics Parameters”](#)

### Configuring Automatic Statistics Calculation for Persistent Optimizer Statistics

The `innodb_stats_auto_recalc` variable, which is enabled by default, controls whether statistics are calculated automatically when a table undergoes changes to more than 10% of its rows. You can also configure automatic statistics recalculation for individual tables by specifying the `STATS_AUTO_RECALC` clause when creating or altering a table.

Because of the asynchronous nature of automatic statistics recalculation, which occurs in the background, statistics may not be recalculated instantly after running a DML operation that affects more than 10% of a table, even when `innodb_stats_auto_recalc` is enabled. Statistics recalculation can be delayed by few seconds in some cases. If up-to-date statistics are required immediately, run `ANALYZE TABLE` to initiate a synchronous (foreground) recalculation of statistics.

If `innodb_stats_auto_recalc` is disabled, you can ensure the accuracy of optimizer statistics by executing the `ANALYZE TABLE` statement after making substantial changes to indexed columns. You might also consider adding `ANALYZE TABLE` to setup scripts that you run after loading data, and running `ANALYZE TABLE` on a schedule at times of low activity.

When an index is added to an existing table, or when a column is added or dropped, index statistics are calculated and added to the `innodb_index_stats` table regardless of the value of `innodb_stats_auto_recalc`.

For a histogram with `AUTO UPDATE` enabled (see [Histogram Statistics Analysis](#)), automatic recalculation of persistent statistics also causes the histogram to be updated.

### Configuring Optimizer Statistics Parameters for Individual Tables

`innodb_stats_persistent`, `innodb_stats_auto_recalc`, and `innodb_stats_persistent_sample_pages` are global variables. To override these system-wide settings and configure optimizer statistics parameters for individual tables, you can define

`STATS_PERSISTENT`, `STATS_AUTO_RECALC`, and `STATS_SAMPLE_PAGES` clauses in `CREATE TABLE` or `ALTER TABLE` statements.

- `STATS_PERSISTENT` specifies whether to enable [persistent statistics](#) for an InnoDB table. The value `DEFAULT` causes the persistent statistics setting for the table to be determined by the `innodb_stats_persistent` setting. A value of `1` enables persistent statistics for the table, while a value of `0` disables the feature. After enabling persistent statistics for an individual table, use `ANALYZE TABLE` to calculate statistics after table data is loaded.
- `STATS_AUTO_RECALC` specifies whether to automatically recalculate [persistent statistics](#). The value `DEFAULT` causes the persistent statistics setting for the table to be determined by the `innodb_stats_auto_recalc` setting. A value of `1` causes statistics to be recalculated when 10% of table data has changed. A value `0` prevents automatic recalculation for the table. When using a value of `0`, use `ANALYZE TABLE` to recalculate statistics after making substantial changes to the table.
- `STATS_SAMPLE_PAGES` specifies the number of index pages to sample when cardinality and other statistics are calculated for an indexed column, by an `ANALYZE TABLE` operation, for example.

All three clauses are specified in the following `CREATE TABLE` example:

```
CREATE TABLE `t1` (
 `id` int(8) NOT NULL auto_increment,
 `data` varchar(255),
 `date` datetime,
 PRIMARY KEY (`id`),
 INDEX `DATE_IX` (`date`)
) ENGINE=InnoDB,
 STATS_PERSISTENT=1,
 STATS_AUTO_RECALC=1,
 STATS_SAMPLE_PAGES=25;
```

## Configuring the Number of Sampled Pages for InnoDB Optimizer Statistics

The optimizer uses estimated [statistics](#) about key distributions to choose the indexes for an execution plan, based on the relative [selectivity](#) of the index. Operations such as `ANALYZE TABLE` cause InnoDB to sample random pages from each index on a table to estimate the [cardinality](#) of the index. This sampling technique is known as a [random dive](#).

The `innodb_stats_persistent_sample_pages` controls the number of sampled pages. You can adjust the setting at runtime to manage the quality of statistics estimates used by the optimizer. The default value is 20. Consider modifying the setting when encountering the following issues:

1. *Statistics are not accurate enough and the optimizer chooses suboptimal plans*, as shown in `EXPLAIN` output. You can check the accuracy of statistics by comparing the actual cardinality of an index (determined by running `SELECT DISTINCT` on the index columns) with the estimates in the `mysql.innodb_index_stats` table.

If it is determined that statistics are not accurate enough, the value of `innodb_stats_persistent_sample_pages` should be increased until the statistics estimates are sufficiently accurate. Increasing `innodb_stats_persistent_sample_pages` too much, however, could cause `ANALYZE TABLE` to run slowly.

2. *`ANALYZE TABLE` is too slow*. In this case `innodb_stats_persistent_sample_pages` should be decreased until `ANALYZE TABLE` execution time is acceptable. Decreasing the value too much, however, could lead to the first problem of inaccurate statistics and suboptimal query execution plans.

If a balance cannot be achieved between accurate statistics and `ANALYZE TABLE` execution time, consider decreasing the number of indexed columns in the table or limiting the number of partitions

to reduce `ANALYZE TABLE` complexity. The number of columns in the table's primary key is also important to consider, as primary key columns are appended to each nonunique index.

For related information, see [Section 17.8.10.3, “Estimating ANALYZE TABLE Complexity for InnoDB Tables”](#).

## Including Delete-marked Records in Persistent Statistics Calculations

By default, `InnoDB` reads uncommitted data when calculating statistics. In the case of an uncommitted transaction that deletes rows from a table, delete-marked records are excluded when calculating row estimates and index statistics, which can lead to non-optimal execution plans for other transactions that are operating on the table concurrently using a transaction isolation level other than `READ UNCOMMITTED`. To avoid this scenario, `innodb_stats_include_delete_marked` can be enabled to ensure that delete-marked records are included when calculating persistent optimizer statistics.

When `innodb_stats_include_delete_marked` is enabled, `ANALYZE TABLE` considers delete-marked records when recalculating statistics.

`innodb_stats_include_delete_marked` is a global setting that affects all `InnoDB` tables, and it is only applicable to persistent optimizer statistics.

## InnoDB Persistent Statistics Tables

The persistent statistics feature relies on the internally managed tables in the `mysql` database, named `innodb_table_stats` and `innodb_index_stats`. These tables are set up automatically in all install, upgrade, and build-from-source procedures.

**Table 17.6 Columns of `innodb_table_stats`**

Column name	Description
<code>database_name</code>	Database name
<code>table_name</code>	Table name, partition name, or subpartition name
<code>last_update</code>	A timestamp indicating the last time that <code>InnoDB</code> updated this row
<code>n_rows</code>	The number of rows in the table
<code>clustered_index_size</code>	The size of the primary index, in pages
<code>sum_of_other_index_sizes</code>	The total size of other (non-primary) indexes, in pages

**Table 17.7 Columns of `innodb_index_stats`**

Column name	Description
<code>database_name</code>	Database name
<code>table_name</code>	Table name, partition name, or subpartition name
<code>index_name</code>	Index name
<code>last_update</code>	A timestamp indicating the last time the row was updated
<code>stat_name</code>	The name of the statistic, whose value is reported in the <code>stat_value</code> column
<code>stat_value</code>	The value of the statistic that is named in <code>stat_name</code> column

Column name	Description
<code>sample_size</code>	The number of pages sampled for the estimate provided in the <code>stat_value</code> column
<code>stat_description</code>	Description of the statistic that is named in the <code>stat_name</code> column

The `innodb_table_stats` and `innodb_index_stats` tables include a `last_update` column that shows when index statistics were last updated:

```
mysql> SELECT * FROM innodb_table_stats \G
***** 1. row *****
 database_name: sakila
 table_name: actor
 last_update: 2014-05-28 16:16:44
 n_rows: 200
 clustered_index_size: 1
sum_of_other_index_sizes: 1
...
```

```
mysql> SELECT * FROM innodb_index_stats \G
***** 1. row *****
 database_name: sakila
 table_name: actor
 index_name: PRIMARY
 last_update: 2014-05-28 16:16:44
 stat_name: n_diff_pfx01
 stat_value: 200
 sample_size: 1
 ...
```

The `innodb_table_stats` and `innodb_index_stats` tables can be updated manually, which makes it possible to force a specific query optimization plan or test alternative plans without modifying the database. If you manually update statistics, use the `FLUSH TABLE tbl_name` statement to load the updated statistics.

Persistent statistics are considered local information, because they relate to the server instance. The `innodb_table_stats` and `innodb_index_stats` tables are therefore not replicated when automatic statistics recalculation takes place. If you run `ANALYZE TABLE` to initiate a synchronous recalculation of statistics, the statement is replicated (unless you suppressed logging for it), and recalculation takes place on replicas.

## InnoDB Persistent Statistics Tables Example

The `innodb_table_stats` table contains one row for each table. The following example demonstrates the type of data collected.

Table `t1` contains a primary index (columns `a`, `b`) secondary index (columns `c`, `d`), and unique index (columns `e`, `f`):

```
CREATE TABLE t1 (
 a INT, b INT, c INT, d INT, e INT, f INT,
 PRIMARY KEY (a, b), KEY i1 (c, d), UNIQUE KEY i2uniq (e, f)
) ENGINE=INNODB;
```

After inserting five rows of sample data, table `t1` appears as follows:

```
mysql> SELECT * FROM t1;
+----+-----+-----+-----+-----+-----+
| a | b | c | d | e | f |
+----+-----+-----+-----+-----+-----+
```

1	1	10	11	100	101
1	2	10	11	200	102
1	3	10	11	100	103
1	4	10	12	200	104
1	5	10	12	100	105

To immediately update statistics, run `ANALYZE TABLE` (if `innodb_stats_auto_recalc` is enabled, statistics are updated automatically within a few seconds assuming that the 10% threshold for changed table rows is reached):

```
mysql> ANALYZE TABLE t1;
+-----+-----+-----+-----+
| Table | Op | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.t1 | analyze | status | OK |
+-----+-----+-----+-----+
```

Table statistics for table `t1` show the last time InnoDB updated the table statistics (2014-03-14 14:36:34), the number of rows in the table (5), the clustered index size (1 page), and the combined size of the other indexes (2 pages).

```
mysql> SELECT * FROM mysql.innodb_table_stats WHERE table_name like 't1'\G
***** 1. row *****
 database_name: test
 table_name: t1
 last_update: 2014-03-14 14:36:34
 n_rows: 5
 clustered_index_size: 1
sum_of_other_index_sizes: 2
```

The `innodb_index_stats` table contains multiple rows for each index. Each row in the `innodb_index_stats` table provides data related to a particular index statistic which is named in the `stat_name` column and described in the `stat_description` column. For example:

```
mysql> SELECT index_name, stat_name, stat_value, stat_description
 FROM mysql.innodb_index_stats WHERE table_name like 't1';
+-----+-----+-----+-----+
| index_name | stat_name | stat_value | stat_description |
+-----+-----+-----+-----+
| PRIMARY | n_diff_pfx01 | 1 | a |
| PRIMARY | n_diff_pfx02 | 5 | a,b |
| PRIMARY | n_leaf_pages | 1 | Number of leaf pages in the index |
| PRIMARY | size | 1 | Number of pages in the index |
| i1 | n_diff_pfx01 | 1 | c |
| i1 | n_diff_pfx02 | 2 | c,d |
| i1 | n_diff_pfx03 | 2 | c,d,a |
| i1 | n_diff_pfx04 | 5 | c,d,a,b |
| i1 | n_leaf_pages | 1 | Number of leaf pages in the index |
| i1 | size | 1 | Number of pages in the index |
| i2uniq | n_diff_pfx01 | 2 | e |
| i2uniq | n_diff_pfx02 | 5 | e,f |
| i2uniq | n_leaf_pages | 1 | Number of leaf pages in the index |
| i2uniq | size | 1 | Number of pages in the index |
+-----+-----+-----+-----+
```

The `stat_name` column shows the following types of statistics:

- `size`: Where `stat_name=size`, the `stat_value` column displays the total number of pages in the index.
- `n_leaf_pages`: Where `stat_name=n_leaf_pages`, the `stat_value` column displays the number of leaf pages in the index.

- `n_diff_pfxNN`: Where `stat_name=n_diff_pfx01`, the `stat_value` column displays the number of distinct values in the first column of the index. Where `stat_name=n_diff_pfx02`, the `stat_value` column displays the number of distinct values in the first two columns of the index, and so on. Where `stat_name=n_diff_pfxNN`, the `stat_description` column shows a comma separated list of the index columns that are counted.

To further illustrate the `n_diff_pfxNN` statistic, which provides cardinality data, consider once again the `t1` table example that was introduced previously. As shown below, the `t1` table is created with a primary index (columns `a, b`), a secondary index (columns `c, d`), and a unique index (columns `e, f`):

```
CREATE TABLE t1 (
 a INT, b INT, c INT, d INT, e INT, f INT,
 PRIMARY KEY (a, b), KEY i1 (c, d), UNIQUE KEY i2uniq (e, f)
) ENGINE=INNODB;
```

After inserting five rows of sample data, table `t1` appears as follows:

```
mysql> SELECT * FROM t1;
+-----+-----+-----+-----+-----+-----+
| a | b | c | d | e | f |
+-----+-----+-----+-----+-----+-----+
| 1 | 1 | 10 | 11 | 100 | 101 |
| 1 | 2 | 10 | 11 | 200 | 102 |
| 1 | 3 | 10 | 11 | 100 | 103 |
| 1 | 4 | 10 | 12 | 200 | 104 |
| 1 | 5 | 10 | 12 | 100 | 105 |
+-----+-----+-----+-----+-----+-----+
```

When you query the `index_name`, `stat_name`, `stat_value`, and `stat_description`, where `stat_name LIKE 'n_diff%'`, the following result set is returned:

```
mysql> SELECT index_name, stat_name, stat_value, stat_description
FROM mysql.innodb_index_stats
WHERE table_name like 't1' AND stat_name LIKE 'n_diff%';
+-----+-----+-----+-----+
| index_name | stat_name | stat_value | stat_description |
+-----+-----+-----+-----+
| PRIMARY | n_diff_pfx01 | 1 | a |
| PRIMARY | n_diff_pfx02 | 5 | a,b |
| i1 | n_diff_pfx01 | 1 | c |
| i1 | n_diff_pfx02 | 2 | c,d |
| i1 | n_diff_pfx03 | 2 | c,d,a |
| i1 | n_diff_pfx04 | 5 | c,d,a,b |
| i2uniq | n_diff_pfx01 | 2 | e |
| i2uniq | n_diff_pfx02 | 5 | e,f |
+-----+-----+-----+-----+
```

For the `PRIMARY` index, there are two `n_diff%` rows. The number of rows is equal to the number of columns in the index.

#### Note

For nonunique indexes, InnoDB appends the columns of the primary key.

- Where `index_name=PRIMARY` and `stat_name=n_diff_pfx01`, the `stat_value` is 1, which indicates that there is a single distinct value in the first column of the index (column `a`). The number of distinct values in column `a` is confirmed by viewing the data in column `a` in table `t1`, in which there is a single distinct value (1). The counted column (`a`) is shown in the `stat_description` column of the result set.
- Where `index_name=PRIMARY` and `stat_name=n_diff_pfx02`, the `stat_value` is 5, which indicates that there are five distinct values in the two columns of the index (`a, b`). The number of distinct

values in columns `a` and `b` is confirmed by viewing the data in columns `a` and `b` in table `t1`, in which there are five distinct values: `(1,1)`, `(1,2)`, `(1,3)`, `(1,4)` and `(1,5)`. The counted columns (`a,b`) are shown in the `stat_description` column of the result set.

For the secondary index (`i1`), there are four `n_diff%` rows. Only two columns are defined for the secondary index (`c,d`) but there are four `n_diff%` rows for the secondary index because InnoDB suffixes all nonunique indexes with the primary key. As a result, there are four `n_diff%` rows instead of two to account for the both the secondary index columns (`c,d`) and the primary key columns (`a,b`).

- Where `index_name=i1` and `stat_name=n_diff_pfx01`, the `stat_value` is 1, which indicates that there is a single distinct value in the first column of the index (column `c`). The number of distinct values in column `c` is confirmed by viewing the data in column `c` in table `t1`, in which there is a single distinct value: `(10)`. The counted column (`c`) is shown in the `stat_description` column of the result set.
- Where `index_name=i1` and `stat_name=n_diff_pfx02`, the `stat_value` is 2, which indicates that there are two distinct values in the first two columns of the index (`c,d`). The number of distinct values in columns `c` and `d` is confirmed by viewing the data in columns `c` and `d` in table `t1`, in which there are two distinct values: `(10,11)` and `(10,12)`. The counted columns (`c,d`) are shown in the `stat_description` column of the result set.
- Where `index_name=i1` and `stat_name=n_diff_pfx03`, the `stat_value` is 2, which indicates that there are two distinct values in the first three columns of the index (`c,d,a`). The number of distinct values in columns `c`, `d`, and `a` is confirmed by viewing the data in column `c`, `d`, and `a` in table `t1`, in which there are two distinct values: `(10,11,1)` and `(10,12,1)`. The counted columns (`c,d,a`) are shown in the `stat_description` column of the result set.
- Where `index_name=i1` and `stat_name=n_diff_pfx04`, the `stat_value` is 5, which indicates that there are five distinct values in the four columns of the index (`c,d,a,b`). The number of distinct values in columns `c`, `d`, `a` and `b` is confirmed by viewing the data in columns `c`, `d`, `a`, and `b` in table `t1`, in which there are five distinct values: `(10,11,1,1)`, `(10,11,1,2)`, `(10,11,1,3)`, `(10,12,1,4)`, and `(10,12,1,5)`. The counted columns (`c,d,a,b`) are shown in the `stat_description` column of the result set.

For the unique index (`i2uniq`), there are two `n_diff%` rows.

- Where `index_name=i2uniq` and `stat_name=n_diff_pfx01`, the `stat_value` is 2, which indicates that there are two distinct values in the first column of the index (column `e`). The number of distinct values in column `e` is confirmed by viewing the data in column `e` in table `t1`, in which there are two distinct values: `(100)` and `(200)`. The counted column (`e`) is shown in the `stat_description` column of the result set.
- Where `index_name=i2uniq` and `stat_name=n_diff_pfx02`, the `stat_value` is 5, which indicates that there are five distinct values in the two columns of the index (`e,f`). The number of distinct values in columns `e` and `f` is confirmed by viewing the data in columns `e` and `f` in table `t1`, in which there are five distinct values: `(100,101)`, `(200,102)`, `(100,103)`, `(200,104)`, and `(100,105)`. The counted columns (`e,f`) are shown in the `stat_description` column of the result set.

## Retrieving Index Size Using the `innodb_index_stats` Table

You can retrieve the index size for tables, partitions, or subpartitions can using the `innodb_index_stats` table. In the following example, index sizes are retrieved for table `t1`. For a definition of table `t1` and corresponding index statistics, see [InnoDB Persistent Statistics Tables Example](#).

```
mysql> SELECT SUM(stat_value) pages, index_name,
SUM(stat_value)*@@innodb_page_size size
FROM mysql.innodb_index_stats WHERE table_name='t1'
```

```
AND stat_name = 'size' GROUP BY index_name;
```

pages	index_name	size
1	PRIMARY	16384
1	i1	16384
1	i2uniq	16384

For partitions or subpartitions, you can use the same query with a modified `WHERE` clause to retrieve index sizes. For example, the following query retrieves index sizes for partitions of table `t1`:

```
mysql> SELECT SUM(stat_value) pages, index_name,
SUM(stat_value)*@@innodb_page_size size
FROM mysql.innodb_index_stats WHERE table_name like 't1#P%'
AND stat_name = 'size' GROUP BY index_name;
```

### 17.8.10.2 Configuring Non-Persistent Optimizer Statistics Parameters

This section describes how to configure non-persistent optimizer statistics. Optimizer statistics are not persisted to disk when `innodb_stats_persistent=OFF` or when individual tables are created or altered with `STATS_PERSISTENT=0`. Instead, statistics are stored in memory, and are lost when the server is shut down. Statistics are also updated periodically by certain operations and under certain conditions.

Optimizer statistics are persisted to disk by default, enabled by the `innodb_stats_persistent` configuration option. For information about persistent optimizer statistics, see [Section 17.8.10.1, “Configuring Persistent Optimizer Statistics Parameters”](#).

#### Optimizer Statistics Updates

Non-persistent optimizer statistics are updated when:

- Running `ANALYZE TABLE`.
- Running `SHOW TABLE STATUS`, `SHOW INDEX`, or querying the Information Schema `TABLES` or `STATISTICS` tables with the `innodb_stats_on_metadata` option enabled.

The default setting for `innodb_stats_on_metadata` is `OFF`. Enabling `innodb_stats_on_metadata` may reduce access speed for schemas that have a large number of tables or indexes, and reduce stability of execution plans for queries that involve InnoDB tables. `innodb_stats_on_metadata` is configured globally using a `SET` statement.

```
SET GLOBAL innodb_stats_on_metadata=ON
```

#### Note

`innodb_stats_on_metadata` only applies when optimizer [statistics](#) are configured to be non-persistent (when `innodb_stats_persistent` is disabled).

- Starting a `mysql` client with the `--auto-rehash` option enabled, which is the default. The `auto-rehash` option causes all InnoDB tables to be opened, and the open table operations cause statistics to be recalculated.

To improve the start up time of the `mysql` client and to updating statistics, you can turn off `auto-rehash` using the `--disable-auto-rehash` option. The `auto-rehash` feature enables automatic name completion of database, table, and column names for interactive users.

- A table is first opened.

- [InnoDB](#) detects that 1 / 16 of table has been modified since the last time statistics were updated.

## Configuring the Number of Sampled Pages

The MySQL query optimizer uses estimated [statistics](#) about key distributions to choose the indexes for an execution plan, based on the relative [selectivity](#) of the index. When [InnoDB](#) updates optimizer statistics, it samples random pages from each index on a table to estimate the [cardinality](#) of the index. (This technique is known as [random dives](#).)

To give you control over the quality of the statistics estimate (and thus better information for the query optimizer), you can change the number of sampled pages using the parameter [innodb\\_stats\\_transient\\_sample\\_pages](#). The default number of sampled pages is 8, which could be insufficient to produce an accurate estimate, leading to poor index choices by the query optimizer. This technique is especially important for large tables and tables used in [joins](#). Unnecessary [full table scans](#) for such tables can be a substantial performance issue. See [Section 10.2.1.23, “Avoiding Full Table Scans”](#) for tips on tuning such queries. [innodb\\_stats\\_transient\\_sample\\_pages](#) is a global parameter that can be set at runtime.

The value of [innodb\\_stats\\_transient\\_sample\\_pages](#) affects the index sampling for all [InnoDB](#) tables and indexes when [innodb\\_stats\\_persistent=0](#). Be aware of the following potentially significant impacts when you change the index sample size:

- Small values like 1 or 2 can result in inaccurate estimates of cardinality.
- Increasing the [innodb\\_stats\\_transient\\_sample\\_pages](#) value might require more disk reads. Values much larger than 8 (say, 100), can cause a significant slowdown in the time it takes to open a table or execute [SHOW TABLE STATUS](#).
- The optimizer might choose very different query plans based on different estimates of index selectivity.

Whatever value of [innodb\\_stats\\_transient\\_sample\\_pages](#) works best for a system, set the option and leave it at that value. Choose a value that results in reasonably accurate estimates for all tables in your database without requiring excessive I/O. Because the statistics are automatically recalculated at various times other than on execution of [ANALYZE TABLE](#), it does not make sense to increase the index sample size, run [ANALYZE TABLE](#), then decrease sample size again.

Smaller tables generally require fewer index samples than larger tables. If your database has many large tables, consider using a higher value for [innodb\\_stats\\_transient\\_sample\\_pages](#) than if you have mostly smaller tables.

### 17.8.10.3 Estimating ANALYZE TABLE Complexity for InnoDB Tables

[ANALYZE TABLE](#) complexity for [InnoDB](#) tables is dependent on:

- The number of pages sampled, as defined by [innodb\\_stats\\_persistent\\_sample\\_pages](#).
- The number of indexed columns in a table
- The number of partitions. If a table has no partitions, the number of partitions is considered to be 1.

Using these parameters, an approximate formula for estimating [ANALYZE TABLE](#) complexity would be:

The value of [innodb\\_stats\\_persistent\\_sample\\_pages](#) \* number of indexed columns in a table \* the number of partitions

Typically, the greater the resulting value, the greater the execution time for [ANALYZE TABLE](#).

**Note**

`innodb_stats_persistent_sample_pages` defines the number of pages sampled at a global level. To set the number of pages sampled for an individual table, use the `STATS_SAMPLE_PAGES` option with `CREATE TABLE` or `ALTER TABLE`. For more information, see [Section 17.8.10.1, “Configuring Persistent Optimizer Statistics Parameters”](#).

If `innodb_stats_persistent=OFF`, the number of pages sampled is defined by `innodb_stats_transient_sample_pages`. See [Section 17.8.10.2, “Configuring Non-Persistent Optimizer Statistics Parameters”](#) for additional information.

For a more in-depth approach to estimating `ANALYZE TABLE` complexity, consider the following example.

In **Big O notation**, `ANALYZE TABLE` complexity is described as:

```
O(n_sample
 * (n_cols_in_uniq_i
 + n_cols_in_non_uniq_i
 + n_cols_in_pk * (1 + n_non_uniq_i))
 * n_part)
```

where:

- `n_sample` is the number of pages sampled (defined by `innodb_stats_persistent_sample_pages`)
- `n_cols_in_uniq_i` is total number of all columns in all unique indexes (not counting the primary key columns)
- `n_cols_in_non_uniq_i` is the total number of all columns in all nonunique indexes
- `n_cols_in_pk` is the number of columns in the primary key (if a primary key is not defined, InnoDB creates a single column primary key internally)
- `n_non_uniq_i` is the number of nonunique indexes in the table
- `n_part` is the number of partitions. If no partitions are defined, the table is considered to be a single partition.

Now, consider the following table (table `t`), which has a primary key (2 columns), a unique index (2 columns), and two nonunique indexes (two columns each):

```
CREATE TABLE t (
 a INT,
 b INT,
 c INT,
 d INT,
 e INT,
 f INT,
 g INT,
 h INT,
 PRIMARY KEY (a, b),
 UNIQUE KEY iluniq (c, d),
 KEY i2nonuniq (e, f),
 KEY i3nonuniq (g, h)
);
```

For the column and index data required by the algorithm described above, query the `mysql.innodb_index_stats` persistent index statistics table for table `t`. The `n_diff_pfx%` statistics

show the columns that are counted for each index. For example, columns `a` and `b` are counted for the primary key index. For the nonunique indexes, the primary key columns (`a,b`) are counted in addition to the user defined columns.

#### Note

For additional information about the [InnoDB](#) persistent statistics tables, see [Section 17.8.10.1, “Configuring Persistent Optimizer Statistics Parameters”](#)

```
mysql> SELECT index_name, stat_name, stat_description
FROM mysql.innodb_index_stats WHERE
database_name='test' AND
table_name='t' AND
stat_name like 'n_diff_pfx%';
```

index_name	stat_name	stat_description
PRIMARY	n_diff_pfx01	a
PRIMARY	n_diff_pfx02	a,b
i1uniq	n_diff_pfx01	c
i1uniq	n_diff_pfx02	c,d
i2nonuniq	n_diff_pfx01	e
i2nonuniq	n_diff_pfx02	e,f
i2nonuniq	n_diff_pfx03	e,f,a
i2nonuniq	n_diff_pfx04	e,f,a,b
i3nonuniq	n_diff_pfx01	g
i3nonuniq	n_diff_pfx02	g,h
i3nonuniq	n_diff_pfx03	g,h,a
i3nonuniq	n_diff_pfx04	g,h,a,b

Based on the index statistics data shown above and the table definition, the following values can be determined:

- `n_cols_in_uniq_i`, the total number of all columns in all unique indexes not counting the primary key columns, is 2 (`c` and `d`)
- `n_cols_in_non_uniq_i`, the total number of all columns in all nonunique indexes, is 4 (`e`, `f`, `g` and `h`)
- `n_cols_in_pk`, the number of columns in the primary key, is 2 (`a` and `b`)
- `n_non_uniq_i`, the number of nonunique indexes in the table, is 2 (`i2nonuniq` and `i3nonuniq`)
- `n_part`, the number of partitions, is 1.

You can now calculate `innodb_stats_persistent_sample_pages * (2 + 4 + 2 * (1 + 2)) * 1` to determine the number of leaf pages that are scanned. With `innodb_stats_persistent_sample_pages` set to the default value of 20, and with a default page size of 16 KiB (`innodb_page_size=16384`), you can then estimate that `20 * 12 * 16384 bytes` are read for table `t`, or about 4 MiB.

#### Note

All 4 MiB may not be read from disk, as some leaf pages may already be cached in the buffer pool.

## 17.8.11 Configuring the Merge Threshold for Index Pages

You can configure the `MERGE_THRESHOLD` value for index pages. If the “page-full” percentage for an index page falls below the `MERGE_THRESHOLD` value when a row is deleted or when a row is shortened

by an `UPDATE` operation, InnoDB attempts to merge the index page with a neighboring index page. The default `MERGE_THRESHOLD` value is 50, which is the previously hardcoded value. The minimum `MERGE_THRESHOLD` value is 1 and the maximum value is 50.

When the “page-full” percentage for an index page falls below 50%, which is the default `MERGE_THRESHOLD` setting, InnoDB attempts to merge the index page with a neighboring page. If both pages are close to 50% full, a page split can occur soon after the pages are merged. If this merge-split behavior occurs frequently, it can have an adverse affect on performance. To avoid frequent merge-splits, you can lower the `MERGE_THRESHOLD` value so that InnoDB attempts page merges at a lower “page-full” percentage. Merging pages at a lower page-full percentage leaves more room in index pages and helps reduce merge-split behavior.

The `MERGE_THRESHOLD` for index pages can be defined for a table or for individual indexes. A `MERGE_THRESHOLD` value defined for an individual index takes priority over a `MERGE_THRESHOLD` value defined for the table. If undefined, the `MERGE_THRESHOLD` value defaults to 50.

## Setting `MERGE_THRESHOLD` for a Table

You can set the `MERGE_THRESHOLD` value for a table using the `table_option COMMENT` clause of the `CREATE TABLE` statement. For example:

```
CREATE TABLE t1 (
 id INT,
 KEY id_index (id)
) COMMENT='MERGE_THRESHOLD=45';
```

You can also set the `MERGE_THRESHOLD` value for an existing table using the `table_option COMMENT` clause with `ALTER TABLE`:

```
CREATE TABLE t1 (
 id INT,
 KEY id_index (id)
);

ALTER TABLE t1 COMMENT='MERGE_THRESHOLD=40';
```

## Setting `MERGE_THRESHOLD` for Individual Indexes

To set the `MERGE_THRESHOLD` value for an individual index, you can use the `index_option COMMENT` clause with `CREATE TABLE`, `ALTER TABLE`, or `CREATE INDEX`, as shown in the following examples:

- Setting `MERGE_THRESHOLD` for an individual index using `CREATE TABLE`:

```
CREATE TABLE t1 (
 id INT,
 KEY id_index (id) COMMENT 'MERGE_THRESHOLD=40'
);
```

- Setting `MERGE_THRESHOLD` for an individual index using `ALTER TABLE`:

```
CREATE TABLE t1 (
 id INT,
 KEY id_index (id)
);

ALTER TABLE t1 DROP KEY id_index;
ALTER TABLE t1 ADD KEY id_index (id) COMMENT 'MERGE_THRESHOLD=40';
```

- Setting `MERGE_THRESHOLD` for an individual index using `CREATE INDEX`:

```
CREATE TABLE t1 (id INT);
CREATE INDEX id_index ON t1 (id) COMMENT 'MERGE_THRESHOLD=40';
```

### Note

You cannot modify the `MERGE_THRESHOLD` value at the index level for `GEN_CLUST_INDEX`, which is the clustered index created by InnoDB when an InnoDB table is created without a primary key or unique key index. You can only modify the `MERGE_THRESHOLD` value for `GEN_CLUST_INDEX` by setting `MERGE_THRESHOLD` for the table.

## Querying the `MERGE_THRESHOLD` Value for an Index

The current `MERGE_THRESHOLD` value for an index can be obtained by querying the `INNODB_INDEXES` table. For example:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_INDEXES WHERE NAME='id_index' \G
***** 1. row *****
 INDEX_ID: 91
 NAME: id_index
 TABLE_ID: 68
 TYPE: 0
 N_FIELDS: 1
 PAGE_NO: 4
 SPACE: 57
MERGE_THRESHOLD: 40
```

You can use `SHOW CREATE TABLE` to view the `MERGE_THRESHOLD` value for a table, if explicitly defined using the `table_option COMMENT` clause:

```
mysql> SHOW CREATE TABLE t2 \G
***** 1. row *****
 Table: t2
Create Table: CREATE TABLE `t2` (
 `id` int(11) DEFAULT NULL,
 KEY `id_index` (`id`) COMMENT 'MERGE_THRESHOLD=40'
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci
```

### Note

A `MERGE_THRESHOLD` value defined at the index level takes priority over a `MERGE_THRESHOLD` value defined for the table. If undefined, `MERGE_THRESHOLD` defaults to 50% (`MERGE_THRESHOLD=50`, which is the previously hardcoded value).

Likewise, you can use `SHOW INDEX` to view the `MERGE_THRESHOLD` value for an index, if explicitly defined using the `index_option COMMENT` clause:

```
mysql> SHOW INDEX FROM t2 \G
***** 1. row *****
 Table: t2
Non_unique: 1
 Key_name: id_index
Seq_in_index: 1
Column_name: id
 Collation: A
Cardinality: 0
 Sub_part: NULL
 Packed: NULL
 Null: YES
Index_type: BTREE
 Comment:
Index_comment: MERGE_THRESHOLD=40
```

## Measuring the Effect of MERGE\_THRESHOLD Settings

The `INNODB_METRICS` table provides two counters that can be used to measure the effect of a `MERGE_THRESHOLD` setting on index page merges.

```
mysql> SELECT NAME, COMMENT FROM INFORMATION_SCHEMA.INNODB_METRICS
 WHERE NAME like '%index_page_merge%';
```

NAME	COMMENT
index_page_merge_attempts	Number of index page merge attempts
index_page_merge_successful	Number of successful index page merges

When lowering the `MERGE_THRESHOLD` value, the objectives are:

- A smaller number of page merge attempts and successful page merges
- A similar number of page merge attempts and successful page merges

A `MERGE_THRESHOLD` setting that is too small could result in large data files due to an excessive amount of empty page space.

For information about using `INNODB_METRICS` counters, see [Section 17.15.6, “InnoDB INFORMATION\\_SCHEMA Metrics Table”](#).

## 17.8.12 Enabling Automatic InnoDB Configuration for a Dedicated MySQL Server

When the server is started with `--innodb-dedicated-server`, InnoDB automatically calculates values for and sets the following system variables:

- `innodb_buffer_pool_size`
- `innodb_redo_log_capacity`
- `innodb_log_file_size`
- `innodb_log_files_in_group`

You should consider using `--innodb-dedicated-server` only if the MySQL instance resides on a dedicated server where it can use all available system resources—for example, if you run MySQL Server in a Docker container or dedicated VM that runs MySQL only. Using `--innodb-dedicated-server` is not recommended if the MySQL instance shares system resources with other applications.

The value for each affected variable is determined and applied by `--innodb-dedicated-server` as described in the following list:

- `innodb_buffer_pool_size`

Buffer pool size is calculated according to the amount of memory detected on the server, as shown in the following table:

**Table 17.8 Automatically Configured Buffer Pool Size**

Detected Server Memory	Buffer Pool Size
Less than 1GB	128MB (the default value)
1GB to 4GB	<code>detected server memory</code> * 0.5

Detected Server Memory	Buffer Pool Size
Greater than 4GB	<i>detected server memory</i> * 0.75

- `innodb_redo_log_capacity`

Redo log capacity is calculated according to the number of logical processors available on the server. The formula is (number of available logical processors / 2) GB, with a maximum dynamic default value of 16 GB.

- `innodb_log_file_size` (deprecated)

Log file size is set according to the automatically configured buffer pool size, as shown in the following table:

**Table 17.9 Automatically Configured Log File Size**

Buffer Pool Size	Log File Size
Less than 8GB	512MB
8GB to 128GB	1024MB
Greater than 128GB	2048MB

- `innodb_log_files_in_group` (deprecated)

The number of log files is determined according to the automatically configured buffer pool size, as shown in the following table:

**Table 17.10 Automatically Configured Number of Log Files**

Buffer Pool Size	Number of Log Files
Less than 8GB	$\text{round}(\text{buffer pool size})$
8GB to 128GB	$\text{round}(\text{buffer pool size} * 0.75)$
Greater than 128GB	64

**Note**

The minimum value for `innodb_log_files_in_group` value is 2; this lower limit is enforced if the rounded buffer pool size value is less than this number.

If one of the variables listed previously is set explicitly in an option file or elsewhere, this explicit value is used, and a startup warning similar to this one is printed to `stderr`:

```
[Warning] [000000] InnoDB: Option innodb_dedicated_server is ignored for
innodb_buffer_pool_size because innodb_buffer_pool_size=134217728 is specified
explicitly.
```

Setting one variable explicitly does not prevent the automatic configuration of other options.

If the server is started with `--innodb-dedicated-server` and `innodb_buffer_pool_size` is set explicitly, variable settings based on buffer pool size use the buffer pool size value calculated according to the amount of memory detected on the server rather than the explicitly defined buffer pool size value.

**Note**

Automatic configuration settings are applied by `--innodb-dedicated-server` only when the MySQL server is started. If you later set any of the affected variables

explicitly, this overrides its predetermined value, and the value that was explicitly set is applied. Setting one of these variables to `DEFAULT` causes it to be set to the actual default value as shown in the variable's description in the Manual, and does *not* cause it to revert to the value set by `--innodb-dedicated-server`. The corresponding system variable `innodb_dedicated_server` is changed only by starting the server with `--innodb-dedicated-server` (or with `--innodb-dedicated-server=ON` or `--innodb-dedicated-server=OFF`); it is otherwise read-only.

## 17.9 InnoDB Table and Page Compression

This section provides information about the [InnoDB](#) table compression and [InnoDB](#) page compression features. The page compression feature is also referred to as [transparent page compression](#).

Using the compression features of [InnoDB](#), you can create tables where the data is stored in compressed form. Compression can help to improve both raw performance and scalability. The compression means less data is transferred between disk and memory, and takes up less space on disk and in memory. The benefits are amplified for tables with [secondary indexes](#), because index data is compressed also. Compression can be especially important for [SSD](#) storage devices, because they tend to have lower capacity than [HDD](#) devices.

### 17.9.1 InnoDB Table Compression

This section describes [InnoDB](#) table compression, which is supported with [InnoDB](#) tables that reside in [file\\_per\\_table](#) tablespaces or [general tablespaces](#). Table compression is enabled using the `ROW_FORMAT=COMPRESSED` attribute with `CREATE TABLE` or `ALTER TABLE`.

#### 17.9.1.1 Overview of Table Compression

Because processors and cache memories have increased in speed more than disk storage devices, many workloads are [disk-bound](#). Data [compression](#) enables smaller database size, reduced I/O, and improved throughput, at the small cost of increased CPU utilization. Compression is especially valuable for read-intensive applications, on systems with enough RAM to keep frequently used data in memory.

An [InnoDB](#) table created with `ROW_FORMAT=COMPRESSED` can use a smaller [page size](#) on disk than the configured `innodb_page_size` value. Smaller pages require less I/O to read from and write to disk, which is especially valuable for [SSD](#) devices.

The compressed page size is specified through the `CREATE TABLE` or `ALTER TABLE KEY_BLOCK_SIZE` parameter. The different page size requires that the table be placed in a [file-per-table](#) tablespace or [general tablespace](#) rather than in the [system tablespace](#), as the system tablespace cannot store compressed tables. For more information, see [Section 17.6.3.2, “File-Per-Table Tablespaces”](#), and [Section 17.6.3.3, “General Tablespaces”](#).

The level of compression is the same regardless of the `KEY_BLOCK_SIZE` value. As you specify smaller values for `KEY_BLOCK_SIZE`, you get the I/O benefits of increasingly smaller pages. But if you specify a value that is too small, there is additional overhead to reorganize the pages when data values cannot be compressed enough to fit multiple rows in each page. There is a hard limit on how small `KEY_BLOCK_SIZE` can be for a table, based on the lengths of the key columns for each of its indexes. Specify a value that is too small, and the `CREATE TABLE` or `ALTER TABLE` statement fails.

In the buffer pool, the compressed data is held in small pages, with a page size based on the `KEY_BLOCK_SIZE` value. For extracting or updating the column values, MySQL also creates an uncompressed page in the buffer pool with the uncompressed data. Within the buffer pool, any updates to

the uncompressed page are also re-written back to the equivalent compressed page. You might need to size your buffer pool to accommodate the additional data of both compressed and uncompressed pages, although the uncompressed pages are [evicted](#) from the buffer pool when space is needed, and then uncompressed again on the next access.

### 17.9.1.2 Creating Compressed Tables

Compressed tables can be created in [file-per-table](#) tablespaces or in [general tablespaces](#). Table compression is not available for the InnoDB [system tablespace](#). The system tablespace (space 0, the [.ibdata files](#)) can contain user-created tables, but it also contains internal system data, which is never compressed. Thus, compression applies only to tables (and indexes) stored in file-per-table or general tablespaces.

#### Creating a Compressed Table in File-Per-Table Tablespace

To create a compressed table in a file-per-table tablespace, [innodb\\_file\\_per\\_table](#) must be enabled (the default). You can set this parameter in the MySQL configuration file ([my.cnf](#) or [my.ini](#)) or dynamically, using a [SET](#) statement.

After the [innodb\\_file\\_per\\_table](#) option is configured, specify the [ROW\\_FORMAT=COMPRESSED](#) clause or [KEY\\_BLOCK\\_SIZE](#) clause, or both, in a [CREATE TABLE](#) or [ALTER TABLE](#) statement to create a compressed table in a file-per-table tablespace.

For example, you might use the following statements:

```
SET GLOBAL innodb_file_per_table=1;
CREATE TABLE t1
 (c1 INT PRIMARY KEY)
 ROW_FORMAT=COMPRESSED
 KEY_BLOCK_SIZE=8;
```

#### Creating a Compressed Table in a General Tablespace

To create a compressed table in a general tablespace, [FILE\\_BLOCK\\_SIZE](#) must be defined for the general tablespace, which is specified when the tablespace is created. The [FILE\\_BLOCK\\_SIZE](#) value must be a valid compressed page size in relation to the [innodb\\_page\\_size](#) value, and the page size of the compressed table, defined by the [CREATE TABLE](#) or [ALTER TABLE KEY\\_BLOCK\\_SIZE](#) clause, must be equal to [FILE\\_BLOCK\\_SIZE/1024](#). For example, if [innodb\\_page\\_size](#)=16384 and [FILE\\_BLOCK\\_SIZE](#)=8192, the [KEY\\_BLOCK\\_SIZE](#) of the table must be 8. For more information, see [Section 17.6.3.3, “General Tablespaces”](#).

The following example demonstrates creating a general tablespace and adding a compressed table. The example assumes a default [innodb\\_page\\_size](#) of 16K. The [FILE\\_BLOCK\\_SIZE](#) of 8192 requires that the compressed table have a [KEY\\_BLOCK\\_SIZE](#) of 8.

```
mysql> CREATE TABLESPACE `ts2` ADD DATAFILE 'ts2.ibd' FILE_BLOCK_SIZE = 8192 Engine=InnoDB;
mysql> CREATE TABLE t4 (c1 INT PRIMARY KEY) TABLESPACE ts2 ROW_FORMAT=COMPRESSED KEY_BLOCK_SIZE=8;
```

#### Notes

- As of MySQL 9.1, the tablespace file for a compressed table is created using the physical page size instead of the [InnoDB](#) page size, which makes the initial size of a tablespace file for an empty compressed table smaller than in previous MySQL releases.
- If you specify [ROW\\_FORMAT=COMPRESSED](#), you can omit [KEY\\_BLOCK\\_SIZE](#); the [KEY\\_BLOCK\\_SIZE](#) setting defaults to half the [innodb\\_page\\_size](#) value.

- If you specify a valid `KEY_BLOCK_SIZE` value, you can omit `ROW_FORMAT=COMPRESSED`; compression is enabled automatically.
- To determine the best value for `KEY_BLOCK_SIZE`, typically you create several copies of the same table with different values for this clause, then measure the size of the resulting `.ibd` files and see how well each performs with a realistic [workload](#). For general tablespaces, keep in mind that dropping a table does not reduce the size of the general tablespace `.ibd` file, nor does it return disk space to the operating system. For more information, see [Section 17.6.3.3, “General Tablespaces”](#).
- The `KEY_BLOCK_SIZE` value is treated as a hint; a different size could be used by InnoDB if necessary. For file-per-table tablespaces, the `KEY_BLOCK_SIZE` can only be less than or equal to the `innodb_page_size` value. If you specify a value greater than the `innodb_page_size` value, the specified value is ignored, a warning is issued, and `KEY_BLOCK_SIZE` is set to half of the `innodb_page_size` value. If `innodb_strict_mode=ON`, specifying an invalid `KEY_BLOCK_SIZE` value returns an error. For general tablespaces, valid `KEY_BLOCK_SIZE` values depend on the `FILE_BLOCK_SIZE` setting of the tablespace. For more information, see [Section 17.6.3.3, “General Tablespaces”](#).
- InnoDB supports 32KB and 64KB page sizes but these page sizes do not support compression. For more information, refer to the `innodb_page_size` documentation.
- The default uncompressed size of InnoDB data [pages](#) is 16KB. Depending on the combination of option values, MySQL uses a page size of 1KB, 2KB, 4KB, 8KB, or 16KB for the tablespace data file (`.ibd` file). The actual compression algorithm is not affected by the `KEY_BLOCK_SIZE` value; the value determines how large each compressed chunk is, which in turn affects how many rows can be packed into each compressed page.
- When creating a compressed table in a file-per-table tablespace, setting `KEY_BLOCK_SIZE` equal to the InnoDB [page size](#) does not typically result in much compression. For example, setting `KEY_BLOCK_SIZE=16` typically would not result in much compression, since the normal InnoDB page size is 16KB. This setting may still be useful for tables with many long `BLOB`, `VARCHAR` or `TEXT` columns, because such values often do compress well, and might therefore require fewer [overflow pages](#) as described in [Section 17.9.1.5, “How Compression Works for InnoDB Tables”](#). For general tablespaces, a `KEY_BLOCK_SIZE` value equal to the InnoDB page size is not permitted. For more information, see [Section 17.6.3.3, “General Tablespaces”](#).
- All indexes of a table (including the [clustered index](#)) are compressed using the same page size, as specified in the `CREATE TABLE` or `ALTER TABLE` statement. Table attributes such as `ROW_FORMAT` and `KEY_BLOCK_SIZE` are not part of the `CREATE INDEX` syntax for InnoDB tables, and are ignored if they are specified (although, if specified, they appear in the output of the `SHOW CREATE TABLE` statement).
- For performance-related configuration options, see [Section 17.9.1.3, “Tuning Compression for InnoDB Tables”](#).

## Restrictions on Compressed Tables

- Compressed tables cannot be stored in the InnoDB system tablespace.
- General tablespaces can contain multiple tables, but compressed and uncompressed tables cannot coexist within the same general tablespace.
- Compression applies to an entire table and all its associated indexes, not to individual rows, despite the clause name `ROW_FORMAT`.
- InnoDB does not support compressed temporary tables. When `innodb_strict_mode` is enabled (the default), `CREATE TEMPORARY TABLE` returns errors if `ROW_FORMAT=COMPRESSED` or `KEY_BLOCK_SIZE` is specified. If `innodb_strict_mode` is disabled, warnings are issued and the

temporary table is created using a non-compressed row format. The same restrictions apply to [ALTER TABLE](#) operations on temporary tables.

### 17.9.1.3 Tuning Compression for InnoDB Tables

Most often, the internal optimizations described in [InnoDB Data Storage and Compression](#) ensure that the system runs well with compressed data. However, because the efficiency of compression depends on the nature of your data, you can make decisions that affect the performance of compressed tables:

- Which tables to compress.
- What compressed page size to use.
- Whether to adjust the size of the buffer pool based on run-time performance characteristics, such as the amount of time the system spends compressing and uncompressing data. Whether the workload is more like a [data warehouse](#) (primarily queries) or an [OLTP](#) system (mix of queries and [DML](#)).
- If the system performs DML operations on compressed tables, and the way the data is distributed leads to expensive [compression failures](#) at runtime, you might adjust additional advanced configuration options.

Use the guidelines in this section to help make those architectural and configuration choices. When you are ready to conduct long-term testing and put compressed tables into production, see [Section 17.9.1.4, “Monitoring InnoDB Table Compression at Runtime”](#) for ways to verify the effectiveness of those choices under real-world conditions.

### When to Use Compression

In general, compression works best on tables that include a reasonable number of character string columns and where the data is read far more often than it is written. Because there are no guaranteed ways to predict whether or not compression benefits a particular situation, always test with a specific [workload](#) and data set running on a representative configuration. Consider the following factors when deciding which tables to compress.

### Data Characteristics and Compression

A key determinant of the efficiency of compression in reducing the size of data files is the nature of the data itself. Recall that compression works by identifying repeated strings of bytes in a block of data. Completely randomized data is the worst case. Typical data often has repeated values, and so compresses effectively. Character strings often compress well, whether defined in [CHAR](#), [VARCHAR](#), [TEXT](#) or [BLOB](#) columns. On the other hand, tables containing mostly binary data (integers or floating point numbers) or data that is previously compressed (for example JPEG or PNG images) may not generally compress well, significantly or at all.

You choose whether to turn on compression for each InnoDB table. A table and all of its indexes use the same (compressed) [page size](#). It might be that the [primary key](#) (clustered) index, which contains the data for all columns of a table, compresses more effectively than the secondary indexes. For those cases where there are long rows, the use of compression might result in long column values being stored “off-page”, as discussed in [DYNAMIC Row Format](#). Those overflow pages may compress well. Given these considerations, for many applications, some tables compress more effectively than others, and you might find that your workload performs best only with a subset of tables compressed.

To determine whether or not to compress a particular table, conduct experiments. You can get a rough estimate of how efficiently your data can be compressed by using a utility that implements LZ77 compression (such as [gzip](#) or WinZip) on a copy of the [.ibd file](#) for an uncompressed table. You can expect less compression from a MySQL compressed table than from file-based compression tools,

because MySQL compresses data in chunks based on the [page size](#), 16KB by default. In addition to user data, the page format includes some internal system data that is not compressed. File-based compression utilities can examine much larger chunks of data, and so might find more repeated strings in a huge file than MySQL can find in an individual page.

Another way to test compression on a specific table is to copy some data from your uncompressed table to a similar, compressed table (having all the same indexes) in a [file-per-table](#) tablespace and look at the size of the resulting `.ibd` file. For example:

```
USE test;
SET GLOBAL innodb_file_per_table=1;
SET GLOBAL autocommit=0;

-- Create an uncompressed table with a million or two rows.
CREATE TABLE big_table AS SELECT * FROM information_schema.columns;
INSERT INTO big_table SELECT * FROM big_table;
INSERT INTO big_table SELECT * FROM big_table;
INSERT INTO big_table SELECT * FROM big_table;
INSERT INTO big_table SELECT * FROM big_table;
INSERT INTO big_table SELECT * FROM big_table;
INSERT INTO big_table SELECT * FROM big_table;
INSERT INTO big_table SELECT * FROM big_table;
INSERT INTO big_table SELECT * FROM big_table;
INSERT INTO big_table SELECT * FROM big_table;
INSERT INTO big_table SELECT * FROM big_table;
COMMIT;
ALTER TABLE big_table ADD id int unsigned NOT NULL PRIMARY KEY auto_increment;

SHOW CREATE TABLE big_table\G

select count(id) from big_table;

-- Check how much space is needed for the uncompressed table.
\! ls -l data/test/big_table.ibd

CREATE TABLE key_block_size_4 LIKE big_table;
ALTER TABLE key_block_size_4 key_block_size=4 row_format=compressed;

INSERT INTO key_block_size_4 SELECT * FROM big_table;
commit;

-- Check how much space is needed for a compressed table
-- with particular compression settings.
\! ls -l data/test/key_block_size_4.ibd
```

This experiment produced the following numbers, which of course could vary considerably depending on your table structure and data:

```
-rw-rw---- 1 cirrus staff 310378496 Jan 9 13:44 data/test/big_table.ibd
-rw-rw---- 1 cirrus staff 83886080 Jan 9 15:10 data/test/key_block_size_4.ibd
```

To see whether compression is efficient for your particular [workload](#):

- For simple tests, use a MySQL instance with no other compressed tables and run queries against the Information Schema [INNODB\\_CMP](#) table.
- For more elaborate tests involving workloads with multiple compressed tables, run queries against the Information Schema [INNODB\\_CMP\\_PER\\_INDEX](#) table. Because the statistics in the [INNODB\\_CMP\\_PER\\_INDEX](#) table are expensive to collect, you must enable the configuration option [innodb\\_cmp\\_per\\_index\\_enabled](#) before querying that table, and you might restrict such testing to a development server or a non-critical replica server.
- Run some typical SQL statements against the compressed table you are testing.

- Examine the ratio of successful compression operations to overall compression operations by querying `INFORMATION_SCHEMA.INNODB_CMP` or `INFORMATION_SCHEMA.INNODB_CMP_PER_INDEX`, and comparing `COMPRESS_OPS` to `COMPRESS_OPS_OK`.
- If a high percentage of compression operations complete successfully, the table might be a good candidate for compression.
- If you get a high proportion of [compression failures](#), you can adjust `innodb_compression_level`, `innodb_compression_failure_threshold_pct`, and `innodb_compression_pad_pct_max` options as described in [Section 17.9.1.6, “Compression for OLTP Workloads”](#), and try further tests.

## Database Compression versus Application Compression

Decide whether to compress data in your application or in the table; do not use both types of compression for the same data. When you compress the data in the application and store the results in a compressed table, extra space savings are extremely unlikely, and the double compression just wastes CPU cycles.

### Compressing in the Database

When enabled, MySQL table compression is automatic and applies to all columns and index values. The columns can still be tested with operators such as `LIKE`, and sort operations can still use indexes even when the index values are compressed. Because indexes are often a significant fraction of the total size of a database, compression could result in significant savings in storage, I/O or processor time. The compression and decompression operations happen on the database server, which likely is a powerful system that is sized to handle the expected load.

### Compressing in the Application

If you compress data such as text in your application, before it is inserted into the database, You might save overhead for data that does not compress well by compressing some columns and not others. This approach uses CPU cycles for compression and uncompression on the client machine rather than the database server, which might be appropriate for a distributed application with many clients, or where the client machine has spare CPU cycles.

### Hybrid Approach

Of course, it is possible to combine these approaches. For some applications, it may be appropriate to use some compressed tables and some uncompressed tables. It may be best to externally compress some data (and store it in uncompressed tables) and allow MySQL to compress (some of) the other tables in the application. As always, up-front design and real-life testing are valuable in reaching the right decision.

## Workload Characteristics and Compression

In addition to choosing which tables to compress (and the page size), the workload is another key determinant of performance. If the application is dominated by reads, rather than updates, fewer pages need to be reorganized and recompressed after the index page runs out of room for the per-page “modification log” that MySQL maintains for compressed data. If the updates predominantly change non-indexed columns or those containing `BLOBS` or large strings that happen to be stored “off-page”, the overhead of compression may be acceptable. If the only changes to a table are `INSERTs` that use a monotonically increasing primary key, and there are few secondary indexes, there is little need to reorganize and recompress index pages. Since MySQL can “delete-mark” and delete rows on compressed pages “in place” by modifying uncompressed data, `DELETE` operations on a table are relatively efficient.

For some environments, the time it takes to load data can be as important as run-time retrieval. Especially in data warehouse environments, many tables may be read-only or read-mostly. In those cases, it might or might not be acceptable to pay the price of compression in terms of increased load time, unless the resulting savings in fewer disk reads or in storage cost is significant.

Fundamentally, compression works best when the CPU time is available for compressing and uncompressing data. Thus, if your workload is I/O bound, rather than CPU-bound, you might find that compression can improve overall performance. When you test your application performance with different compression configurations, test on a platform similar to the planned configuration of the production system.

## Configuration Characteristics and Compression

Reading and writing database [pages](#) from and to disk is the slowest aspect of system performance. Compression attempts to reduce I/O by using CPU time to compress and uncompress data, and is most effective when I/O is a relatively scarce resource compared to processor cycles.

This is often especially the case when running in a multi-user environment with fast, multi-core CPUs. When a page of a compressed table is in memory, MySQL often uses additional memory, typically 16KB, in the [buffer pool](#) for an uncompressed copy of the page. The adaptive LRU algorithm attempts to balance the use of memory between compressed and uncompressed pages to take into account whether the workload is running in an I/O-bound or CPU-bound manner. Still, a configuration with more memory dedicated to the buffer pool tends to run better when using compressed tables than a configuration where memory is highly constrained.

## Choosing the Compressed Page Size

The optimal setting of the compressed page size depends on the type and distribution of data that the table and its indexes contain. The compressed page size should always be bigger than the maximum record size, or operations may fail as noted in [Compression of B-Tree Pages](#).

Setting the compressed page size too large wastes some space, but the pages do not have to be compressed as often. If the compressed page size is set too small, inserts or updates may require time-consuming recompression, and the [B-tree](#) nodes may have to be split more frequently, leading to bigger data files and less efficient indexing.

Typically, you set the compressed page size to 8K or 4K bytes. Given that the maximum row size for an InnoDB table is around 8K, [KEY\\_BLOCK\\_SIZE=8](#) is usually a safe choice.

### 17.9.1.4 Monitoring InnoDB Table Compression at Runtime

Overall application performance, CPU and I/O utilization and the size of disk files are good indicators of how effective compression is for your application. This section builds on the performance tuning advice from [Section 17.9.1.3, “Tuning Compression for InnoDB Tables”](#), and shows how to find problems that might not turn up during initial testing.

To dig deeper into performance considerations for compressed tables, you can monitor compression performance at runtime using the [Information Schema](#) tables described in [Example 17.1, “Using the Compression Information Schema Tables”](#). These tables reflect the internal use of memory and the rates of compression used overall.

The [INNODB\\_CMP](#) table reports information about compression activity for each compressed page size ([KEY\\_BLOCK\\_SIZE](#)) in use. The information in these tables is system-wide: it summarizes the compression statistics across all compressed tables in your database. You can use this data to help decide whether or not to compress a table by examining these tables when no other compressed tables are being accessed. It involves relatively low overhead on the server, so you might query it periodically on a production server to check the overall efficiency of the compression feature.

The [INNODB\\_CMP\\_PER\\_INDEX](#) table reports information about compression activity for individual tables and indexes. This information is more targeted and more useful for evaluating compression efficiency and diagnosing performance issues one table or index at a time. (Because that each [InnoDB](#) table is represented as a clustered index, MySQL does not make a big distinction between tables and indexes

in this context.) The `INNODB_CMP_PER_INDEX` table does involve substantial overhead, so it is more suitable for development servers, where you can compare the effects of different [workloads](#), data, and compression settings in isolation. To guard against imposing this monitoring overhead by accident, you must enable the `innodb_cmp_per_index_enabled` configuration option before you can query the `INNODB_CMP_PER_INDEX` table.

The key statistics to consider are the number of, and amount of time spent performing, compression and uncompression operations. Since MySQL splits [B-tree](#) nodes when they are too full to contain the compressed data following a modification, compare the number of “successful” compression operations with the number of such operations overall. Based on the information in the `INNODB_CMP` and `INNODB_CMP_PER_INDEX` tables and overall application performance and hardware resource utilization, you might make changes in your hardware configuration, adjust the size of the buffer pool, choose a different page size, or select a different set of tables to compress.

If the amount of CPU time required for compressing and uncompressing is high, changing to faster or multi-core CPUs can help improve performance with the same data, application workload and set of compressed tables. Increasing the size of the buffer pool might also help performance, so that more uncompressed pages can stay in memory, reducing the need to uncompress pages that exist in memory only in compressed form.

A large number of compression operations overall (compared to the number of [INSERT](#), [UPDATE](#) and [DELETE](#) operations in your application and the size of the database) could indicate that some of your compressed tables are being updated too heavily for effective compression. If so, choose a larger page size, or be more selective about which tables you compress.

If the number of “successful” compression operations (`COMPRESS_OPS_OK`) is a high percentage of the total number of compression operations (`COMPRESS_OPS`), then the system is likely performing well. If the ratio is low, then MySQL is reorganizing, recompressing, and splitting B-tree nodes more often than is desirable. In this case, avoid compressing some tables, or increase `KEY_BLOCK_SIZE` for some of the compressed tables. You might turn off compression for tables that cause the number of “compression failures” in your application to be more than 1% or 2% of the total. (Such a failure ratio might be acceptable during a temporary operation such as a data load).

### 17.9.1.5 How Compression Works for InnoDB Tables

This section describes some internal implementation details about [compression](#) for InnoDB tables. The information presented here may be helpful in tuning for performance, but is not necessary to know for basic use of compression.

#### Compression Algorithms

Some operating systems implement compression at the file system level. Files are typically divided into fixed-size blocks that are compressed into variable-size blocks, which easily leads into fragmentation. Every time something inside a block is modified, the whole block is recompressed before it is written to disk. These properties make this compression technique unsuitable for use in an update-intensive database system.

MySQL implements compression with the help of the well-known [zlib library](#), which implements the LZ77 compression algorithm. This compression algorithm is mature, robust, and efficient in both CPU utilization and in reduction of data size. The algorithm is “lossless”, so that the original uncompressed data can always be reconstructed from the compressed form. LZ77 compression works by finding sequences of data that are repeated within the data to be compressed. The patterns of values in your data determine how well it compresses, but typical user data often compresses by 50% or more.

Unlike compression performed by an application, or compression features of some other database management systems, InnoDB compression applies both to user data and to indexes. In many cases,

indexes can constitute 40-50% or more of the total database size, so this difference is significant. When compression is working well for a data set, the size of the InnoDB data files (the [file-per-table](#) tablespace or [general tablespace](#) `.ibd` files) is 25% to 50% of the uncompressed size or possibly smaller. Depending on the [workload](#), this smaller database can in turn lead to a reduction in I/O, and an increase in throughput, at a modest cost in terms of increased CPU utilization. You can adjust the balance between compression level and CPU overhead by modifying the `innodb_compression_level` configuration option.

## InnoDB Data Storage and Compression

All user data in InnoDB tables is stored in pages comprising a [B-tree](#) index (the [clustered index](#)). In some other database systems, this type of index is called an “index-organized table”. Each row in the index node contains the values of the (user-specified or system-generated) [primary key](#) and all the other columns of the table.

[Secondary indexes](#) in InnoDB tables are also B-trees, containing pairs of values: the index key and a pointer to a row in the clustered index. The pointer is in fact the value of the primary key of the table, which is used to access the clustered index if columns other than the index key and primary key are required. Secondary index records must always fit on a single B-tree page.

The compression of B-tree nodes (of both clustered and secondary indexes) is handled differently from compression of [overflow pages](#) used to store long `VARCHAR`, `BLOB`, or `TEXT` columns, as explained in the following sections.

## Compression of B-Tree Pages

Because they are frequently updated, B-tree pages require special treatment. It is important to minimize the number of times B-tree nodes are split, as well as to minimize the need to uncompress and recompress their content.

One technique MySQL uses is to maintain some system information in the B-tree node in uncompressed form, thus facilitating certain in-place updates. For example, this allows rows to be delete-marked and deleted without any compression operation.

In addition, MySQL attempts to avoid unnecessary uncompression and recompression of index pages when they are changed. Within each B-tree page, the system keeps an uncompressed “modification log” to record changes made to the page. Updates and inserts of small records may be written to this modification log without requiring the entire page to be completely reconstructed.

When the space for the modification log runs out, InnoDB uncompresses the page, applies the changes and recompresses the page. If recompression fails (a situation known as a [compression failure](#)), the B-tree nodes are split and the process is repeated until the update or insert succeeds.

To avoid frequent compression failures in write-intensive workloads, such as for [OLTP](#) applications, MySQL sometimes reserves some empty space (padding) in the page, so that the modification log fills up sooner and the page is recompressed while there is still enough room to avoid splitting it. The amount of padding space left in each page varies as the system keeps track of the frequency of page splits. On a busy server doing frequent writes to compressed tables, you can adjust the `innodb_compression_failure_threshold_pct`, and `innodb_compression_pad_pct_max` configuration options to fine-tune this mechanism.

Generally, MySQL requires that each B-tree page in an InnoDB table can accommodate at least two records. For compressed tables, this requirement has been relaxed. Leaf pages of B-tree nodes (whether of the primary key or secondary indexes) only need to accommodate one record, but that record must fit, in uncompressed form, in the per-page modification log. If `innodb_strict_mode` is `ON`, MySQL checks the maximum row size during `CREATE TABLE` or `CREATE INDEX`. If the row does not fit, the following error message is issued: `ERROR HY000: Too big row`.

If you create a table when `innodb_strict_mode` is OFF, and a subsequent `INSERT` or `UPDATE` statement attempts to create an index entry that does not fit in the size of the compressed page, the operation fails with `ERROR 42000: Row size too large`. (This error message does not name the index for which the record is too large, or mention the length of the index record or the maximum record size on that particular index page.) To solve this problem, rebuild the table with `ALTER TABLE` and select a larger compressed page size (`KEY_BLOCK_SIZE`), shorten any column prefix indexes, or disable compression entirely with `ROW_FORMAT=DYNAMIC` or `ROW_FORMAT=COMPACT`.

`innodb_strict_mode` is not applicable to general tablespaces, which also support compressed tables. Tablespace management rules for general tablespaces are strictly enforced independently of `innodb_strict_mode`. For more information, see [Section 15.1.21, “CREATE TABLESPACE Statement”](#).

## Compressing BLOB, VARCHAR, and TEXT Columns

In an InnoDB table, `BLOB`, `VARCHAR`, and `TEXT` columns that are not part of the primary key may be stored on separately allocated [overflow pages](#). We refer to these columns as [off-page columns](#). Their values are stored on singly-linked lists of overflow pages.

For tables created in `ROW_FORMAT=DYNAMIC` or `ROW_FORMAT=COMPRESSED`, the values of `BLOB`, `TEXT`, or `VARCHAR` columns may be stored fully off-page, depending on their length and the length of the entire row. For columns that are stored off-page, the clustered index record only contains 20-byte pointers to the overflow pages, one per column. Whether any columns are stored off-page depends on the page size and the total size of the row. When the row is too long to fit entirely within the page of the clustered index, MySQL chooses the longest columns for off-page storage until the row fits on the clustered index page. As noted above, if a row does not fit by itself on a compressed page, an error occurs.

### Note

For tables created in `ROW_FORMAT=DYNAMIC` or `ROW_FORMAT=COMPRESSED`, `TEXT` and `BLOB` columns that are less than or equal to 40 bytes are always stored in-line.

Tables that use `ROW_FORMAT=REDUNDANT` and `ROW_FORMAT=COMPACT` store the first 768 bytes of `BLOB`, `VARCHAR`, and `TEXT` columns in the clustered index record along with the primary key. The 768-byte prefix is followed by a 20-byte pointer to the overflow pages that contain the rest of the column value.

When a table is in `COMPRESSED` format, all data written to overflow pages is compressed “as is”; that is, MySQL applies the zlib compression algorithm to the entire data item. Other than the data, compressed overflow pages contain an uncompressed header and trailer comprising a page checksum and a link to the next overflow page, among other things. Therefore, very significant storage savings can be obtained for longer `BLOB`, `TEXT`, or `VARCHAR` columns if the data is highly compressible, as is often the case with text data. Image data, such as `JPEG`, is typically already compressed and so does not benefit much from being stored in a compressed table; the double compression can waste CPU cycles for little or no space savings.

The overflow pages are of the same size as other pages. A row containing ten columns stored off-page occupies ten overflow pages, even if the total length of the columns is only 8K bytes. In an uncompressed table, ten uncompressed overflow pages occupy 160K bytes. In a compressed table with an 8K page size, they occupy only 80K bytes. Thus, it is often more efficient to use compressed table format for tables with long column values.

For [file-per-table](#) tablespaces, using a 16K compressed page size can reduce storage and I/O costs for `BLOB`, `VARCHAR`, or `TEXT` columns, because such data often compress well, and might therefore require fewer overflow pages, even though the B-tree nodes themselves take as many pages as in the uncompressed form. General tablespaces do not support a 16K compressed page size (`KEY_BLOCK_SIZE`). For more information, see [Section 17.6.3.3, “General Tablespaces”](#).

## Compression and the InnoDB Buffer Pool

In a compressed InnoDB table, every compressed page (whether 1K, 2K, 4K or 8K) corresponds to an uncompressed page of 16K bytes (or a smaller size if `innodb_page_size` is set). To access the data in a page, MySQL reads the compressed page from disk if it is not already in the buffer pool, then uncompresses the page to its original form. This section describes how InnoDB manages the buffer pool with respect to pages of compressed tables.

To minimize I/O and to reduce the need to uncompress a page, at times the buffer pool contains both the compressed and uncompressed form of a database page. To make room for other required database pages, MySQL can evict from the buffer pool an uncompressed page, while leaving the compressed page in memory. Or, if a page has not been accessed in a while, the compressed form of the page might be written to disk, to free space for other data. Thus, at any given time, the buffer pool might contain both the compressed and uncompressed forms of the page, or only the compressed form of the page, or neither.

MySQL keeps track of which pages to keep in memory and which to evict using a least-recently-used (LRU) list, so that hot (frequently accessed) data tends to stay in memory. When compressed tables are accessed, MySQL uses an adaptive LRU algorithm to achieve an appropriate balance of compressed and uncompressed pages in memory. This adaptive algorithm is sensitive to whether the system is running in an I/O-bound or CPU-bound manner. The goal is to avoid spending too much processing time uncompressing pages when the CPU is busy, and to avoid doing excess I/O when the CPU has spare cycles that can be used for uncompressing compressed pages (that may already be in memory). When the system is I/O-bound, the algorithm prefers to evict the uncompressed copy of a page rather than both copies, to make more room for other disk pages to become memory resident. When the system is CPU-bound, MySQL prefers to evict both the compressed and uncompressed page, so that more memory can be used for “hot” pages and reducing the need to uncompress data in memory only in compressed form.

## Compression and the InnoDB Redo Log Files

Before a compressed page is written to a data file, MySQL writes a copy of the page to the redo log (if it has been recompressed since the last time it was written to the database). This is done to ensure that redo logs are usable for crash recovery, even in the unlikely case that the `zlib` library is upgraded and that change introduces a compatibility problem with the compressed data. Therefore, some increase in the size of log files, or a need for more frequent checkpoints, can be expected when using compression. The amount of increase in the log file size or checkpoint frequency depends on the number of times compressed pages are modified in a way that requires reorganization and recompression.

To create a compressed table in a file-per-table tablespace, `innodb_file_per_table` must be enabled. There is no dependence on the `innodb_file_per_table` setting when creating a compressed table in a general tablespace. For more information, see [Section 17.6.3.3, “General Tablespaces”](#).

### 17.9.1.6 Compression for OLTP Workloads

Traditionally, the InnoDB compression feature was recommended primarily for read-only or read-mostly workloads, such as in a data warehouse configuration. The rise of SSD storage devices, which are fast but relatively small and expensive, makes compression attractive also for OLTP workloads: high-traffic, interactive websites can reduce their storage requirements and their I/O operations per second (IOPS) by using compressed tables with applications that do frequent INSERT, UPDATE, and DELETE operations.

These configuration options let you adjust the way compression works for a particular MySQL instance, with an emphasis on performance and scalability for write-intensive operations:

- `innodb_compression_level` lets you turn the degree of compression up or down. A higher value lets you fit more data onto a storage device, at the expense of more CPU overhead during compression. A lower value lets you reduce CPU overhead when storage space is not critical, or you expect the data is not especially compressible.

- `innodb_compression_failure_threshold_pct` specifies a cutoff point for [compression failures](#) during updates to a compressed table. When this threshold is passed, MySQL begins to leave additional free space within each new compressed page, dynamically adjusting the amount of free space up to the percentage of page size specified by `innodb_compression_pad_pct_max`.
- `innodb_compression_pad_pct_max` lets you adjust the maximum amount of space reserved within each [page](#) to record changes to compressed rows, without needing to compress the entire page again. The higher the value, the more changes can be recorded without recompressing the page. MySQL uses a variable amount of free space for the pages within each compressed table, only when a designated percentage of compression operations “fail” at runtime, requiring an expensive operation to split the compressed page.
- `innodb_log_compressed_pages` lets you disable writing of images of [re-compressed pages](#) to the [redo log](#). Re-compression may occur when changes are made to compressed data. This option is enabled by default to prevent corruption that could occur if a different version of the `zlib` compression algorithm is used during recovery. If you are certain that the `zlib` version is not subject to change, disable `innodb_log_compressed_pages` to reduce redo log generation for workloads that modify compressed data.

Because working with compressed data sometimes involves keeping both compressed and uncompressed versions of a page in memory at the same time, when using compression with an OLTP-style workload, be prepared to increase the value of the `innodb_buffer_pool_size` configuration option.

### 17.9.1.7 SQL Compression Syntax Warnings and Errors

This section describes syntax warnings and errors that you may encounter when using the table compression feature with [file-per-table](#) tablespaces and [general tablespaces](#).

#### SQL Compression Syntax Warnings and Errors for File-Per-Table Tablespaces

When `innodb_strict_mode` is enabled (the default), specifying `ROW_FORMAT=COMPRESSED` or `KEY_BLOCK_SIZE` in `CREATE TABLE` or `ALTER TABLE` statements produces the following error if `innodb_file_per_table` is disabled.

```
ERROR 1031 (HY000): Table storage engine for 't1' doesn't have this option
```

#### Note

The table is not created if the current configuration does not permit using compressed tables.

When `innodb_strict_mode` is disabled, specifying `ROW_FORMAT=COMPRESSED` or `KEY_BLOCK_SIZE` in `CREATE TABLE` or `ALTER TABLE` statements produces the following warnings if `innodb_file_per_table` is disabled.

```
mysql> SHOW WARNINGS;
```

Level	Code	Message
Warning	1478	InnoDB: KEY_BLOCK_SIZE requires innodb_file_per_table.
Warning	1478	InnoDB: ignoring KEY_BLOCK_SIZE=4.
Warning	1478	InnoDB: ROW_FORMAT=COMPRESSED requires innodb_file_per_table.
Warning	1478	InnoDB: assuming ROW_FORMAT=DYNAMIC.

#### Note

These messages are only warnings, not errors, and the table is created without compression, as if the options were not specified.

The “non-strict” behavior lets you import a `mysqldump` file into a database that does not support compressed tables, even if the source database contained compressed tables. In that case, MySQL creates the table in `ROW_FORMAT=DYNAMIC` instead of preventing the operation.

To import the dump file into a new database, and have the tables re-created as they exist in the original database, ensure the server has the proper setting for the `innodb_file_per_table` configuration parameter.

The attribute `KEY_BLOCK_SIZE` is permitted only when `ROW_FORMAT` is specified as `COMPRESSED` or is omitted. Specifying a `KEY_BLOCK_SIZE` with any other `ROW_FORMAT` generates a warning that you can view with `SHOW WARNINGS`. However, the table is non-compressed; the specified `KEY_BLOCK_SIZE` is ignored).

Level	Code	Message
Warning	1478	InnoDB: ignoring KEY_BLOCK_SIZE=n unless ROW_FORMAT=COMPRESSED.

If you are running with `innodb_strict_mode` enabled, the combination of a `KEY_BLOCK_SIZE` with any `ROW_FORMAT` other than `COMPRESSED` generates an error, not a warning, and the table is not created.

Table 17.11, “`ROW_FORMAT` and `KEY_BLOCK_SIZE` Options” provides an overview the `ROW_FORMAT` and `KEY_BLOCK_SIZE` options that are used with `CREATE TABLE` or `ALTER TABLE`.

**Table 17.11 `ROW_FORMAT` and `KEY_BLOCK_SIZE` Options**

Option	Usage Notes	Description
<code>ROW_FORMAT=REDUNDANT</code>	Storage format used prior to MySQL 5.0.3	Less efficient than <code>ROW_FORMAT=COMPACT</code> ; for backward compatibility
<code>ROW_FORMAT=COMPACT</code>	Default storage format since MySQL 5.0.3	Stores a prefix of 768 bytes of long column values in the clustered index page, with the remaining bytes stored in an overflow page
<code>ROW_FORMAT=DYNAMIC</code>		Store values within the clustered index page if they fit; if not, stores only a 20-byte pointer to an overflow page (no prefix)
<code>ROW_FORMAT=COMPRESSED</code>		Compresses the table and indexes using zlib
<code>KEY_BLOCK_SIZE=n</code>		Specifies compressed page size of 1, 2, 4, 8 or 16 kilobytes; implies <code>ROW_FORMAT=COMPRESSED</code> . For general tablespaces, a <code>KEY_BLOCK_SIZE</code> value equal to the InnoDB page size is not permitted.

Table 17.12, “`CREATE/ALTER TABLE` Warnings and Errors when InnoDB Strict Mode is OFF” summarizes error conditions that occur with certain combinations of configuration parameters and options on the `CREATE TABLE` or `ALTER TABLE` statements, and how the options appear in the output of `SHOW TABLE STATUS`.

When `innodb_strict_mode` is `OFF`, MySQL creates or alters the table, but ignores certain settings as shown below. You can see the warning messages in the MySQL error log. When `innodb_strict_mode` is `ON`, these specified combinations of options generate errors, and the table is not created or altered. To see the full description of the error condition, issue the `SHOW ERRORS` statement: example:

```
mysql> CREATE TABLE x (id INT PRIMARY KEY, c INT)
 -> ENGINE=INNODB KEY_BLOCK_SIZE=33333;
ERROR 1005 (HY000): Can't create table 'test.x' (errno: 1478)
mysql> SHOW ERRORS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Error | 1478 | InnoDB: invalid KEY_BLOCK_SIZE=33333. |
| Error | 1005 | Can't create table 'test.x' (errno: 1478) |
+-----+-----+-----+
```

**Table 17.12 CREATE/ALTER TABLE Warnings and Errors when InnoDB Strict Mode is OFF**

Syntax	Warning or Error Condition	Resulting <code>ROW_FORMAT</code> , as shown in <code>SHOW TABLE STATUS</code>
<code>ROW_FORMAT=REDUNDANT</code>	None	<code>REDUNDANT</code>
<code>ROW_FORMAT=COMPACT</code>	None	<code>COMPACT</code>
<code>ROW_FORMAT=COMPRESSED</code> or <code>ROW_FORMAT=DYNAMIC</code> or <code>KEY_BLOCK_SIZE</code> is specified	Ignored for file-per-table tablespaces unless <code>innodb_file_per_table</code> is enabled. General tablespaces support all row formats. See <a href="#">Section 17.6.3.3, “General Tablespaces”</a> .	the default row format for file-per-table tablespaces; the specified row format for general tablespaces
Invalid <code>KEY_BLOCK_SIZE</code> is specified (not 1, 2, 4, 8 or 16)	<code>KEY_BLOCK_SIZE</code> is ignored	the specified row format, or the default row format
<code>ROW_FORMAT=COMPRESSED</code> and valid <code>KEY_BLOCK_SIZE</code> are specified	None; <code>KEY_BLOCK_SIZE</code> specified is used	<code>COMPRESSED</code>
<code>KEY_BLOCK_SIZE</code> is specified with <code>REDUNDANT</code> , <code>COMPACT</code> or <code>DYNAMIC</code> row format	<code>KEY_BLOCK_SIZE</code> is ignored	<code>REDUNDANT</code> , <code>COMPACT</code> or <code>DYNAMIC</code>
<code>ROW_FORMAT</code> is not one of <code>REDUNDANT</code> , <code>COMPACT</code> , <code>DYNAMIC</code> or <code>COMPRESSED</code>	Ignored if recognized by the MySQL parser. Otherwise, an error is issued.	the default row format or N/A

When `innodb_strict_mode` is `ON`, MySQL rejects invalid `ROW_FORMAT` or `KEY_BLOCK_SIZE` parameters and issues errors. Strict mode is `ON` by default. When `innodb_strict_mode` is `OFF`, MySQL issues warnings instead of errors for ignored invalid parameters.

It is not possible to see the chosen `KEY_BLOCK_SIZE` using `SHOW TABLE STATUS`. The statement `SHOW CREATE TABLE` displays the `KEY_BLOCK_SIZE` (even if it was ignored when creating the table). The real compressed page size of the table cannot be displayed by MySQL.

## SQL Compression Syntax Warnings and Errors for General Tablespaces

- If `FILE_BLOCK_SIZE` was not defined for the general tablespace when the tablespace was created, the tablespace cannot contain compressed tables. If you attempt to add a compressed table, an error is returned, as shown in the following example:

```
mysql> CREATE TABLESPACE `ts1` ADD DATAFILE 'ts1.ibd' Engine=InnoDB;

mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY) TABLESPACE ts1 ROW_FORMAT=COMPRESSED
 KEY_BLOCK_SIZE=8;
ERROR 1478 (HY000): InnoDB: Tablespace `ts1` cannot contain a COMPRESSED table
```

- Attempting to add a table with an invalid `KEY_BLOCK_SIZE` to a general tablespace returns an error, as shown in the following example:

```
mysql> CREATE TABLESPACE `ts2` ADD DATAFILE 'ts2.ibd' FILE_BLOCK_SIZE = 8192 Engine=InnoDB;

mysql> CREATE TABLE t2 (c1 INT PRIMARY KEY) TABLESPACE ts2 ROW_FORMAT=COMPRESSED
 KEY_BLOCK_SIZE=4;
ERROR 1478 (HY000): InnoDB: Tablespace `ts2` uses block size 8192 and cannot
contain a table with physical page size 4096
```

For general tablespaces, the `KEY_BLOCK_SIZE` of the table must be equal to the `FILE_BLOCK_SIZE` of the tablespace divided by 1024. For example, if the `FILE_BLOCK_SIZE` of the tablespace is 8192, the `KEY_BLOCK_SIZE` of the table must be 8.

- Attempting to add a table with an uncompressed row format to a general tablespace configured to store compressed tables returns an error, as shown in the following example:

```
mysql> CREATE TABLESPACE `ts3` ADD DATAFILE 'ts3.ibd' FILE_BLOCK_SIZE = 8192 Engine=InnoDB;

mysql> CREATE TABLE t3 (c1 INT PRIMARY KEY) TABLESPACE ts3 ROW_FORMAT=COMPACT;
ERROR 1478 (HY000): InnoDB: Tablespace `ts3` uses block size 8192 and cannot
contain a table with physical page size 16384
```

`innodb_strict_mode` is not applicable to general tablespaces. Tablespace management rules for general tablespaces are strictly enforced independently of `innodb_strict_mode`. For more information, see [Section 15.1.21, “CREATE TABLESPACE Statement”](#).

For more information about using compressed tables with general tablespaces, see [Section 17.6.3.3, “General Tablespaces”](#).

## 17.9.2 InnoDB Page Compression

InnoDB supports page-level compression for tables that reside in [file-per-table](#) tablespaces. This feature is referred to as *Transparent Page Compression*. Page compression is enabled by specifying the `COMPRESSION` attribute with `CREATE TABLE` or `ALTER TABLE`. Supported compression algorithms include [Zlib](#) and [LZ4](#).

### Supported Platforms

Page compression requires sparse file and hole punching support. Page compression is supported on Windows with NTFS, and on the following subset of MySQL-supported Linux platforms where the kernel level provides hole punching support:

- RHEL 7 and derived distributions that use kernel version 3.10.0-123 or higher
- OEL 5.10 (UEK2) kernel version 2.6.39 or higher
- OEL 6.5 (UEK3) kernel version 3.8.13 or higher
- OEL 7.0 kernel version 3.8.13 or higher
- SLE11 kernel version 3.0-x

- SLE12 kernel version 3.12-x
- OES11 kernel version 3.0-x
- Ubuntu 14.0.4 LTS kernel version 3.13 or higher
- Ubuntu 12.0.4 LTS kernel version 3.2 or higher
- Debian 7 kernel version 3.2 or higher

#### Note

All of the available file systems for a given Linux distribution may not support hole punching.

## How Page Compression Works

When a page is written, it is compressed using the specified compression algorithm. The compressed data is written to disk, where the hole punching mechanism releases empty blocks from the end of the page. If compression fails, data is written out as-is.

## Hole Punch Size on Linux

On Linux systems, the file system block size is the unit size used for hole punching. Therefore, page compression only works if page data can be compressed to a size that is less than or equal to the [InnoDB](#) page size minus the file system block size. For example, if `innodb_page_size=16K` and the file system block size is 4K, page data must compress to less than or equal to 12K to make hole punching possible.

## Hole Punch Size on Windows

On Windows systems, the underlying infrastructure for sparse files is based on NTFS compression. Hole punching size is the NTFS compression unit, which is 16 times the NTFS cluster size. Cluster sizes and their compression units are shown in the following table:

**Table 17.13 Windows NTFS Cluster Size and Compression Units**

Cluster Size	Compression Unit
512 Bytes	8 KB
1 KB	16 KB
2 KB	32 KB
4 KB	64 KB

Page compression on Windows systems only works if page data can be compressed to a size that is less than or equal to the [InnoDB](#) page size minus the compression unit size.

The default NTFS cluster size is 4KB, for which the compression unit size is 64KB. This means that page compression has no benefit for an out-of-the box Windows NTFS configuration, as the maximum `innodb_page_size` is also 64KB.

For page compression to work on Windows, the file system must be created with a cluster size smaller than 4K, and the `innodb_page_size` must be at least twice the size of the compression unit. For example, for page compression to work on Windows, you could build the file system with a cluster size of 512 Bytes (which has a compression unit of 8KB) and initialize [InnoDB](#) with an `innodb_page_size` value of 16K or greater.

## Enabling Page Compression

To enable page compression, specify the `COMPRESSION` attribute in the `CREATE TABLE` statement. For example:

```
CREATE TABLE t1 (c1 INT) COMPRESSION="zlib";
```

You can also enable page compression in an `ALTER TABLE` statement. However, `ALTER TABLE ... COMPRESSION` only updates the tablespace compression attribute. Writes to the tablespace that occur after setting the new compression algorithm use the new setting, but to apply the new compression algorithm to existing pages, you must rebuild the table using `OPTIMIZE TABLE`.

```
ALTER TABLE t1 COMPRESSION="zlib";
OPTIMIZE TABLE t1;
```

## Disabling Page Compression

To disable page compression, set `COMPRESSION=None` using `ALTER TABLE`. Writes to the tablespace that occur after setting `COMPRESSION=None` no longer use page compression. To uncompress existing pages, you must rebuild the table using `OPTIMIZE TABLE` after setting `COMPRESSION=None`.

```
ALTER TABLE t1 COMPRESSION="None";
OPTIMIZE TABLE t1;
```

## Page Compression Metadata

Page compression metadata is found in the Information Schema `INNODB_TABLESPACES` table, in the following columns:

- `FS_BLOCK_SIZE`: The file system block size, which is the unit size used for hole punching.
- `FILE_SIZE`: The apparent size of the file, which represents the maximum size of the file, uncompressed.
- `ALLOCATED_SIZE`: The actual size of the file, which is the amount of space allocated on disk.

### Note

On Unix-like systems, `ls -l tablespace_name.ibd` shows the apparent file size (equivalent to `FILE_SIZE`) in bytes. To view the actual amount of space allocated on disk (equivalent to `ALLOCATED_SIZE`), use `du --block-size=1 tablespace_name.ibd`. The `--block-size=1` option prints the allocated space in bytes instead of blocks, so that it can be compared to `ls -l` output.

Use `SHOW CREATE TABLE` to view the current page compression setting (`zlib`, `Lz4`, or `None`). A table may contain a mix of pages with different compression settings.

In the following example, page compression metadata for the `employees` table is retrieved from the Information Schema `INNODB_TABLESPACES` table.

```
Create the employees table with Zlib page compression

CREATE TABLE employees (
 emp_no INT NOT NULL,
 birth_date DATE NOT NULL,
 first_name VARCHAR(14) NOT NULL,
 last_name VARCHAR(16) NOT NULL,
 gender ENUM ('M','F') NOT NULL,
 hire_date DATE NOT NULL,
```

```

 PRIMARY KEY (emp_no)
) COMPRESSION="zlib";

Insert data (not shown)

Query page compression metadata in INFORMATION_SCHEMA.INNODB_TABLESPACES

mysql> SELECT SPACE, NAME, FS_BLOCK_SIZE, FILE_SIZE, ALLOCATED_SIZE FROM
 INFORMATION_SCHEMA.INNODB_TABLESPACES WHERE NAME='employees/employees'\G
***** 1. row *****
SPACE: 45
NAME: employees/employees
FS_BLOCK_SIZE: 4096
FILE_SIZE: 23068672
ALLOCATED_SIZE: 19415040

```

Page compression metadata for the employees table shows that the apparent file size is 23068672 bytes while the actual file size (with page compression) is 19415040 bytes. The file system block size is 4096 bytes, which is the block size used for hole punching.

## Identifying Tables Using Page Compression

To identify tables for which page compression is enabled, you can check the Information Schema `TABLES` table's `CREATE_OPTIONS` column for tables defined with the `COMPRESSION` attribute:

```

mysql> SELECT TABLE_NAME, TABLE_SCHEMA, CREATE_OPTIONS FROM INFORMATION_SCHEMA.TABLES
 WHERE CREATE_OPTIONS LIKE '%COMPRESSION=%';
+-----+-----+-----+
| TABLE_NAME | TABLE_SCHEMA | CREATE_OPTIONS |
+-----+-----+-----+
| employees | test | COMPRESSION="zlib" |
+-----+-----+-----+

```

`SHOW CREATE TABLE` also shows the `COMPRESSION` attribute, if used.

## Page Compression Limitations and Usage Notes

- Page compression is disabled if the file system block size (or compression unit size on Windows) \* 2 > `innodb_page_size`.
- Page compression is not supported for tables that reside in shared tablespaces, which include the system tablespace, temporary tablespaces, and general tablespaces.
- Page compression is not supported for undo log tablespaces.
- Page compression is not supported for redo log pages.
- R-tree pages, which are used for spatial indexes, are not compressed.
- Pages that belong to compressed tables (`ROW_FORMAT=COMPRESSED`) are left as-is.
- During recovery, updated pages are written out in an uncompressed form.
- Loading a page-compressed tablespace on a server that does not support the compression algorithm that was used causes an I/O error.
- Before downgrading to an earlier version of MySQL that does not support page compression, uncompress the tables that use the page compression feature. To uncompress a table, run `ALTER TABLE ... COMPRESSION=None` and `OPTIMIZE TABLE`.
- Page-compressed tablespaces can be copied between Linux and Windows servers if the compression algorithm that was used is available on both servers.

- Preserving page compression when moving a page-compressed tablespace file from one host to another requires a utility that preserves sparse files.
- Better page compression may be achieved on Fusion-io hardware with NVMFS than on other platforms, as NVMFS is designed to take advantage of punch hole functionality.
- Using the page compression feature with a large [InnoDB](#) page size and relatively small file system block size could result in write amplification. For example, a maximum [InnoDB](#) page size of 64KB with a 4KB file system block size may improve compression but may also increase demand on the buffer pool, leading to increased I/O and potential write amplification.

## 17.10 InnoDB Row Formats

The row format of a table determines how its rows are physically stored, which in turn can affect the performance of queries and DML operations. As more rows fit into a single disk page, queries and index lookups can work faster, less cache memory is required in the buffer pool, and less I/O is required to write out updated values.

The data in each table is divided into pages. The pages that make up each table are arranged in a tree data structure called a B-tree index. Table data and secondary indexes both use this type of structure. The B-tree index that represents an entire table is known as the clustered index, which is organized according to the primary key columns. The nodes of a clustered index data structure contain the values of all columns in the row. The nodes of a secondary index structure contain the values of index columns and primary key columns.

Variable-length columns are an exception to the rule that column values are stored in B-tree index nodes. Variable-length columns that are too long to fit on a B-tree page are stored on separately allocated disk pages called overflow pages. Such columns are referred to as off-page columns. The values of off-page columns are stored in singly-linked lists of overflow pages, with each such column having its own list of one or more overflow pages. Depending on column length, all or a prefix of variable-length column values are stored in the B-tree to avoid wasting storage and having to read a separate page.

The [InnoDB](#) storage engine supports four row formats: [REDUNDANT](#), [COMPACT](#), [DYNAMIC](#), and [COMPRESSED](#).

**Table 17.14 InnoDB Row Format Overview**

Row Format	Compact Storage Characteristics	Enhanced Variable-Length Column Storage	Large Index Key Prefix Support	Compression Support	Supported Tablespace Types
<a href="#">REDUNDANT</a>	No	No	No	No	system, file-per-table, general
<a href="#">COMPACT</a>	Yes	No	No	No	system, file-per-table, general
<a href="#">DYNAMIC</a>	Yes	Yes	Yes	No	system, file-per-table, general
<a href="#">COMPRESSED</a>	Yes	Yes	Yes	Yes	file-per-table, general

The topics that follow describe row format storage characteristics and how to define and determine the row format of a table.

- [REDUNDANT Row Format](#)

- [COMPACT Row Format](#)
- [DYNAMIC Row Format](#)
- [COMPRESSED Row Format](#)
- [Defining the Row Format of a Table](#)
- [Determining the Row Format of a Table](#)

## REDUNDANT Row Format

The [REDUNDANT](#) format provides compatibility with older versions of MySQL.

Tables that use the [REDUNDANT](#) row format store the first 768 bytes of variable-length column values ([VARCHAR](#), [VARBINARY](#), and [BLOB](#) and [TEXT](#) types) in the index record within the B-tree node, with the remainder stored on overflow pages. Fixed-length columns greater than or equal to 768 bytes are encoded as variable-length columns, which can be stored off-page. For example, a [CHAR\(255\)](#) column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with [utf8mb4](#).

If the value of a column is 768 bytes or less, an overflow page is not used, and some savings in I/O may result, since the value is stored entirely in the B-tree node. This works well for relatively short [BLOB](#) column values, but may cause B-tree nodes to fill with data rather than key values, reducing their efficiency. Tables with many [BLOB](#) columns could cause B-tree nodes to become too full, and contain too few rows, making the entire index less efficient than if rows were shorter or column values were stored off-page.

## REDUNDANT Row Format Storage Characteristics

The [REDUNDANT](#) row format has the following storage characteristics:

- Each index record contains a 6-byte header. The header is used to link together consecutive records, and for row-level locking.
- Records in the clustered index contain fields for all user-defined columns. In addition, there is a 6-byte transaction ID field and a 7-byte roll pointer field.
- If no primary key is defined for a table, each clustered index record also contains a 6-byte row ID field.
- Each secondary index record contains all the primary key columns defined for the clustered index key that are not in the secondary index.
- A record contains a pointer to each field of the record. If the total length of the fields in a record is less than 128 bytes, the pointer is one byte; otherwise, two bytes. The array of pointers is called the record directory. The area where the pointers point is the data part of the record.
- Internally, fixed-length character columns such as [CHAR\(10\)](#) are stored in fixed-length format. Trailing spaces are not truncated from [VARCHAR](#) columns.
- Fixed-length columns greater than or equal to 768 bytes are encoded as variable-length columns, which can be stored off-page. For example, a [CHAR\(255\)](#) column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with [utf8mb4](#).
- An SQL [NULL](#) value reserves one or two bytes in the record directory. An SQL [NULL](#) value reserves zero bytes in the data part of the record if stored in a variable-length column. For a fixed-length column, the fixed length of the column is reserved in the data part of the record. Reserving fixed space for [NULL](#) values permits columns to be updated in place from [NULL](#) to non-[NULL](#) values without causing index page fragmentation.

## COMPACT Row Format

The **COMPACT** row format reduces row storage space by about 20% compared to the **REDUNDANT** row format, at the cost of increasing CPU use for some operations. If your workload is a typical one that is limited by cache hit rates and disk speed, **COMPACT** format is likely to be faster. If the workload is limited by CPU speed, compact format might be slower.

Tables that use the **COMPACT** row format store the first 768 bytes of variable-length column values (**VARCHAR**, **VARBINARY**, and **BLOB** and **TEXT** types) in the index record within the **B-tree** node, with the remainder stored on overflow pages. Fixed-length columns greater than or equal to 768 bytes are encoded as variable-length columns, which can be stored off-page. For example, a **CHAR(255)** column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with **utf8mb4**.

If the value of a column is 768 bytes or less, an overflow page is not used, and some savings in I/O may result, since the value is stored entirely in the B-tree node. This works well for relatively short **BLOB** column values, but may cause B-tree nodes to fill with data rather than key values, reducing their efficiency. Tables with many **BLOB** columns could cause B-tree nodes to become too full, and contain too few rows, making the entire index less efficient than if rows were shorter or column values were stored off-page.

### COMPACT Row Format Storage Characteristics

The **COMPACT** row format has the following storage characteristics:

- Each index record contains a 5-byte header that may be preceded by a variable-length header. The header is used to link together consecutive records, and for row-level locking.
- The variable-length part of the record header contains a bit vector for indicating **NULL** columns. If the number of columns in the index that can be **NULL** is *N*, the bit vector occupies **CEILING(N/8)** bytes. (For example, if there are anywhere from 9 to 16 columns that can be **NULL**, the bit vector uses two bytes.) Columns that are **NULL** do not occupy space other than the bit in this vector. The variable-length part of the header also contains the lengths of variable-length columns. Each length takes one or two bytes, depending on the maximum length of the column. If all columns in the index are **NOT NULL** and have a fixed length, the record header has no variable-length part.
- For each non-**NULL** variable-length field, the record header contains the length of the column in one or two bytes. Two bytes are only needed if part of the column is stored externally in overflow pages or the maximum length exceeds 255 bytes and the actual length exceeds 127 bytes. For an externally stored column, the 2-byte length indicates the length of the internally stored part plus the 20-byte pointer to the externally stored part. The internal part is 768 bytes, so the length is 768+20. The 20-byte pointer stores the true length of the column.
- The record header is followed by the data contents of non-**NULL** columns.
- Records in the clustered index contain fields for all user-defined columns. In addition, there is a 6-byte transaction ID field and a 7-byte roll pointer field.
- If no primary key is defined for a table, each clustered index record also contains a 6-byte row ID field.
- Each secondary index record contains all the primary key columns defined for the clustered index key that are not in the secondary index. If any of the primary key columns are variable length, the record header for each secondary index has a variable-length part to record their lengths, even if the secondary index is defined on fixed-length columns.
- Internally, for nonvariable-length character sets, fixed-length character columns such as **CHAR(10)** are stored in a fixed-length format.

Trailing spaces are not truncated from **VARCHAR** columns.

- Internally, for variable-length character sets such as `utf8mb3` and `utf8mb4`, InnoDB attempts to store `CHAR(N)` in  $N$  bytes by trimming trailing spaces. If the byte length of a `CHAR(N)` column value exceeds  $N$  bytes, trailing spaces are trimmed to a maximum of the column value byte length. The maximum length of a `CHAR(N)` column is the maximum character byte length  $\times N$ .

A minimum of  $N$  bytes is reserved for `CHAR(N)`. Reserving the minimum space  $N$  in many cases enables column updates to be done in place without causing index page fragmentation. By comparison, `CHAR(N)` columns occupy the maximum character byte length  $\times N$  when using the `REDUNDANT` row format.

Fixed-length columns greater than or equal to 768 bytes are encoded as variable-length fields, which can be stored off-page. For example, a `CHAR(255)` column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with `utf8mb4`.

## DYNAMIC Row Format

The `DYNAMIC` row format offers the same storage characteristics as the `COMPACT` row format but adds enhanced storage capabilities for long variable-length columns and supports large index key prefixes.

When a table is created with `ROW_FORMAT=DYNAMIC`, InnoDB can store long variable-length column values (for `VARCHAR`, `VARBINARY`, and `BLOB` and `TEXT` types) fully off-page, with the clustered index record containing only a 20-byte pointer to the overflow page. Fixed-length fields greater than or equal to 768 bytes are encoded as variable-length fields. For example, a `CHAR(255)` column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with `utf8mb4`.

Whether columns are stored off-page depends on the page size and the total size of the row. When a row is too long, the longest columns are chosen for off-page storage until the clustered index record fits on the `B-tree` page. `TEXT` and `BLOB` columns that are less than or equal to 40 bytes are stored in line.

The `DYNAMIC` row format maintains the efficiency of storing the entire row in the index node if it fits (as do the `COMPACT` and `REDUNDANT` formats), but the `DYNAMIC` row format avoids the problem of filling B-tree nodes with a large number of data bytes of long columns. The `DYNAMIC` row format is based on the idea that if a portion of a long data value is stored off-page, it is usually most efficient to store the entire value off-page. With `DYNAMIC` format, shorter columns are likely to remain in the B-tree node, minimizing the number of overflow pages required for a given row.

The `DYNAMIC` row format supports index key prefixes up to 3072 bytes.

Tables that use the `DYNAMIC` row format can be stored in the system tablespace, file-per-table tablespaces, and general tablespaces. To store `DYNAMIC` tables in the system tablespace, either disable `innodb_file_per_table` and use a regular `CREATE TABLE` or `ALTER TABLE` statement, or use the `TABLESPACE [=] innodb_system` table option with `CREATE TABLE` or `ALTER TABLE`. The `innodb_file_per_table` variable is not applicable to general tablespaces, nor is it applicable when using the `TABLESPACE [=] innodb_system` table option to store `DYNAMIC` tables in the system tablespace.

## DYNAMIC Row Format Storage Characteristics

The `DYNAMIC` row format is a variation of the `COMPACT` row format. For storage characteristics, see [COMPACT Row Format Storage Characteristics](#).

## COMPRESSED Row Format

The `COMPRESSED` row format offers the same storage characteristics and capabilities as the `DYNAMIC` row format but adds support for table and index data compression.

The [COMPRESSED](#) row format uses similar internal details for off-page storage as the [DYNAMIC](#) row format, with additional storage and performance considerations from the table and index data being compressed and using smaller page sizes. With the [COMPRESSED](#) row format, the [KEY\\_BLOCK\\_SIZE](#) option controls how much column data is stored in the clustered index, and how much is placed on overflow pages. For more information about the [COMPRESSED](#) row format, see [Section 17.9, “InnoDB Table and Page Compression”](#).

The [COMPRESSED](#) row format supports index key prefixes up to 3072 bytes.

Tables that use the [COMPRESSED](#) row format can be created in file-per-table tablespaces or general tablespaces. The system tablespace does not support the [COMPRESSED](#) row format. To store a [COMPRESSED](#) table in a file-per-table tablespace, the [innodb\\_file\\_per\\_table](#) variable must be enabled. The [innodb\\_file\\_per\\_table](#) variable is not applicable to general tablespaces. General tablespaces support all row formats with the caveat that compressed and uncompressed tables cannot coexist in the same general tablespace due to different physical page sizes. For more information, see [Section 17.6.3.3, “General Tablespaces”](#).

## Compressed Row Format Storage Characteristics

The [COMPRESSED](#) row format is a variation of the [COMPACT](#) row format. For storage characteristics, see [COMPACT Row Format Storage Characteristics](#).

## Defining the Row Format of a Table

The default row format for InnoDB tables is defined by [innodb\\_default\\_row\\_format](#) variable, which has a default value of [DYNAMIC](#). The default row format is used when the [ROW\\_FORMAT](#) table option is not defined explicitly or when [ROW\\_FORMAT=DEFAULT](#) is specified.

The row format of a table can be defined explicitly using the [ROW\\_FORMAT](#) table option in a [CREATE TABLE](#) or [ALTER TABLE](#) statement. For example:

```
CREATE TABLE t1 (c1 INT) ROW_FORMAT=DYNAMIC;
```

An explicitly defined [ROW\\_FORMAT](#) setting overrides the default row format. Specifying [ROW\\_FORMAT=DEFAULT](#) is equivalent to using the implicit default.

The [innodb\\_default\\_row\\_format](#) variable can be set dynamically:

```
mysql> SET GLOBAL innodb_default_row_format=DYNAMIC;
```

Valid [innodb\\_default\\_row\\_format](#) options include [DYNAMIC](#), [COMPACT](#), and [REDUNDANT](#). The [COMPRESSED](#) row format, which is not supported for use in the system tablespace, cannot be defined as the default. It can only be specified explicitly in a [CREATE TABLE](#) or [ALTER TABLE](#) statement. Attempting to set the [innodb\\_default\\_row\\_format](#) variable to [COMPRESSED](#) returns an error:

```
mysql> SET GLOBAL innodb_default_row_format=COMPRESSED;
ERROR 1231 (42000): Variable 'innodb_default_row_format'
can't be set to the value of 'COMPRESSED'
```

Newly created tables use the row format defined by the [innodb\\_default\\_row\\_format](#) variable when a [ROW\\_FORMAT](#) option is not specified explicitly, or when [ROW\\_FORMAT=DEFAULT](#) is used. For example, the following [CREATE TABLE](#) statements use the row format defined by the [innodb\\_default\\_row\\_format](#) variable.

```
CREATE TABLE t1 (c1 INT);
```

```
CREATE TABLE t2 (c1 INT) ROW_FORMAT=DEFAULT;
```

When a `ROW_FORMAT` option is not specified explicitly, or when `ROW_FORMAT=DEFAULT` is used, an operation that rebuilds a table silently changes the row format of the table to the format defined by the `innodb_default_row_format` variable.

Table-rebuilding operations include `ALTER TABLE` operations that use `ALGORITHM=COPY` or `ALGORITHM=INPLACE` where table rebuilding is required. See [Section 17.12.1, “Online DDL Operations”](#) for more information. `OPTIMIZE TABLE` is also a table-rebuilding operation.

The following example demonstrates a table-rebuilding operation that silently changes the row format of a table created without an explicitly defined row format.

```
mysql> SELECT @@innodb_default_row_format;
+-----+
| @@innodb_default_row_format |
+-----+
| dynamic |
+-----+

mysql> CREATE TABLE t1 (c1 INT);

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TABLES WHERE NAME LIKE 'test/t1' \G
***** 1. row *****
 TABLE_ID: 54
 NAME: test/t1
 FLAG: 33
 N_COLS: 4
 SPACE: 35
 ROW_FORMAT: Dynamic
ZIP_PAGE_SIZE: 0
 SPACE_TYPE: Single

mysql> SET GLOBAL innodb_default_row_format=COMPACT;

mysql> ALTER TABLE t1 ADD COLUMN (c2 INT);

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TABLES WHERE NAME LIKE 'test/t1' \G
***** 1. row *****
 TABLE_ID: 55
 NAME: test/t1
 FLAG: 1
 N_COLS: 5
 SPACE: 36
 ROW_FORMAT: Compact
ZIP_PAGE_SIZE: 0
 SPACE_TYPE: Single
```

Consider the following potential issues before changing the row format of existing tables from `REDUNDANT` or `COMPACT` to `DYNAMIC`.

- The `REDUNDANT` and `COMPACT` row formats support a maximum index key prefix length of 767 bytes whereas `DYNAMIC` and `COMPRESSED` row formats support an index key prefix length of 3072 bytes. In a replication environment, if the `innodb_default_row_format` variable is set to `DYNAMIC` on the source, and set to `COMPACT` on the replica, the following DDL statement, which does not explicitly define a row format, succeeds on the source but fails on the replica:

```
CREATE TABLE t1 (c1 INT PRIMARY KEY, c2 VARCHAR(5000), KEY i1(c2(3070)));
```

For related information, see [Section 17.21, “InnoDB Limits”](#).

- Importing a table that does not explicitly define a row format results in a schema mismatch error if the `innodb_default_row_format` setting on the source server differs from the setting on the destination server. For more information, see [Section 17.6.1.3, “Importing InnoDB Tables”](#).

## Determining the Row Format of a Table

To determine the row format of a table, use `SHOW TABLE STATUS`:

```
mysql> SHOW TABLE STATUS IN test1\G
***** 1. row *****
 Name: t1
 Engine: InnoDB
 Version: 10
 Row_format: Dynamic
 Rows: 0
 Avg_row_length: 0
 Data_length: 16384
 Max_data_length: 0
 Index_length: 16384
 Data_free: 0
 Auto_increment: 1
 Create_time: 2016-09-14 16:29:38
 Update_time: NULL
 Check_time: NULL
 Collation: utf8mb4_0900_ai_ci
 Checksum: NULL
 Create_options:
 Comment:
```

Alternatively, query the Information Schema `INNODB_TABLES` table:

```
mysql> SELECT NAME, ROW_FORMAT FROM INFORMATION_SCHEMA.INNODB_TABLES WHERE NAME='test1/t1';
+-----+-----+
| NAME | ROW_FORMAT |
+-----+-----+
| test1/t1 | Dynamic |
+-----+-----+
```

## 17.11 InnoDB Disk I/O and File Space Management

As a DBA, you must manage disk I/O to keep the I/O subsystem from becoming saturated, and manage disk space to avoid filling up storage devices. The [ACID](#) design model requires a certain amount of I/O that might seem redundant, but helps to ensure data reliability. Within these constraints, [InnoDB](#) tries to optimize the database work and the organization of disk files to minimize the amount of disk I/O. Sometimes, I/O is postponed until the database is not busy, or until everything needs to be brought to a consistent state, such as during a database restart after a [fast shutdown](#).

This section discusses the main considerations for I/O and disk space with the default kind of MySQL tables (also known as [InnoDB](#) tables):

- Controlling the amount of background I/O used to improve query performance.
- Enabling or disabling features that provide extra durability at the expense of additional I/O.
- Organizing tables into many small files, a few larger files, or a combination of both.
- Balancing the size of redo log files against the I/O activity that occurs when the log files become full.
- How to reorganize a table for optimal query performance.

### 17.11.1 InnoDB Disk I/O

[InnoDB](#) uses asynchronous disk I/O where possible, by creating a number of threads to handle I/O operations, while permitting other database operations to proceed while the I/O is still in progress. On

Linux and Windows platforms, [InnoDB](#) uses the available OS and library functions to perform “native” asynchronous I/O. On other platforms, [InnoDB](#) still uses I/O threads, but the threads may actually wait for I/O requests to complete; this technique is known as “simulated” asynchronous I/O.

## Read-Ahead

If [InnoDB](#) can determine there is a high probability that data might be needed soon, it performs read-ahead operations to bring that data into the buffer pool so that it is available in memory. Making a few large read requests for contiguous data can be more efficient than making several small, spread-out requests. There are two read-ahead heuristics in [InnoDB](#):

- In sequential read-ahead, if [InnoDB](#) notices that the access pattern to a segment in the tablespace is sequential, it posts in advance a batch of reads of database pages to the I/O system.
- In random read-ahead, if [InnoDB](#) notices that some area in a tablespace seems to be in the process of being fully read into the buffer pool, it posts the remaining reads to the I/O system.

For information about configuring read-ahead heuristics, see [Section 17.8.3.4, “Configuring InnoDB Buffer Pool Prefetching \(Read-Ahead\)”](#).

## Doublewrite Buffer

[InnoDB](#) uses a novel file flush technique involving a structure called the [doublewrite buffer](#), which is enabled by default in most cases (`innodb_doublewrite=ON`). It adds safety to recovery following an unexpected exit or power outage, and improves performance on most varieties of Unix by reducing the need for `fsync()` operations.

Before writing pages to a data file, [InnoDB](#) first writes them to a storage area called the doublewrite buffer. Only after the write and the flush to the doublewrite buffer has completed does [InnoDB](#) write the pages to their proper positions in the data file. If there is an operating system, storage subsystem, or unexpected `mysqld` process exit in the middle of a page write (causing a [torn page](#) condition), [InnoDB](#) can later find a good copy of the page from the doublewrite buffer during recovery.

For more information about the doublewrite buffer, see [Section 17.6.4, “Doublewrite Buffer”](#).

## 17.11.2 File Space Management

The data files that you define in the configuration file using the `innodb_data_file_path` configuration option form the [InnoDB system tablespace](#). The files are logically concatenated to form the system tablespace. There is no striping in use. You cannot define where within the system tablespace your tables are allocated. In a newly created system tablespace, [InnoDB](#) allocates space starting from the first data file.

To avoid the issues that come with storing all tables and indexes inside the system tablespace, you can enable the `innodb_file_per_table` configuration option (the default), which stores each newly created table in a separate tablespace file (with extension `.ibd`). For tables stored this way, there is less fragmentation within the disk file, and when the table is truncated, the space is returned to the operating system rather than still being reserved by [InnoDB](#) within the system tablespace. For more information, see [Section 17.6.3.2, “File-Per-Table Tablespaces”](#).

You can also store tables in [general tablespaces](#). General tablespaces are shared tablespaces created using `CREATE TABLESPACE` syntax. They can be created outside of the MySQL data directory, are capable of holding multiple tables, and support tables of all row formats. For more information, see [Section 17.6.3.3, “General Tablespaces”](#).

## Pages, Extents, Segments, and Tablespaces

Each tablespace consists of database [pages](#). Every tablespace in a MySQL instance has the same [page size](#). By default, all tablespaces have a page size of 16KB; you can reduce the page size to 8KB or 4KB by specifying the [innodb\\_page\\_size](#) option when you create the MySQL instance. You can also increase the page size to 32KB or 64KB. For more information, refer to the [innodb\\_page\\_size](#) documentation.

The pages are grouped into [extents](#) of size 1MB for pages up to 16KB in size (64 consecutive 16KB pages, or 128 8KB pages, or 256 4KB pages). For a page size of 32KB, extent size is 2MB. For page size of 64KB, extent size is 4MB. The “files” inside a tablespace are called [segments](#) in [InnoDB](#). (These segments are different from the [rollback segment](#), which actually contains many tablespace segments.)

When a segment grows inside the tablespace, [InnoDB](#) allocates the first 32 pages to it one at a time. After that, [InnoDB](#) starts to allocate whole extents to the segment. [InnoDB](#) can add up to 4 extents at a time to a large segment to ensure good sequentiality of data.

Two segments are allocated for each index in [InnoDB](#). One is for nonleaf nodes of the [B-tree](#), the other is for the leaf nodes. Keeping the leaf nodes contiguous on disk enables better sequential I/O operations, because these leaf nodes contain the actual table data.

Some pages in the tablespace contain bitmaps of other pages, and therefore a few extents in an [InnoDB](#) tablespace cannot be allocated to segments as a whole, but only as individual pages.

When you ask for available free space in the tablespace by issuing a [SHOW TABLE STATUS](#) statement, [InnoDB](#) reports the extents that are definitely free in the tablespace. [InnoDB](#) always reserves some extents for cleanup and other internal purposes; these reserved extents are not included in the free space.

When you delete data from a table, [InnoDB](#) contracts the corresponding B-tree indexes. Whether the freed space becomes available for other users depends on whether the pattern of deletes frees individual pages or extents to the tablespace. Dropping a table or deleting all rows from it is guaranteed to release the space to other users, but remember that deleted rows are physically removed only by the [purge](#) operation, which happens automatically some time after they are no longer needed for transaction rollbacks or consistent reads. (See [Section 17.3, “InnoDB Multi-Versioning”](#).)

## Configuring the Percentage of Reserved File Segment Pages

The [innodb\\_segment\\_reserve\\_factor](#) variable permits defining the percentage of tablespace file segment pages reserved as empty pages. A percentage of pages are reserved for future growth so that pages in the B-tree can be allocated contiguously. The ability to modify the percentage of reserved pages permits fine-tuning [InnoDB](#) to address issues of data fragmentation or inefficient use of storage space.

The setting is applicable to file-per-table and general tablespaces. The [innodb\\_segment\\_reserve\\_factor](#) default setting is 12.5 percent.

The [innodb\\_segment\\_reserve\\_factor](#) variable is dynamic and can be configured using a [SET](#) statement. For example:

```
mysql> SET GLOBAL innodb_segment_reserve_factor=10;
```

## How Pages Relate to Table Rows

For 4KB, 8KB, 16KB, and 32KB [innodb\\_page\\_size](#) settings, the maximum row length is slightly less than half a database page size. For example, the maximum row length is slightly less than 8KB for the default 16KB [InnoDB](#) page size. For a 64KB [innodb\\_page\\_size](#) setting, the maximum row length is slightly less than 16KB.

If a row does not exceed the maximum row length, all of it is stored locally within the page. If a row exceeds the maximum row length, [variable-length columns](#) are chosen for external off-page storage until the row fits within the maximum row length limit. External off-page storage for variable-length columns differs by row format:

- *COMPACT and REDUNDANT Row Formats*

When a variable-length column is chosen for external off-page storage, [InnoDB](#) stores the first 768 bytes locally in the row, and the rest externally into overflow pages. Each such column has its own list of overflow pages. The 768-byte prefix is accompanied by a 20-byte value that stores the true length of the column and points into the overflow list where the rest of the value is stored. See [Section 17.10, “InnoDB Row Formats”](#).

- *DYNAMIC and COMPRESSED Row Formats*

When a variable-length column is chosen for external off-page storage, [InnoDB](#) stores a 20-byte pointer locally in the row, and the rest externally into overflow pages. See [Section 17.10, “InnoDB Row Formats”](#).

[LONGBLOB](#) and [LONGTEXT](#) columns must be less than 4GB, and the total row length, including [BLOB](#) and [TEXT](#) columns, must be less than 4GB.

### 17.11.3 InnoDB Checkpoints

Making your [log files](#) very large may reduce disk I/O during [checkpointing](#). It often makes sense to set the total size of the log files as large as the buffer pool or even larger.

#### How Checkpoint Processing Works

[InnoDB](#) implements a [checkpoint](#) mechanism known as [fuzzy checkpointing](#). [InnoDB](#) flushes modified database pages from the buffer pool in small batches. There is no need to flush the buffer pool in one single batch, which would disrupt processing of user SQL statements during the checkpointing process.

During [crash recovery](#), [InnoDB](#) looks for a checkpoint label written to the log files. It knows that all modifications to the database before the label are present in the disk image of the database. Then [InnoDB](#) scans the log files forward from the checkpoint, applying the logged modifications to the database.

### 17.11.4 Defragmenting a Table

Random insertions into or deletions from a secondary index can cause the index to become fragmented. Fragmentation means that the physical ordering of the index pages on the disk is not close to the index ordering of the records on the pages, or that there are many unused pages in the 64-page blocks that were allocated to the index.

One symptom of fragmentation is that a table takes more space than it “should” take. How much that is exactly, is difficult to determine. All [InnoDB](#) data and indexes are stored in [B-trees](#), and their [fill factor](#) may vary from 50% to 100%. Another symptom of fragmentation is that a table scan such as this takes more time than it “should” take:

```
SELECT COUNT(*) FROM t WHERE non_indexed_column <> 12345;
```

The preceding query requires MySQL to perform a full table scan, the slowest type of query for a large table.

To speed up index scans, you can periodically perform a “null” [ALTER TABLE](#) operation, which causes MySQL to rebuild the table:

```
ALTER TABLE tbl_name ENGINE=INNODB
```

You can also use `ALTER TABLE tbl_name FORCE` to perform a “null” alter operation that rebuilds the table.

Both `ALTER TABLE tbl_name ENGINE=INNODB` and `ALTER TABLE tbl_name FORCE` use [online DDL](#). For more information, see [Section 17.12, “InnoDB and Online DDL”](#).

Another way to perform a defragmentation operation is to use `mysqldump` to dump the table to a text file, drop the table, and reload it from the dump file.

If the insertions into an index are always ascending and records are deleted only from the end, the [InnoDB](#) filesystem management algorithm guarantees that fragmentation in the index does not occur.

### 17.11.5 Reclaiming Disk Space with TRUNCATE TABLE

To reclaim operating system disk space when [truncating](#) an [InnoDB](#) table, the table must be stored in its own `.ibd` file. For a table to be stored in its own `.ibd` file, `innodb_file_per_table` must be enabled when the table is created. Additionally, there cannot be a [foreign key](#) constraint between the table being truncated and other tables, otherwise the `TRUNCATE TABLE` operation fails. A foreign key constraint between two columns in the same table, however, is permitted.

When a table is truncated, it is dropped and re-created in a new `.ibd` file, and the freed space is returned to the operating system. This is in contrast to truncating [InnoDB](#) tables that are stored within the [InnoDB system tablespace](#) (tables created when `innodb_file_per_table=OFF`) and tables stored in shared [general tablespaces](#), where only [InnoDB](#) can use the freed space after the table is truncated.

The ability to truncate tables and return disk space to the operating system also means that [physical backups](#) can be smaller. Truncating tables that are stored in the system tablespace (tables created when `innodb_file_per_table=OFF`) or in a general tablespace leaves blocks of unused space in the tablespace.

## 17.12 InnoDB and Online DDL

The online DDL feature provides support for instant and in-place table alterations and concurrent DML. Benefits of this feature include:

- Improved responsiveness and availability in busy production environments, where making a table unavailable for minutes or hours is not practical.
- For in-place operations, the ability to adjust the balance between performance and concurrency during DDL operations using the `LOCK` clause. See [The LOCK clause](#).
- Less disk space usage and I/O overhead than the table-copy method.

Typically, you do not need to do anything special to enable online DDL. By default, MySQL performs the operation instantly or in place, as permitted, with as little locking as possible.

You can control aspects of a DDL operation using the `ALGORITHM` and `LOCK` clauses of the `ALTER TABLE` statement. These clauses are placed at the end of the statement, separated from the table and column specifications by commas. For example:

```
ALTER TABLE tbl_name ADD PRIMARY KEY (column), ALGORITHM=INPLACE;
```

The `LOCK` clause may be used for operations that are performed in place and is useful for fine-tuning the degree of concurrent access to the table during operations. Only `LOCK=DEFAULT` is supported for operations that are performed instantly. The `ALGORITHM` clause is primarily intended for performance comparisons and as a fallback to the older table-copying behavior in case you encounter any issues. For example:

- To avoid accidentally making the table unavailable for reads, writes, or both, during an in-place [ALTER TABLE](#) operation, specify a clause on the [ALTER TABLE](#) statement such as [LOCK=NONE](#) (permit reads and writes) or [LOCK=SHARED](#) (permit reads). The operation halts immediately if the requested level of concurrency is not available.
- To compare performance between algorithms, run a statement with [ALGORITHM=INSTANT](#), [ALGORITHM=INPLACE](#) and [ALGORITHM=COPY](#). You can also run a statement with the [old\\_alter\\_table](#) configuration option enabled to force the use of [ALGORITHM=COPY](#).
- To avoid tying up the server with an [ALTER TABLE](#) operation that copies the table, include [ALGORITHM=INSTANT](#) or [ALGORITHM=INPLACE](#). The statement halts immediately if it cannot use the specified algorithm.

## 17.12.1 Online DDL Operations

Online support details, syntax examples, and usage notes for DDL operations are provided under the following topics in this section.

- [Index Operations](#)
- [Primary Key Operations](#)
- [Column Operations](#)
- [Generated Column Operations](#)
- [Foreign Key Operations](#)
- [Table Operations](#)
- [Tablespace Operations](#)
- [Partitioning Operations](#)

### Index Operations

The following table provides an overview of online DDL support for index operations. An asterisk indicates additional information, an exception, or a dependency. For details, see [Syntax and Usage Notes](#).

**Table 17.15 Online DDL Support for Index Operations**

Operation	Instant	In Place	Rebuilds Table	Permits Concurrent DML	Only Modifies Metadata
Creating or adding a secondary index	No	Yes	No	Yes	No
Dropping an index	No	Yes	No	Yes	Yes
Renaming an index	No	Yes	No	Yes	Yes
Adding a <a href="#">FULLTEXT</a> index	No	Yes*	No*	No	No

Operation	Instant	In Place	Rebuilds Table	Permits Concurrent DML	Only Modifies Metadata
Adding a <a href="#">SPATIAL</a> index	No	Yes	No	No	No
Changing the index type	Yes	Yes	No	Yes	Yes

## Syntax and Usage Notes

- Creating or adding a secondary index

```
CREATE INDEX name ON table (col_list);
```

```
ALTER TABLE tbl_name ADD INDEX name (col_list);
```

The table remains available for read and write operations while the index is being created. The [CREATE INDEX](#) statement only finishes after all transactions that are accessing the table are completed, so that the initial state of the index reflects the most recent contents of the table.

Online DDL support for adding secondary indexes means that you can generally speed the overall process of creating and loading a table and associated indexes by creating the table without secondary indexes, then adding secondary indexes after the data is loaded.

A newly created secondary index contains only the committed data in the table at the time the [CREATE INDEX](#) or [ALTER TABLE](#) statement finishes executing. It does not contain any uncommitted values, old versions of values, or values marked for deletion but not yet removed from the old index.

Some factors affect the performance, space usage, and semantics of this operation. For details, see [Section 17.12.8, “Online DDL Limitations”](#).

- Dropping an index

```
DROP INDEX name ON table;
```

```
ALTER TABLE tbl_name DROP INDEX name;
```

The table remains available for read and write operations while the index is being dropped. The [DROP INDEX](#) statement only finishes after all transactions that are accessing the table are completed, so that the initial state of the index reflects the most recent contents of the table.

- Renaming an index

```
ALTER TABLE tbl_name RENAME INDEX old_index_name TO new_index_name, ALGORITHM=INPLACE, LOCK=NONE;
```

- Adding a [FULLTEXT](#) index

```
CREATE FULLTEXT INDEX name ON table(column);
```

Adding the first [FULLTEXT](#) index rebuilds the table if there is no user-defined [FTS\\_DOC\\_ID](#) column. Additional [FULLTEXT](#) indexes may be added without rebuilding the table.

- Adding a [SPATIAL](#) index

```
CREATE TABLE geom (g GEOMETRY NOT NULL);
ALTER TABLE geom ADD SPATIAL INDEX(g), ALGORITHM=INPLACE, LOCK=SHARED;
```

- Changing the index type ([USING](#) {[BTREE](#) | [HASH](#)})

```
ALTER TABLE tbl_name DROP INDEX i1, ADD INDEX i1(key_part,...) USING BTREE, ALGORITHM=INSTANT;
```

## Primary Key Operations

The following table provides an overview of online DDL support for primary key operations. An asterisk indicates additional information, an exception, or a dependency. See [Syntax and Usage Notes](#).

**Table 17.16 Online DDL Support for Primary Key Operations**

Operation	Instant	In Place	Rebuilds Table	Permits Concurrent DML	Only Modifies Metadata
Adding a primary key	No	Yes*	Yes*	Yes	No
Dropping a primary key	No	No	Yes	No	No
Dropping a primary key and adding another	No	Yes	Yes	Yes	No

## Syntax and Usage Notes

- Adding a primary key

```
ALTER TABLE tbl_name ADD PRIMARY KEY (column), ALGORITHM=INPLACE, LOCK=NONE;
```

Rebuilds the table in place. Data is reorganized substantially, making it an expensive operation. `ALGORITHM=INPLACE` is not permitted under certain conditions if columns have to be converted to `NOT NULL`.

Restructuring the [clustered index](#) always requires copying of table data. Thus, it is best to define the [primary key](#) when you create a table, rather than issuing `ALTER TABLE ... ADD PRIMARY KEY` later.

When you create a `UNIQUE` or `PRIMARY KEY` index, MySQL must do some extra work. For `UNIQUE` indexes, MySQL checks that the table contains no duplicate values for the key. For a `PRIMARY KEY` index, MySQL also checks that none of the `PRIMARY KEY` columns contains a `NULL`.

When you add a primary key using the `ALGORITHM=COPY` clause, MySQL converts `NULL` values in the associated columns to default values: 0 for numbers, an empty string for character-based columns and BLOBs, and 0000-00-00 00:00:00 for `DATETIME`. This is a non-standard behavior that Oracle recommends you not rely on. Adding a primary key using `ALGORITHM=INPLACE` is only permitted when the `SQL_MODE` setting includes the `strict_trans_tables` or `strict_all_tables` flags; when the `SQL_MODE` setting is strict, `ALGORITHM=INPLACE` is permitted, but the statement can still fail if the requested primary key columns contain `NULL` values. The `ALGORITHM=INPLACE` behavior is more standard-compliant.

If you create a table without a primary key, `InnoDB` chooses one for you, which can be the first `UNIQUE` key defined on `NOT NULL` columns, or a system-generated key. To avoid uncertainty and the potential space requirement for an extra hidden column, specify the `PRIMARY KEY` clause as part of the `CREATE TABLE` statement.

MySQL creates a new clustered index by copying the existing data from the original table to a temporary table that has the desired index structure. Once the data is completely copied to the temporary table, the original table is renamed with a different temporary table name. The temporary table comprising the new

clustered index is renamed with the name of the original table, and the original table is dropped from the database.

The online performance enhancements that apply to operations on secondary indexes do not apply to the primary key index. The rows of an InnoDB table are stored in a [clustered index](#) organized based on the [primary key](#), forming what some database systems call an “index-organized table”. Because the table structure is closely tied to the primary key, redefining the primary key still requires copying the data.

When an operation on the primary key uses `ALGORITHM=INPLACE`, even though the data is still copied, it is more efficient than using `ALGORITHM=COPY` because:

- No undo logging or associated redo logging is required for `ALGORITHM=INPLACE`. These operations add overhead to DDL statements that use `ALGORITHM=COPY`.
- The secondary index entries are pre-sorted, and so can be loaded in order.
- The change buffer is not used, because there are no random-access inserts into the secondary indexes.
- Dropping a primary key

```
ALTER TABLE tbl_name DROP PRIMARY KEY, ALGORITHM=COPY;
```

Only `ALGORITHM=COPY` supports dropping a primary key without adding a new one in the same `ALTER TABLE` statement.

- Dropping a primary key and adding another

```
ALTER TABLE tbl_name DROP PRIMARY KEY, ADD PRIMARY KEY (column), ALGORITHM=INPLACE, LOCK=NONE;
```

Data is reorganized substantially, making it an expensive operation.

## Column Operations

The following table provides an overview of online DDL support for column operations. An asterisk indicates additional information, an exception, or a dependency. For details, see [Syntax and Usage Notes](#).

**Table 17.17 Online DDL Support for Column Operations**

Operation	Instant	In Place	Rebuilds Table	Permits Concurrent DML	Only Modifies Metadata
Adding a column	Yes*	Yes	No*	Yes*	Yes
Dropping a column	Yes*	Yes	Yes	Yes	Yes
Renaming a column	Yes*	Yes	No	Yes*	Yes
Reordering columns	No	Yes	Yes	Yes	No
Setting a column default value	Yes	Yes	No	Yes	Yes
Changing the column data type	No	No	Yes	No	No

Operation	Instant	In Place	Rebuilds Table	Permits Concurrent DML	Only Modifies Metadata
Extending <code>VARCHAR</code> column size	No	Yes	No	Yes	Yes
Dropping the column default value	Yes	Yes	No	Yes	Yes
Changing the auto-increment value	No	Yes	No	Yes	No*
Making a column <code>NULL</code>	No	Yes	Yes*	Yes	No
Making a column <code>NOT NULL</code>	No	Yes*	Yes*	Yes	No
Modifying the definition of an <code>ENUM</code> or <code>SET</code> column	Yes	Yes	No	Yes	Yes

## Syntax and Usage Notes

- Adding a column

```
ALTER TABLE tbl_name ADD COLUMN column_name column_definition, ALGORITHM=INSTANT;
```

`INSTANT` is the default algorithm in MySQL 9.1.

The following limitations apply when the `INSTANT` algorithm adds a column:

- A statement cannot combine the addition of a column with other `ALTER TABLE` actions that do not support the `INSTANT` algorithm.
- The `INSTANT` algorithm can add a column at any position in the table.
- Columns cannot be added to tables that use `ROW_FORMAT=COMPRESSED`, tables with a `FULLTEXT` index, tables that reside in the data dictionary tablespace, or temporary tables. Temporary tables only support `ALGORITHM=COPY`.
- MySQL checks the row size when the `INSTANT` algorithm adds a column, and throws the following error if the addition exceeds the limit.

```
ERROR 4092 (HY000): Column can't be added with ALGORITHM=INSTANT as
after this max possible row size crosses max permissible row size. Try
ALGORITHM=INPLACE/COPY.
```

- The maximum number of columns in the internal representation of the table cannot exceed 1022 after column addition with the `INSTANT` algorithm. The error message is:

```
ERROR 4158 (HY000): Column can't be added to tbl_name with
ALGORITHM=INSTANT anymore. Please try ALGORITHM=INPLACE/COPY
```

- The `INSTANT` algorithm can not add or drop columns to system schema tables, such as the internal `mysql` table.
- A column with a functional index cannot be dropped using the `INSTANT` algorithm.

Multiple columns may be added in the same `ALTER TABLE` statement. For example:

```
ALTER TABLE t1 ADD COLUMN c2 INT, ADD COLUMN c3 INT, ALGORITHM=INSTANT;
```

A new row version is created after each `ALTER TABLE ... ALGORITHM=INSTANT` operation that adds one or more columns, drops one or more columns, or adds and drops one or more columns in the same operation. The `INFORMATION_SCHEMA.INNODB_TABLES.TOTAL_ROW_VERSIONS` column tracks the number of row versions for a table. The value is incremented each time a column is instantly added or dropped. The initial value is 0.

```
mysql> SELECT NAME, TOTAL_ROW_VERSIONS FROM INFORMATION_SCHEMA.INNODB_TABLES
 WHERE NAME LIKE 'test/t1';
+-----+-----+
| NAME | TOTAL_ROW_VERSIONS |
+-----+-----+
| test/t1 | 0 |
+-----+-----+
```

When a table with instantly added or dropped columns is rebuilt by table-rebuilding `ALTER TABLE` or `OPTIMIZE TABLE` operation, the `TOTAL_ROW_VERSIONS` value is reset to 0. The maximum number of row versions permitted is 255 in MySQL 9.1.0 and later, as each row version requires additional space for table metadata. When the row version limit is reached, `ADD COLUMN` and `DROP COLUMN` operations using `ALGORITHM=INSTANT` are rejected with an error message that recommends rebuilding the table using the `COPY` or `INPLACE` algorithm.

```
ERROR 4080 (HY000): Maximum row versions reached for table test/t1. No more
columns can be added or dropped instantly. Please use COPY/INPLACE.
```

The following `INFORMATION_SCHEMA` columns provide additional metadata for instantly added columns. Refer to the descriptions of those columns for more information. See [Section 28.4.9, “The INFORMATION\\_SCHEMA INNODB\\_COLUMNS Table”](#), and [Section 28.4.23, “The INFORMATION\\_SCHEMA INNODB\\_TABLES Table”](#).

- `INNODB_COLUMNS.DEFAULT_VALUE`
- `INNODB_COLUMNS.HAS_DEFAULT`
- `INNODB_TABLES.INSTANT_COLS`

Concurrent DML is not permitted when adding an `auto-increment` column. Data is reorganized substantially, making it an expensive operation. At a minimum, `ALGORITHM=INPLACE`, `LOCK=SHARED` is required.

The table is rebuilt if `ALGORITHM=INPLACE` is used to add a column.

- Dropping a column

```
ALTER TABLE tbl_name DROP COLUMN column_name, ALGORITHM=INSTANT;
```

`INSTANT` is the default algorithm in MySQL 9.1.

The following limitations apply when the `INSTANT` algorithm is used to drop a column:

- Dropping a column cannot be combined in the same statement with other `ALTER TABLE` actions that do not support `ALGORITHM=INSTANT`.
- Columns cannot be dropped from tables that use `ROW_FORMAT=COMPRESSED`, tables with a `FULLTEXT` index, tables that reside in the data dictionary tablespace, or temporary tables. Temporary tables only support `ALGORITHM=COPY`.

Multiple columns may be dropped in the same `ALTER TABLE` statement; for example:

```
ALTER TABLE t1 DROP COLUMN c4, DROP COLUMN c5, ALGORITHM=INSTANT;
```

Each time a column is added or dropped using `ALGORITHM=INSTANT`, a new row version is created. The `INFORMATION_SCHEMA.INNODB_TABLES.TOTAL_ROW_VERSIONS` column tracks the number of row versions for a table. The value is incremented each time a column is instantly added or dropped. The initial value is 0.

```
mysql> SELECT NAME, TOTAL_ROW_VERSIONS FROM INFORMATION_SCHEMA.INNODB_TABLES
 WHERE NAME LIKE 'test/t1';
+-----+-----+
| NAME | TOTAL_ROW_VERSIONS |
+-----+-----+
| test/t1 | 0 |
+-----+-----+
```

When a table with instantly added or dropped columns is rebuilt by table-rebuilding `ALTER TABLE` or `OPTIMIZE TABLE` operation, the `TOTAL_ROW_VERSIONS` value is reset to 0. The maximum number of row versions permitted is 255 in MySQL 9.1.0 and later, as each row version requires additional space for table metadata. When the row version limit is reached, `ADD COLUMN` and `DROP COLUMN` operations using `ALGORITHM=INSTANT` are rejected with an error message that recommends rebuilding the table using the `COPY` or `INPLACE` algorithm.

```
ERROR 4080 (HY000): Maximum row versions reached for table test/t1. No more
columns can be added or dropped instantly. Please use COPY/INPLACE.
```

If an algorithm other than `ALGORITHM=INSTANT` is used, data is reorganized substantially, making it an expensive operation.

- Renaming a column

```
ALTER TABLE tbl CHANGE old_col_name new_col_name data_type, ALGORITHM=INSTANT;
```

To permit concurrent DML, keep the same data type and only change the column name.

When you keep the same data type and `[NOT] NULL` attribute, only changing the column name, the operation can always be performed online.

Renaming a column referenced from another table is only permitted with `ALGORITHM=INPLACE`. If you use `ALGORITHM=INSTANT`, `ALGORITHM=COPY`, or some other condition that causes the operation to use those algorithms, the `ALTER TABLE` statement fails.

`ALGORITHM=INSTANT` supports renaming a virtual column; `ALGORITHM=INPLACE` does not.

`ALGORITHM=INSTANT` and `ALGORITHM=INPLACE` do not support renaming a column when adding or dropping a virtual column in the same statement. In this case, only `ALGORITHM=COPY` is supported.

- Reordering columns

To reorder columns, use `FIRST` or `AFTER` in `CHANGE` or `MODIFY` operations.

```
ALTER TABLE tbl_name MODIFY COLUMN col_name column_definition FIRST, ALGORITHM=INPLACE, LOCK=NONE;
```

Data is reorganized substantially, making it an expensive operation.

- Changing the column data type

```
ALTER TABLE tbl_name CHANGE c1 c1 BIGINT, ALGORITHM=COPY;
```

Changing the column data type is only supported with `ALGORITHM=COPY`.

- Extending `VARCHAR` column size

```
ALTER TABLE tbl_name CHANGE COLUMN c1 c1 VARCHAR(255), ALGORITHM=INPLACE, LOCK=NONE;
```

The number of length bytes required by a `VARCHAR` column must remain the same. For `VARCHAR` columns of 0 to 255 bytes in size, one length byte is required to encode the value. For `VARCHAR` columns of 256 bytes in size or more, two length bytes are required. As a result, in-place `ALTER TABLE` only supports increasing `VARCHAR` column size from 0 to 255 bytes, or from 256 bytes to a greater size. In-place `ALTER TABLE` does not support increasing the size of a `VARCHAR` column from less than 256 bytes to a size equal to or greater than 256 bytes. In this case, the number of required length bytes changes from 1 to 2, which is only supported by a table copy (`ALGORITHM=COPY`). For example, attempting to change `VARCHAR` column size for a single byte character set from `VARCHAR(255)` to `VARCHAR(256)` using in-place `ALTER TABLE` returns this error:

```
ALTER TABLE tbl_name ALGORITHM=INPLACE, CHANGE COLUMN c1 c1 VARCHAR(256);
ERROR 0A000: ALGORITHM=INPLACE is not supported. Reason: Cannot change
column type INPLACE. Try ALGORITHM=COPY.
```

#### Note

The byte length of a `VARCHAR` column is dependant on the byte length of the character set.

Decreasing `VARCHAR` size using in-place `ALTER TABLE` is not supported. Decreasing `VARCHAR` size requires a table copy (`ALGORITHM=COPY`).

- Setting a column default value

```
ALTER TABLE tbl_name ALTER COLUMN col SET DEFAULT literal, ALGORITHM=INSTANT;
```

Only modifies table metadata. Default column values are stored in the [data dictionary](#).

- Dropping a column default value

```
ALTER TABLE tbl ALTER COLUMN col DROP DEFAULT, ALGORITHM=INSTANT;
```

- Changing the auto-increment value

```
ALTER TABLE table AUTO_INCREMENT=next_value, ALGORITHM=INPLACE, LOCK=NONE;
```

Modifies a value stored in memory, not the data file.

In a distributed system using replication or sharding, you sometimes reset the auto-increment counter for a table to a specific value. The next row inserted into the table uses the specified value for its auto-increment column. You might also use this technique in a data warehousing environment where you periodically empty all the tables and reload them, and restart the auto-increment sequence from 1.

- Making a column **NULL**

```
ALTER TABLE tbl_name MODIFY COLUMN column_name data_type NULL, ALGORITHM=INPLACE, LOCK=NONE;
```

Rebuilds the table in place. Data is reorganized substantially, making it an expensive operation.

- Making a column **NOT NULL**

```
ALTER TABLE tbl_name MODIFY COLUMN column_name data_type NOT NULL, ALGORITHM=INPLACE, LOCK=NONE;
```

Rebuilds the table in place. **STRICT\_ALL\_TABLES** or **STRICT\_TRANS\_TABLES SQL\_MODE** is required for the operation to succeed. The operation fails if the column contains NULL values. The server prohibits changes to foreign key columns that have the potential to cause loss of referential integrity. See [Section 15.1.9, “ALTER TABLE Statement”](#). Data is reorganized substantially, making it an expensive operation.

- Modifying the definition of an **ENUM** or **SET** column

```
CREATE TABLE t1 (c1 ENUM('a', 'b', 'c'));
ALTER TABLE t1 MODIFY COLUMN c1 ENUM('a', 'b', 'c', 'd'), ALGORITHM=INSTANT;
```

Modifying the definition of an **ENUM** or **SET** column by adding new enumeration or set members to the *end* of the list of valid member values may be performed instantly or in place, as long as the storage size of the data type does not change. For example, adding a member to a **SET** column that has 8 members changes the required storage per value from 1 byte to 2 bytes; this requires a table copy. Adding members in the middle of the list causes renumbering of existing members, which requires a table copy.

## Generated Column Operations

The following table provides an overview of online DDL support for generated column operations. For details, see [Syntax and Usage Notes](#).

**Table 17.18 Online DDL Support for Generated Column Operations**

Operation	Instant	In Place	Rebuilds Table	Permits Concurrent DML	Only Modifies Metadata
Adding a <b>STORED</b> column	No	No	Yes	No	No
Modifying <b>STORED</b> column order	No	No	Yes	No	No
Dropping a <b>STORED</b> column	No	Yes	Yes	Yes	No

Operation	Instant	In Place	Rebuilds Table	Permits Concurrent DML	Only Modifies Metadata
Adding a <a href="#">VIRTUAL</a> column	Yes	Yes	No	Yes	Yes
Modifying <a href="#">VIRTUAL</a> column order	No	No	Yes	No	No
Dropping a <a href="#">VIRTUAL</a> column	Yes	Yes	No	Yes	Yes

## Syntax and Usage Notes

- Adding a [STORED](#) column

```
ALTER TABLE t1 ADD COLUMN (c2 INT GENERATED ALWAYS AS (c1 + 1) STORED), ALGORITHM=COPY;
```

[ADD COLUMN](#) is not an in-place operation for stored columns (done without using a temporary table) because the expression must be evaluated by the server.

- Modifying [STORED](#) column order

```
ALTER TABLE t1 MODIFY COLUMN c2 INT GENERATED ALWAYS AS (c1 + 1) STORED FIRST, ALGORITHM=COPY;
```

Rebuilds the table in place.

- Dropping a [STORED](#) column

```
ALTER TABLE t1 DROP COLUMN c2, ALGORITHM=INPLACE, LOCK=NONE;
```

Rebuilds the table in place.

- Adding a [VIRTUAL](#) column

```
ALTER TABLE t1 ADD COLUMN (c2 INT GENERATED ALWAYS AS (c1 + 1) VIRTUAL), ALGORITHM=INSTANT;
```

Adding a virtual column can be performed instantly or in place for non-partitioned tables.

Adding a [VIRTUAL](#) is not an in-place operation for partitioned tables.

- Modifying [VIRTUAL](#) column order

```
ALTER TABLE t1 MODIFY COLUMN c2 INT GENERATED ALWAYS AS (c1 + 1) VIRTUAL FIRST, ALGORITHM=COPY;
```

- Dropping a [VIRTUAL](#) column

```
ALTER TABLE t1 DROP COLUMN c2, ALGORITHM=INSTANT;
```

Dropping a [VIRTUAL](#) column can be performed instantly or in place for non-partitioned tables.

## Foreign Key Operations

The following table provides an overview of online DDL support for foreign key operations. An asterisk indicates additional information, an exception, or a dependency. For details, see [Syntax and Usage Notes](#).

Table 17.19 Online DDL Support for Foreign Key Operations

Operation	Instant	In Place	Rebuilds Table	Permits Concurrent DML	Only Modifies Metadata
Adding a foreign key constraint	No	Yes*	No	Yes	Yes
Dropping a foreign key constraint	No	Yes	No	Yes	Yes

## Syntax and Usage Notes

- Adding a foreign key constraint

The `INPLACE` algorithm is supported when `foreign_key_checks` is disabled. Otherwise, only the `COPY` algorithm is supported.

```
ALTER TABLE tbl1 ADD CONSTRAINT fk_name FOREIGN KEY index (col1)
REFERENCES tbl2(col2) referential_actions;
```

- Dropping a foreign key constraint

```
ALTER TABLE tbl DROP FOREIGN KEY fk_name;
```

Dropping a foreign key can be performed online with the `foreign_key_checks` option enabled or disabled.

If you do not know the names of the foreign key constraints on a particular table, issue the following statement and find the constraint name in the `CONSTRAINT` clause for each foreign key:

```
SHOW CREATE TABLE table\G
```

Or, query the Information Schema `TABLE_CONSTRAINTS` table and use the `CONSTRAINT_NAME` and `CONSTRAINT_TYPE` columns to identify the foreign key names.

You can also drop a foreign key and its associated index in a single statement:

```
ALTER TABLE table DROP FOREIGN KEY constraint, DROP INDEX index;
```

### Note

If **foreign keys** are already present in the table being altered (that is, it is a **child table** containing a `FOREIGN KEY ... REFERENCE` clause), additional restrictions apply to online DDL operations, even those not directly involving the foreign key columns:

- An `ALTER TABLE` on the child table could wait for another transaction to commit, if a change to the parent table causes associated changes in the child table through an `ON UPDATE` or `ON DELETE` clause using the `CASCADE` or `SET NULL` parameters.
- In the same way, if a table is the **parent table** in a foreign key relationship, even though it does not contain any `FOREIGN KEY` clauses, it could wait for the `ALTER TABLE` to complete if an `INSERT`, `UPDATE`, or `DELETE` statement causes an `ON UPDATE` or `ON DELETE` action in the child table.

## Table Operations

The following table provides an overview of online DDL support for table operations. An asterisk indicates additional information, an exception, or a dependency. For details, see [Syntax and Usage Notes](#).

**Table 17.20 Online DDL Support for Table Operations**

Operation	Instant	In Place	Rebuilds Table	Permits Concurrent DML	Only Modifies Metadata
Changing the <a href="#">ROW_FORMAT</a>	No	Yes	Yes	Yes	No
Changing the <a href="#">KEY_BLOCK_SIZE</a>	No	Yes	Yes	Yes	No
Setting persistent table statistics	No	Yes	No	Yes	Yes
Specifying a character set	No	Yes	Yes*	Yes	No
Converting a character set	No	No	Yes*	No	No
Optimizing a table	No	Yes*	Yes	Yes	No
Rebuilding with the <a href="#">FORCE</a> option	No	Yes*	Yes	Yes	No
Performing a null rebuild	No	Yes*	Yes	Yes	No
Renaming a table	Yes	Yes	No	Yes	Yes

## Syntax and Usage Notes

- Changing the [ROW\\_FORMAT](#)

```
ALTER TABLE tbl_name ROW_FORMAT = row_format, ALGORITHM=INPLACE, LOCK=NONE;
```

Data is reorganized substantially, making it an expensive operation.

For additional information about the [ROW\\_FORMAT](#) option, see [Table Options](#).

- Changing the [KEY\\_BLOCK\\_SIZE](#)

```
ALTER TABLE tbl_name KEY_BLOCK_SIZE = value, ALGORITHM=INPLACE, LOCK=NONE;
```

Data is reorganized substantially, making it an expensive operation.

For additional information about the [KEY\\_BLOCK\\_SIZE](#) option, see [Table Options](#).

- Setting persistent table statistics options

```
ALTER TABLE tbl_name STATS_PERSISTENT=0, STATS_SAMPLE_PAGES=20, STATS_AUTO_RECALC=1, ALGORITHM=INPLACE, LOCK=NONE;
```

Only modifies table metadata.

Persistent statistics include `STATS_PERSISTENT`, `STATS_AUTO_RECALC`, and `STATS_SAMPLE_PAGES`. For more information, see [Section 17.8.10.1, “Configuring Persistent Optimizer Statistics Parameters”](#).

- Specifying a character set

```
ALTER TABLE tbl_name CHARACTER SET = charset_name, ALGORITHM=INPLACE, LOCK=NONE;
```

Rebuilds the table if the new character encoding is different.

- Converting a character set

```
ALTER TABLE tbl_name CONVERT TO CHARACTER SET charset_name, ALGORITHM=COPY;
```

Rebuilds the table if the new character encoding is different.

- Optimizing a table

```
OPTIMIZE TABLE tbl_name;
```

In-place operation is not supported for tables with `FULLTEXT` indexes. The operation uses the `INPLACE` algorithm, but `ALGORITHM` and `LOCK` syntax is not permitted.

- Rebuilding a table with the `FORCE` option

```
ALTER TABLE tbl_name FORCE, ALGORITHM=INPLACE, LOCK=NONE;
```

Uses `ALGORITHM=INPLACE` as of MySQL 5.6.17. `ALGORITHM=INPLACE` is not supported for tables with `FULLTEXT` indexes.

- Performing a "null" rebuild

```
ALTER TABLE tbl_name ENGINE=InnoDB, ALGORITHM=INPLACE, LOCK=NONE;
```

Uses `ALGORITHM=INPLACE` as of MySQL 5.6.17. `ALGORITHM=INPLACE` is not supported for tables with `FULLTEXT` indexes.

- Renaming a table

```
ALTER TABLE old_tbl_name RENAME TO new_tbl_name, ALGORITHM=INSTANT;
```

Renaming a table can be performed instantly or in place. MySQL renames files that correspond to the table *tbl\_name* without making a copy. (You can also use the `RENAME TABLE` statement to rename tables. See [Section 15.1.36, “RENAME TABLE Statement”](#).) Privileges granted specifically for the renamed table are not migrated to the new name. They must be changed manually.

## Tablespace Operations

The following table provides an overview of online DDL support for tablespace operations. For details, see [Syntax and Usage Notes](#).

**Table 17.21 Online DDL Support for Tablespace Operations**

Operation	Instant	In Place	Rebuilds Table	Permits Concurrent DML	Only Modifies Metadata
Renaming a general tablespace	No	Yes	No	Yes	Yes

Operation	Instant	In Place	Rebuilds Table	Permits Concurrent DML	Only Modifies Metadata
Enabling or disabling general tablespace encryption	No	Yes	No	Yes	No
Enabling or disabling file-per-table tablespace encryption	No	No	Yes	No	No

## Syntax and Usage Notes

- Renaming a general tablespace

```
ALTER TABLESPACE tablespace_name RENAME TO new_tablespace_name;
```

`ALTER TABLESPACE ... RENAME TO` uses the `INPLACE` algorithm but does not support the `ALGORITHM` clause.

- Enabling or disabling general tablespace encryption

```
ALTER TABLESPACE tablespace_name ENCRYPTION='Y';
```

`ALTER TABLESPACE ... ENCRYPTION` uses the `INPLACE` algorithm but does not support the `ALGORITHM` clause.

For related information, see [Section 17.13, “InnoDB Data-at-Rest Encryption”](#).

- Enabling or disabling file-per-table tablespace encryption

```
ALTER TABLE tbl_name ENCRYPTION='Y', ALGORITHM=COPY;
```

For related information, see [Section 17.13, “InnoDB Data-at-Rest Encryption”](#).

## Partitioning Operations

With the exception of some `ALTER TABLE` partitioning clauses, online DDL operations for partitioned `InnoDB` tables follow the same rules that apply to regular `InnoDB` tables.

Some `ALTER TABLE` partitioning clauses do not go through the same internal online DDL API as regular non-partitioned `InnoDB` tables. As a result, online support for `ALTER TABLE` partitioning clauses varies.

The following table shows the online status for each `ALTER TABLE` partitioning statement. Regardless of the online DDL API that is used, MySQL attempts to minimize data copying and locking where possible.

`ALTER TABLE` partitioning options that use `ALGORITHM=COPY` or that only permit “`ALGORITHM=DEFAULT`, `LOCK=DEFAULT`”, repartition the table using the `COPY` algorithm. In other words, a new partitioned table is created with the new partitioning scheme. The newly created table includes any changes applied by the `ALTER TABLE` statement, and table data is copied into the new table structure.

Table 17.22 Online DDL Support for Partitioning Operations

Partitioning Clause	Instant	In Place	Permits DML	Notes
<code>PARTITION BY</code>	No	No	No	Permits <code>ALGORITHM=COPY</code> , <code>LOCK={DEFAULT   SHARED   EXCLUSIVE}</code>
<code>ADD PARTITION</code>	No	Yes*	Yes*	<code>ALGORITHM=INPLACE</code> , <code>LOCK={DEFAULT   NONE   SHARED   EXCLUSIVE}</code> is supported for <code>RANGE</code> and <code>LIST</code> partitions, <code>ALGORITHM=INPLACE</code> , <code>LOCK={DEFAULT   SHARED   EXCLUSIVE}</code> for <code>HASH</code> and <code>KEY</code> partitions, and <code>ALGORITHM=COPY</code> , <code>LOCK={SHARED   EXCLUSIVE}</code> for all partition types. Does not copy existing data for tables partitioned by <code>RANGE</code> or <code>LIST</code> . Concurrent queries are permitted with <code>ALGORITHM=COPY</code> for tables partitioned by <code>HASH</code> or <code>LIST</code> , as MySQL copies the data while holding a shared lock.
<code>DROP PARTITION</code>	No	Yes*	Yes*	<code>ALGORITHM=INPLACE</code> , <code>LOCK={DEFAULT   NONE   SHARED   EXCLUSIVE}</code> is supported. Does not copy data for tables partitioned by <code>RANGE</code> or <code>LIST</code> .  <code>DROP PARTITION</code> with <code>ALGORITHM=INPLACE</code> deletes data stored in the partition and

Partitioning Clause	Instant	In Place	Permits DML	Notes
				drops the partition. However, <code>DROP PARTITION</code> with <code>ALGORITHM=COPY</code> or <code>old_alter_table=ON</code> rebuilds the partitioned table and attempts to move data from the dropped partition to another partition with a compatible <code>PARTITION ... VALUES</code> definition. Data that cannot be moved to another partition is deleted.
<code>DISCARD PARTITION</code>	No	No	No	Only permits <code>ALGORITHM=DEFAULT</code> , <code>LOCK=DEFAULT</code>
<code>IMPORT PARTITION</code>	No	No	No	Only permits <code>ALGORITHM=DEFAULT</code> , <code>LOCK=DEFAULT</code>
<code>TRUNCATE PARTITION</code>	No	Yes	Yes	Does not copy existing data. It merely deletes rows; it does not alter the definition of the table itself, or of any of its partitions.
<code>COALESCE PARTITION</code>	No	Yes*	No	<code>ALGORITHM=INPLACE</code> , <code>LOCK={DEFAULT   SHARED   EXCLUSIVE}</code> is supported.
<code>REORGANIZE PARTITION</code>	No	Yes*	No	<code>ALGORITHM=INPLACE</code> , <code>LOCK={DEFAULT   SHARED   EXCLUSIVE}</code> is supported.
<code>EXCHANGE PARTITION</code>	No	Yes	Yes	
<code>ANALYZE PARTITION</code>	No	Yes	Yes	
<code>CHECK PARTITION</code>	No	Yes	Yes	
<code>OPTIMIZE PARTITION</code>	No	No	No	<code>ALGORITHM</code> and <code>LOCK</code> clauses are

Partitioning Clause	Instant	In Place	Permits DML	Notes
				ignored. Rebuilds the entire table. See <a href="#">Section 26.3.4, “Maintenance of Partitions”</a> .
<code>REBUILD PARTITION</code>	No	Yes*	No	<code>ALGORITHM=INPLACE</code> , <code>LOCK={DEFAULT   SHARED   EXCLUSIVE}</code> is supported.
<code>REPAIR PARTITION</code>	No	Yes	Yes	
<code>REMOVE PARTITIONING</code>	No	No	No	Permits <code>ALGORITHM=COPY</code> , <code>LOCK={DEFAULT   SHARED   EXCLUSIVE}</code>

Non-partitioning online `ALTER TABLE` operations on partitioned tables follow the same rules that apply to regular tables. However, `ALTER TABLE` performs online operations on each table partition, which causes increased demand on system resources due to operations being performed on multiple partitions.

For additional information about `ALTER TABLE` partitioning clauses, see [Partitioning Options](#), and [Section 15.1.9.1, “ALTER TABLE Partition Operations”](#). For information about partitioning in general, see [Chapter 26, Partitioning](#).

## 17.12.2 Online DDL Performance and Concurrency

Online DDL improves several aspects of MySQL operation:

- Applications that access the table are more responsive because queries and DML operations on the table can proceed while the DDL operation is in progress. Reduced locking and waiting for MySQL server resources leads to greater scalability, even for operations that are not involved in the DDL operation.
- Instant operations only modify metadata in the data dictionary. An exclusive metadata lock on the table may be taken briefly during the execution phase of the operation. Table data is unaffected, making operations instantaneous. Concurrent DML is permitted.
- Online operations avoid the disk I/O and CPU cycles associated with the table-copy method, which minimizes overall load on the database. Minimizing load helps maintain good performance and high throughput during the DDL operation.
- Online operations read less data into the buffer pool than table-copy operations, which reduces purging of frequently accessed data from memory. Purging of frequently accessed data can cause a temporary performance dip after a DDL operation.

### The LOCK clause

By default, MySQL uses as little locking as possible during a DDL operation. The `LOCK` clause can be specified for in-place operations and some copy operations to enforce more restrictive locking, if required. If the `LOCK` clause specifies a less restrictive level of locking than is permitted for a particular DDL

operation, the statement fails with an error. `LOCK` clauses are described below, in order of least to most restrictive:

- `LOCK=NONE`:

Permits concurrent queries and DML.

For example, use this clause for tables involving customer signups or purchases, to avoid making the tables unavailable during lengthy DDL operations.

- `LOCK=SHARED`:

Permits concurrent queries but blocks DML.

For example, use this clause on data warehouse tables, where you can delay data load operations until the DDL operation is finished, but queries cannot be delayed for long periods.

- `LOCK=DEFAULT`:

Permits as much concurrency as possible (concurrent queries, DML, or both). Omitting the `LOCK` clause is the same as specifying `LOCK=DEFAULT`.

Use this clause when you do not expect the default locking level of the DDL statement to cause any availability problems for the table.

- `LOCK=EXCLUSIVE`:

Blocks concurrent queries and DML.

Use this clause if the primary concern is finishing the DDL operation in the shortest amount of time possible, and concurrent query and DML access is not necessary. You might also use this clause if the server is supposed to be idle, to avoid unexpected table accesses.

## Online DDL and Metadata Locks

Online DDL operations can be viewed as having three phases:

- *Phase 1: Initialization*

In the initialization phase, the server determines how much concurrency is permitted during the operation, taking into account storage engine capabilities, operations specified in the statement, and user-specified `ALGORITHM` and `LOCK` options. During this phase, a shared upgradeable metadata lock is taken to protect the current table definition.

- *Phase 2: Execution*

In this phase, the statement is prepared and executed. Whether the metadata lock is upgraded to exclusive depends on the factors assessed in the initialization phase. If an exclusive metadata lock is required, it is only taken briefly during statement preparation.

- *Phase 3: Commit Table Definition*

In the commit table definition phase, the metadata lock is upgraded to exclusive to evict the old table definition and commit the new one. Once granted, the duration of the exclusive metadata lock is brief.

Due to the exclusive metadata lock requirements outlined above, an online DDL operation may have to wait for concurrent transactions that hold metadata locks on the table to commit or rollback. Transactions started before or during the DDL operation can hold metadata locks on the table being altered. In the case

of a long running or inactive transaction, an online DDL operation can time out waiting for an exclusive metadata lock. Additionally, a pending exclusive metadata lock requested by an online DDL operation blocks subsequent transactions on the table.

The following example demonstrates an online DDL operation waiting for an exclusive metadata lock, and how a pending metadata lock blocks subsequent transactions on the table.

Session 1:

```
mysql> CREATE TABLE t1 (c1 INT) ENGINE=InnoDB;
mysql> START TRANSACTION;
mysql> SELECT * FROM t1;
```

The session 1 `SELECT` statement takes a shared metadata lock on table t1.

Session 2:

```
mysql> ALTER TABLE t1 ADD COLUMN x INT, ALGORITHM=INPLACE, LOCK=NONE;
```

The online DDL operation in session 2, which requires an exclusive metadata lock on table t1 to commit table definition changes, must wait for the session 1 transaction to commit or roll back.

Session 3:

```
mysql> SELECT * FROM t1;
```

The `SELECT` statement issued in session 3 is blocked waiting for the exclusive metadata lock requested by the `ALTER TABLE` operation in session 2 to be granted.

You can use `SHOW FULL PROCESSLIST` to determine if transactions are waiting for a metadata lock.

```
mysql> SHOW FULL PROCESSLIST\G
...
***** 2. row *****
 Id: 5
 User: root
 Host: localhost
 db: test
 Command: Query
 Time: 44
 State: Waiting for table metadata lock
 Info: ALTER TABLE t1 ADD COLUMN x INT, ALGORITHM=INPLACE, LOCK=NONE
...
***** 4. row *****
 Id: 7
 User: root
 Host: localhost
 db: test
 Command: Query
 Time: 5
 State: Waiting for table metadata lock
 Info: SELECT * FROM t1
4 rows in set (0.00 sec)
```

Metadata lock information is also exposed through the Performance Schema `metadata_locks` table, which provides information about metadata lock dependencies between sessions, the metadata lock a session is waiting for, and the session that currently holds the metadata lock. For more information, see [Section 29.12.13.3, “The metadata\\_locks Table”](#).

## Online DDL Performance

The performance of a DDL operation is largely determined by whether the operation is performed instantly, in place, and whether it rebuilds the table.

To assess the relative performance of a DDL operation, you can compare results using `ALGORITHM=INSTANT`, `ALGORITHM=INPLACE`, and `ALGORITHM=COPY`. A statement can also be run with `old_alter_table` enabled to force the use of `ALGORITHM=COPY`.

For DDL operations that modify table data, you can determine whether a DDL operation performs changes in place or performs a table copy by looking at the “rows affected” value displayed after the command finishes. For example:

- Changing the default value of a column (fast, does not affect the table data):

```
Query OK, 0 rows affected (0.07 sec)
```

- Adding an index (takes time, but 0 rows affected shows that the table is not copied):

```
Query OK, 0 rows affected (21.42 sec)
```

- Changing the data type of a column (takes substantial time and requires rebuilding all the rows of the table):

```
Query OK, 1671168 rows affected (1 min 35.54 sec)
```

Before running a DDL operation on a large table, check whether the operation is fast or slow as follows:

1. Clone the table structure.
2. Populate the cloned table with a small amount of data.
3. Run the DDL operation on the cloned table.
4. Check whether the “rows affected” value is zero or not. A nonzero value means the operation copies table data, which might require special planning. For example, you might do the DDL operation during a period of scheduled downtime, or on each replica server one at a time.

#### Note

For a greater understanding of the MySQL processing associated with a DDL operation, examine Performance Schema and `INFORMATION_SCHEMA` tables related to `InnoDB` before and after DDL operations to see the number of physical reads, writes, memory allocations, and so on.

Performance Schema stage events can be used to monitor `ALTER TABLE` progress. See [Section 17.16.1, “Monitoring ALTER TABLE Progress for InnoDB Tables Using Performance Schema”](#).

Because there is some processing work involved with recording the changes made by concurrent DML operations, then applying those changes at the end, an online DDL operation could take longer overall than the table-copy mechanism that blocks table access from other sessions. The reduction in raw performance is balanced against better responsiveness for applications that use the table. When evaluating the techniques for changing table structure, consider end-user perception of performance, based on factors such as load times for web pages.

## 17.12.3 Online DDL Space Requirements

Disk space requirements for online DDL operations are outlined below. The requirements do not apply to operations that are performed instantly.

- Temporary log files:

A temporary log file records concurrent DML when an online DDL operation creates an index or alters a table. The temporary log file is extended as required by the value of `innodb_sort_buffer_size` up to a maximum specified by `innodb_online_alter_log_max_size`. If the operation takes a long time and concurrent DML modifies the table so much that the size of the temporary log file exceeds the value of `innodb_online_alter_log_max_size`, the online DDL operation fails with a `DB_ONLINE_LOG_TOO_BIG` error, and uncommitted concurrent DML operations are rolled back. A large `innodb_online_alter_log_max_size` setting permits more DML during an online DDL operation, but it also extends the period of time at the end of the DDL operation when the table is locked to apply logged DML.

The `innodb_sort_buffer_size` variable also defines the size of the temporary log file read buffer and write buffer.

- Temporary sort files:

Online DDL operations that rebuild the table write temporary sort files to the MySQL temporary directory (`$TMPDIR` on Unix, `%TEMP%` on Windows, or the directory specified by `--tmpdir`) during index creation. Temporary sort files are not created in the directory that contains the original table. Each temporary sort file is large enough to hold one column of data, and each sort file is removed when its data is merged into the final table or index. Operations involving temporary sort files may require temporary space equal to the amount of data in the table plus indexes. An error is reported if online DDL operation uses all of the available disk space on the file system where the data directory resides.

If the MySQL temporary directory is not large enough to hold the sort files, set `tmpdir` to a different directory. Alternatively, define a separate temporary directory for online DDL operations using `innodb_tmpdir`. This option was introduced to help avoid temporary directory overflows that could occur as a result of large temporary sort files.

- Intermediate table files:

Some online DDL operations that rebuild the table create a temporary intermediate table file in the same directory as the original table. An intermediate table file may require space equal to the size of the original table. Intermediate table file names begin with `#sql-ib` prefix and only appear briefly during the online DDL operation.

The `innodb_tmpdir` option is not applicable to intermediate table files.

## 17.12.4 Online DDL Memory Management

Online DDL operations that create or rebuild secondary indexes allocate temporary buffers during different phases of index creation. The `innodb_ddl_buffer_size` variable defines the maximum buffer size for online DDL operations. The default setting is 1048576 bytes (1 MB). The setting applies to buffers created by threads executing online DDL operations. Defining an appropriate buffer size limit avoids potential out of memory errors for online DDL operations that create or rebuild secondary indexes. The maximum buffer size per DDL thread is the maximum buffer size divided by the number of DDL threads (`innodb_ddl_buffer_size/innodb_ddl_threads`).

## 17.12.5 Configuring Parallel Threads for Online DDL Operations

The workflow of an online DDL operation that creates or rebuilds a secondary index involves:

- Scanning the clustered index and writing data to temporary sort files
- Sorting the data
- Loading sorted data from the temporary sort files into the secondary index

The number of parallel threads that can be used to scan clustered index is defined by the `innodb_parallel_read_threads` variable. The default setting is calculated by the number of available logical processors on the system divided by 8, with a minimum default value of 4. The maximum setting is 256, which is the maximum number for all sessions. The actual number of threads that scan the clustered index is the number defined by the `innodb_parallel_read_threads` setting or the number of index subtrees to scan, whichever is smaller. If the thread limit is reached, sessions fall back to using a single thread.

The number of parallel threads that sort and load data is controlled by the `innodb_ddl_threads` variable. The default setting is 4.

The following limitations apply:

- Parallel threads are not supported for building indexes that include virtual columns.
- Parallel threads are not supported for full-text index creation.
- Parallel threads are not supported for spatial index creation.
- Parallel scan is not supported on tables defined with virtual columns.
- Parallel scan is not supported on tables defined with a full-text index.
- Parallel scan is not supported on tables defined with a spatial index.

## 17.12.6 Simplifying DDL Statements with Online DDL

Before the introduction of [online DDL](#), it was common practice to combine many DDL operations into a single `ALTER TABLE` statement. Because each `ALTER TABLE` statement involved copying and rebuilding the table, it was more efficient to make several changes to the same table at once, since those changes could all be done with a single rebuild operation for the table. The downside was that SQL code involving DDL operations was harder to maintain and to reuse in different scripts. If the specific changes were different each time, you might have to construct a new complex `ALTER TABLE` for each slightly different scenario.

For DDL operations that can be done online, you can separate them into individual `ALTER TABLE` statements for easier scripting and maintenance, without sacrificing efficiency. For example, you might take a complicated statement such as:

```
ALTER TABLE t1 ADD INDEX i1(c1), ADD UNIQUE INDEX i2(c2),
CHANGE c4_old_name c4_new_name INTEGER UNSIGNED;
```

and break it down into simpler parts that can be tested and performed independently, such as:

```
ALTER TABLE t1 ADD INDEX i1(c1);
ALTER TABLE t1 ADD UNIQUE INDEX i2(c2);
ALTER TABLE t1 CHANGE c4_old_name c4_new_name INTEGER UNSIGNED NOT NULL;
```

You might still use multi-part `ALTER TABLE` statements for:

- Operations that must be performed in a specific sequence, such as creating an index followed by a foreign key constraint that uses that index.
- Operations all using the same specific `LOCK` clause, that you want to either succeed or fail as a group.
- Operations that cannot be performed online, that is, that still use the table-copy method.
- Operations for which you specify `ALGORITHM=COPY` or `old_alter_table=1`, to force the table-copying behavior if needed for precise backward-compatibility in specialized scenarios.

## 17.12.7 Online DDL Failure Conditions

The failure of an online DDL operation is typically due to one of the following conditions:

- An `ALGORITHM` clause specifies an algorithm that is not compatible with the particular type of DDL operation or storage engine.
- A `LOCK` clause specifies a low degree of locking (`SHARED` or `NONE`) that is not compatible with the particular type of DDL operation.
- A timeout occurs while waiting for an `exclusive lock` on the table, which may be needed briefly during the initial and final phases of the DDL operation.
- The `tmpdir` or `innodb_tmpdir` file system runs out of disk space, while MySQL writes temporary sort files on disk during index creation. For more information, see [Section 17.12.3, “Online DDL Space Requirements”](#).
- The operation takes a long time and concurrent DML modifies the table so much that the size of the temporary online log exceeds the value of the `innodb_online_alter_log_max_size` configuration option. This condition causes a `DB_ONLINE_LOG_TOO_BIG` error.
- Concurrent DML makes changes to the table that are allowed with the original table definition, but not with the new one. The operation only fails at the very end, when MySQL tries to apply all the changes from concurrent DML statements. For example, you might insert duplicate values into a column while a unique index is being created, or you might insert `NULL` values into a column while creating a `primary key` index on that column. The changes made by the concurrent DML take precedence, and the `ALTER TABLE` operation is effectively `rolled back`.

## 17.12.8 Online DDL Limitations

The following limitations apply to online DDL operations:

- The table is copied when creating an index on a `TEMPORARY TABLE`.
- The `ALTER TABLE` clause `LOCK=NONE` is not permitted if there are `ON...CASCADE` or `ON...SET NULL` constraints on the table.
- Before an in-place online DDL operation can finish, it must wait for transactions that hold metadata locks on the table to commit or roll back. An online DDL operation may briefly require an exclusive metadata lock on the table during its execution phase, and always requires one in the final phase of the operation when updating the table definition. Consequently, transactions holding metadata locks on the table can cause an online DDL operation to block. The transactions that hold metadata locks on the table may have been started before or during the online DDL operation. A long running or inactive transaction that holds a metadata lock on the table can cause an online DDL operation to timeout.
- When running an in-place online DDL operation, the thread that runs the `ALTER TABLE` statement applies an online log of DML operations that were run concurrently on the same table from other connection threads. When the DML operations are applied, it is possible to encounter a duplicate key entry error (`ERROR 1062 (23000): Duplicate entry`), even if the duplicate entry is only temporary and would be reverted by a later entry in the online log. This is similar to the idea of a foreign key constraint check in `InnoDB` in which constraints must hold during a transaction.
- `OPTIMIZE TABLE` for an `InnoDB` table is mapped to an `ALTER TABLE` operation to rebuild the table and update index statistics and free unused space in the clustered index. Secondary indexes are not created as efficiently because keys are inserted in the order they appeared in the primary key. `OPTIMIZE TABLE` is supported with the addition of online DDL support for rebuilding regular and partitioned `InnoDB` tables.

- Tables created before MySQL 5.6 that include temporal columns ([DATE](#), [DATETIME](#) or [TIMESTAMP](#)) and have not been rebuilt using [ALGORITHM=COPY](#) do not support [ALGORITHM=INPLACE](#). In this case, an [ALTER TABLE ... ALGORITHM=INPLACE](#) operation returns the following error:

```
ERROR 1846 (0A000): ALGORITHM=INPLACE is not supported.
Reason: Cannot change column type INPLACE. Try ALGORITHM=COPY.
```

- The following limitations are generally applicable to online DDL operations on large tables that involve rebuilding the table:
  - There is no mechanism to pause an online DDL operation or to throttle I/O or CPU usage for an online DDL operation.
  - Rollback of an online DDL operation can be expensive should the operation fail.
  - Long running online DDL operations can cause replication lag. An online DDL operation must finish running on the source before it is run on the replica. Also, DML that was processed concurrently on the source is only processed on the replica after the DDL operation on the replica is completed.

For additional information related to running online DDL operations on large tables, see [Section 17.12.2, “Online DDL Performance and Concurrency”](#).

## 17.13 InnoDB Data-at-Rest Encryption

[InnoDB](#) supports data-at-rest encryption for [file-per-table](#) tablespaces, [general](#) tablespaces, the [mysql](#) system tablespace, redo logs, and undo logs.

You can set an encryption default for schemas and general tablespaces; this permits DBAs to control whether tables created in those schemas and tablespaces are encrypted.

[InnoDB](#) data-at-rest encryption features and capabilities are described under the following topics in this section.

- [About Data-at-Rest Encryption](#)
- [Encryption Prerequisites](#)
- [Defining an Encryption Default for Schemas and General Tablespaces](#)
- [File-Per-Table Tablespace Encryption](#)
- [General Tablespace Encryption](#)
- [Doublewrite File Encryption](#)
- [mysql System Tablespace Encryption](#)
- [Redo Log Encryption](#)
- [Undo Log Encryption](#)
- [Master Key Rotation](#)
- [Encryption and Recovery](#)
- [Exporting Encrypted Tablespaces](#)
- [Encryption and Replication](#)
- [Identifying Encrypted Tablespaces and Schemas](#)

- [Monitoring Encryption Progress](#)
- [Encryption Usage Notes](#)
- [Encryption Limitations](#)

## About Data-at-Rest Encryption

[InnoDB](#) uses a two tier encryption key architecture, consisting of a master encryption key and tablespace keys. When a tablespace is encrypted, a tablespace key is encrypted and stored in the tablespace header. When an application or authenticated user wants to access encrypted tablespace data, [InnoDB](#) uses a master encryption key to decrypt the tablespace key. The decrypted version of a tablespace key never changes, but the master encryption key can be changed as required. This action is referred to as *master key rotation*.

The data-at-rest encryption feature relies on a keyring component or plugin for master encryption key management.

All MySQL editions provide a `component_keyring_file` component, which stores keyring data in a file local to the server host.

MySQL Enterprise Edition offers additional keyring components and plugins:

- `component_keyring_encrypted_file`: Stores keyring data in an encrypted, password-protected file local to the server host.
- `keyring_okv`: A KMIP 1.1 plugin for use with KMIP-compatible back end keyring storage products. Supported KMIP-compatible products include centralized key management solutions such as Oracle Key Vault, Gemalto KeySecure, Thales Vormetric key management server, and Fornetix Key Orchestration.
- `keyring_aws`: Communicates with the Amazon Web Services Key Management Service (AWS KMS) as a back end for key generation and uses a local file for key storage.
- `keyring_hashicorp`: Communicates with HashiCorp Vault for back end storage.

### Warning

For encryption key management, the `component_keyring_file` and `component_keyring_encrypted_file` components are not intended as a regulatory compliance solution. Security standards such as PCI, FIPS, and others require use of key management systems to secure, manage, and protect encryption keys in key vaults or hardware security modules (HSMs).

A secure and robust encryption key management solution is critical for security and for compliance with various security standards. When the data-at-rest encryption feature uses a centralized key management solution, the feature is referred to as “MySQL Enterprise Transparent Data Encryption (TDE)”.

The data-at-rest encryption feature supports the Advanced Encryption Standard (AES) block-based encryption algorithm. It uses Electronic Codebook (ECB) block encryption mode for tablespace key encryption and Cipher Block Chaining (CBC) block encryption mode for data encryption.

For frequently asked questions about the data-at-rest encryption feature, see [Section A.17, “MySQL 9.1 FAQ: InnoDB Data-at-Rest Encryption”](#).

## Encryption Prerequisites

- A keyring component or plugin must be installed and configured at startup. Early loading ensures that the component or plugin is available prior to initialization of the [InnoDB](#) storage engine. For keyring

installation and configuration instructions, see [Section 8.4.4, “The MySQL Keyring”](#). The instructions show how to ensure that the chosen component or plugin is active.

Only one keyring component or plugin should be enabled at a time. Enabling multiple keyring components or plugins is unsupported and results may not be as anticipated.

### Important

Once encrypted tablespaces are created in a MySQL instance, the keyring component or plugin that was loaded when creating the encrypted tablespace must continue to be loaded at startup. Failing to do so results in errors when starting the server and during [InnoDB](#) recovery.

- When encrypting production data, ensure that you take steps to prevent loss of the master encryption key. *If the master encryption key is lost, data stored in encrypted tablespace files is unrecoverable.* If you use the [component\\_keyring\\_file](#) or [component\\_keyring\\_encrypted\\_file](#) component create a backup of the keyring data file immediately after creating the first encrypted tablespace, before master key rotation, and after master key rotation. For each component, its configuration file indicates the data file location. If you use the [keyring\\_okv](#) or [keyring\\_aws](#) plugin, ensure that you have performed the necessary configuration. For instructions, see [Section 8.4.4, “The MySQL Keyring”](#).

## Defining an Encryption Default for Schemas and General Tablespaces

[default\\_table\\_encryption](#) system variable defines the default encryption setting for schemas and general tablespaces. [CREATE TABLESPACE](#) and [CREATE SCHEMA](#) operations apply the [default\\_table\\_encryption](#) setting when an [ENCRYPTION](#) clause is not specified explicitly.

[ALTER SCHEMA](#) and [ALTER TABLESPACE](#) operations do not apply the [default\\_table\\_encryption](#) setting. An [ENCRYPTION](#) clause must be specified explicitly to alter the encryption of an existing schema or general tablespace.

The [default\\_table\\_encryption](#) variable can be set for an individual client connection or globally using [SET](#) syntax. For example, the following statement enables default schema and tablespace encryption globally:

```
mysql> SET GLOBAL default_table_encryption=ON;
```

The default encryption setting for a schema can also be defined using the [DEFAULT ENCRYPTION](#) clause when creating or altering a schema, as in this example:

```
mysql> CREATE SCHEMA test DEFAULT ENCRYPTION = 'Y';
```

If the [DEFAULT ENCRYPTION](#) clause is not specified when creating a schema, the [default\\_table\\_encryption](#) setting is applied. The [DEFAULT ENCRYPTION](#) clause must be specified to alter the default encryption of an existing schema. Otherwise, the schema retains its current encryption setting.

By default, a table inherits the encryption setting of the schema or general tablespace it is created in. For example, a table created in an encryption-enabled schema is encrypted by default. This behavior enables a DBA to control table encryption usage by defining and enforcing schema and general tablespace encryption defaults.

Encryption defaults are enforced by enabling the [table\\_encryption\\_privilege\\_check](#) system variable. When [table\\_encryption\\_privilege\\_check](#) is enabled, a privilege check occurs when creating or altering a schema or general tablespace with an encryption setting that differs from the [default\\_table\\_encryption](#) setting, or when creating or altering a table with an encryption setting that

differs from the default schema encryption. When `table_encryption_privilege_check` is disabled (the default), the privilege check does not occur and the previously mentioned operations are permitted to proceed with a warning.

The `TABLE_ENCRYPTION_ADMIN` privilege is required to override default encryption settings when `table_encryption_privilege_check` is enabled. A DBA can grant this privilege to enable a user to deviate from the `default_table_encryption` setting when creating or altering a schema or general tablespace, or to deviate from the default schema encryption when creating or altering a table. This privilege does not permit deviating from the encryption of a general tablespace when creating or altering a table. A table must have the same encryption setting as the general tablespace it resides in.

## File-Per-Table Tablespace Encryption

A file-per-table tablespace inherits the default encryption of the schema in which the table is created unless an `ENCRYPTION` clause is specified explicitly in the `CREATE TABLE` statement.

```
mysql> CREATE TABLE t1 (c1 INT) ENCRYPTION = 'Y';
```

To alter the encryption of an existing file-per-table tablespace, an `ENCRYPTION` clause must be specified.

```
mysql> ALTER TABLE t1 ENCRYPTION = 'Y';
```

`table_encryption_privilege_check` is enabled, specifying an `ENCRYPTION` clause with a setting that differs from the default schema encryption requires the `TABLE_ENCRYPTION_ADMIN` privilege. See [Defining an Encryption Default for Schemas and General Tablespace](#)s.

## General Tablespace Encryption

The `default_table_encryption` variable determines the encryption of a newly created general tablespace unless an `ENCRYPTION` clause is specified explicitly in the `CREATE TABLESPACE` statement.

```
mysql> CREATE TABLESPACE `ts1` ADD DATAFILE 'ts1.ibd' ENCRYPTION = 'Y' Engine=InnoDB;
```

To alter the encryption of an existing general tablespace, an `ENCRYPTION` clause must be specified.

```
mysql> ALTER TABLESPACE ts1 ENCRYPTION = 'Y';
```

If `table_encryption_privilege_check` is enabled, specifying an `ENCRYPTION` clause with a setting that differs from the `default_table_encryption` setting requires the `TABLE_ENCRYPTION_ADMIN` privilege. See [Defining an Encryption Default for Schemas and General Tablespace](#)s.

## Doublewrite File Encryption

In MySQL 9.1, `InnoDB` automatically encrypts doublewrite file pages that belong to encrypted tablespaces. No action is required. Doublewrite file pages are encrypted using the encryption key of the associated tablespace. The same encrypted page written to a tablespace data file is also written to a doublewrite file. Doublewrite file pages that belong to an unencrypted tablespace remain unencrypted.

During recovery, encrypted doublewrite file pages are unencrypted and checked for corruption.

## mysql System Tablespace Encryption

The `mysql` system tablespace contains the `mysql` system database and MySQL data dictionary tables. It is unencrypted by default. To enable encryption for the `mysql` system tablespace, specify the tablespace name and the `ENCRYPTION` option in an `ALTER TABLESPACE` statement.

```
mysql> ALTER TABLESPACE mysql ENCRYPTION = 'Y';
```

To disable encryption for the `mysql` system tablespace, set `ENCRYPTION = 'N'` using an `ALTER TABLESPACE` statement.

```
mysql> ALTER TABLESPACE mysql ENCRYPTION = 'N';
```

Enabling or disabling encryption for the `mysql` system tablespace requires the `CREATE TABLESPACE` privilege on all tables in the instance (`CREATE TABLESPACE on *.*`).

## Redo Log Encryption

Redo log data encryption is enabled using the `innodb_redo_log_encrypt` configuration option. Redo log encryption is disabled by default.

As with tablespace data, redo log data encryption occurs when redo log data is written to disk, and decryption occurs when redo log data is read from disk. Once redo log data is read into memory, it is in unencrypted form. Redo log data is encrypted and decrypted using the tablespace encryption key.

When `innodb_redo_log_encrypt` is enabled, unencrypted redo log pages that are present on disk remain unencrypted, and new redo log pages are written to disk in encrypted form. Likewise, when `innodb_redo_log_encrypt` is disabled, encrypted redo log pages that are present on disk remain encrypted, and new redo log pages are written to disk in unencrypted form.

Redo log encryption metadata, including the tablespace encryption key, is stored in the header of the redo log file with the most recent checkpoint LSN. If the redo log file with the encryption metadata is removed, redo log encryption is disabled.

Once redo log encryption is enabled, a normal restart without the keyring component or plugin or without the encryption key is not possible, as `InnoDB` must be able to scan redo pages during startup, which is not possible if redo log pages are encrypted. Without the keyring component or plugin or the encryption key, only a forced startup without the redo logs (`SRV_FORCE_NO_LOG_REDO`) is possible. See [Section 17.20.3, “Forcing InnoDB Recovery”](#).

## Undo Log Encryption

Undo log data encryption is enabled using the `innodb_undo_log_encrypt` configuration option. Undo log encryption applies to undo logs that reside in [undo tablespaces](#). See [Section 17.6.3.4, “Undo Tablespaces”](#). Undo log data encryption is disabled by default.

As with tablespace data, undo log data encryption occurs when undo log data is written to disk, and decryption occurs when undo log data is read from disk. Once undo log data is read into memory, it is in unencrypted form. Undo log data is encrypted and decrypted using the tablespace encryption key.

When `innodb_undo_log_encrypt` is enabled, unencrypted undo log pages that are present on disk remain unencrypted, and new undo log pages are written to disk in encrypted form. Likewise, when `innodb_undo_log_encrypt` is disabled, encrypted undo log pages that are present on disk remain encrypted, and new undo log pages are written to disk in unencrypted form.

Undo log encryption metadata, including the tablespace encryption key, is stored in the header of the undo log file.

### Note

When undo log encryption is disabled, the server continues to require the keyring component or plugin that was used to encrypt undo log data until the undo tablespaces that contained the encrypted undo log data are truncated. (An encryption header is only removed from an undo tablespace when the undo

tablespace is truncated.) For information about truncating undo tablespaces, see [Truncating Undo Tablespaces](#).

## Master Key Rotation

The master encryption key should be rotated periodically and whenever you suspect that the key has been compromised.

Master key rotation is an atomic, instance-level operation. Each time the master encryption key is rotated, all tablespace keys in the MySQL instance are re-encrypted and saved back to their respective tablespace headers. As an atomic operation, re-encryption must succeed for all tablespace keys once a rotation operation is initiated. If master key rotation is interrupted by a server failure, [InnoDB](#) rolls the operation forward on server restart. For more information, see [Encryption and Recovery](#).

Rotating the master encryption key only changes the master encryption key and re-encrypts tablespace keys. It does not decrypt or re-encrypt associated tablespace data.

Rotating the master encryption key requires the [ENCRYPTION\\_KEY\\_ADMIN](#) privilege (or the deprecated [SUPER](#) privilege).

To rotate the master encryption key, run:

```
mysql> ALTER INSTANCE ROTATE INNODB MASTER KEY;
```

[ALTER INSTANCE ROTATE INNODB MASTER KEY](#) supports concurrent DML. However, it cannot be run concurrently with tablespace encryption operations, and locks are taken to prevent conflicts that could arise from concurrent execution. If an [ALTER INSTANCE ROTATE INNODB MASTER KEY](#) operation is running, it must finish before a tablespace encryption operation can proceed, and vice versa.

## Encryption and Recovery

If a server failure occurs during an encryption operation, the operation is rolled forward when the server is restarted. For general tablespaces, the encryption operation is resumed in a background thread from the last processed page.

If a server failure occurs during master key rotation, [InnoDB](#) continues the operation on server restart.

The keyring component or plugin must be loaded prior to storage engine initialization so that the information necessary to decrypt tablespace data pages can be retrieved from tablespace headers before [InnoDB](#) initialization and recovery activities access tablespace data. (See [Encryption Prerequisites](#).)

When [InnoDB](#) initialization and recovery begin, the master key rotation operation resumes. Due to the server failure, some tablespace keys may already be encrypted using the new master encryption key. [InnoDB](#) reads the encryption data from each tablespace header, and if the data indicates that the tablespace key is encrypted using the old master encryption key, [InnoDB](#) retrieves the old key from the keyring and uses it to decrypt the tablespace key. [InnoDB](#) then re-encrypts the tablespace key using the new master encryption key and saves the re-encrypted tablespace key back to the tablespace header.

## Exporting Encrypted Tablespaces

Tablespace export is only supported for file-per-table tablespaces.

When an encrypted tablespace is exported, [InnoDB](#) generates a *transfer key* that is used to encrypt the tablespace key. The encrypted tablespace key and transfer key are stored in a `tablespace_name.cfp` file. This file together with the encrypted tablespace file is required to perform an import operation. On import, [InnoDB](#) uses the transfer key to decrypt the tablespace key in the `tablespace_name.cfp` file. For related information, see [Section 17.6.1.3, “Importing InnoDB Tables”](#).

## Encryption and Replication

- The `ALTER INSTANCE ROTATE INNODB MASTER KEY` statement is only supported in replication environments where the source and replica run a version of MySQL that supports tablespace encryption.
- Successful `ALTER INSTANCE ROTATE INNODB MASTER KEY` statements are written to the binary log for replication on replicas.
- If an `ALTER INSTANCE ROTATE INNODB MASTER KEY` statement fails, it is not logged to the binary log and is not replicated on replicas.
- Replication of an `ALTER INSTANCE ROTATE INNODB MASTER KEY` operation fails if the keyring component or plugin is installed on the source but not on the replica.

## Identifying Encrypted Tablespaces and Schemas

The Information Schema `INNODB_TABLESPACES` table includes an `ENCRYPTION` column that can be used to identify encrypted tablespaces.

```
mysql> SELECT SPACE, NAME, SPACE_TYPE, ENCRYPTION FROM INFORMATION_SCHEMA.INNODB_TABLESPACES
 WHERE ENCRYPTION='Y'\G
***** 1. row *****
 SPACE: 4294967294
 NAME: mysql
SPACE_TYPE: General
ENCRYPTION: Y
***** 2. row *****
 SPACE: 2
 NAME: test/t1
SPACE_TYPE: Single
ENCRYPTION: Y
***** 3. row *****
 SPACE: 3
 NAME: ts1
SPACE_TYPE: General
ENCRYPTION: Y
```

When the `ENCRYPTION` option is specified in a `CREATE TABLE` or `ALTER TABLE` statement, it is recorded in the `CREATE_OPTIONS` column of `INFORMATION_SCHEMA.TABLES`. This column can be queried to identify tables that reside in encrypted file-per-table tablespaces.

```
mysql> SELECT TABLE_SCHEMA, TABLE_NAME, CREATE_OPTIONS FROM INFORMATION_SCHEMA.TABLES
 WHERE CREATE_OPTIONS LIKE '%ENCRYPTION%';
+-----+-----+-----+
| TABLE_SCHEMA | TABLE_NAME | CREATE_OPTIONS |
+-----+-----+-----+
| test | t1 | ENCRYPTION="Y" |
+-----+-----+-----+
```

Query the Information Schema `INNODB_TABLESPACES` table to retrieve information about the tablespace associated with a particular schema and table.

```
mysql> SELECT SPACE, NAME, SPACE_TYPE FROM INFORMATION_SCHEMA.INNODB_TABLESPACES WHERE NAME='test/t1';
+-----+-----+-----+
| SPACE | NAME | SPACE_TYPE |
+-----+-----+-----+
| 3 | test/t1 | Single |
+-----+-----+-----+
```

You can identify encryption-enabled schemas by querying the Information Schema `SCHEMATA` table.

```
mysql> SELECT SCHEMA_NAME, DEFAULT_ENCRYPTION FROM INFORMATION_SCHEMA.SCHEMATA
 WHERE DEFAULT_ENCRYPTION='YES';
```

SCHEMA_NAME	DEFAULT_ENCRYPTION
test	YES

`SHOW CREATE SCHEMA` also shows the `DEFAULT ENCRYPTION` clause.

## Monitoring Encryption Progress

You can monitor general tablespace and `mysql` system tablespace encryption progress using [Performance Schema](#).

The `stage/innodb/alter tablespace (encryption)` stage event instrument reports `WORK_ESTIMATED` and `WORK_COMPLETED` information for general tablespace encryption operations.

The following example demonstrates how to enable the `stage/innodb/alter tablespace (encryption)` stage event instrument and related consumer tables to monitor general tablespace or `mysql` system tablespace encryption progress. For information about Performance Schema stage event instruments and related consumers, see [Section 29.12.5, “Performance Schema Stage Event Tables”](#).

1. Enable the `stage/innodb/alter tablespace (encryption)` instrument:

```
mysql> USE performance_schema;
mysql> UPDATE setup_instruments SET ENABLED = 'YES'
 WHERE NAME LIKE 'stage/innodb/alter tablespace (encryption)';
```

2. Enable the stage event consumer tables, which include `events_stages_current`, `events_stages_history`, and `events_stages_history_long`.

```
mysql> UPDATE setup_consumers SET ENABLED = 'YES' WHERE NAME LIKE '%stages%';
```

3. Run a tablespace encryption operation. In this example, a general tablespace named `ts1` is encrypted.

```
mysql> ALTER TABLESPACE ts1 ENCRYPTION = 'Y';
```

4. Check the progress of the encryption operation by querying the Performance Schema `events_stages_current` table. `WORK_ESTIMATED` reports the total number of pages in the tablespace. `WORK_COMPLETED` reports the number of pages processed.

```
mysql> SELECT EVENT_NAME, WORK_COMPLETED, WORK_ESTIMATED FROM events_stages_current;
+-----+-----+-----+
| EVENT_NAME | WORK_COMPLETED | WORK_ESTIMATED |
+-----+-----+-----+
| stage/innodb/alter tablespace (encryption) | 1056 | 1407 |
+-----+-----+-----+
```

The `events_stages_current` table returns an empty set if the encryption operation has completed. In this case, you can check the `events_stages_history` table to view event data for the completed operation. For example:

```
mysql> SELECT EVENT_NAME, WORK_COMPLETED, WORK_ESTIMATED FROM events_stages_history;
+-----+-----+-----+
| EVENT_NAME | WORK_COMPLETED | WORK_ESTIMATED |
+-----+-----+-----+
| stage/innodb/alter tablespace (encryption) | 1407 | 1407 |
+-----+-----+-----+
```

## Encryption Usage Notes

- Plan appropriately when altering an existing file-per-table tablespace with the `ENCRYPTION` option. Tables residing in file-per-table tablespaces are rebuilt using the `COPY` algorithm. The `INPLACE`

algorithm is used when altering the [ENCRYPTION](#) attribute of a general tablespace or the [mysql](#) system tablespace. The [INPLACE](#) algorithm permits concurrent DML on tables that reside in the general tablespace. Concurrent DDL is blocked.

- When a general tablespace or the [mysql](#) system tablespace is encrypted, all tables residing in the tablespace are encrypted. Likewise, a table created in an encrypted tablespace is encrypted.
- If the server exits or is stopped during normal operation, it is recommended to restart the server using the same encryption settings that were configured previously.
- The first master encryption key is generated when the first new or existing tablespace is encrypted.
- Master key rotation re-encrypts tablespace keys but does not change the tablespace key itself. To change a tablespace key, you must disable and re-enable encryption. For file-per-table tablespaces, re-encrypting the tablespace is an [ALGORITHM=COPY](#) operation that rebuilds the table. For general tablespaces and the [mysql](#) system tablespace, it is an [ALGORITHM=INPLACE](#) operation, which does not require rebuilding tables that reside in the tablespace.
- If a table is created with both the [COMPRESSION](#) and [ENCRYPTION](#) options, compression is performed before tablespace data is encrypted.
- Uninstalling the [component\\_keyring\\_file](#) or [component\\_keyring\\_encrypted\\_file](#) component does not remove an existing keyring data file.
- It is recommended that you not place a keyring data file under the same directory as tablespace data files.
- Encryption is supported for the [InnoDB FULLTEXT](#) index tables that are created implicitly when adding a [FULLTEXT](#) index. For related information, see [InnoDB Full-Text Index Tables](#).

## Encryption Limitations

- Advanced Encryption Standard (AES) is the only supported encryption algorithm. [InnoDB](#) tablespace encryption uses Electronic Codebook (ECB) block encryption mode for tablespace key encryption and Cipher Block Chaining (CBC) block encryption mode for data encryption. Padding is not used with CBC block encryption mode. Instead, [InnoDB](#) ensures that the text to be encrypted is a multiple of the block size.
- Encryption is supported only for [file-per-table](#) tablespaces, [general](#) tablespaces, and the [mysql](#) system tablespace. Encryption is not supported for other tablespace types including the [InnoDB system tablespace](#).
- You cannot move or copy a table from an encrypted [file-per-table](#) tablespace, [general](#) tablespace, or the [mysql](#) system tablespace to a tablespace type that does not support encryption.
- You cannot move or copy a table from an encrypted tablespace to an unencrypted tablespace. However, moving a table from an unencrypted tablespace to an encrypted one is permitted. For example, you can move or copy a table from a unencrypted [file-per-table](#) or [general](#) tablespace to an encrypted general tablespace.
- By default, tablespace encryption only applies to data in the tablespace. Redo log and undo log data can be encrypted by enabling [innodb\\_redo\\_log\\_encrypt](#) and [innodb\\_undo\\_log\\_encrypt](#). See [Redo Log Encryption](#), and [Undo Log Encryption](#). For information about binary log file and relay log file encryption, see [Section 19.3.2, “Encrypting Binary Log Files and Relay Log Files”](#).
- It is not permitted to change the storage engine of a table that resides in, or previously resided in, an encrypted tablespace.

## 17.14 InnoDB Startup Options and System Variables

- [InnoDB Startup Options](#)
- [InnoDB System Variables](#)
- System variables that are true or false can be enabled at server startup by naming them, or disabled by using a `--skip-` prefix. For example, to enable or disable the InnoDB adaptive hash index, you can use `--innodb-adaptive-hash-index` or `--skip-innodb-adaptive-hash-index` on the command line, or `innodb_adaptive_hash_index` or `skip_innodb_adaptive_hash_index` in an option file.
- Some variable descriptions refer to “enabling” or “disabling” a variable. These variables can be enabled with the `SET` statement by setting them to `ON` or `1`, or disabled by setting them to `OFF` or `0`. Boolean variables can be set at startup to the values `ON`, `TRUE`, `OFF`, and `FALSE` (not case-sensitive), as well as `1` and `0`. See [Section 6.2.2.4, “Program Option Modifiers”](#).
- System variables that take a numeric value can be specified as `--var_name=value` on the command line or as `var_name=value` in option files.
- Many system variables can be changed at runtime (see [Section 7.1.9.2, “Dynamic System Variables”](#)).
- For information about `GLOBAL` and `SESSION` variable scope modifiers, refer to the `SET` statement documentation.
- Certain options control the locations and layout of the InnoDB data files. [Section 17.8.1, “InnoDB Startup Configuration”](#) explains how to use these options.
- Some options, which you might not use initially, help tune InnoDB performance characteristics based on machine capacity and database workload.
- For more information on specifying options and system variables, see [Section 6.2.2, “Specifying Program Options”](#).

## InnoDB Startup Options

- `--innodb-dedicated-server`

Command-Line Format	<code>--innodb-dedicated-server[={OFF ON}]</code>
System Variable	<code>innodb_dedicated_server</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

When this option is set by starting the server with `--innodb-dedicated-server` or `--innodb-dedicated-server=ON`, either on the command line or in a `my.cnf` file, InnoDB automatically calculates and sets the values of the following variables:

- `innodb_buffer_pool_size`
- `innodb_redo_log_capacity`

You should consider using `--innodb-dedicated-server` only if the MySQL instance resides on a dedicated server where it can use all available system resources. Using this option is not recommended if the MySQL instance shares system resources with other applications.

It is strongly recommended that you read [Section 17.8.12, “Enabling Automatic InnoDB Configuration for a Dedicated MySQL Server”](#), before using this option in production.

- `--innodb-status-file`

Command-Line Format	<code>--innodb-status-file[={OFF ON}]</code>
Type	Boolean
Default Value	OFF

The `--innodb-status-file` startup option controls whether InnoDB creates a file named `innodb_status.pid` in the data directory and writes `SHOW ENGINE INNODB STATUS` output to it every 15 seconds, approximately.

The `innodb_status.pid` file is not created by default. To create it, start `mysqld` with the `--innodb-status-file` option. InnoDB removes the file when the server is shut down normally. If an abnormal shutdown occurs, the status file may have to be removed manually.

The `--innodb-status-file` option is intended for temporary use, as `SHOW ENGINE INNODB STATUS` output generation can affect performance, and the `innodb_status.pid` file can become quite large over time.

For related information, see [Section 17.17.2, “Enabling InnoDB Monitors”](#).

## InnoDB System Variables

- `innodb_adaptive_flushing`

Command-Line Format	<code>--innodb-adaptive-flushing[={OFF ON}]</code>
System Variable	<code>innodb_adaptive_flushing</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	ON

Specifies whether to dynamically adjust the rate of flushing [dirty pages](#) in the InnoDB buffer pool based on the workload. Adjusting the flush rate dynamically is intended to avoid bursts of I/O activity. This setting is enabled by default. See [Section 17.8.3.5, “Configuring Buffer Pool Flushing”](#) for more information. For general I/O tuning advice, see [Section 10.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_adaptive_flushing_lwm`

Command-Line Format	<code>--innodb-adaptive-flushing-lwm=#</code>
System Variable	<code>innodb_adaptive_flushing_lwm</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer

Default Value	10
Minimum Value	0
Maximum Value	70

Defines the low water mark representing percentage of redo log capacity at which [adaptive flushing](#) is enabled. For more information, see [Section 17.8.3.5, “Configuring Buffer Pool Flushing”](#).

- [innodb\\_adaptive\\_hash\\_index](#)

Command-Line Format	<code>--innodb-adaptive-hash-index[={OFF ON}]</code>
System Variable	<a href="#">innodb_adaptive_hash_index</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Boolean
Default Value	OFF

Whether the [InnoDB adaptive hash index](#) is enabled or disabled. It may be desirable, depending on your workload, to dynamically enable or disable [adaptive hash indexing](#) to improve query performance. Because the adaptive hash index may not be useful for all workloads, conduct benchmarks with it both enabled and disabled, using realistic workloads. See [Section 17.5.3, “Adaptive Hash Index”](#) for details.

This variable is disabled by default. You can modify this parameter using the [SET GLOBAL](#) statement, without restarting the server. Changing the setting at runtime requires privileges sufficient to set global system variables. See [Section 7.1.9.1, “System Variable Privileges”](#). You can also use `--innodb-adaptive-hash-index` at server startup to enable it.

Disabling the adaptive hash index empties the hash table immediately. Normal operations can continue while the hash table is emptied, and executing queries that were using the hash table access the index B-trees directly instead. When the adaptive hash index is re-enabled, the hash table is populated again during normal operation.

Before MySQL 8.4, this option was enabled by default.

- [innodb\\_adaptive\\_hash\\_index\\_parts](#)

Command-Line Format	<code>--innodb-adaptive-hash-index-parts=#</code>
System Variable	<a href="#">innodb_adaptive_hash_index_parts</a>
Scope	Global
Dynamic	No
<a href="#">SET_VAR</a> Hint Applies	No
Type	Numeric
Default Value	8
Minimum Value	1

Maximum Value	512
---------------	-----

Partitions the adaptive hash index search system. Each index is bound to a specific partition, with each partition protected by a separate latch.

The adaptive hash index search system is partitioned into 8 parts by default. The maximum setting is 512.

For related information, see [Section 17.5.3, “Adaptive Hash Index”](#).

- [innodb\\_adaptive\\_max\\_sleep\\_delay](#)

Command-Line Format	<code>--innodb-adaptive-max-sleep-delay=#</code>
System Variable	<a href="#">innodb_adaptive_max_sleep_delay</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	150000
Minimum Value	0
Maximum Value	1000000
Unit	microseconds

Permits InnoDB to automatically adjust the value of [innodb\\_thread\\_sleep\\_delay](#) up or down according to the current workload. Any nonzero value enables automated, dynamic adjustment of the [innodb\\_thread\\_sleep\\_delay](#) value, up to the maximum value specified in the [innodb\\_adaptive\\_max\\_sleep\\_delay](#) option. The value represents the number of microseconds. This option can be useful in busy systems, with greater than 16 InnoDB threads. (In practice, it is most valuable for MySQL systems with hundreds or thousands of simultaneous connections.)

For more information, see [Section 17.8.4, “Configuring Thread Concurrency for InnoDB”](#).

- [innodb\\_autoextend\\_increment](#)

Command-Line Format	<code>--innodb-autoextend-increment=#</code>
System Variable	<a href="#">innodb_autoextend_increment</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	64
Minimum Value	1
Maximum Value	1000
Unit	megabytes

The increment size (in megabytes) for extending the size of an auto-extending InnoDB system tablespace file when it becomes full. The default value is 64. For related information, see [System Tablespace Data File Configuration](#), and [Resizing the System Tablespace](#).

The `innodb_autoextend_increment` setting does not affect [file-per-table](#) tablespace files or [general tablespace](#) files. These files are auto-extending regardless of the `innodb_autoextend_increment` setting. The initial extensions are by small amounts, after which extensions occur in increments of 4MB.

- `innodb_autoinc_lock_mode`

Command-Line Format	<code>--innodb-autoinc-lock-mode=#</code>
System Variable	<code>innodb_autoinc_lock_mode</code>
Scope	Global
Dynamic	No
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	2
Valid Values	0 1 2

The [lock mode](#) to use for generating [auto-increment](#) values. Permissible values are 0, 1, or 2, for traditional, consecutive, or interleaved, respectively.

The default setting is 2 (interleaved), for compatibility with row-based replication.

For the characteristics of each lock mode, see [InnoDB AUTO\\_INCREMENT Lock Modes](#).

- `innodb_background_drop_list_empty`

Command-Line Format	<code>--innodb-background-drop-list-empty[={OFF ON}]</code>
System Variable	<code>innodb_background_drop_list_empty</code>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Boolean
Default Value	OFF

Enabling the `innodb_background_drop_list_empty` debug option helps avoid test case failures by delaying table creation until the background drop list is empty. For example, if test case A places table `t1` on the background drop list, test case B waits until the background drop list is empty before creating table `t1`.

- `innodb_buffer_pool_chunk_size`

Command-Line Format	<code>--innodb-buffer-pool-chunk-size=#</code>
System Variable	<code>innodb_buffer_pool_chunk_size</code>
Scope	Global
Dynamic	No

SET_VAR Hint Applies	No
Type	Integer
Default Value	134217728
Minimum Value	1048576
Maximum Value	<code>innodb_buffer_pool_size / innodb_buffer_pool_instances</code>
Unit	bytes

`innodb_buffer_pool_chunk_size` defines the chunk size for InnoDB buffer pool resizing operations.

To avoid copying all buffer pool pages during resizing operations, the operation is performed in “chunks”. By default, `innodb_buffer_pool_chunk_size` is 128MB (134217728 bytes). The number of pages contained in a chunk depends on the value of `innodb_page_size`. `innodb_buffer_pool_chunk_size` can be increased or decreased in units of 1MB (1048576 bytes).

The following conditions apply when altering the `innodb_buffer_pool_chunk_size` value:

- If `innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances` is larger than the current buffer pool size when the buffer pool is initialized, `innodb_buffer_pool_chunk_size` is truncated to `innodb_buffer_pool_size / innodb_buffer_pool_instances`.
- Buffer pool size must always be equal to or a multiple of `innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances`. If you alter `innodb_buffer_pool_chunk_size`, `innodb_buffer_pool_size` is automatically rounded to a value that is equal to or a multiple of `innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances`. The adjustment occurs when the buffer pool is initialized.

#### Important

Care should be taken when changing `innodb_buffer_pool_chunk_size`, as changing this value can automatically increase the size of the buffer pool. Before changing `innodb_buffer_pool_chunk_size`, calculate its effect on `innodb_buffer_pool_size` to ensure that the resulting buffer pool size is acceptable.

To avoid potential performance issues, the number of chunks (`innodb_buffer_pool_size / innodb_buffer_pool_chunk_size`) should not exceed 1000.

The `innodb_buffer_pool_size` variable is dynamic, which permits resizing the buffer pool while the server is online. However, the buffer pool size must be equal to or a multiple of `innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances`, and changing either of those variable settings requires restarting the server.

See [Section 17.8.3.1, “Configuring InnoDB Buffer Pool Size”](#) for more information.

- `innodb_buffer_pool_debug`

Command-Line Format	<code>--innodb-buffer-pool-debug[={OFF ON}]</code>
System Variable	<code>innodb_buffer_pool_debug</code>
Scope	Global
Dynamic	No

<a href="#">SET_VAR</a> Hint Applies	No
Type	Boolean
Default Value	<a href="#">OFF</a>

Enabling this option permits multiple buffer pool instances when the buffer pool is less than 1GB in size, ignoring the 1GB minimum buffer pool size constraint imposed on [innodb\\_buffer\\_pool\\_instances](#). The [innodb\\_buffer\\_pool\\_debug](#) option is only available if debugging support is compiled in using the [WITH\\_DEBUG](#) CMake option.

- [innodb\\_buffer\\_pool\\_dump\\_at\\_shutdown](#)

Command-Line Format	<code>--innodb-buffer-pool-dump-at-shutdown[={OFF ON}]</code>
System Variable	<a href="#">innodb_buffer_pool_dump_at_shutdown</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Boolean
Default Value	<a href="#">ON</a>

Specifies whether to record the pages cached in the [InnoDB buffer pool](#) when the MySQL server is shut down, to shorten the [warmup](#) process at the next restart. Typically used in combination with [innodb\\_buffer\\_pool\\_load\\_at\\_startup](#). The [innodb\\_buffer\\_pool\\_dump\\_pct](#) option defines the percentage of most recently used buffer pool pages to dump.

Both [innodb\\_buffer\\_pool\\_dump\\_at\\_shutdown](#) and [innodb\\_buffer\\_pool\\_load\\_at\\_startup](#) are enabled by default.

For more information, see [Section 17.8.3.6, “Saving and Restoring the Buffer Pool State”](#).

- [innodb\\_buffer\\_pool\\_dump\\_now](#)

Command-Line Format	<code>--innodb-buffer-pool-dump-now[={OFF ON}]</code>
System Variable	<a href="#">innodb_buffer_pool_dump_now</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Boolean

Default Value	OFF
---------------	-----

Immediately makes a record of pages cached in the [InnoDB buffer pool](#). Typically used in combination with [innodb\\_buffer\\_pool\\_load\\_now](#).

Enabling [innodb\\_buffer\\_pool\\_dump\\_now](#) triggers the recording action but does not alter the variable setting, which always remains `OFF` or `0`. To view buffer pool dump status after triggering a dump, query the [Innodb\\_buffer\\_pool\\_dump\\_status](#) variable.

Enabling [innodb\\_buffer\\_pool\\_dump\\_now](#) triggers the dump action but does not alter the variable setting, which always remains `OFF` or `0`. To view buffer pool dump status after triggering a dump, query the [Innodb\\_buffer\\_pool\\_dump\\_status](#) variable.

For more information, see [Section 17.8.3.6, “Saving and Restoring the Buffer Pool State”](#).

- [innodb\\_buffer\\_pool\\_dump\\_pct](#)

Command-Line Format	<code>--innodb-buffer-pool-dump-pct=#</code>
System Variable	<a href="#">innodb_buffer_pool_dump_pct</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	25
Minimum Value	1
Maximum Value	100

Specifies the percentage of the most recently used pages for each buffer pool to read out and dump. The range is 1 to 100. The default value is 25. For example, if there are 4 buffer pools with 100 pages each, and [innodb\\_buffer\\_pool\\_dump\\_pct](#) is set to 25, the 25 most recently used pages from each buffer pool are dumped.

- [innodb\\_buffer\\_pool\\_filename](#)

Command-Line Format	<code>--innodb-buffer-pool-filename=file_name</code>
System Variable	<a href="#">innodb_buffer_pool_filename</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	File name
Default Value	<a href="#">ib_buffer_pool</a>

Specifies the name of the file that holds the list of tablespace IDs and page IDs produced by [innodb\\_buffer\\_pool\\_dump\\_at\\_shutdown](#) or [innodb\\_buffer\\_pool\\_dump\\_now](#). Tablespace IDs and page IDs are saved in the following format: `space, page_id`. By default, the file is named

`ib_buffer_pool` and is located in the `InnoDB` data directory. A non-default location must be specified relative to the data directory.

A file name can be specified at runtime, using a `SET` statement:

```
SET GLOBAL innodb_buffer_pool_filename='file_name';
```

You can also specify a file name at startup, in a startup string or MySQL configuration file. When specifying a file name at startup, the file must exist or `InnoDB` returns a startup error indicating that there is no such file or directory.

For more information, see [Section 17.8.3.6, “Saving and Restoring the Buffer Pool State”](#).

- `innodb_buffer_pool_in_core_file`

Command-Line Format	<code>--innodb-buffer-pool-in-core-file[={OFF ON}]</code>
System Variable	<code>innodb_buffer_pool_in_core_file</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Disabling (default) the `innodb_buffer_pool_in_core_file` variable reduces the size of core files by excluding `InnoDB` buffer pool pages.

To use this variable, the `core_file` variable must be enabled, and to disable this option the operating system must support the `MADV_DONTDUMP` non-POSIX extension to `madvise()`, which is supported in Linux 3.4 and later. For more information, see [Section 17.8.3.7, “Excluding or Including Buffer Pool Pages from Core Files”](#).

This is disabled by default on systems that support `MADV_DONTDUMP`, which is typically only Linux and not macOS or Windows.

Before MySQL 8.4, this option was enabled by default.

- `innodb_buffer_pool_instances`

Command-Line Format	<code>--innodb-buffer-pool-instances=#</code>
System Variable	<code>innodb_buffer_pool_instances</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	<a href="#">see description</a>
Minimum Value	1

Maximum Value	64
---------------	----

The number of regions that the [InnoDB buffer pool](#) is divided into. For systems with buffer pools in the multi-gigabyte range, dividing the buffer pool into separate instances can improve concurrency, by reducing contention as different threads read and write to cached pages. Each page that is stored in or read from the buffer pool is assigned to one of the buffer pool instances randomly, using a hashing function. Each buffer pool manages its own free lists, [flush lists](#), [LRUs](#), and all other data structures connected to a buffer pool, and is protected by its own buffer pool [mutex](#).

The total buffer pool size is divided among all the buffer pools. For best efficiency, specify a combination of [innodb\\_buffer\\_pool\\_instances](#) and [innodb\\_buffer\\_pool\\_size](#) so that each buffer pool instance is at least 1GB.

If [innodb\\_buffer\\_pool\\_size](#) ≤ 1 GiB, then the default [innodb\\_buffer\\_pool\\_instances](#) value is 1.

If [innodb\\_buffer\\_pool\\_size](#) > 1 GiB, then the default [innodb\\_buffer\\_pool\\_instances](#) value is the minimum value from the following two calculated hints, within a range of 1-64:

- Buffer pool hint: calculated as 1/2 of ([innodb\\_buffer\\_pool\\_size](#) / [innodb\\_buffer\\_pool\\_chunk\\_size](#))
- CPU hint: calculated as 1/4 of available logical processors

For related information, see [Section 17.8.3.1, “Configuring InnoDB Buffer Pool Size”](#).

- [innodb\\_buffer\\_pool\\_load\\_abort](#)

Command-Line Format	<code>--innodb-buffer-pool-load-abort[={OFF ON}]</code>
System Variable	<a href="#">innodb_buffer_pool_load_abort</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Interrupts the process of restoring [InnoDB buffer pool](#) contents triggered by [innodb\\_buffer\\_pool\\_load\\_at\\_startup](#) or [innodb\\_buffer\\_pool\\_load\\_now](#).

Enabling [innodb\\_buffer\\_pool\\_load\\_abort](#) triggers the abort action but does not alter the variable setting, which always remains `OFF` or 0. To view buffer pool load status after triggering an abort action, query the [Innodb\\_buffer\\_pool\\_load\\_status](#) variable.

For more information, see [Section 17.8.3.6, “Saving and Restoring the Buffer Pool State”](#).

- [innodb\\_buffer\\_pool\\_load\\_at\\_startup](#)

Command-Line Format	<code>--innodb-buffer-pool-load-at-startup[={OFF ON}]</code>
System Variable	<a href="#">innodb_buffer_pool_load_at_startup</a>
Scope	Global

Dynamic	No
<a href="#">SET_VAR</a> Hint Applies	No
Type	Boolean
Default Value	ON

Specifies that, on MySQL server startup, the [InnoDB buffer pool](#) is automatically [warmed up](#) by loading the same pages it held at an earlier time. Typically used in combination with [innodb\\_buffer\\_pool\\_dump\\_at\\_shutdown](#).

Both [innodb\\_buffer\\_pool\\_dump\\_at\\_shutdown](#) and [innodb\\_buffer\\_pool\\_load\\_at\\_startup](#) are enabled by default.

For more information, see [Section 17.8.3.6, “Saving and Restoring the Buffer Pool State”](#).

- [innodb\\_buffer\\_pool\\_load\\_now](#)

Command-Line Format	<code>--innodb-buffer-pool-load-now[={OFF ON}]</code>
System Variable	<a href="#">innodb_buffer_pool_load_now</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Boolean
Default Value	OFF

Immediately [warms up](#) the [InnoDB buffer pool](#) by loading data pages without waiting for a server restart. Can be useful to bring cache memory back to a known state during benchmarking or to ready the MySQL server to resume its normal workload after running queries for reports or maintenance.

Enabling [innodb\\_buffer\\_pool\\_load\\_now](#) triggers the load action but does not alter the variable setting, which always remains `OFF` or `0`. To view buffer pool load progress after triggering a load, query the [InnoDB\\_buffer\\_pool\\_load\\_status](#) variable.

For more information, see [Section 17.8.3.6, “Saving and Restoring the Buffer Pool State”](#).

- [innodb\\_buffer\\_pool\\_size](#)

Command-Line Format	<code>--innodb-buffer-pool-size=#</code>
System Variable	<a href="#">innodb_buffer_pool_size</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	134217728
Minimum Value	5242880
Maximum Value (64-bit platforms)	$2^{**64}-1$
Maximum Value (32-bit platforms)	$2^{**32}-1$

Unit	bytes
------	-------

The size in bytes of the [buffer pool](#), the memory area where [InnoDB](#) caches table and index data. The default value is 134217728 bytes (128MB). The maximum value depends on the CPU architecture; the maximum is 4294967295 ( $2^{32}-1$ ) on 32-bit systems and 18446744073709551615 ( $2^{64}-1$ ) on 64-bit systems. On 32-bit systems, the CPU architecture and operating system may impose a lower practical maximum size than the stated maximum. When the size of the buffer pool is greater than 1GB, setting [innodb\\_buffer\\_pool\\_instances](#) to a value greater than 1 can improve the scalability on a busy server.

A larger buffer pool requires less disk I/O to access the same table data more than once. On a dedicated database server, you might set the buffer pool size to 80% of the machine's physical memory size. Be aware of the following potential issues when configuring buffer pool size, and be prepared to scale back the size of the buffer pool if necessary.

- Competition for physical memory can cause paging in the operating system.
- [InnoDB](#) reserves additional memory for buffers and control structures, so that the total allocated space is approximately 10% greater than the specified buffer pool size.
- Address space for the buffer pool must be contiguous, which can be an issue on Windows systems with DLLs that load at specific addresses.
- The time to initialize the buffer pool is roughly proportional to its size. On instances with large buffer pools, initialization time might be significant. To reduce the initialization period, you can save the buffer pool state at server shutdown and restore it at server startup. See [Section 17.8.3.6, “Saving and Restoring the Buffer Pool State”](#).

When you increase or decrease buffer pool size, the operation is performed in chunks. Chunk size is defined by the [innodb\\_buffer\\_pool\\_chunk\\_size](#) variable, which has a default of 128 MB.

Buffer pool size must always be equal to or a multiple of [innodb\\_buffer\\_pool\\_chunk\\_size](#) \* [innodb\\_buffer\\_pool\\_instances](#). If you alter the buffer pool size to a value that is not equal to or a multiple of [innodb\\_buffer\\_pool\\_chunk\\_size](#) \* [innodb\\_buffer\\_pool\\_instances](#), buffer pool size is automatically adjusted to a value that is equal to or a multiple of [innodb\\_buffer\\_pool\\_chunk\\_size](#) \* [innodb\\_buffer\\_pool\\_instances](#).

[innodb\\_buffer\\_pool\\_size](#) can be set dynamically, which allows you to resize the buffer pool without restarting the server. The [Innodb\\_buffer\\_pool\\_resize\\_status](#) status variable reports the status of online buffer pool resizing operations. See [Section 17.8.3.1, “Configuring InnoDB Buffer Pool Size”](#) for more information.

If the server is started with `--innodb-dedicated-server`, the value of [innodb\\_buffer\\_pool\\_size](#) is set automatically if it is not explicitly defined. For more information, see [Section 17.8.12, “Enabling Automatic InnoDB Configuration for a Dedicated MySQL Server”](#).

- [innodb\\_change\\_buffer\\_max\\_size](#)

Command-Line Format	<code>--innodb-change-buffer-max-size=#</code>
System Variable	<a href="#">innodb_change_buffer_max_size</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No

Type	Integer
Default Value	25
Minimum Value	0
Maximum Value	50

Maximum size for the [InnoDB change buffer](#), as a percentage of the total size of the [buffer pool](#). You might increase this value for a MySQL server with heavy insert, update, and delete activity, or decrease it for a MySQL server with unchanging data used for reporting. For more information, see [Section 17.5.2, “Change Buffer”](#). For general I/O tuning advice, see [Section 10.5.8, “Optimizing InnoDB Disk I/O”](#).

- [innodb\\_change\\_buffering](#)

Command-Line Format	<code>--innodb-change-buffering=value</code>
System Variable	<a href="#">innodb_change_buffering</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Enumeration
Default Value	<a href="#">none</a>
Valid Values	<a href="#">none</a> <a href="#">inserts</a> <a href="#">deletes</a> <a href="#">changes</a> <a href="#">purges</a> <a href="#">all</a>

Whether [InnoDB](#) performs [change buffering](#), an optimization that delays write operations to secondary indexes so that the I/O operations can be performed sequentially. Permitted values are described in the following table. Values may also be specified numerically.

**Table 17.24 Permitted Values for [innodb\\_change\\_buffering](#)**

Value	Numeric Value	Description
<a href="#">none</a>	0	Default. Do not buffer any operations.
<a href="#">inserts</a>	1	Buffer insert operations.
<a href="#">deletes</a>	2	Buffer delete marking operations; strictly speaking, the writes that mark index records for later deletion during a purge operation.
<a href="#">changes</a>	3	Buffer inserts and delete-marking operations.

Value	Numeric Value	Description
<code>purges</code>	4	Buffer the physical deletion operations that happen in the background.
<code>all</code>	5	Buffer inserts, delete-marking operations, and purges.

Before MySQL 8.4, the default value was `all`.

For more information, see [Section 17.5.2, “Change Buffer”](#). For general I/O tuning advice, see [Section 10.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_change_buffering_debug`

Command-Line Format	<code>--innodb-change-buffering-debug=#</code>
System Variable	<code>innodb_change_buffering_debug</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	2

Sets a debug flag for `InnoDB` change buffering. A value of 1 forces all changes to the change buffer. A value of 2 causes an unexpected exit at merge. A default value of 0 indicates that the change buffering debug flag is not set. This option is only available when debugging support is compiled in using the `WITH_DEBUG CMake` option.

- `innodb_checkpoint_disabled`

Command-Line Format	<code>--innodb-checkpoint-disabled[={OFF ON}]</code>
System Variable	<code>innodb_checkpoint_disabled</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

This is a debug option that is only intended for expert debugging use. It disables checkpoints so that a deliberate server exit always initiates `InnoDB` recovery. It should only be enabled for a short interval, typically before running DML operations that write redo log entries that would require recovery following a server exit. This option is only available if debugging support is compiled in using the `WITH_DEBUG CMake` option.

- `innodb_checksum_algorithm`

Command-Line Format	<code>--innodb-checksum-algorithm=value</code>
System Variable	<code>innodb_checksum_algorithm</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	<code>crc32</code>
Valid Values	<code>crc32</code>  <code>strict_crc32</code>  <code>innodb</code>  <code>strict_innodb</code>  <code>none</code>  <code>strict_none</code>

Specifies how to generate and verify the `checksum` stored in the disk blocks of `InnoDB tablespaces`. The default value for `innodb_checksum_algorithm` is `crc32`.

The value `innodb` is backward-compatible with earlier versions of MySQL. The value `crc32` uses an algorithm that is faster to compute the checksum for every modified block, and to check the checksums for each disk read. It scans blocks 64 bits at a time, which is faster than the `innodb` checksum algorithm, which scans blocks 8 bits at a time. The value `none` writes a constant value in the checksum field rather than computing a value based on the block data. The blocks in a tablespace can use a mix of old, new, and no checksum values, being updated gradually as the data is modified; once blocks in a tablespace are modified to use the `crc32` algorithm, the associated tables cannot be read by earlier versions of MySQL.

The strict form of a checksum algorithm reports an error if it encounters a valid but non-matching checksum value in a tablespace. It is recommended that you only use strict settings in a new instance, to set up tablespaces for the first time. Strict settings are somewhat faster, because they do not need to compute all checksum values during disk reads.

The following table shows the difference between the `none`, `innodb`, and `crc32` option values, and their strict counterparts. `none`, `innodb`, and `crc32` write the specified type of checksum value into each data block, but for compatibility accept other checksum values when verifying a block during a read operation. Strict settings also accept valid checksum values but print an error message when a valid non-matching checksum value is encountered. Using the strict form can make verification faster if all `InnoDB` data files in an instance are created under an identical `innodb_checksum_algorithm` value.

**Table 17.25 Permitted `innodb_checksum_algorithm` Values**

Value	Generated checksum (when writing)	Permitted checksums (when reading)
<code>none</code>	A constant number.	Any of the checksums generated by <code>none</code> , <code>innodb</code> , or <code>crc32</code> .

Value	Generated checksum (when writing)	Permitted checksums (when reading)
innodb	A checksum calculated in software, using the original algorithm from InnoDB.	Any of the checksums generated by <code>none</code> , <code>innodb</code> , or <code>crc32</code> .
crc32	A checksum calculated using the <code>crc32</code> algorithm, possibly done with a hardware assist.	Any of the checksums generated by <code>none</code> , <code>innodb</code> , or <code>crc32</code> .
strict_none	A constant number	Any of the checksums generated by <code>none</code> , <code>innodb</code> , or <code>crc32</code> . InnoDB prints an error message if a valid but non-matching checksum is encountered.
strict_innodb	A checksum calculated in software, using the original algorithm from InnoDB.	Any of the checksums generated by <code>none</code> , <code>innodb</code> , or <code>crc32</code> . InnoDB prints an error message if a valid but non-matching checksum is encountered.
strict_crc32	A checksum calculated using the <code>crc32</code> algorithm, possibly done with a hardware assist.	Any of the checksums generated by <code>none</code> , <code>innodb</code> , or <code>crc32</code> . InnoDB prints an error message if a valid but non-matching checksum is encountered.

- `innodb_cmp_per_index_enabled`

Command-Line Format	<code>--innodb-cmp-per-index-enabled[={OFF ON}]</code>
System Variable	<code>innodb_cmp_per_index_enabled</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Enables per-index compression-related statistics in the Information Schema `INNODB_CMP_PER_INDEX` table. Because these statistics can be expensive to gather, only enable this option on development, test, or replica instances during performance tuning related to InnoDB compressed tables.

For more information, see [Section 28.4.8, “The INFORMATION\\_SCHEMA INNODB\\_CMP\\_PER\\_INDEX and INNODB\\_CMP\\_PER\\_INDEX\\_RESET Tables”](#), and [Section 17.9.1.4, “Monitoring InnoDB Table Compression at Runtime”](#).

- `innodb_commit_concurrency`

Command-Line Format	<code>--innodb-commit-concurrency=#</code>
System Variable	<code>innodb_commit_concurrency</code>
Scope	Global

Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	1000

The number of [threads](#) that can [commit](#) at the same time. A value of 0 (the default) permits any number of [transactions](#) to commit simultaneously.

The value of [innodb\\_commit\\_concurrency](#) cannot be changed at runtime from zero to nonzero or vice versa. The value can be changed from one nonzero value to another.

- [innodb\\_compress\\_debug](#)

Command-Line Format	<a href="#">--innodb-compress-debug=value</a>
System Variable	<a href="#">innodb_compress_debug</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Enumeration
Default Value	<a href="#">none</a>
Valid Values	<a href="#">none</a>  <a href="#">zlib</a>  <a href="#">lz4</a>  <a href="#">lz4hc</a>

Compresses all tables using a specified compression algorithm without having to define a [COMPRESSION](#) attribute for each table. This option is only available if debugging support is compiled in using the [WITH\\_DEBUG](#) CMake option.

For related information, see [Section 17.9.2, “InnoDB Page Compression”](#).

- [innodb\\_compression\\_failure\\_threshold\\_pct](#)

Command-Line Format	<a href="#">--innodb-compression-failure-threshold-pct=#</a>
System Variable	<a href="#">innodb_compression_failure_threshold_pct</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	5
Minimum Value	0

Maximum Value	100
---------------	-----

Defines the compression failure rate threshold for a table, as a percentage, at which point MySQL begins adding padding within [compressed](#) pages to avoid expensive [compression failures](#). When this threshold is passed, MySQL begins to leave additional free space within each new compressed page, dynamically adjusting the amount of free space up to the percentage of page size specified by [innodb\\_compression\\_pad\\_pct\\_max](#). A value of zero disables the mechanism that monitors compression efficiency and dynamically adjusts the padding amount.

For more information, see [Section 17.9.1.6, “Compression for OLTP Workloads”](#).

- [innodb\\_compression\\_level](#)

Command-Line Format	<code>--innodb-compression-level=#</code>
System Variable	<a href="#">innodb_compression_level</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	6
Minimum Value	0
Maximum Value	9

Specifies the level of zlib compression to use for [InnoDB compressed](#) tables and indexes. A higher value lets you fit more data onto a storage device, at the expense of more CPU overhead during compression. A lower value lets you reduce CPU overhead when storage space is not critical, or you expect the data is not especially compressible.

For more information, see [Section 17.9.1.6, “Compression for OLTP Workloads”](#).

- [innodb\\_compression\\_pad\\_pct\\_max](#)

Command-Line Format	<code>--innodb-compression-pad-pct-max=#</code>
System Variable	<a href="#">innodb_compression_pad_pct_max</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	50
Minimum Value	0
Maximum Value	75

Specifies the maximum percentage that can be reserved as free space within each compressed [page](#), allowing room to reorganize the data and modification log within the page when a [compressed](#) table or index is updated and the data might be recompressed. Only applies when

`innodb_compression_failure_threshold_pct` is set to a nonzero value, and the rate of [compression failures](#) passes the cutoff point.

For more information, see [Section 17.9.1.6, “Compression for OLTP Workloads”](#).

- `innodb_concurrency_tickets`

Command-Line Format	<code>--innodb-concurrency-tickets=#</code>
System Variable	<code>innodb_concurrency_tickets</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	5000
Minimum Value	1
Maximum Value	4294967295

Determines the number of [threads](#) that can enter [InnoDB](#) concurrently. A thread is placed in a queue when it tries to enter [InnoDB](#) if the number of threads has already reached the concurrency limit. When a thread is permitted to enter [InnoDB](#), it is given a number of “tickets” equal to the value of `innodb_concurrency_tickets`, and the thread can enter and leave [InnoDB](#) freely until it has used up its tickets. After that point, the thread again becomes subject to the concurrency check (and possible queuing) the next time it tries to enter [InnoDB](#). The default value is 5000.

With a small `innodb_concurrency_tickets` value, small transactions that only need to process a few rows compete fairly with larger transactions that process many rows. The disadvantage of a small `innodb_concurrency_tickets` value is that large transactions must loop through the queue many times before they can complete, which extends the amount of time required to complete their task.

With a large `innodb_concurrency_tickets` value, large transactions spend less time waiting for a position at the end of the queue (controlled by `innodb_thread_concurrency`) and more time retrieving rows. Large transactions also require fewer trips through the queue to complete their task. The disadvantage of a large `innodb_concurrency_tickets` value is that too many large transactions running at the same time can starve smaller transactions by making them wait a longer time before executing.

With a nonzero `innodb_thread_concurrency` value, you may need to adjust the `innodb_concurrency_tickets` value up or down to find the optimal balance between larger and smaller transactions. The `SHOW ENGINE INNODB STATUS` report shows the number of tickets remaining for an executing transaction in its current pass through the queue. This data may also be obtained from the `TRX_CONCURRENCY_TICKETS` column of the Information Schema `INNODB_TRX` table.

For more information, see [Section 17.8.4, “Configuring Thread Concurrency for InnoDB”](#).

- `innodb_data_file_path`

Command-Line Format	<code>--innodb-data-file-path=file_name</code>
System Variable	<code>innodb_data_file_path</code>
Scope	Global
Dynamic	No

<a href="#">SET_VAR</a> Hint Applies	No
Type	String
Default Value	<code>ibdata1:12M:autoextend</code>

Defines the name, size, and attributes of InnoDB system tablespace data files. If you do not specify a value for `innodb_data_file_path`, the default behavior is to create a single auto-extending data file, slightly larger than 12MB, named `ibdata1`.

The full syntax for a data file specification includes the file name, file size, `autoextend` attribute, and `max` attribute:

```
file_name:file_size[:autoextend[:max:max_file_size]]
```

File sizes are specified in kilobytes, megabytes, or gigabytes by appending `K`, `M` or `G` to the size value. If specifying the data file size in kilobytes, do so in multiples of 1024. Otherwise, KB values are rounded to nearest megabyte (MB) boundary. The sum of file sizes must be, at a minimum, slightly larger than 12MB.

For additional configuration information, see [System Tablespace Data File Configuration](#). For resizing instructions, see [Resizing the System Tablespace](#).

- `innodb_data_home_dir`

Command-Line Format	<code>--innodb-data-home-dir=dir_name</code>
System Variable	<code>innodb_data_home_dir</code>
Scope	Global
Dynamic	No
<a href="#">SET_VAR</a> Hint Applies	No
Type	Directory name

The common part of the directory path for InnoDB [system tablespace](#) data files. The default value is the MySQL `data` directory. The setting is concatenated with the `innodb_data_file_path` setting, unless that setting is defined with an absolute path.

A trailing slash is required when specifying a value for `innodb_data_home_dir`. For example:

```
[mysqld]
innodb_data_home_dir = /path/to/myibdata/
```

This setting does not affect the location of [file-per-table](#) tablespaces.

For related information, see [Section 17.8.1, “InnoDB Startup Configuration”](#).

- `innodb_ddl_buffer_size`

Command-Line Format	<code>--innodb-ddl-buffer-size=#</code>
System Variable	<code>innodb_ddl_buffer_size</code>
Scope	Session
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer

Default Value	1048576
Minimum Value	65536
Maximum Value	4294967295
Unit	bytes

Defines the maximum buffer size for DDL operations. The default setting is 1048576 bytes (approximately 1 MB). Applies to online DDL operations that create or rebuild secondary indexes. See [Section 17.12.4, “Online DDL Memory Management”](#). The maximum buffer size per DDL thread is the maximum buffer size divided by the number of DDL threads (`innodb_ddl_buffer_size/innodb_ddl_threads`).

- `innodb_ddl_log_crash_reset_debug`

Command-Line Format	<code>--innodb-ddl-log-crash-reset-debug[={OFF ON}]</code>
System Variable	<code>innodb_ddl_log_crash_reset_debug</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	OFF

Enable this debug option to reset DDL log crash injection counters to 1. This option is only available when debugging support is compiled in using the `WITH_DEBUG CMake` option.

- `innodb_ddl_threads`

Command-Line Format	<code>--innodb-ddl-threads=#</code>
System Variable	<code>innodb_ddl_threads</code>
Scope	Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	4
Minimum Value	1
Maximum Value	64

Defines the maximum number of parallel threads for the sort and build phases of index creation. Applies to online DDL operations that create or rebuild secondary indexes. For related information, see [Section 17.12.5, “Configuring Parallel Threads for Online DDL Operations”](#), and [Section 17.12.4, “Online DDL Memory Management”](#).

- `innodb_deadlock_detect`

Command-Line Format	<code>--innodb-deadlock-detect[={OFF ON}]</code>
System Variable	<code>innodb_deadlock_detect</code>
Scope	Global

Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Boolean
Default Value	<a href="#">ON</a>

This option is used to disable deadlock detection. On high concurrency systems, deadlock detection can cause a slowdown when numerous threads wait for the same lock. At times, it may be more efficient to disable deadlock detection and rely on the [innodb\\_lock\\_wait\\_timeout](#) setting for transaction rollback when a deadlock occurs.

For related information, see [Section 17.7.5.2, “Deadlock Detection”](#).

- [innodb\\_default\\_row\\_format](#)

Command-Line Format	<a href="#">--innodb-default-row-format=value</a>
System Variable	<a href="#">innodb_default_row_format</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Enumeration
Default Value	<a href="#">DYNAMIC</a>
Valid Values	<a href="#">REDUNDANT</a>  <a href="#">COMPACT</a>  <a href="#">DYNAMIC</a>

The [innodb\\_default\\_row\\_format](#) option defines the default row format for InnoDB tables and user-created temporary tables. The default setting is [DYNAMIC](#). Other permitted values are [COMPACT](#) and [REDUNDANT](#). The [COMPRESSED](#) row format, which is not supported for use in the [system tablespace](#), cannot be defined as the default.

Newly created tables use the row format defined by [innodb\\_default\\_row\\_format](#) when a [ROW\\_FORMAT](#) option is not specified explicitly or when [ROW\\_FORMAT=DEFAULT](#) is used.

When a [ROW\\_FORMAT](#) option is not specified explicitly or when [ROW\\_FORMAT=DEFAULT](#) is used, any operation that rebuilds a table also silently changes the row format of the table to the format defined by [innodb\\_default\\_row\\_format](#). For more information, see [Defining the Row Format of a Table](#).

Internal InnoDB temporary tables created by the server to process queries use the [DYNAMIC](#) row format, regardless of the [innodb\\_default\\_row\\_format](#) setting.

- [innodb\\_directories](#)

Command-Line Format	<a href="#">--innodb-directories=dir_name</a>
System Variable	<a href="#">innodb_directories</a>
Scope	Global
Dynamic	No
<a href="#">SET_VAR</a> Hint Applies	No

Type	Directory name
Default Value	<code>NULL</code>

Defines directories to scan at startup for tablespace files. This option is used when moving or restoring tablespace files to a new location while the server is offline. It is also used to specify directories of tablespace files created using an absolute path or that reside outside of the data directory.

Tablespace discovery during crash recovery relies on the `innodb_directories` setting to identify tablespaces referenced in the redo logs. For more information, see [Tablespace Discovery During Crash Recovery](#).

The default value is `NULL`, but directories defined by `innodb_data_home_dir`, `innodb_undo_directory`, and `datadir` are always appended to the `innodb_directories` argument value when InnoDB builds a list of directories to scan at startup. These directories are appended regardless of whether an `innodb_directories` setting is specified explicitly.

`innodb_directories` may be specified as an option in a startup command or in a MySQL option file. Quotes surround the argument value because otherwise some command interpreters interpret semicolon (;) as a special character. (For example, Unix shells treat it as a command terminator.)

Startup command:

```
mysqld --innodb-directories="directory_path_1;directory_path_2"
```

MySQL option file:

```
[mysqld]
innodb_directories="directory_path_1;directory_path_2"
```

Wildcard expressions cannot be used to specify directories.

The `innodb_directories` scan also traverses the subdirectories of specified directories. Duplicate directories and subdirectories are discarded from the list of directories to be scanned.

For more information, see [Section 17.6.3.6, “Moving Tablespace Files While the Server is Offline”](#).

- `innodb_disable_sort_file_cache`

Command-Line Format	<code>--innodb-disable-sort-file-cache[={OFF ON}]</code>
System Variable	<code>innodb_disable_sort_file_cache</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Disables the operating system file system cache for merge-sort temporary files. The effect is to open such files with the equivalent of `O_DIRECT`.

- `innodb_doublewrite`

Command-Line Format	<code>--innodb-doublewrite=value</code>	3391
---------------------	-----------------------------------------	------

System Variable	<code>innodb_doublewrite</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Enumeration
Default Value	<code>ON</code>
Valid Values	<code>ON</code> <code>OFF</code> <code>DETECT_AND_RECOVER</code> <code>DETECT_ONLY</code>

The `innodb_doublewrite` variable controls doublewrite buffering. Doublewrite buffering is enabled by default in most cases.

You can set `innodb_doublewrite` to `ON` or `OFF` when starting the server to enable or disable doublewrite buffering, respectively. `DETECT_AND_RECOVER` is the same as `ON`. With this setting, except that the doublewrite buffer is fully enabled, with database page content written to the doublewrite buffer where it is accessed during recovery to fix incomplete page writes. With `DETECT_ONLY`, only metadata is written to the doublewrite buffer. Database page content is not written to the doublewrite buffer, and recovery does not use the doublewrite buffer to fix incomplete page writes. This lightweight setting is intended for detecting incomplete page writes only.

MySQL supports dynamic changes to the `innodb_doublewrite` setting that enables the doublewrite buffer, between `ON`, `DETECT_AND_RECOVER`, and `DETECT_ONLY`. MySQL does not support dynamic changes between a setting that enables the doublewrite buffer and `OFF` or vice versa.

If the doublewrite buffer is located on a Fusion-io device that supports atomic writes, the doublewrite buffer is automatically disabled and data file writes are performed using Fusion-io atomic writes instead. However, be aware that the `innodb_doublewrite` setting is global. When the doublewrite buffer is disabled, it is disabled for all data files including those that do not reside on Fusion-io hardware. This feature is only supported on Fusion-io hardware and is only enabled for Fusion-io NVMFS on Linux. To take full advantage of this feature, an `innodb_flush_method` setting of `O_DIRECT` is recommended.

For related information, see [Section 17.6.4, “Doublewrite Buffer”](#).

- `innodb_doublewrite_batch_size`

Command-Line Format	<code>--innodb-doublewrite-batch-size=#</code>
System Variable	<code>innodb_doublewrite_batch_size</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	<code>0</code>
Minimum Value	<code>0</code>

Maximum Value	256
---------------	-----

This variable was intended to represent the number of doublewrite pages to write in a batch. This functionality was replaced by `innodb_doublewrite_pages`.

For more information, see [Section 17.6.4, “Doublewrite Buffer”](#).

- `innodb_doublewrite_dir`

Command-Line Format	<code>--innodb-doublewrite-dir=dir_name</code>
System Variable	<code>innodb_doublewrite_dir</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Directory name

Defines the directory for doublewrite files. If no directory is specified, doublewrite files are created in the `innodb_data_home_dir` directory, which defaults to the data directory if unspecified.

For more information, see [Section 17.6.4, “Doublewrite Buffer”](#).

- `innodb_doublewrite_files`

Command-Line Format	<code>--innodb-doublewrite-files=#</code>
System Variable	<code>innodb_doublewrite_files</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	2
Minimum Value	1
Maximum Value	256

Defines the number of doublewrite files. By default, two doublewrite files are created for each buffer pool instance.

At a minimum, there are two doublewrite files. The maximum number of doublewrite files is two times the number of buffer pool instances. (The number of buffer pool instances is controlled by the `innodb_buffer_pool_instances` variable.)

For more information, see [Section 17.6.4, “Doublewrite Buffer”](#).

- `innodb_doublewrite_pages`

Command-Line Format	<code>--innodb-doublewrite-pages=#</code>
System Variable	<code>innodb_doublewrite_pages</code>
Scope	Global
Dynamic	No

<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	128
Minimum Value	1
Maximum Value	512

Defines the maximum number of doublewrite pages per thread for a batch write. If no value is specified, [innodb\\_doublewrite\\_pages](#) defaults to 128.

Before MySQL 8.4, the default value was the [innodb\\_write\\_io\\_threads](#) value, which is 4 by default.

For more information, see [Section 17.6.4, “Doublewrite Buffer”](#).

- [innodb\\_extend\\_and\\_initialize](#)

Command-Line Format	<code>--innodb=extend-and-initialize[={OFF ON}]</code>
System Variable	<a href="#">innodb_extend_and_initialize</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Boolean
Default Value	ON

Controls how space is allocated to file-per-table and general tablespaces on Linux systems.

When enabled, [InnoDB](#) writes NULLs to newly allocated pages. When disabled, space is allocated using [posix\\_fallocate\(\)](#) calls, which reserve space without physically writing NULLs.

For more information, see [Section 17.6.3.8, “Optimizing Tablespace Space Allocation on Linux”](#).

- [innodb\\_fast\\_shutdown](#)

Command-Line Format	<code>--innodb-fast-shutdown=#</code>
System Variable	<a href="#">innodb_fast_shutdown</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	1
Valid Values	0 1 2

The [InnoDB shutdown](#) mode. If the value is 0, [InnoDB](#) does a [slow shutdown](#), a full [purge](#) and a change buffer merge before shutting down. If the value is 1 (the default), [InnoDB](#) skips these operations at

shutdown, a process known as a [fast shutdown](#). If the value is 2, [InnoDB](#) flushes its logs and shuts down cold, as if MySQL had crashed; no committed transactions are lost, but the [crash recovery](#) operation makes the next startup take longer.

The slow shutdown can take minutes, or even hours in extreme cases where substantial amounts of data are still buffered. Use the slow shutdown technique before upgrading or downgrading between MySQL major releases, so that all data files are fully prepared in case the upgrade process updates the file format.

Use `innodb_fast_shutdown=2` in emergency or troubleshooting situations, to get the absolute fastest shutdown if data is at risk of corruption.

- [innodb\\_fil\\_make\\_page\\_dirty\\_debug](#)

Command-Line Format	<code>--innodb-fil-make-page-dirty-debug=#</code>
System Variable	<a href="#">innodb_fil_make_page_dirty_debug</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	$2^{32}-1$

By default, setting [innodb\\_fil\\_make\\_page\\_dirty\\_debug](#) to the ID of a tablespace immediately dirties the first page of the tablespace. If [innodb\\_saved\\_page\\_number\\_debug](#) is set to a non-default value, setting [innodb\\_fil\\_make\\_page\\_dirty\\_debug](#) dirties the specified page. The [innodb\\_fil\\_make\\_page\\_dirty\\_debug](#) option is only available if debugging support is compiled in using the `WITH_DEBUG CMake` option.

- [innodb\\_file\\_per\\_table](#)

Command-Line Format	<code>--innodb-file-per-table[={OFF ON}]</code>
System Variable	<a href="#">innodb_file_per_table</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Boolean
Default Value	ON

When [innodb\\_file\\_per\\_table](#) is enabled, tables are created in file-per-table tablespaces by default. When disabled, tables are created in the system tablespace by default. For information about file-per-table tablespaces, see [Section 17.6.3.2, “File-Per-Table Tablespaces”](#). For information about the [InnoDB](#) system tablespace, see [Section 17.6.3.1, “The System Tablespace”](#).

The [innodb\\_file\\_per\\_table](#) variable can be configured at runtime using a `SET GLOBAL` statement, specified on the command line at startup, or specified in an option file. Configuration at runtime requires

privileges sufficient to set global system variables (see [Section 7.1.9.1, “System Variable Privileges”](#)) and immediately affects the operation of all connections.

When a table that resides in a file-per-table tablespace is truncated or dropped, the freed space is returned to the operating system. Truncating or dropping a table that resides in the system tablespace only frees space in the system tablespace. Freed space in the system tablespace can be used again for InnoDB data but is not returned to the operating system, as system tablespace data files never shrink.

The `innodb_file_per-table` setting does not affect the creation of temporary tables; temporary tables are created in session temporary tablespaces. See [Section 17.6.3.5, “Temporary Tablespaces”](#).

- `innodb_fill_factor`

Command-Line Format	<code>--innodb-fill-factor=#</code>
System Variable	<code>innodb_fill_factor</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	100
Minimum Value	10
Maximum Value	100

InnoDB performs a bulk load when creating or rebuilding indexes. This method of index creation is known as a “sorted index build”.

`innodb_fill_factor` defines the percentage of space on each B-tree page that is filled during a sorted index build, with the remaining space reserved for future index growth. For example, setting `innodb_fill_factor` to 80 reserves 20 percent of the space on each B-tree page for future index growth. Actual percentages may vary. The `innodb_fill_factor` setting is interpreted as a hint rather than a hard limit.

An `innodb_fill_factor` setting of 100 leaves 1/16 of the space in clustered index pages free for future index growth.

`innodb_fill_factor` applies to both B-tree leaf and non-leaf pages. It does not apply to external pages used for `TEXT` or `BLOB` entries.

For more information, see [Section 17.6.2.3, “Sorted Index Builds”](#).

- `innodb_flush_log_at_timeout`

Command-Line Format	<code>--innodb-flush-log-at-timeout=#</code>
System Variable	<code>innodb_flush_log_at_timeout</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	1

Minimum Value	1
Maximum Value	2700
Unit	seconds

Write and flush the logs every *N* seconds. `innodb_flush_log_at_timeout` allows the timeout period between flushes to be increased in order to reduce flushing and avoid impacting performance of binary log group commit. The default setting for `innodb_flush_log_at_timeout` is once per second.

- `innodb_flush_log_at_trx_commit`

Command-Line Format	<code>--innodb-flush-log-at-trx-commit=#</code>
System Variable	<code>innodb_flush_log_at_trx_commit</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Enumeration
Default Value	1
Valid Values	0 1 2

Controls the balance between strict **ACID** compliance for **commit** operations and higher performance that is possible when commit-related I/O operations are rearranged and done in batches. You can achieve better performance by changing the default value but then you can lose transactions in a crash.

- The default setting of 1 is required for full ACID compliance. Logs are written and flushed to disk at each transaction commit.
- With a setting of 0, logs are written and flushed to disk once per second. Transactions for which logs have not been flushed can be lost in a crash.
- With a setting of 2, logs are written after each transaction commit and flushed to disk once per second. Transactions for which logs have not been flushed can be lost in a crash.
- For settings 0 and 2, once-per-second flushing is not 100% guaranteed. Flushing may occur more frequently due to DDL changes and other internal InnoDB activities that cause logs to be flushed independently of the `innodb_flush_log_at_trx_commit` setting, and sometimes less frequently due to scheduling issues. If logs are flushed once per second, up to one second of transactions can be lost in a crash. If logs are flushed more or less frequently than once per second, the amount of transactions that can be lost varies accordingly.
- Log flushing frequency is controlled by `innodb_flush_log_at_timeout`, which allows you to set log flushing frequency to *N* seconds (where *N* is 1 ... 2700, with a default value of 1). However, any unexpected `mysqld` process exit can erase up to *N* seconds of transactions.
- DDL changes and other internal InnoDB activities flush the log independently of the `innodb_flush_log_at_trx_commit` setting.

- [InnoDB crash recovery](#) works regardless of the `innodb_flush_log_at_trx_commit` setting. Transactions are either applied entirely or erased entirely.

For durability and consistency in a replication setup that uses [InnoDB](#) with transactions:

- If binary logging is enabled, set `sync_binlog=1`.
- Always set `innodb_flush_log_at_trx_commit=1`.

For information on the combination of settings on a replica that is most resilient to unexpected halts, see [Section 19.4.2, “Handling an Unexpected Halt of a Replica”](#).

### Caution

Many operating systems and some disk hardware fool the flush-to-disk operation. They may tell `mysqld` that the flush has taken place, even though it has not. In this case, the durability of transactions is not guaranteed even with the recommended settings, and in the worst case, a power outage can corrupt [InnoDB](#) data. Using a battery-backed disk cache in the SCSI disk controller or in the disk itself speeds up file flushes, and makes the operation safer. You can also try to disable the caching of disk writes in hardware caches.

- `innodb_flush_method`

Command-Line Format	<code>--innodb-flush-method=value</code>
System Variable	<code>innodb_flush_method</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value (Unix)	<code>O_DIRECT</code> if supported, otherwise <code>fsync</code>
Default Value (Windows)	<code>unbuffered</code>
Valid Values (Unix)	<code>fsync</code>  <code>O_DSYNC</code>  <code>littlesync</code>  <code>nosync</code>  <code>O_DIRECT</code>  <code>O_DIRECT_NO_FSYNC</code>
Valid Values (Windows)	<code>unbuffered</code>

normal

Defines the method used to **flush** data to **InnoDB data files** and **log files**, which can affect I/O throughput.

On Unix-like systems, the default value is `O_DIRECT` if supported otherwise defaults to `fsync`. On Windows, the default value is `unbuffered`.

The `innodb_flush_method` options for Unix-like systems include:

- `fsync` or 0: InnoDB uses the `fsync()` system call to flush both the data and log files.
- `O_DSYNC` or 1: InnoDB uses `O_SYNC` to open and flush the log files, and `fsync()` to flush the data files. InnoDB does not use `O_DSYNC` directly because there have been problems with it on many varieties of Unix.
- `littlesync` or 2: This option is used for internal performance testing and is currently unsupported. Use at your own risk.
- `nosync` or 3: This option is used for internal performance testing and is currently unsupported. Use at your own risk.
- `O_DIRECT` or 4: InnoDB uses `O_DIRECT` (or `directio()` on Solaris) to open the data files, and uses `fsync()` to flush both the data and log files. This option is available on some GNU/Linux versions, FreeBSD, and Solaris.
- `O_DIRECT_NO_FSYNC`: InnoDB uses `O_DIRECT` during flushing I/O, but skips the `fsync()` system call after each write operation.

MySQL calls `fsync()` after creating a new file, after increasing file size, and after closing a file, to ensure that file system metadata changes are synchronized. The `fsync()` system call is still skipped after each write operation.

Data loss is possible if redo log files and data files reside on different storage devices, and an unexpected exit occurs before data file writes are flushed from a device cache that is not battery-backed. If you use or intend to use different storage devices for redo log files and data files, and your data files reside on a device with a cache that is not battery-backed, use `O_DIRECT` instead.

On platforms that support `fdatasync()` system calls, the `innodb_use_fdatasync` variable permits `innodb_flush_method` options that use `fsync()` to use `fdatasync()` instead. An `fdatasync()` system call does not flush changes to file metadata unless required for subsequent data retrieval, providing a potential performance benefit.

The `innodb_flush_method` options for Windows systems include:

- `unbuffered` or 0: InnoDB uses non-buffered I/O.

#### Note

Running MySQL server on a 4K sector hard drive on Windows is not supported with `unbuffered`. The workaround is to use `innodb_flush_method=normal`.

- `normal` or `1`: InnoDB uses buffered I/O.

How each setting affects performance depends on hardware configuration and workload. Benchmark your particular configuration to decide which setting to use, or whether to keep the default setting. Examine the `InnoDB_data_fsyncs` status variable to see the overall number of `fsync()` calls (or `fdatasync()` calls if `innodb_use_fdatasync` is enabled) for each setting. The mix of read and write operations in your workload can affect how a setting performs. For example, on a system with a hardware RAID controller and battery-backed write cache, `O_DIRECT` can help to avoid double buffering between the InnoDB buffer pool and the operating system file system cache. On some systems where InnoDB data and log files are located on a SAN, the default value or `O_DSYNC` might be faster for a read-heavy workload with mostly `SELECT` statements. Always test this parameter with hardware and workload that reflect your production environment. For general I/O tuning advice, see [Section 10.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_flush_neighbors`

Command-Line Format	<code>--innodb-flush-neighbors=#</code>
System Variable	<code>innodb_flush_neighbors</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Enumeration
Default Value	0
Valid Values	0 1 2

Specifies whether **flushing** a page from the InnoDB buffer pool also flushes other **dirty pages** in the same **extent**.

- A setting of 0 disables `innodb_flush_neighbors`. Dirty pages in the same extent are not flushed.
- A setting of 1 flushes contiguous dirty pages in the same extent.
- A setting of 2 flushes dirty pages in the same extent.

When the table data is stored on a traditional **HDD** storage device, flushing such **neighbor pages** in one operation reduces I/O overhead (primarily for disk seek operations) compared to flushing individual pages at different times. For table data stored on **SSD**, seek time is not a significant factor and you can set this option to 0 to spread out write operations. For related information, see [Section 17.8.3.5, “Configuring Buffer Pool Flushing”](#).

- `innodb_flush_sync`

Command-Line Format	<code>--innodb-flush-sync[={OFF ON}]</code>
System Variable	<code>innodb_flush_sync</code>
Scope	Global
Dynamic	Yes

<a href="#">SET_VAR</a> Hint Applies	No
Type	Boolean
Default Value	ON

The `innodb_flush_sync` variable, which is enabled by default, causes the `innodb_io_capacity` and `innodb_io_capacity_max` settings to be ignored during bursts of I/O activity that occur at [checkpoints](#). To adhere to the I/O rate defined by `innodb_io_capacity` and `innodb_io_capacity_max`, disable `innodb_flush_sync`.

For information about configuring the `innodb_flush_sync` variable, see [Section 17.8.7, “Configuring InnoDB I/O Capacity”](#).

- `innodb_flushing_avg_loops`

Command-Line Format	<code>--innodb-flushing-avg-loops=#</code>
System Variable	<code>innodb_flushing_avg_loops</code>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	30
Minimum Value	1
Maximum Value	1000

Number of iterations for which InnoDB keeps the previously calculated snapshot of the flushing state, controlling how quickly [adaptive flushing](#) responds to changing [workloads](#). Increasing the value makes the rate of [flush](#) operations change smoothly and gradually as the workload changes. Decreasing the value makes adaptive flushing adjust quickly to workload changes, which can cause spikes in flushing activity if the workload increases and decreases suddenly.

For related information, see [Section 17.8.3.5, “Configuring Buffer Pool Flushing”](#).

- `innodb_force_load_corrupted`

Command-Line Format	<code>--innodb-force-load-corrupted[={OFF ON}]</code>
System Variable	<code>innodb_force_load_corrupted</code>
Scope	Global
Dynamic	No
<a href="#">SET_VAR</a> Hint Applies	No
Type	Boolean
Default Value	OFF

Permits InnoDB to load tables at startup that are marked as corrupted. Use only during troubleshooting, to recover data that is otherwise inaccessible. When troubleshooting is complete, disable this setting and restart the server.

- [innodb\\_force\\_recovery](#)

Command-Line Format	<code>--innodb-force-recovery=#</code>
System Variable	<a href="#">innodb_force_recovery</a>
Scope	Global
Dynamic	No
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	6

The [crash recovery](#) mode, typically only changed in serious troubleshooting situations. Possible values are from 0 to 6. For the meanings of these values and important information about [innodb\\_force\\_recovery](#), see [Section 17.20.3, “Forcing InnoDB Recovery”](#).

#### Warning

Only set this variable to a value greater than 0 in an emergency situation so that you can start [InnoDB](#) and dump your tables. As a safety measure, [InnoDB](#) prevents [INSERT](#), [UPDATE](#), or [DELETE](#) operations when [innodb\\_force\\_recovery](#) is greater than 0. An [innodb\\_force\\_recovery](#) setting of 4 or greater places [InnoDB](#) into read-only mode.

These restrictions may cause replication administration commands to fail with an error, as replication stores the replica status logs in [InnoDB](#) tables.

- [innodb\\_fsync\\_threshold](#)

Command-Line Format	<code>--innodb-fsync-threshold=#</code>
System Variable	<a href="#">innodb_fsync_threshold</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	$2^{*}64-1$

By default, when [InnoDB](#) creates a new data file, such as a new log file or tablespace file, the file is fully written to the operating system cache before it is flushed to disk, which can cause a large amount of disk write activity to occur at once. To force smaller, periodic flushes of data from the operating system cache, you can use the [innodb\\_fsync\\_threshold](#) variable to define a threshold value, in bytes. When the byte threshold is reached, the contents of the operating system cache are flushed to disk. The

default value of 0 forces the default behavior, which is to flush data to disk only after a file is fully written to the cache.

Specifying a threshold to force smaller, periodic flushes may be beneficial in cases where multiple MySQL instances use the same storage devices. For example, creating a new MySQL instance and its associated data files could cause large surges of disk write activity, impeding the performance of other MySQL instances that use the same storage devices. Configuring a threshold helps avoid such surges in write activity.

- [innodb\\_ft\\_aux\\_table](#)

System Variable	<a href="#">innodb_ft_aux_table</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	String

Specifies the qualified name of an [InnoDB](#) table containing a [FULLTEXT](#) index. This variable is intended for diagnostic purposes and can only be set at runtime. For example:

```
SET GLOBAL innodb_ft_aux_table = 'test/t1';
```

After you set this variable to a name in the format *db\_name/table\_name*, the [INFORMATION\\_SCHEMA](#) tables [INNODB\\_FT\\_INDEX\\_TABLE](#), [INNODB\\_FT\\_INDEX\\_CACHE](#), [INNODB\\_FT\\_CONFIG](#), [INNODB\\_FT\\_DELETED](#), and [INNODB\\_FT\\_BEING\\_DELETED](#) show information about the search index for the specified table.

For more information, see [Section 17.15.4, “InnoDB INFORMATION\\_SCHEMA FULLTEXT Index Tables”](#).

- [innodb\\_ft\\_cache\\_size](#)

Command-Line Format	<a href="#">--innodb-ft-cache-size=#</a>
System Variable	<a href="#">innodb_ft_cache_size</a>
Scope	Global
Dynamic	No
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	<a href="#">8000000</a>
Minimum Value	<a href="#">1600000</a>
Maximum Value	<a href="#">80000000</a>
Unit	bytes

The memory allocated, in bytes, for the [InnoDB FULLTEXT](#) search index cache, which holds a parsed document in memory while creating an [InnoDB FULLTEXT](#) index. Index inserts and updates are only committed to disk when the [innodb\\_ft\\_cache\\_size](#) size limit is reached. [innodb\\_ft\\_cache\\_size](#) defines the cache size on a per table basis. To set a global limit for all tables, see [innodb\\_ft\\_total\\_cache\\_size](#).

- `innodb_ft_enable_diag_print`

Command-Line Format	<code>--innodb-ft-enable-diag-print[={OFF ON}]</code>
System Variable	<code>innodb_ft_enable_diag_print</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Whether to enable additional full-text search (FTS) diagnostic output. This option is primarily intended for advanced FTS debugging and is not of interest to most users. Output is printed to the error log and includes information such as:

- FTS index sync progress (when the FTS cache limit is reached). For example:

```
FTS SYNC for table test, deleted count: 100 size: 10000 bytes
SYNC words: 100
```

- FTS optimize progress. For example:

```
FTS start optimize test
FTS_OPTIMIZE: optimize "mysql"
FTS_OPTIMIZE: processed "mysql"
```

- FTS index build progress. For example:

```
Number of doc processed: 1000
```

- For FTS queries, the query parsing tree, word weight, query processing time, and memory usage are printed. For example:

```
FTS Search Processing time: 1 secs: 100 millisec: row(s) 10000
Full Search Memory: 245666 (bytes), Row: 10000
```

- `innodb_ft_enable_stopword`

Command-Line Format	<code>--innodb-ft-enable-stopword[={OFF ON}]</code>
System Variable	<code>innodb_ft_enable_stopword</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>ON</code>

Specifies that a set of [stopwords](#) is associated with an [InnoDB FULLTEXT](#) index at the time the index is created. If the `innodb_ft_user_stopword_table` option is set, the stopwords are taken from that

table. Else, if the `innodb_ft_server_stopword_table` option is set, the stopwords are taken from that table. Otherwise, a built-in set of default stopwords is used.

For more information, see [Section 14.9.4, “Full-Text Stopwords”](#).

- `innodb_ft_max_token_size`

Command-Line Format	<code>--innodb-ft-max-token-size=#</code>
System Variable	<code>innodb_ft_max_token_size</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	84
Minimum Value	10
Maximum Value	84

Maximum character length of words that are stored in an `InnoDB FULLTEXT` index. Setting a limit on this value reduces the size of the index, thus speeding up queries, by omitting long keywords or arbitrary collections of letters that are not real words and are not likely to be search terms.

For more information, see [Section 14.9.6, “Fine-Tuning MySQL Full-Text Search”](#).

- `innodb_ft_min_token_size`

Command-Line Format	<code>--innodb-ft-min-token-size=#</code>
System Variable	<code>innodb_ft_min_token_size</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	3
Minimum Value	0
Maximum Value	16

Minimum length of words that are stored in an `InnoDB FULLTEXT` index. Increasing this value reduces the size of the index, thus speeding up queries, by omitting common words that are unlikely to be significant in a search context, such as the English words “a” and “to”. For content using a CJK (Chinese, Japanese, Korean) character set, specify a value of 1.

For more information, see [Section 14.9.6, “Fine-Tuning MySQL Full-Text Search”](#).

- `innodb_ft_num_word_optimize`

Command-Line Format	<code>--innodb-ft-num-word-optimize=#</code>
System Variable	<code>innodb_ft_num_word_optimize</code>
Scope	Global
Dynamic	Yes

<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	2000
Minimum Value	1000
Maximum Value	10000

Number of words to process during each [OPTIMIZE TABLE](#) operation on an [InnoDB FULLTEXT](#) index. Because a bulk insert or update operation to a table containing a full-text search index could require substantial index maintenance to incorporate all changes, you might do a series of [OPTIMIZE TABLE](#) statements, each picking up where the last left off.

For more information, see [Section 14.9.6, “Fine-Tuning MySQL Full-Text Search”](#).

- [innodb\\_ft\\_result\\_cache\\_limit](#)

Command-Line Format	<code>--innodb-ft-result-cache-limit=#</code>
System Variable	<a href="#">innodb_ft_result_cache_limit</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	2000000000
Minimum Value	1000000
Maximum Value	$2^{32}-1$
Unit	bytes

The [InnoDB](#) full-text search query result cache limit (defined in bytes) per full-text search query or per thread. Intermediate and final [InnoDB](#) full-text search query results are handled in memory. Use [innodb\\_ft\\_result\\_cache\\_limit](#) to place a size limit on the full-text search query result cache to avoid excessive memory consumption in case of very large [InnoDB](#) full-text search query results (millions or hundreds of millions of rows, for example). Memory is allocated as required when a full-text search query is processed. If the result cache size limit is reached, an error is returned indicating that the query exceeds the maximum allowed memory.

The maximum value of [innodb\\_ft\\_result\\_cache\\_limit](#) for all platform types and bit sizes is  $2^{32}-1$ .

- [innodb\\_ft\\_server\\_stopword\\_table](#)

Command-Line Format	<code>--innodb-ft-server-stopword-table=db_name/table_name</code>
System Variable	<a href="#">innodb_ft_server_stopword_table</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	String

Default Value	NULL
---------------	------

This option is used to specify your own InnoDB FULLTEXT index stopwords list for all InnoDB tables. To configure your own stopwords list for a specific InnoDB table, use `innodb_ft_user_stopword_table`.

Set `innodb_ft_server_stopword_table` to the name of the table containing a list of stopwords, in the format `db_name/table_name`.

The stopwords table must exist before you configure `innodb_ft_server_stopword_table`. `innodb_ft_enable_stopword` must be enabled and `innodb_ft_server_stopword_table` option must be configured before you create the FULLTEXT index.

The stopwords table must be an InnoDB table, containing a single VARCHAR column named `value`.

For more information, see [Section 14.9.4, “Full-Text Stopwords”](#).

- `innodb_ft_sort_pll_degree`

Command-Line Format	<code>--innodb-ft-sort-pll-degree=#</code>
System Variable	<code>innodb_ft_sort_pll_degree</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value	2
Minimum Value	1
Maximum Value	16

Number of threads used in parallel to index and tokenize text in an InnoDB FULLTEXT index when building a [search index](#).

For related information, see [Section 17.6.2.4, “InnoDB Full-Text Indexes”](#), and `innodb_sort_buffer_size`.

- `innodb_ft_total_cache_size`

Command-Line Format	<code>--innodb-ft-total-cache-size=#</code>
System Variable	<code>innodb_ft_total_cache_size</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value	640000000
Minimum Value	32000000
Maximum Value	1600000000

Unit	bytes
------	-------

The total memory allocated, in bytes, for the [InnoDB](#) full-text search index cache for all tables. Creating numerous tables, each with a [FULLTEXT](#) search index, could consume a significant portion of available memory. [innodb\\_ft\\_total\\_cache\\_size](#) defines a global memory limit for all full-text search indexes to help avoid excessive memory consumption. If the global limit is reached by an index operation, a forced sync is triggered.

For more information, see [InnoDB Full-Text Index Cache](#).

- [innodb\\_ft\\_user\\_stopword\\_table](#)

Command-Line Format	<code>--innodb-ft-user-stopword-table=db_name/table_name</code>
System Variable	<a href="#">innodb_ft_user_stopword_table</a>
Scope	Global, Session
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	String
Default Value	<a href="#">NULL</a>

This option is used to specify your own [InnoDB](#) [FULLTEXT](#) index stopwords list on a specific table. To configure your own stopwords list for all [InnoDB](#) tables, use [innodb\\_ft\\_server\\_stopword\\_table](#).

Set [innodb\\_ft\\_user\\_stopword\\_table](#) to the name of the table containing a list of stopwords, in the format [db\\_name/table\\_name](#).

The stopwords table must exist before you configure [innodb\\_ft\\_user\\_stopword\\_table](#). [innodb\\_ft\\_enable\\_stopword](#) must be enabled and [innodb\\_ft\\_user\\_stopword\\_table](#) must be configured before you create the [FULLTEXT](#) index.

The stopwords table must be an [InnoDB](#) table, containing a single [VARCHAR](#) column named [value](#).

For more information, see [Section 14.9.4, “Full-Text Stopwords”](#).

- [innodb\\_idle\\_flush\\_pct](#)

Command-Line Format	<code>--innodb-idle-flush-pct=#</code>
System Variable	<a href="#">innodb_idle_flush_pct</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	<a href="#">100</a>
Minimum Value	<a href="#">0</a>

Maximum Value	100
---------------	-----

Limits page flushing when InnoDB is idle. The `innodb_idle_flush_pct` value is a percentage of the `innodb_io_capacity` setting, which defines the number of I/O operations per second available to InnoDB. For more information, see [Limiting Buffer Flushing During Idle Periods](#).

- `innodb_io_capacity`

Command-Line Format	<code>--innodb-io-capacity=#</code>
System Variable	<code>innodb_io_capacity</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	10000
Minimum Value	100
Maximum Value	$2^{32}-1$

The `innodb_io_capacity` variable defines the number of I/O operations per second (IOPS) available to InnoDB background tasks, such as [flushing](#) pages from the [buffer pool](#) and merging data from the [change buffer](#).

For information about configuring the `innodb_io_capacity` variable, see [Section 17.8.7, “Configuring InnoDB I/O Capacity”](#).

- `innodb_io_capacity_max`

Command-Line Format	<code>--innodb-io-capacity-max=#</code>
System Variable	<code>innodb_io_capacity_max</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	$2 * \text{innodb\_io\_capacity}$
Minimum Value	100
Maximum Value	$2^{32}-1$

If flushing activity falls behind, InnoDB can flush more aggressively, at a higher rate of I/O operations per second (IOPS) than defined by the `innodb_io_capacity` variable. The `innodb_io_capacity_max` variable defines a maximum number of IOPS performed by InnoDB background tasks in such situations. This option does not control `innodb_flush_sync` behavior.

The default value is twice the value of `innodb_io_capacity`.

For information about configuring the `innodb_io_capacity_max` variable, see [Section 17.8.7, “Configuring InnoDB I/O Capacity”](#).

- `innodb_limit_optimistic_insert_debug`

Command-Line Format	<code>--innodb-limit-optimistic-insert-debug=#</code>
System Variable	<code>innodb_limit_optimistic_insert_debug</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	$2^{32}-1$

Limits the number of records per [B-tree](#) page. A default value of 0 means that no limit is imposed. This option is only available if debugging support is compiled in using the `WITH_DEBUG` CMake option.

- `innodb_lock_wait_timeout`

Command-Line Format	<code>--innodb-lock-wait-timeout=#</code>
System Variable	<code>innodb_lock_wait_timeout</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	50
Minimum Value	1
Maximum Value	1073741824
Unit	seconds

The length of time in seconds an [InnoDB transaction](#) waits for a [row lock](#) before giving up. The default value is 50 seconds. A transaction that tries to access a row that is locked by another [InnoDB](#) transaction waits at most this many seconds for write access to the row before issuing the following error:

```
ERROR 1205 (HY000): Lock wait timeout exceeded; try restarting transaction
```

When a lock wait timeout occurs, the current statement is [rolled back](#) (not the entire transaction). To have the entire transaction roll back, start the server with the `--innodb-rollback-on-timeout` option. See also [Section 17.20.5, “InnoDB Error Handling”](#).

You might decrease this value for highly interactive applications or [OLTP](#) systems, to display user feedback quickly or put the update into a queue for processing later. You might increase this value for

long-running back-end operations, such as a transform step in a data warehouse that waits for other large insert or update operations to finish.

`innodb_lock_wait_timeout` applies to InnoDB row locks. A MySQL [table lock](#) does not happen inside InnoDB and this timeout does not apply to waits for table locks.

The lock wait timeout value does not apply to [deadlocks](#) when `innodb_deadlock_detect` is enabled (the default) because InnoDB detects deadlocks immediately and rolls back one of the deadlocked transactions. When `innodb_deadlock_detect` is disabled, InnoDB relies on `innodb_lock_wait_timeout` for transaction rollback when a deadlock occurs. See [Section 17.7.5.2, “Deadlock Detection”](#).

`innodb_lock_wait_timeout` can be set at runtime with the `SET GLOBAL` or `SET SESSION` statement. Changing the `GLOBAL` setting requires privileges sufficient to set global system variables (see [Section 7.1.9.1, “System Variable Privileges”](#)) and affects the operation of all clients that subsequently connect. Any client can change the `SESSION` setting for `innodb_lock_wait_timeout`, which affects only that client.

- `innodb_log_buffer_size`

Command-Line Format	<code>--innodb-log-buffer-size=#</code>
System Variable	<code>innodb_log_buffer_size</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	67108864
Minimum Value	1048576
Maximum Value	4294967295

The size in bytes of the buffer that InnoDB uses to write to the [log files](#) on disk. The default is 64MB. A large [log buffer](#) enables large [transactions](#) to run without the need to write the log to disk before the transactions [commit](#). Thus, if you have transactions that update, insert, or delete many rows, making the log buffer larger saves disk I/O. For related information, see [Memory Configuration](#), and [Section 10.5.4, “Optimizing InnoDB Redo Logging”](#). For general I/O tuning advice, see [Section 10.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_log_checkpoint_fuzzy_now`

Command-Line Format	<code>--innodb-log-checkpoint-fuzzy-now[={OFF ON}]</code>
System Variable	<code>innodb_log_checkpoint_fuzzy_now</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean

Default Value	OFF
---------------	-----

Enable this debug option to force [InnoDB](#) to write a fuzzy checkpoint. This option is only available if debugging support is compiled in using the [WITH\\_DEBUG CMake](#) option.

- [innodb\\_log\\_checkpoint\\_now](#)

Command-Line Format	<code>--innodb-log-checkpoint-now[={OFF ON}]</code>
System Variable	<a href="#">innodb_log_checkpoint_now</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Boolean
Default Value	OFF

Enable this debug option to force [InnoDB](#) to write a checkpoint. This option is only available if debugging support is compiled in using the [WITH\\_DEBUG CMake](#) option.

- [innodb\\_log\\_checksums](#)

Command-Line Format	<code>--innodb-log-checksums[={OFF ON}]</code>
System Variable	<a href="#">innodb_log_checksums</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Boolean
Default Value	ON

Enables or disables checksums for redo log pages.

[innodb\\_log\\_checksums=ON](#) enables the [CRC-32C](#) checksum algorithm for redo log pages. When [innodb\\_log\\_checksums](#) is disabled, the contents of the redo log page checksum field are ignored.

Checksums on the redo log header page and redo log checkpoint pages are never disabled.

- [innodb\\_log\\_compressed\\_pages](#)

Command-Line Format	<code>--innodb-log-compressed-pages[={OFF ON}]</code>
System Variable	<a href="#">innodb_log_compressed_pages</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Boolean

Default Value	ON
---------------	----

Specifies whether images of [re-compressed pages](#) are written to the [redo log](#). Re-compression may occur when changes are made to compressed data.

[innodb\\_log\\_compressed\\_pages](#) is enabled by default to prevent corruption that could occur if a different version of the [zlib](#) compression algorithm is used during recovery. If you are certain that the [zlib](#) version is not subject to change, you can disable [innodb\\_log\\_compressed\\_pages](#) to reduce redo log generation for workloads that modify compressed data.

To measure the effect of enabling or disabling [innodb\\_log\\_compressed\\_pages](#), compare redo log generation for both settings under the same workload. Options for measuring redo log generation include observing the [Log sequence number](#) (LSN) in the [LOG](#) section of [SHOW ENGINE INNODB STATUS](#) output, or monitoring [Innodb\\_os\\_log\\_written](#) status for the number of bytes written to the redo log files.

For related information, see [Section 17.9.1.6, “Compression for OLTP Workloads”](#).

- [innodb\\_log\\_file\\_size](#)

Command-Line Format	<code>--innodb-log-file-size=#</code>
Deprecated	Yes
System Variable	<a href="#">innodb_log_file_size</a>
Scope	Global
Dynamic	No
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	50331648
Minimum Value	4194304
Maximum Value	512GB / <a href="#">innodb_log_files_in_group</a>
Unit	bytes

#### Note

[innodb\\_log\\_file\\_size](#) and [innodb\\_log\\_files\\_in\\_group](#) have been superseded by [innodb\\_redo\\_log\\_capacity](#); see [Section 17.6.5, “Redo Log”](#).

The size in bytes of each [log file](#) in a [log group](#). The combined size of log files ([innodb\\_log\\_file\\_size](#) \* [innodb\\_log\\_files\\_in\\_group](#)) cannot exceed a maximum value that is slightly less than 512GB. A pair of 255 GB log files, for example, approaches the limit but does not exceed it. The default value is 48MB.

Generally, the combined size of the log files should be large enough that the server can smooth out peaks and troughs in workload activity, which often means that there is enough redo log space to handle

more than an hour of write activity. The larger the value, the less checkpoint flush activity is required in the buffer pool, saving disk I/O. Larger log files also make [crash recovery](#) slower.

The minimum `innodb_log_file_size` is 4MB.

For related information, see [Redo Log Configuration](#). For general I/O tuning advice, see [Section 10.5.8, “Optimizing InnoDB Disk I/O”](#).

If the server is started with `--innodb-dedicated-server`, the value of `innodb_log_file_size` is set automatically if it is not explicitly defined. For more information, see [Section 17.8.12, “Enabling Automatic InnoDB Configuration for a Dedicated MySQL Server”](#).

- `innodb_log_files_in_group`

Command-Line Format	<code>--innodb-log-files-in-group=#</code>
Deprecated	Yes
System Variable	<code>innodb_log_files_in_group</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	2
Minimum Value	2
Maximum Value	100

#### Note

`innodb_log_file_size` and `innodb_log_files_in_group` have been superseded by `innodb_redo_log_capacity`; see [Section 17.6.5, “Redo Log”](#).

The number of [log files](#) in the [log group](#). InnoDB writes to the files in a circular fashion. The default (and recommended) value is 2. The location of the files is specified by `innodb_log_group_home_dir`. The combined size of log files (`innodb_log_file_size * innodb_log_files_in_group`) can be up to 512GB.

For related information, see [Redo Log Configuration](#).

If the server is started with `--innodb-dedicated-server`, the value of `innodb_log_files_in_group` is set automatically if it is not explicitly defined. For more information, see [Section 17.8.12, “Enabling Automatic InnoDB Configuration for a Dedicated MySQL Server”](#).

- `innodb_log_group_home_dir`

Command-Line Format	<code>--innodb-log-group-home-dir=dir_name</code>
System Variable	<code>innodb_log_group_home_dir</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No

Type	Directory name
------	----------------

The directory path to the [InnoDB redo log](#) files.

For related information, see [Redo Log Configuration](#).

- [innodb\\_log\\_spin\\_cpu\\_abs\\_lwm](#)

Command-Line Format	<code>--innodb-log-spin-cpu-abs-lwm=#</code>
System Variable	<a href="#">innodb_log_spin_cpu_abs_lwm</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	80
Minimum Value	0
Maximum Value	4294967295

Defines the minimum amount of CPU usage below which user threads no longer spin while waiting for flushed redo. The value is expressed as a sum of CPU core usage. For example, The default value of 80 is 80% of a single CPU core. On a system with a multi-core processor, a value of 150 represents 100% usage of one CPU core plus 50% usage of a second CPU core.

For related information, see [Section 10.5.4, “Optimizing InnoDB Redo Logging”](#).

- [innodb\\_log\\_spin\\_cpu\\_pct\\_hwm](#)

Command-Line Format	<code>--innodb-log-spin-cpu-pct-hwm=#</code>
System Variable	<a href="#">innodb_log_spin_cpu_pct_hwm</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	50
Minimum Value	0
Maximum Value	100

Defines the maximum amount of CPU usage above which user threads no longer spin while waiting for flushed redo. The value is expressed as a percentage of the combined total processing power of all CPU cores. The default value is 50%. For example, 100% usage of two CPU cores is 50% of the combined CPU processing power on a server with four CPU cores.

The [innodb\\_log\\_spin\\_cpu\\_pct\\_hwm](#) variable respects processor affinity. For example, if a server has 48 cores but the `mysqld` process is pinned to only four CPU cores, the other 44 CPU cores are ignored.

For related information, see [Section 10.5.4, “Optimizing InnoDB Redo Logging”](#).

- [innodb\\_log\\_wait\\_for\\_flush\\_spin\\_hwm](#)

Command-Line Format	<code>--innodb-log-wait-for-flush-spin-hwm=#</code>
System Variable	<code>innodb_log_wait_for_flush_spin_hwm</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	400
Minimum Value	0
Maximum Value	$2^{32}-1$
Unit	microseconds

Defines the maximum average log flush time beyond which user threads no longer spin while waiting for flushed redo. The default value is 400 microseconds.

For related information, see [Section 10.5.4, “Optimizing InnoDB Redo Logging”](#).

- `innodb_log_write_ahead_size`

Command-Line Format	<code>--innodb-log-write-ahead-size=#</code>
System Variable	<code>innodb_log_write_ahead_size</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	8192
Minimum Value	512 (log file block size)
Maximum Value	Equal to <code>innodb_page_size</code>
Unit	bytes

Defines the write-ahead block size for the redo log, in bytes. To avoid “read-on-write”, set `innodb_log_write_ahead_size` to match the operating system or file system cache block size. The default setting is 8192 bytes. Read-on-write occurs when redo log blocks are not entirely cached to the operating system or file system due to a mismatch between write-ahead block size for the redo log and operating system or file system cache block size.

Valid values for `innodb_log_write_ahead_size` are multiples of the InnoDB log file block size ( $2^n$ ). The minimum value is the InnoDB log file block size (512). Write-ahead does not occur when the minimum value is specified. The maximum value is equal to the `innodb_page_size` value. If you specify a value for `innodb_log_write_ahead_size` that is larger than the `innodb_page_size` value, the `innodb_log_write_ahead_size` setting is truncated to the `innodb_page_size` value.

Setting the `innodb_log_write_ahead_size` value too low in relation to the operating system or file system cache block size results in “read-on-write”. Setting the value too high may have a slight impact on `fsync` performance for log file writes due to several blocks being written at once.

For related information, see [Section 10.5.4, “Optimizing InnoDB Redo Logging”](#).

- `innodb_log_writer_threads`

Command-Line Format	<code>--innodb-log-writer-threads[={OFF ON}]</code>
System Variable	<code>innodb_log_writer_threads</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	ON, if available logical processors $\geq 32$ , otherwise OFF

Enables dedicated log writer threads for writing redo log records from the log buffer to the system buffers and flushing the system buffers to the redo log files. Dedicated log writer threads can improve performance on high-concurrency systems, but for low-concurrency systems, disabling dedicated log writer threads provides better performance.

The default value was `ON` prior to MySQL 9.1.0.

For more information, see [Section 10.5.4, “Optimizing InnoDB Redo Logging”](#).

- `innodb_lru_scan_depth`

Command-Line Format	<code>--innodb-lru-scan-depth=#</code>
System Variable	<code>innodb_lru_scan_depth</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	1024
Minimum Value	100
Maximum Value	$2^{32}-1$

A parameter that influences the algorithms and heuristics for the [flush](#) operation for the [InnoDB buffer pool](#). Primarily of interest to performance experts tuning I/O-intensive workloads. It specifies, per buffer pool instance, how far down the buffer pool LRU page list the page cleaner thread scans looking for [dirty pages](#) to flush. This is a background operation performed once per second.

A setting smaller than the default is generally suitable for most workloads. A value that is much higher than necessary may impact performance. Only consider increasing the value if you have spare I/O capacity under a typical workload. Conversely, if a write-intensive workload saturates your I/O capacity, decrease the value, especially in the case of a large buffer pool.

When tuning `innodb_lru_scan_depth`, start with a low value and configure the setting upward with the goal of rarely seeing zero free pages. Also, consider adjusting `innodb_lru_scan_depth` when changing the number of buffer pool instances, since `innodb_lru_scan_depth` \*

`innodb_buffer_pool_instances` defines the amount of work performed by the page cleaner thread each second.

For related information, see [Section 17.8.3.5, “Configuring Buffer Pool Flushing”](#). For general I/O tuning advice, see [Section 10.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_max_dirty_pages_pct`

Command-Line Format	<code>--innodb-max-dirty-pages-pct=#</code>
System Variable	<code>innodb_max_dirty_pages_pct</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Numeric
Default Value	90
Minimum Value	0
Maximum Value	99.999

InnoDB tries to [flush](#) data from the [buffer pool](#) so that the percentage of [dirty pages](#) does not exceed this value.

The `innodb_max_dirty_pages_pct` setting establishes a target for flushing activity. It does not affect the rate of flushing. For information about managing the rate of flushing, see [Section 17.8.3.5, “Configuring Buffer Pool Flushing”](#).

For related information, see [Section 17.8.3.5, “Configuring Buffer Pool Flushing”](#). For general I/O tuning advice, see [Section 10.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_max_dirty_pages_pct_lwm`

Command-Line Format	<code>--innodb-max-dirty-pages-pct-lwm=#</code>
System Variable	<code>innodb_max_dirty_pages_pct_lwm</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Numeric
Default Value	10
Minimum Value	0
Maximum Value	99.999

Defines a low water mark representing the percentage of [dirty pages](#) at which preflushing is enabled to control the dirty page ratio. A value of 0 disables the pre-flushing behavior entirely. The configured value should always be lower than the `innodb_max_dirty_pages_pct` value. For more information, see [Section 17.8.3.5, “Configuring Buffer Pool Flushing”](#).

- `innodb_max_purge_lag`

Command-Line Format	<code>--innodb-max-purge-lag=#</code>
---------------------	---------------------------------------

System Variable	<code>innodb_max_purge_lag</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	4294967295

Defines the desired maximum purge lag. If this value is exceeded, a delay is imposed on `INSERT`, `UPDATE`, and `DELETE` operations to allow time for purge to catch up. The default value is 0, which means there is no maximum purge lag and no delay.

For more information, see [Section 17.8.9, “Purge Configuration”](#).

- `innodb_max_purge_lag_delay`

Command-Line Format	<code>--innodb-max-purge-lag-delay=#</code>
System Variable	<code>innodb_max_purge_lag_delay</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	10000000
Unit	microseconds

Specifies the maximum delay in microseconds for the delay imposed when the `innodb_max_purge_lag` threshold is exceeded. The specified `innodb_max_purge_lag_delay` value is an upper limit on the delay period calculated by the `innodb_max_purge_lag` formula.

For more information, see [Section 17.8.9, “Purge Configuration”](#).

- `innodb_max_undo_log_size`

Command-Line Format	<code>--innodb-max-undo-log-size=#</code>
System Variable	<code>innodb_max_undo_log_size</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	1073741824
Minimum Value	10485760
Maximum Value	$2^{*}64-1$

Unit	bytes
------	-------

Defines a threshold size for undo tablespaces. If an undo tablespace exceeds the threshold, it can be marked for truncation when `innodb_undo_log_truncate` is enabled. The default value is 1073741824 bytes (1024 MiB).

For more information, see [Truncating Undo Tablespaces](#).

- `innodb_merge_threshold_set_all_debug`

Command-Line Format	<code>--innodb-merge-threshold-set-all-debug=#</code>
System Variable	<code>innodb_merge_threshold_set_all_debug</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	50
Minimum Value	1
Maximum Value	50

Defines a page-full percentage value for index pages that overrides the current `MERGE_THRESHOLD` setting for all indexes that are currently in the dictionary cache. This option is only available if debugging support is compiled in using the `WITH_DEBUG CMake` option. For related information, see [Section 17.8.11, “Configuring the Merge Threshold for Index Pages”](#).

- `innodb_monitor_disable`

Command-Line Format	<code>--innodb-monitor-disable={counter module pattern all}</code>
System Variable	<code>innodb_monitor_disable</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String

This variable acts as a switch, disabling [InnoDB metrics counters](#). Counter data may be queried using the Information Schema `INNODB_METRICS` table. For usage information, see [Section 17.15.6, “InnoDB INFORMATION\\_SCHEMA Metrics Table”](#).

`innodb_monitor_disable='latch'` disables statistics collection for `SHOW ENGINE INNODB MUTEX`. For more information, see [Section 15.7.7.16, “SHOW ENGINE Statement”](#).

- `innodb_monitor_enable`

Command-Line Format	<code>--innodb-monitor-enable={counter module pattern all}</code>
System Variable	<code>innodb_monitor_enable</code>
Scope	Global

Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	String

This variable acts as a switch, enabling [InnoDB metrics counters](#). Counter data may be queried using the Information Schema [INNODB\\_METRICS](#) table. For usage information, see [Section 17.15.6, “InnoDB INFORMATION\\_SCHEMA Metrics Table”](#).

`innodb_monitor_enable='latch'` enables statistics collection for `SHOW ENGINE INNODB MUTEX`. For more information, see [Section 15.7.7.16, “SHOW ENGINE Statement”](#).

- `innodb_monitor_reset`

Command-Line Format	<code>--innodb-monitor-reset={counter module pattern all}</code>
System Variable	<code>innodb_monitor_reset</code>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Enumeration
Default Value	<code>NULL</code>
Valid Values	<code>counter</code> <code>module</code> <code>pattern</code> <code>all</code>

This variable acts as a switch, resetting the count value for [InnoDB metrics counters](#) to zero. Counter data may be queried using the Information Schema [INNODB\\_METRICS](#) table. For usage information, see [Section 17.15.6, “InnoDB INFORMATION\\_SCHEMA Metrics Table”](#).

`innodb_monitor_reset='latch'` resets statistics reported by `SHOW ENGINE INNODB MUTEX`. For more information, see [Section 15.7.7.16, “SHOW ENGINE Statement”](#).

- `innodb_monitor_reset_all`

Command-Line Format	<code>--innodb-monitor-reset-all={counter module pattern all}</code>
System Variable	<code>innodb_monitor_reset_all</code>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Enumeration
Default Value	<code>NULL</code>
Valid Values	<code>counter</code>

	<code>module</code>
	<code>pattern</code>
	<code>all</code>

This variable acts as a switch, resetting all values (minimum, maximum, and so on) for [InnoDB metrics counters](#). Counter data may be queried using the Information Schema `INNODB_METRICS` table. For usage information, see [Section 17.15.6, “InnoDB INFORMATION\\_SCHEMA Metrics Table”](#).

- `innodb_numa_interleave`

Command-Line Format	<code>--innodb-numa-interleave[={OFF ON}]</code>
System Variable	<code>innodb_numa_interleave</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>ON</code>

Enables the NUMA interleave memory policy for allocation of the [InnoDB buffer pool](#). When `innodb_numa_interleave` is enabled, the NUMA memory policy is set to `MPOL_INTERLEAVE` for the `mysqld` process. After the [InnoDB buffer pool](#) is allocated, the NUMA memory policy is set back to `MPOL_DEFAULT`. For the `innodb_numa_interleave` option to be available, MySQL must be compiled on a NUMA-enabled Linux system. The default value is `ON` if the system supports it, otherwise it defaults to `OFF`.

`CMake` sets the default `WITH_NUMA` value based on whether the current platform has `NUMA` support. For more information, see [Section 2.8.7, “MySQL Source-Configuration Options”](#).

- `innodb_old_blocks_pct`

Command-Line Format	<code>--innodb-old-blocks-pct=#</code>
System Variable	<code>innodb_old_blocks_pct</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	<code>37</code>
Minimum Value	<code>5</code>
Maximum Value	<code>95</code>

Specifies the approximate percentage of the [InnoDB buffer pool](#) used for the old block [sublist](#). The range of values is 5 to 95. The default value is 37 (that is, 3/8 of the pool). Often used in combination with `innodb_old_blocks_time`.

For more information, see [Section 17.8.3.3, “Making the Buffer Pool Scan Resistant”](#). For information about buffer pool management, the [LRU](#) algorithm, and [eviction](#) policies, see [Section 17.5.1, “Buffer Pool”](#).

- `innodb_old_blocks_time`

Command-Line Format	<code>--innodb-old-blocks-time=#</code>
System Variable	<code>innodb_old_blocks_time</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	1000
Minimum Value	0
Maximum Value	$2^{32}-1$
Unit	milliseconds

Non-zero values protect against the [buffer pool](#) being filled by data that is referenced only for a brief period, such as during a [full table scan](#). Increasing this value offers more protection against full table scans interfering with data cached in the buffer pool.

Specifies how long in milliseconds a block inserted into the old [sublist](#) must stay there after its first access before it can be moved to the new sublist. If the value is 0, a block inserted into the old sublist moves immediately to the new sublist the first time it is accessed, no matter how soon after insertion the access occurs. If the value is greater than 0, blocks remain in the old sublist until an access occurs at least that many milliseconds after the first access. For example, a value of 1000 causes blocks to stay in the old sublist for 1 second after the first access before they become eligible to move to the new sublist.

The default value is 1000.

This variable is often used in combination with `innodb_old_blocks_pct`. For more information, see [Section 17.8.3.3, “Making the Buffer Pool Scan Resistant”](#). For information about buffer pool management, the [LRU](#) algorithm, and [eviction](#) policies, see [Section 17.5.1, “Buffer Pool”](#).

- `innodb_online_alter_log_max_size`

Command-Line Format	<code>--innodb-online-alter-log-max-size=#</code>
System Variable	<code>innodb_online_alter_log_max_size</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	134217728
Minimum Value	65536
Maximum Value	$2^{64}-1$
Unit	bytes

Specifies an upper limit in bytes on the size of the temporary log files used during [online DDL](#) operations for [InnoDB](#) tables. There is one such log file for each index being created or table being altered. This log file stores data inserted, updated, or deleted in the table during the DDL operation. The temporary log file is extended when needed by the value of `innodb_sort_buffer_size`, up to the maximum specified by `innodb_online_alter_log_max_size`. If a temporary log file exceeds the upper size limit, the

`ALTER TABLE` operation fails and all uncommitted concurrent DML operations are rolled back. Thus, a large value for this option allows more DML to happen during an online DDL operation, but also extends the period of time at the end of the DDL operation when the table is locked to apply the data from the log.

- `innodb_open_files`

Command-Line Format	<code>--innodb-open-files=#</code>
System Variable	<code>innodb_open_files</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	-1 (signifies autosizing; do not assign this literal value)
Minimum Value	10
Maximum Value	2147483647

Specifies the maximum number of files that InnoDB can have open at one time. The minimum value is 10. If `innodb_file_per_table` is disabled, the default value is 300; otherwise, the default value is 300 or the `table_open_cache` setting, whichever is higher.

The `innodb_open_files` limit can be set at runtime using a `SELECT innodb_set_open_files_limit(N)` statement, where *N* is the desired `innodb_open_files` limit; for example:

```
mysql> SELECT innodb_set_open_files_limit(1000);
```

The statement executes a stored procedure that sets the new limit. If the procedure is successful, it returns the value of the newly set limit; otherwise, a failure message is returned.

It is not permitted to set `innodb_open_files` using a `SET` statement. To set `innodb_open_files` at runtime, use the `SELECT innodb_set_open_files_limit(N)` statement described above.

Setting `innodb_open_files=default` is not supported. Only integer values are permitted.

To prevent non-LRU managed files from consuming the entire `innodb_open_files` limit, non-LRU managed files are limited to 90 percent of this limit, which reserves 10 percent of it for LRU managed files.

- `innodb_optimize_fulltext_only`

Command-Line Format	<code>--innodb-optimize-fulltext-only[={OFF ON}]</code>
System Variable	<code>innodb_optimize_fulltext_only</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean

Default Value	OFF
---------------	-----

Changes the way `OPTIMIZE TABLE` operates on InnoDB tables. Intended to be enabled temporarily, during maintenance operations for InnoDB tables with `FULLTEXT` indexes.

By default, `OPTIMIZE TABLE` reorganizes data in the [clustered index](#) of the table. When this option is enabled, `OPTIMIZE TABLE` skips the reorganization of table data, and instead processes newly added, deleted, and updated token data for InnoDB `FULLTEXT` indexes. For more information, see [Optimizing InnoDB Full-Text Indexes](#).

- `innodb_page_cleaners`

Command-Line Format	<code>--innodb-page-cleaners=#</code>
System Variable	<code>innodb_page_cleaners</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	<code>innodb_buffer_pool_instances</code>
Minimum Value	1
Maximum Value	64

The number of page cleaner threads that flush dirty pages from buffer pool instances. Page cleaner threads perform flush list and LRU flushing. When there are multiple page cleaner threads, buffer pool flushing tasks for each buffer pool instance are dispatched to idle page cleaner threads. The `innodb_page_cleaners` default value is set to the same value as `innodb_buffer_pool_instances`. If the specified number of page cleaner threads exceeds the number of buffer pool instances, then `innodb_page_cleaners` is automatically set to the same value as `innodb_buffer_pool_instances`.

If your workload is write-IO bound when flushing dirty pages from buffer pool instances to data files, and if your system hardware has available capacity, increasing the number of page cleaner threads may help improve write-IO throughput.

Multithreaded page cleaner support extends to shutdown and recovery phases.

The `setpriority()` system call is used on Linux platforms where it is supported, and where the `mysqld` execution user is authorized to give `page_cleaner` threads priority over other MySQL and InnoDB threads to help page flushing keep pace with the current workload. `setpriority()` support is indicated by this InnoDB startup message:

```
[Note] InnoDB: If the mysqld execution user is authorized, page cleaner
thread priority can be changed. See the man page of setpriority().
```

For systems where server startup and shutdown is not managed by `systemd`, `mysqld` execution user authorization can be configured in `/etc/security/limits.conf`. For example, if `mysqld` is run under the `mysql` user, you can authorize the `mysql` user by adding these lines to `/etc/security/limits.conf`:

```
mysql hard nice -20
```

```
mysql soft nice -20
```

For systemd managed systems, the same can be achieved by specifying `LimitNICE=-20` in a localized systemd configuration file. For example, create a file named `override.conf` in `/etc/systemd/system/mysql.service.d/override.conf` and add this entry:

```
[Service]
LimitNICE=-20
```

After creating or changing `override.conf`, reload the systemd configuration, then tell systemd to restart the MySQL service:

```
systemctl daemon-reload
systemctl restart mysqld # RPM platforms
systemctl restart mysql # Debian platforms
```

For more information about using a localized systemd configuration file, see [Configuring systemd for MySQL](#).

After authorizing the `mysqld` execution user, use the `cat` command to verify the configured `Nice` limits for the `mysqld` process:

```
$> cat /proc/mysqld_pid/limits | grep nice
Max nice priority 18446744073709551596 18446744073709551596
```

- `innodb_page_size`

Command-Line Format	<code>--innodb-page-size=#</code>
System Variable	<code>innodb_page_size</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Enumeration
Default Value	16384
Valid Values	4096 8192 16384 32768 65536

Specifies the [page size](#) for [InnoDB tablespaces](#). Values can be specified in bytes or kilobytes. For example, a 16 kilobyte page size value can be specified as 16384, 16KB, or 16k.

`innodb_page_size` can only be configured prior to initializing the MySQL instance and cannot be changed afterward. If no value is specified, the instance is initialized using the default page size. See [Section 17.8.1, “InnoDB Startup Configuration”](#).

For both 32KB and 64KB page sizes, the maximum row length is approximately 16000 bytes. `ROW_FORMAT=COMPRESSED` is not supported when `innodb_page_size` is set to 32KB or 64KB. For `innodb_page_size=32KB`, extent size is 2MB. For `innodb_page_size=64KB`, extent size is 4MB.

`innodb_log_buffer_size` should be set to at least 16MB (the default is 64MB) when using 32KB or 64KB page sizes.

The default 16KB page size or larger is appropriate for a wide range of [workloads](#), particularly for queries involving table scans and DML operations involving bulk updates. Smaller page sizes might be more efficient for [OLTP](#) workloads involving many small writes, where contention can be an issue when single pages contain many rows. Smaller pages might also be efficient with [SSD](#) storage devices, which typically use small block sizes. Keeping the [InnoDB](#) page size close to the storage device block size minimizes the amount of unchanged data that is rewritten to disk.

The minimum file size for the first system tablespace data file (`ibdata1`) differs depending on the `innodb_page_size` value. See the `innodb_data_file_path` option description for more information.

A MySQL instance using a particular [InnoDB](#) page size cannot use data files or log files from an instance that uses a different page size.

For general I/O tuning advice, see [Section 10.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_parallel_read_threads`

Command-Line Format	<code>--innodb-parallel-read-threads=#</code>
System Variable	<code>innodb_parallel_read_threads</code>
Scope	Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	<code>(available logical processors / 8), min of 4</code>
Minimum Value	1
Maximum Value	256

Defines the number of threads that can be used for parallel clustered index reads. Parallel scanning of partitions is also supported. Parallel read threads can improve [CHECK TABLE](#) performance. [InnoDB](#) reads the clustered index twice during a [CHECK TABLE](#) operation. The second read can be performed in parallel. This feature does not apply to secondary index scans. The `innodb_parallel_read_threads` session variable must be set to a value greater than 1 for parallel clustered index reads to occur. The actual number of threads used to perform a parallel clustered index read is determined by the `innodb_parallel_read_threads` setting or the number of index subtrees to scan, whichever is smaller. The pages read into the buffer pool during the scan are kept at the tail of the buffer pool LRU list so that they can be discarded quickly when free buffer pool pages are required.

The maximum number of parallel read threads (256) is the total number of threads for all client connections. If the thread limit is reached, connections fall back to using a single thread. The default value is calculated by the number of available logical processors on the system divided by 8, with a minimum default value of 4.

Before MySQL 8.4, the default value was always 4.

- `innodb_print_all_deadlocks`

Command-Line Format	<code>--innodb-print-all-deadlocks[={OFF ON}]</code>
System Variable	<code>innodb_print_all_deadlocks</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

When this option is enabled, information about all [deadlocks](#) in [InnoDB](#) user transactions is recorded in the [mysqld error log](#). Otherwise, you see information about only the last deadlock, using the `SHOW ENGINE INNODB STATUS` statement. An occasional [InnoDB](#) deadlock is not necessarily an issue, because [InnoDB](#) detects the condition immediately and rolls back one of the transactions automatically. You might use this option to troubleshoot why deadlocks are occurring if an application does not have appropriate error-handling logic to detect the rollback and retry its operation. A large number of deadlocks might indicate the need to restructure transactions that issue [DML](#) or `SELECT ... FOR UPDATE` statements for multiple tables, so that each transaction accesses the tables in the same order, thus avoiding the deadlock condition.

For related information, see [Section 17.7.5, “Deadlocks in InnoDB”](#).

- `innodb_print_ddl_logs`

Command-Line Format	<code>--innodb-print-ddl-logs[={OFF ON}]</code>
System Variable	<code>innodb_print_ddl_logs</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Enabling this option causes MySQL to write DDL logs to `stderr`. For more information, see [Viewing DDL Logs](#).

- `innodb_purge_batch_size`

Command-Line Format	<code>--innodb-purge-batch-size=#</code>
System Variable	<code>innodb_purge_batch_size</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	<code>300</code>
Minimum Value	<code>1</code>

Maximum Value	5000
---------------	------

Defines the number of undo log pages that purge parses and processes in one batch from the [history list](#). In a multithreaded purge configuration, the coordinator purge thread divides [innodb\\_purge\\_batch\\_size](#) by [innodb\\_purge\\_threads](#) and assigns that number of pages to each purge thread. The [innodb\\_purge\\_batch\\_size](#) variable also defines the number of undo log pages that purge frees after every 128 iterations through the undo logs.

The [innodb\\_purge\\_batch\\_size](#) option is intended for advanced performance tuning in combination with the [innodb\\_purge\\_threads](#) setting. Most users need not change [innodb\\_purge\\_batch\\_size](#) from its default value.

For related information, see [Section 17.8.9, “Purge Configuration”](#).

- [innodb\\_purge\\_threads](#)

Command-Line Format	<code>--innodb-purge-threads=#</code>
System Variable	<a href="#">innodb_purge_threads</a>
Scope	Global
Dynamic	No
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	1 if # of available logical processors is <= 16; otherwise 4
Minimum Value	1
Maximum Value	32

The number of background threads devoted to the [InnoDB purge](#) operation. Increasing the value creates additional purge threads, which can improve efficiency on systems where [DML](#) operations are performed on multiple tables.

For related information, see [Section 17.8.9, “Purge Configuration”](#).

- [innodb\\_purge\\_rseg\\_truncate\\_frequency](#)

Command-Line Format	<code>--innodb-purge-rseg-truncate-frequency=#</code>
System Variable	<a href="#">innodb_purge_rseg_truncate_frequency</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	128
Minimum Value	1
Maximum Value	128

Defines the frequency with which the purge system frees rollback segments in terms of the number of times that purge is invoked. An undo tablespace cannot be truncated until its rollback segments are

freed. Normally, the purge system frees rollback segments once every 128 times that purge is invoked. The default value is 128. Reducing this value increases the frequency with which the purge thread frees rollback segments.

`innodb_purge_rseg_truncate_frequency` is intended for use with `innodb_undo_log_truncate`. For more information, see [Truncating Undo Tablespaces](#).

- `innodb_random_read_ahead`

Command-Line Format	<code>--innodb-random-read-ahead[={OFF ON}]</code>
System Variable	<code>innodb_random_read_ahead</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Enables the random [read-ahead](#) technique for optimizing InnoDB I/O.

For details about performance considerations for different types of read-ahead requests, see [Section 17.8.3.4, “Configuring InnoDB Buffer Pool Prefetching \(Read-Ahead\)”](#). For general I/O tuning advice, see [Section 10.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_read_ahead_threshold`

Command-Line Format	<code>--innodb-read-ahead-threshold=#</code>
System Variable	<code>innodb_read_ahead_threshold</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	56
Minimum Value	0
Maximum Value	64

Controls the sensitivity of linear [read-ahead](#) that InnoDB uses to prefetch pages into the [buffer pool](#). If InnoDB reads at least `innodb_read_ahead_threshold` pages sequentially from an [extent](#) (64 pages), it initiates an asynchronous read for the entire following extent. The permissible range of values is 0 to 64. A value of 0 disables read-ahead. For the default of 56, InnoDB must read at least 56 pages sequentially from an extent to initiate an asynchronous read for the following extent.

Knowing how many pages are read through the read-ahead mechanism, and how many of these pages are evicted from the buffer pool without ever being accessed, can be useful when fine-tuning the `innodb_read_ahead_threshold` setting. `SHOW ENGINE INNODB STATUS` output displays counter information from the `Innodb_buffer_pool_read_ahead` and `Innodb_buffer_pool_read_ahead_evicted` global status variables, which report the number of pages brought into the [buffer pool](#) by read-ahead requests, and the number of such pages [evicted](#) from

the buffer pool without ever being accessed, respectively. The status variables report global values since the last server restart.

`SHOW ENGINE INNODB STATUS` also shows the rate at which the read-ahead pages are read and the rate at which such pages are evicted without being accessed. The per-second averages are based on the statistics collected since the last invocation of `SHOW ENGINE INNODB STATUS` and are displayed in the `BUFFER POOL AND MEMORY` section of the `SHOW ENGINE INNODB STATUS` output.

For more information, see [Section 17.8.3.4, “Configuring InnoDB Buffer Pool Prefetching \(Read-Ahead\)”](#). For general I/O tuning advice, see [Section 10.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_read_io_threads`

Command-Line Format	<code>--innodb-read-io-threads=#</code>
System Variable	<code>innodb_read_io_threads</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	<code>(available logical processors / 2), min of 4</code>
Minimum Value	1
Maximum Value	64

The number of I/O threads for read operations in InnoDB. Its counterpart for write threads is `innodb_write_io_threads`. For more information, see [Section 17.8.5, “Configuring the Number of Background InnoDB I/O Threads”](#). For general I/O tuning advice, see [Section 10.5.8, “Optimizing InnoDB Disk I/O”](#). The default value is the number of available logical processors on the system divided by 2, with a minimum default value of 4.

Before MySQL 8.4, the default value was always 4.

#### Note

On Linux systems, running multiple MySQL servers (typically more than 12) with default settings for `innodb_read_io_threads`, `innodb_write_io_threads`, and the Linux `aio-max-nr` setting can exceed system limits. Ideally, increase the `aio-max-nr` setting; as a workaround, you might reduce the settings for one or both of the MySQL variables.

- `innodb_read_only`

Command-Line Format	<code>--innodb-read-only[={OFF ON}]</code>
System Variable	<code>innodb_read_only</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Boolean

Default Value	OFF
---------------	-----

Starts [InnoDB](#) in read-only mode. For distributing database applications or data sets on read-only media. Can also be used in data warehouses to share the same data directory between multiple instances. For more information, see [Section 17.8.2, “Configuring InnoDB for Read-Only Operation”](#).

Enabling [innodb\\_read\\_only](#) prevents creating and dropping tables for all storage engines, and not only [InnoDB](#). Table creation and drop operations for any storage engine modify data dictionary tables in the [mysql](#) system database, but those tables use the [InnoDB](#) storage engine and cannot be modified when [innodb\\_read\\_only](#) is enabled. The same principle applies to other table operations that require modifying data dictionary tables. Examples:

- If the [innodb\\_read\\_only](#) system variable is enabled, [ANALYZE TABLE](#) may fail because it cannot update statistics tables in the data dictionary, which use [InnoDB](#). For [ANALYZE TABLE](#) operations that update the key distribution, failure may occur even if the operation updates the table itself (for example, if it is a [MyISAM](#) table). To obtain the updated distribution statistics, set [information\\_schema\\_stats\\_expiry=0](#).
- [ALTER TABLE tbl\\_name ENGINE=engine\\_name](#) fails because it updates the storage engine designation, which is stored in the data dictionary.

In addition, other tables in the [mysql](#) system database use the [InnoDB](#) storage engine. Making those tables read-only results in restrictions on operations that modify them. Examples:

- Account-management statements such as [CREATE USER](#) and [GRANT](#) fail because the grant tables use [InnoDB](#).
- The [INSTALL PLUGIN](#) and [UNINSTALL PLUGIN](#) plugin-management statements fail because the [mysql.plugin](#) system table uses [InnoDB](#).
- The [CREATE FUNCTION](#) and [DROP FUNCTION](#) loadable function-management statements fail because the [mysql.func](#) system table uses [InnoDB](#).
- [innodb\\_redo\\_log\\_archive\\_dirs](#)

Command-Line Format	<a href="#">--innodb-redo-log-archive-dirs</a>
System Variable	<a href="#">innodb_redo_log_archive_dirs</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	String
Default Value	<a href="#">NULL</a>

Defines labeled directories where redo log archive files can be created. You can define multiple labeled directories in a semicolon-separated list. For example:

```
innodb_redo_log_archive_dirs='label1:/backups1;label2:/backups2'
```

A label can be any string of characters, with the exception of colons (:), which are not permitted. An empty label is also permitted, but the colon (:) is still required in this case.

A path must be specified, and the directory must exist. The path can contain colons (':'), but semicolons (;) are not permitted.

- `innodb_redo_log_capacity`

Command-Line Format	<code>--innodb-redo-log-capacity=#</code>
System Variable	<code>innodb_redo_log_capacity</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	104857600
Minimum Value	8388608
Maximum Value	549755813888
Unit	bytes

Defines the amount of disk space occupied by redo log files.

`innodb_redo_log_capacity` supercedes the `innodb_log_files_in_group` and `innodb_log_file_size` variables, which are both ignored if `innodb_redo_log_capacity` is defined.

If `innodb_redo_log_capacity` is not defined, and if neither `innodb_log_file_size` or `innodb_log_files_in_group` are defined, then the default `innodb_redo_log_capacity` value is used.

If `innodb_redo_log_capacity` is not defined, and if `innodb_log_file_size` and/or `innodb_log_files_in_group` is defined, then the InnoDB redo log capacity is calculated as  $(innodb\_log\_files\_in\_group * innodb\_log\_file\_size)$ . This calculation does not modify the unused `innodb_redo_log_capacity` setting's value.

The `Innodb_redo_log_capacity_resized` server status variable indicates the total redo log capacity for all redo log files.

If the server is started with `--innodb-dedicated-server`, the value of `innodb_redo_log_capacity` is set automatically if it is not explicitly defined. or more information, see [Section 17.8.12, “Enabling Automatic InnoDB Configuration for a Dedicated MySQL Server”](#).

For more information, see [Section 17.6.5, “Redo Log”](#).

- `innodb_redo_log_encrypt`

Command-Line Format	<code>--innodb-redo-log-encrypt[={OFF ON}]</code>
System Variable	<code>innodb_redo_log_encrypt</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean

Default Value	OFF
---------------	-----

Controls encryption of redo log data for tables encrypted using the [InnoDB data-at-rest encryption feature](#). Encryption of redo log data is disabled by default. For more information, see [Redo Log Encryption](#).

- [innodb\\_replication\\_delay](#)

Command-Line Format	<code>--innodb-replication-delay=#</code>
System Variable	<a href="#">innodb_replication_delay</a>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	4294967295
Unit	milliseconds

The replication thread delay in milliseconds on a replica server if [innodb\\_thread\\_concurrency](#) is reached.

- [innodb\\_rollback\\_on\\_timeout](#)

Command-Line Format	<code>--innodb-rollback-on-timeout[={OFF ON}]</code>
System Variable	<a href="#">innodb_rollback_on_timeout</a>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

InnoDB [rolls back](#) only the last statement on a transaction timeout by default. If `--innodb-rollback-on-timeout` is specified, a transaction timeout causes InnoDB to abort and roll back the entire transaction.

For more information, see [Section 17.20.5, “InnoDB Error Handling”](#).

- [innodb\\_rollback\\_segments](#)

Command-Line Format	<code>--innodb-rollback-segments=#</code>
System Variable	<a href="#">innodb_rollback_segments</a>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer

Default Value	128
Minimum Value	1
Maximum Value	128

`innodb_rollback_segments` defines the number of [rollback segments](#) allocated to each undo tablespace and the global temporary tablespace for transactions that generate undo records. The number of transactions that each rollback segment supports depends on the [InnoDB](#) page size and the number of undo logs assigned to each transaction. For more information, see [Section 17.6.6, “Undo Logs”](#).

For related information, see [Section 17.3, “InnoDB Multi-Versioning”](#). For information about undo tablespaces, see [Section 17.6.3.4, “Undo Tablespaces”](#).

- `innodb_saved_page_number_debug`

Command-Line Format	<code>--innodb-saved-page-number-debug=#</code>
System Variable	<code>innodb_saved_page_number_debug</code>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	$2^{32}-1$

Saves a page number. Setting the `innodb_fil_make_page_dirty_debug` option dirties the page defined by `innodb_saved_page_number_debug`. The `innodb_saved_page_number_debug` option is only available if debugging support is compiled in using the `WITH_DEBUG` CMake option.

- `innodb_segment_reserve_factor`

Command-Line Format	<code>--innodb-segment-reserve-factor=#</code>
System Variable	<code>innodb_segment_reserve_factor</code>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Numeric
Default Value	12.5
Minimum Value	0.03
Maximum Value	40

Defines the percentage of tablespace file segment pages reserved as empty pages. The setting is applicable to file-per-table and general tablespaces. The `innodb_segment_reserve_factor` default setting is 12.5 percent, which is the same percentage of pages reserved in previous MySQL releases.

For more information, see [Configuring the Percentage of Reserved File Segment Pages](#).

- `innodb_sort_buffer_size`

Command-Line Format	<code>--innodb-sort-buffer-size=#</code>
System Variable	<code>innodb_sort_buffer_size</code>
Scope	Global
Dynamic	No
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	1048576
Minimum Value	65536
Maximum Value	67108864
Unit	bytes

This variable defines the amount by which the temporary log file is extended when recording concurrent DML during an [online DDL](#) operation, and the size of the temporary log file read buffer and write buffer.

For more information, see [Section 17.12.3, “Online DDL Space Requirements”](#).

- `innodb_spin_wait_delay`

Command-Line Format	<code>--innodb-spin-wait-delay=#</code>
System Variable	<code>innodb_spin_wait_delay</code>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	6
Minimum Value	0
Maximum Value	1000

The maximum delay between polls for a [spin](#) lock. The low-level implementation of this mechanism varies depending on the combination of hardware and operating system, so the delay does not correspond to a fixed time interval.

Can be used in combination with the `innodb_spin_wait_pause_multiplier` variable for greater control over the duration of spin-lock polling delays.

For more information, see [Section 17.8.8, “Configuring Spin Lock Polling”](#).

- `innodb_spin_wait_pause_multiplier`

Command-Line Format	<code>--innodb-spin-wait-pause-multiplier=#</code>
System Variable	<code>innodb_spin_wait_pause_multiplier</code>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer

Default Value	50
Minimum Value	0
Maximum Value	100

Defines a multiplier value used to determine the number of PAUSE instructions in spin-wait loops that occur when a thread waits to acquire a mutex or rw-lock.

For more information, see [Section 17.8.8, “Configuring Spin Lock Polling”](#).

- `innodb_stats_auto_recalc`

Command-Line Format	<code>--innodb-stats-auto-recalc[={OFF ON}]</code>
System Variable	<code>innodb_stats_auto_recalc</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	ON

Causes InnoDB to automatically recalculate [persistent statistics](#) after the data in a table is changed substantially. The threshold value is 10% of the rows in the table. This setting applies to tables created when the `innodb_stats_persistent` option is enabled. Automatic statistics recalculation may also be configured by specifying `STATS_AUTO_RECALC=1` in a `CREATE TABLE` or `ALTER TABLE` statement. The amount of data sampled to produce the statistics is controlled by the `innodb_stats_persistent_sample_pages` variable.

For more information, see [Section 17.8.10.1, “Configuring Persistent Optimizer Statistics Parameters”](#).

- `innodb_stats_include_delete_marked`

Command-Line Format	<code>--innodb-stats-include-delete-marked[={OFF ON}]</code>
System Variable	<code>innodb_stats_include_delete_marked</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

By default, InnoDB reads uncommitted data when calculating statistics. In the case of an uncommitted transaction that deletes rows from a table, InnoDB excludes records that are delete-marked when calculating row estimates and index statistics, which can lead to non-optimal execution plans for other transactions that are operating on the table concurrently using a transaction isolation level other than `READ UNCOMMITTED`. To avoid this scenario, `innodb_stats_include_delete_marked` can be

enabled to ensure that [InnoDB](#) includes delete-marked records when calculating persistent optimizer statistics.

When [innodb\\_stats\\_include\\_delete\\_marked](#) is enabled, [ANALYZE TABLE](#) considers delete-marked records when recalculating statistics.

[innodb\\_stats\\_include\\_delete\\_marked](#) is a global setting that affects all [InnoDB](#) tables. It is only applicable to persistent optimizer statistics.

For related information, see [Section 17.8.10.1, “Configuring Persistent Optimizer Statistics Parameters”](#).

- [innodb\\_stats\\_method](#)

Command-Line Format	<a href="#">--innodb-stats-method=value</a>
System Variable	<a href="#">innodb_stats_method</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Enumeration
Default Value	<a href="#">nulls_equal</a>
Valid Values	<a href="#">nulls_equal</a> <a href="#">nulls_unequal</a> <a href="#">nulls_ignored</a>

How the server treats [NULL](#) values when collecting [statistics](#) about the distribution of index values for [InnoDB](#) tables. Permitted values are [nulls\\_equal](#), [nulls\\_unequal](#), and [nulls\\_ignored](#). For [nulls\\_equal](#), all [NULL](#) index values are considered equal and form a single value group with a size equal to the number of [NULL](#) values. For [nulls\\_unequal](#), [NULL](#) values are considered unequal, and each [NULL](#) forms a distinct value group of size 1. For [nulls\\_ignored](#), [NULL](#) values are ignored.

The method used to generate table statistics influences how the optimizer chooses indexes for query execution, as described in [Section 10.3.8, “InnoDB and MyISAM Index Statistics Collection”](#).

- [innodb\\_stats\\_on\\_metadata](#)

Command-Line Format	<a href="#">--innodb-stats-on-metadata[={OFF ON}]</a>
System Variable	<a href="#">innodb_stats_on_metadata</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Boolean
Default Value	<a href="#">OFF</a>

This option only applies when optimizer [statistics](#) are configured to be non-persistent. Optimizer statistics are not persisted to disk when [innodb\\_stats\\_persistent](#) is disabled or when individual tables

are created or altered with `STATS_PERSISTENT=0`. For more information, see [Section 17.8.10.2, “Configuring Non-Persistent Optimizer Statistics Parameters”](#).

When `innodb_stats_on_metadata` is enabled, InnoDB updates non-persistent [statistics](#) when metadata statements such as `SHOW TABLE STATUS` or when accessing the Information Schema `TABLES` or `STATISTICS` tables. (These updates are similar to what happens for `ANALYZE TABLE`.) When disabled, InnoDB does not update statistics during these operations. Leaving the setting disabled can improve access speed for schemas that have a large number of tables or indexes. It can also improve the stability of [execution plans](#) for queries that involve InnoDB tables.

To change the setting, issue the statement `SET GLOBAL innodb_stats_on_metadata=mode`, where *mode* is either `ON` or `OFF` (or `1` or `0`). Changing the setting requires privileges sufficient to set global system variables (see [Section 7.1.9.1, “System Variable Privileges”](#)) and immediately affects the operation of all connections.

- `innodb_stats_persistent`

Command-Line Format	<code>--innodb-stats-persistent[={OFF ON}]</code>
System Variable	<code>innodb_stats_persistent</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>ON</code>

Specifies whether InnoDB index statistics are persisted to disk. Otherwise, statistics may be recalculated frequently which can lead to variations in [query execution plans](#). This setting is stored with each table when the table is created. You can set `innodb_stats_persistent` at the global level before creating a table, or use the `STATS_PERSISTENT` clause of the `CREATE TABLE` and `ALTER TABLE` statements to override the system-wide setting and configure persistent statistics for individual tables.

For more information, see [Section 17.8.10.1, “Configuring Persistent Optimizer Statistics Parameters”](#).

- `innodb_stats_persistent_sample_pages`

Command-Line Format	<code>--innodb-stats-persistent-sample-pages=#</code>
System Variable	<code>innodb_stats_persistent_sample_pages</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	<code>20</code>
Minimum Value	<code>1</code>
Maximum Value	<code>18446744073709551615</code>

The number of index [pages](#) to sample when estimating [cardinality](#) and other [statistics](#) for an indexed column, such as those calculated by `ANALYZE TABLE`. Increasing the value improves the accuracy of

index statistics, which can improve the [query execution plan](#), at the expense of increased I/O during the execution of `ANALYZE TABLE` for an InnoDB table. For more information, see [Section 17.8.10.1, “Configuring Persistent Optimizer Statistics Parameters”](#).

#### Note

Setting a high value for `innodb_stats_persistent_sample_pages` could result in lengthy `ANALYZE TABLE` execution time. To estimate the number of database pages accessed by `ANALYZE TABLE`, see [Section 17.8.10.3, “Estimating ANALYZE TABLE Complexity for InnoDB Tables”](#).

`innodb_stats_persistent_sample_pages` only applies when `innodb_stats_persistent` is enabled for a table; when `innodb_stats_persistent` is disabled, `innodb_stats_transient_sample_pages` applies instead.

- `innodb_stats_transient_sample_pages`

Command-Line Format	<code>--innodb-stats-transient-sample-pages=#</code>
System Variable	<code>innodb_stats_transient_sample_pages</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	8
Minimum Value	1
Maximum Value	18446744073709551615

The number of index [pages](#) to sample when estimating [cardinality](#) and other [statistics](#) for an indexed column, such as those calculated by `ANALYZE TABLE`. The default value is 8. Increasing the value improves the accuracy of index statistics, which can improve the [query execution plan](#), at the expense of increased I/O when opening an InnoDB table or recalculating statistics. For more information, see [Section 17.8.10.2, “Configuring Non-Persistent Optimizer Statistics Parameters”](#).

#### Note

Setting a high value for `innodb_stats_transient_sample_pages` could result in lengthy `ANALYZE TABLE` execution time. To estimate the number of database pages accessed by `ANALYZE TABLE`, see [Section 17.8.10.3, “Estimating ANALYZE TABLE Complexity for InnoDB Tables”](#).

`innodb_stats_transient_sample_pages` only applies when `innodb_stats_persistent` is disabled for a table; when `innodb_stats_persistent` is enabled, `innodb_stats_persistent_sample_pages` applies instead. Takes the place of `innodb_stats_sample_pages` that was removed in MySQL 8.0. For more information, see [Section 17.8.10.2, “Configuring Non-Persistent Optimizer Statistics Parameters”](#).

- `innodb_status_output`

Command-Line Format	<code>--innodb-status-output[={OFF ON}]</code>
System Variable	<code>innodb_status_output</code>

Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Boolean
Default Value	<a href="#">OFF</a>

Enables or disables periodic output for the standard [InnoDB](#) Monitor. Also used in combination with [innodb\\_status\\_output\\_locks](#) to enable or disable periodic output for the [InnoDB](#) Lock Monitor. For more information, see [Section 17.17.2, “Enabling InnoDB Monitors”](#).

- [innodb\\_status\\_output\\_locks](#)

Command-Line Format	<code>--innodb-status-output-locks[={OFF ON} ]</code>
System Variable	<a href="#">innodb_status_output_locks</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Boolean
Default Value	<a href="#">OFF</a>

Enables or disables the [InnoDB](#) Lock Monitor. When enabled, the [InnoDB](#) Lock Monitor prints additional information about locks in `SHOW ENGINE INNODB STATUS` output and in periodic output printed to the MySQL error log. Periodic output for the [InnoDB](#) Lock Monitor is printed as part of the standard [InnoDB](#) Monitor output. The standard [InnoDB](#) Monitor must therefore be enabled for the [InnoDB](#) Lock Monitor to print data to the MySQL error log periodically. For more information, see [Section 17.17.2, “Enabling InnoDB Monitors”](#).

- [innodb\\_strict\\_mode](#)

Command-Line Format	<code>--innodb-strict-mode[={OFF ON} ]</code>
System Variable	<a href="#">innodb_strict_mode</a>
Scope	Global, Session
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Boolean

Default Value	ON
---------------	----

When `innodb_strict_mode` is enabled, InnoDB returns errors rather than warnings when checking for invalid or incompatible table options.

It checks that `KEY_BLOCK_SIZE`, `ROW_FORMAT`, `DATA DIRECTORY`, `TEMPORARY`, and `TABLESPACE` options are compatible with each other and other settings.

`innodb_strict_mode=ON` also enables a row size check when creating or altering a table, to prevent `INSERT` or `UPDATE` from failing due to the record being too large for the selected page size.

You can enable or disable `innodb_strict_mode` on the command line when starting `mysqld`, or in a MySQL [configuration file](#). You can also enable or disable `innodb_strict_mode` at runtime with the statement `SET [GLOBAL|SESSION] innodb_strict_mode=mode`, where `mode` is either `ON` or `OFF`. Changing the `GLOBAL` setting requires privileges sufficient to set global system variables (see [Section 7.1.9.1, “System Variable Privileges”](#)) and affects the operation of all clients that subsequently connect. Any client can change the `SESSION` setting for `innodb_strict_mode`, and the setting affects only that client.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 7.1.9.1, “System Variable Privileges”](#).

- `innodb_sync_array_size`

Command-Line Format	<code>--innodb-sync-array-size=#</code>
System Variable	<code>innodb_sync_array_size</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	1
Minimum Value	1
Maximum Value	1024

Defines the size of the mutex/lock wait array. Increasing the value splits the internal data structure used to coordinate threads, for higher concurrency in workloads with large numbers of waiting threads. This setting must be configured when the MySQL instance is starting up, and cannot be changed afterward. Increasing the value is recommended for workloads that frequently produce a large number of waiting threads, typically greater than 768.

- `innodb_sync_spin_loops`

Command-Line Format	<code>--innodb-sync-spin-loops=#</code>
System Variable	<code>innodb_sync_spin_loops</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	30

Minimum Value	0
Maximum Value	4294967295

The number of times a thread waits for an [InnoDB](#) mutex to be freed before the thread is suspended.

- [innodb\\_sync\\_debug](#)

Command-Line Format	<code>--innodb-sync-debug[={OFF ON}]</code>
System Variable	<a href="#">innodb_sync_debug</a>
Scope	Global
Dynamic	No
<a href="#">SET_VAR</a> Hint Applies	No
Type	Boolean
Default Value	<a href="#">OFF</a>

Enables sync debug checking for the [InnoDB](#) storage engine. This option is only available if debugging support is compiled in using the [WITH\\_DEBUG CMake](#) option.

- [innodb\\_table\\_locks](#)

Command-Line Format	<code>--innodb-table-locks[={OFF ON}]</code>
System Variable	<a href="#">innodb_table_locks</a>
Scope	Global, Session
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Boolean
Default Value	<a href="#">ON</a>

If `autocommit = 0`, [InnoDB](#) honors [LOCK TABLES](#); MySQL does not return from [LOCK TABLES ... WRITE](#) until all other threads have released all their locks to the table. The default value of [innodb\\_table\\_locks](#) is 1, which means that [LOCK TABLES](#) causes [InnoDB](#) to lock a table internally if `autocommit = 0`.

[innodb\\_table\\_locks = 0](#) has no effect for tables locked explicitly with [LOCK TABLES ... WRITE](#). It does have an effect for tables locked for read or write by [LOCK TABLES ... WRITE](#) implicitly (for example, through triggers) or by [LOCK TABLES ... READ](#).

For related information, see [Section 17.7, “InnoDB Locking and Transaction Model”](#).

- [innodb\\_temp\\_data\\_file\\_path](#)

Command-Line Format	<code>--innodb-temp-data-file-path=file_name</code>
System Variable	<a href="#">innodb_temp_data_file_path</a>
Scope	Global
Dynamic	No
<a href="#">SET_VAR</a> Hint Applies	No
Type	String

Default Value	<code>ibtmp1:12M:autoextend</code>
---------------	------------------------------------

Defines the relative path, name, size, and attributes of global temporary tablespace data files. The global temporary tablespace stores rollback segments for changes made to user-created temporary tables.

If no value is specified for `innodb_temp_data_file_path`, the default behavior is to create a single auto-extending data file named `ibtmp1` in the `innodb_data_home_dir` directory. The initial file size is slightly larger than 12MB.

The syntax for a global temporary tablespace data file specification includes the file name, file size, and `autoextend` and `max` attributes:

```
file_name:file_size[:autoextend[:max:max_file_size]]
```

The global temporary tablespace data file cannot have the same name as another InnoDB data file. Any inability or error creating the global temporary tablespace data file is treated as fatal and server startup is refused.

File sizes are specified in KB, MB, or GB by appending `K`, `M` or `G` to the size value. The sum of file sizes must be slightly larger than 12MB.

The size limit of individual files is determined by the operating system. File size can be more than 4GB on operating systems that support large files. Use of raw disk partitions for global temporary tablespace data files is not supported.

The `autoextend` and `max` attributes can be used only for the data file specified last in the `innodb_temp_data_file_path` setting. For example:

```
[mysqld]
innodb_temp_data_file_path=ibtmp1:50M;ibtmp2:12M:autoextend:max:500M
```

The `autoextend` option causes the data file to automatically increase in size when it runs out of free space. The `autoextend` increment is 64MB by default. To modify the increment, change the `innodb_autoextend_increment` variable setting.

The directory path for global temporary tablespace data files is formed by concatenating the paths defined by `innodb_data_home_dir` and `innodb_temp_data_file_path`.

Before running InnoDB in read-only mode, set `innodb_temp_data_file_path` to a location outside of the data directory. The path must be relative to the data directory. For example:

```
--innodb-temp-data-file-path=../../tmp/ibtmp1:12M:autoextend
```

For more information, see [Global Temporary Tablespace](#).

- `innodb_temp_tablespaces_dir`

Command-Line Format	<code>--innodb-temp-tablespaces-dir=dir_name</code>
System Variable	<code>innodb_temp_tablespaces_dir</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Directory name

Default Value	<code>#innodb_temp</code>
---------------	---------------------------

Defines the location where InnoDB creates a pool of session temporary tablespaces at startup. The default location is the `#innodb_temp` directory in the data directory. A fully qualified path or path relative to the data directory is permitted.

Session temporary tablespaces always store user-created temporary tables and internal temporary tables created by the optimizer using InnoDB. (Previously, the on-disk storage engine for internal temporary tables was determined by the `internal_tmp_disk_storage_engine` system variable, which is no longer supported. See [Storage Engine for On-Disk Internal Temporary Tables](#).)

For more information, see [Session Temporary Tablespaces](#).

- `innodb_thread_concurrency`

Command-Line Format	<code>--innodb-thread-concurrency=#</code>
System Variable	<code>innodb_thread_concurrency</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	1000

Defines the maximum number of threads permitted inside of InnoDB. A value of 0 (the default) is interpreted as infinite concurrency (no limit). This variable is intended for performance tuning on high concurrency systems.

InnoDB tries to keep the number of threads inside InnoDB less than or equal to the `innodb_thread_concurrency` limit. Threads waiting for locks are not counted in the number of concurrently executing threads.

The correct setting depends on workload and computing environment. Consider setting this variable if your MySQL instance shares CPU resources with other applications or if your workload or number of concurrent users is growing. Test a range of values to determine the setting that provides the best performance. `innodb_thread_concurrency` is a dynamic variable, which permits experimenting with different settings on a live test system. If a particular setting performs poorly, you can quickly set `innodb_thread_concurrency` back to 0.

Use the following guidelines to help find and maintain an appropriate setting:

- If the number of concurrent user threads for a workload is consistently small and does not affect performance, set `innodb_thread_concurrency=0` (no limit).
- If your workload is consistently heavy or occasionally spikes, set an `innodb_thread_concurrency` value and adjust it until you find the number of threads that provides the best performance. For example, suppose that your system typically has 40 to 50 users, but periodically the number increases to 60, 70, or more. Through testing, you find that performance remains largely stable with a limit of 80 concurrent users. In this case, set `innodb_thread_concurrency` to 80.

- If you do not want [InnoDB](#) to use more than a certain number of virtual CPUs for user threads (20 virtual CPUs, for example), set [innodb\\_thread\\_concurrency](#) to this number (or possibly lower, depending on performance testing). If your goal is to isolate MySQL from other applications, consider binding the [mysqld](#) process exclusively to the virtual CPUs. Be aware, however, that exclusive binding can result in non-optimal hardware usage if the [mysqld](#) process is not consistently busy. In this case, you can bind the [mysqld](#) process to the virtual CPUs but allow other applications to use some or all of the virtual CPUs.

**Note**

From an operating system perspective, using a resource management solution to manage how CPU time is shared among applications may be preferable to binding the [mysqld](#) process. For example, you could assign 90% of virtual CPU time to a given application while other critical processes *are not* running, and scale that value back to 40% when other critical processes *are* running.

- In some cases, the optimal [innodb\\_thread\\_concurrency](#) setting can be smaller than the number of virtual CPUs.
- An [innodb\\_thread\\_concurrency](#) value that is too high can cause performance regression due to increased contention on system internals and resources.
- Monitor and analyze your system regularly. Changes to workload, number of users, or computing environment may require that you adjust the [innodb\\_thread\\_concurrency](#) setting.

A value of 0 disables the [queries inside InnoDB](#) and [queries in queue](#) counters in the [ROW OPERATIONS](#) section of [SHOW ENGINE INNODB STATUS](#) output.

For related information, see [Section 17.8.4, “Configuring Thread Concurrency for InnoDB”](#).

- [innodb\\_thread\\_sleep\\_delay](#)

Command-Line Format	<a href="#">--innodb-thread-sleep-delay=#</a>
System Variable	<a href="#">innodb_thread_sleep_delay</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	<a href="#">10000</a>
Minimum Value	<a href="#">0</a>
Maximum Value	<a href="#">1000000</a>
Unit	microseconds

How long [InnoDB](#) threads sleep before joining the [InnoDB](#) queue, in microseconds. The default value is 10000. A value of 0 disables sleep. You can set [innodb\\_adaptive\\_max\\_sleep\\_delay](#) to the highest value you would allow for [innodb\\_thread\\_sleep\\_delay](#), and [InnoDB](#) automatically adjusts [innodb\\_thread\\_sleep\\_delay](#) up or down depending on current thread-scheduling activity. This dynamic adjustment helps the thread scheduling mechanism to work smoothly during times when the system is lightly loaded or when it is operating near full capacity.

For more information, see [Section 17.8.4, “Configuring Thread Concurrency for InnoDB”](#).

- `innodb_tmpdir`

Command-Line Format	<code>--innodb-tmpdir=dir_name</code>
System Variable	<code>innodb_tmpdir</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Directory name
Default Value	<code>NULL</code>

Used to define an alternate directory for temporary sort files created during online `ALTER TABLE` operations that rebuild the table.

Online `ALTER TABLE` operations that rebuild the table also create an *intermediate* table file in the same directory as the original table. The `innodb_tmpdir` option is not applicable to intermediate table files.

A valid value is any directory path other than the MySQL data directory path. If the value is `NULL` (the default), temporary files are created MySQL temporary directory (`$TMPDIR` on Unix, `%TEMP%` on Windows, or the directory specified by the `--tmpdir` configuration option). If a directory is specified, existence of the directory and permissions are only checked when `innodb_tmpdir` is configured using a `SET` statement. If a symlink is provided in a directory string, the symlink is resolved and stored as an absolute path. The path should not exceed 512 bytes. An online `ALTER TABLE` operation reports an error if `innodb_tmpdir` is set to an invalid directory. `innodb_tmpdir` overrides the MySQL `tmpdir` setting but only for online `ALTER TABLE` operations.

The `FILE` privilege is required to configure `innodb_tmpdir`.

The `innodb_tmpdir` option was introduced to help avoid overflowing a temporary file directory located on a `tmpfs` file system. Such overflows could occur as a result of large temporary sort files created during online `ALTER TABLE` operations that rebuild the table.

In replication environments, only consider replicating the `innodb_tmpdir` setting if all servers have the same operating system environment. Otherwise, replicating the `innodb_tmpdir` setting could result in a replication failure when running online `ALTER TABLE` operations that rebuild the table. If server operating environments differ, it is recommended that you configure `innodb_tmpdir` on each server individually.

For more information, see [Section 17.12.3, “Online DDL Space Requirements”](#). For information about online `ALTER TABLE` operations, see [Section 17.12, “InnoDB and Online DDL”](#).

- `innodb_trx_purge_view_update_only_debug`

Command-Line Format	<code>--innodb-trx-purge-view-update-only-debug[={OFF ON}]</code>
System Variable	<code>innodb_trx_purge_view_update_only_debug</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean

Default Value	OFF
---------------	-----

Pauses purging of delete-marked records while allowing the purge view to be updated. This option artificially creates a situation in which the purge view is updated but purges have not yet been performed. This option is only available if debugging support is compiled in using the `WITH_DEBUG CMake` option.

- `innodb_trx_rseg_n_slots_debug`

Command-Line Format	<code>--innodb-trx-rseg-n-slots-debug=#</code>
System Variable	<code>innodb_trx_rseg_n_slots_debug</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	1024

Sets a debug flag that limits `TRX_RSEG_N_SLOTS` to a given value for the `trx_rsegf_undo_find_free` function that looks for free slots for undo log segments. This option is only available if debugging support is compiled in using the `WITH_DEBUG CMake` option.

- `innodb_undo_directory`

Command-Line Format	<code>--innodb-undo-directory=dir_name</code>
System Variable	<code>innodb_undo_directory</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Directory name

The path where `InnoDB` creates undo tablespaces. Typically used to place undo tablespaces on a different storage device.

There is no default value (it is NULL). If the `innodb_undo_directory` variable is undefined, undo tablespaces are created in the data directory.

The default undo tablespaces (`innodb_undo_001` and `innodb_undo_002`) created when the MySQL instance is initialized always reside in the directory defined by the `innodb_undo_directory` variable.

Undo tablespaces created using `CREATE UNDO TABLESPACE` syntax are created in the directory defined by the `innodb_undo_directory` variable if a different path is not specified.

For more information, see [Section 17.6.3.4, “Undo Tablespaces”](#).

- `innodb_undo_log_encrypt`

Command-Line Format	<code>--innodb-undo-log-encrypt [= {OFF ON} ]</code>
---------------------	------------------------------------------------------

System Variable	<code>innodb_undo_log_encrypt</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Controls encryption of undo log data for tables encrypted using the [InnoDB data-at-rest encryption feature](#). Only applies to undo logs that reside in separate [undo tablespaces](#). See [Section 17.6.3.4, “Undo Tablespaces”](#). Encryption is not supported for undo log data that resides in the system tablespace. For more information, see [Undo Log Encryption](#).

- `innodb_undo_log_truncate`

Command-Line Format	<code>--innodb-undo-log-truncate[={OFF ON}]</code>
System Variable	<code>innodb_undo_log_truncate</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>ON</code>

When enabled, undo tablespaces that exceed the threshold value defined by `innodb_max_undo_log_size` are marked for truncation. Only undo tablespaces can be truncated. Truncating undo logs that reside in the system tablespace is not supported. For truncation to occur, there must be at least two undo tablespaces.

The `innodb_purge_rseg_truncate_frequency` variable can be used to expedite truncation of undo tablespaces.

For more information, see [Truncating Undo Tablespaces](#).

- `innodb_undo_tablespaces`

Command-Line Format	<code>--innodb-undo-tablespaces=#</code>
Deprecated	Yes
System Variable	<code>innodb_undo_tablespaces</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	<code>2</code>
Minimum Value	<code>2</code>

Maximum Value	127
---------------	-----

Defines the number of [undo tablespaces](#) used by [InnoDB](#). The default and minimum value is 2.

#### Note

The `innodb_undo_tablespaces` variable is deprecated; setting it has no effect. You should expect it to be removed in a future MySQL release.

For more information, see [Section 17.6.3.4, “Undo Tablespaces”](#).

- `innodb_use_fdatasync`

Command-Line Format	<code>--innodb-use-fdatasync[={OFF ON}]</code>
System Variable	<code>innodb_use_fdatasync</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	ON

On platforms that support `fdatasync()` system calls, having `innodb_use_fdatasync` enabled permits using `fdatasync()` instead of `fsync()` system calls for operating system flushes. An `fdatasync()` call does not flush changes to file metadata unless required for subsequent data retrieval, providing a potential performance benefit.

A subset of `innodb_flush_method` settings such as `fsync`, `O_DSYNC`, and `O_DIRECT` use `fsync()` system calls. The `innodb_use_fdatasync` variable is applicable when using those settings.

Before MySQL 8.4, this option was disabled by default.

- `innodb_use_native_aio`

Command-Line Format	<code>--innodb-use-native-aio[={OFF ON}]</code>
System Variable	<code>innodb_use_native_aio</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Boolean

Default Value	ON
---------------	----

Specifies whether to use the [asynchronous I/O](#) subsystem. This variable cannot be changed while the server is running. Normally, you do not need to configure this option, because it is enabled by default.

This feature improves the scalability of heavily I/O-bound systems, which typically show many pending reads/writes in `SHOW ENGINE INNODB STATUS` output.

Running with a large number of [InnoDB I/O](#) threads, and especially running multiple such instances on the same server machine, can exceed capacity limits on Linux systems. In this case, you may receive the following error:

```
EAGAIN: The specified maxevents exceeds the user's limit of available events.
```

You can typically address this error by writing a higher limit to `/proc/sys/fs/aio-max-nr`.

However, if a problem with the asynchronous I/O subsystem in the OS prevents [InnoDB](#) from starting, you can start the server with `innodb_use_native_aio=0`. This option may also be disabled automatically during startup if [InnoDB](#) detects a potential problem such as a combination of `tmpdir` location, `tmpfs` file system, and Linux kernel that does not support AIO on `tmpfs`.

For more information, see [Section 17.8.6, “Using Asynchronous I/O on Linux”](#).

- [innodb\\_validate\\_tablespace\\_paths](#)

Command-Line Format	<code>--innodb-validate-tablespace-paths[={OFF ON}]</code>
System Variable	<code>innodb_validate_tablespace_paths</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	ON

Controls tablespace file path validation. At startup, [InnoDB](#) validates the paths of known tablespace files against tablespace file paths stored in the data dictionary in case tablespace files have been moved to a different location. The `innodb_validate_tablespace_paths` variable permits disabling tablespace path validation. This feature is intended for environments where tablespaces files are not moved. Disabling path validation improves startup time on systems with a large number of tablespace files.

#### Warning

Starting the server with tablespace path validation disabled after moving tablespace files can lead to undefined behavior.

For more information, see [Section 17.6.3.7, “Disabling Tablespace Path Validation”](#).

- [innodb\\_version](#)

The [InnoDB](#) version number. This is a legacy variable, the value is the same as the MySQL server `version`.

- `innodb_write_io_threads`

Command-Line Format	<code>--innodb-write-io-threads=#</code>
System Variable	<code>innodb_write_io_threads</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Integer
Default Value	4
Minimum Value	1
Maximum Value	64

The number of I/O threads for write operations in InnoDB. The default value is 4. Its counterpart for read threads is `innodb_read_io_threads`. For more information, see [Section 17.8.5, “Configuring the Number of Background InnoDB I/O Threads”](#). For general I/O tuning advice, see [Section 10.5.8, “Optimizing InnoDB Disk I/O”](#).

#### Note

On Linux systems, running multiple MySQL servers (typically more than 12) with default settings for `innodb_read_io_threads`, `innodb_write_io_threads`, and the Linux `aio-max-nr` setting can exceed system limits. Ideally, increase the `aio-max-nr` setting; as a workaround, you might reduce the settings for one or both of the MySQL variables.

Also take into consideration the value of `sync_binlog`, which controls synchronization of the binary log to disk.

For general I/O tuning advice, see [Section 10.5.8, “Optimizing InnoDB Disk I/O”](#).

## 17.15 InnoDB INFORMATION\_SCHEMA Tables

This section provides information and usage examples for InnoDB INFORMATION\_SCHEMA tables.

InnoDB INFORMATION\_SCHEMA tables provide metadata, status information, and statistics about various aspects of the InnoDB storage engine. You can view a list of InnoDB INFORMATION\_SCHEMA tables by issuing a `SHOW TABLES` statement on the INFORMATION\_SCHEMA database:

```
mysql> SHOW TABLES FROM INFORMATION_SCHEMA LIKE 'INNODB%';
```

For table definitions, see [Section 28.4, “INFORMATION\\_SCHEMA InnoDB Tables”](#). For general information regarding the MySQL INFORMATION\_SCHEMA database, see [Chapter 28, INFORMATION\\_SCHEMA Tables](#).

### 17.15.1 InnoDB INFORMATION\_SCHEMA Tables about Compression

There are two pairs of InnoDB INFORMATION\_SCHEMA tables about compression that can provide insight into how well compression is working overall:

- `INNODB_CMP` and `INNODB_CMP_RESET` provide information about the number of compression operations and the amount of time spent performing compression.

- [INNODB\\_CMPMEM](#) and [INNODB\\_CMPMEM\\_RESET](#) provide information about the way memory is allocated for compression.

### 17.15.1.1 INNODB\_CMP and INNODB\_CMP\_RESET

The [INNODB\\_CMP](#) and [INNODB\\_CMP\\_RESET](#) tables provide status information about operations related to compressed tables, which are described in [Section 17.9, “InnoDB Table and Page Compression”](#). The [PAGE\\_SIZE](#) column reports the compressed [page size](#).

These two tables have identical contents, but reading from [INNODB\\_CMP\\_RESET](#) resets the statistics on compression and uncompression operations. For example, if you archive the output of [INNODB\\_CMP\\_RESET](#) every 60 minutes, you see the statistics for each hourly period. If you monitor the output of [INNODB\\_CMP](#) (making sure never to read [INNODB\\_CMP\\_RESET](#)), you see the cumulative statistics since InnoDB was started.

For the table definition, see [Section 28.4.6, “The INFORMATION\\_SCHEMA INNODB\\_CMP and INNODB\\_CMP\\_RESET Tables”](#).

### 17.15.1.2 INNODB\_CMPMEM and INNODB\_CMPMEM\_RESET

The [INNODB\\_CMPMEM](#) and [INNODB\\_CMPMEM\\_RESET](#) tables provide status information about compressed pages that reside in the buffer pool. Please consult [Section 17.9, “InnoDB Table and Page Compression”](#) for further information on compressed tables and the use of the buffer pool. The [INNODB\\_CMP](#) and [INNODB\\_CMP\\_RESET](#) tables should provide more useful statistics on compression.

#### Internal Details

InnoDB uses a [buddy allocator](#) system to manage memory allocated to [pages of various sizes](#), from 1KB to 16KB. Each row of the two tables described here corresponds to a single page size.

The [INNODB\\_CMPMEM](#) and [INNODB\\_CMPMEM\\_RESET](#) tables have identical contents, but reading from [INNODB\\_CMPMEM\\_RESET](#) resets the statistics on relocation operations. For example, if every 60 minutes you archived the output of [INNODB\\_CMPMEM\\_RESET](#), it would show the hourly statistics. If you never read [INNODB\\_CMPMEM\\_RESET](#) and monitored the output of [INNODB\\_CMPMEM](#) instead, it would show the cumulative statistics since InnoDB was started.

For the table definition, see [Section 28.4.7, “The INFORMATION\\_SCHEMA INNODB\\_CMPMEM and INNODB\\_CMPMEM\\_RESET Tables”](#).

### 17.15.1.3 Using the Compression Information Schema Tables

#### Example 17.1 Using the Compression Information Schema Tables

The following is sample output from a database that contains compressed tables (see [Section 17.9, “InnoDB Table and Page Compression”](#), [INNODB\\_CMP](#), [INNODB\\_CMP\\_PER\\_INDEX](#), and [INNODB\\_CMPMEM](#)).

The following table shows the contents of [INFORMATION\\_SCHEMA.INNODB\\_CMP](#) under a light [workload](#). The only compressed page size that the buffer pool contains is 8K. Compressing or uncompressing pages has consumed less than a second since the time the statistics were reset, because the columns [COMPRESS\\_TIME](#) and [UNCOMPRESS\\_TIME](#) are zero.

page size	compress ops	compress ops ok	compress time	uncompress ops	uncompress time
1024	0	0	0	0	0
2048	0	0	0	0	0

page size	compress ops	compress ops ok	compress time	uncompress ops	uncompress time
4096	0	0	0	0	0
8192	1048	921	0	61	0
16384	0	0	0	0	0

According to `INNODB_CMPMEM`, there are 6169 compressed 8KB pages in the `buffer pool`. The only other allocated block size is 64 bytes. The smallest `PAGE_SIZE` in `INNODB_CMPMEM` is used for block descriptors of those compressed pages for which no uncompressed page exists in the buffer pool. We see that there are 5910 such pages. Indirectly, we see that 259 (6169-5910) compressed pages also exist in the buffer pool in uncompressed form.

The following table shows the contents of `INFORMATION_SCHEMA.INNODB_CMPMEM` under a light `workload`. Some memory is unusable due to fragmentation of the memory allocator for compressed pages: `SUM(PAGE_SIZE*PAGES_FREE)=6784`. This is because small memory allocation requests are fulfilled by splitting bigger blocks, starting from the 16K blocks that are allocated from the main buffer pool, using the buddy allocation system. The fragmentation is this low because some allocated blocks have been relocated (copied) to form bigger adjacent free blocks. This copying of `SUM(PAGE_SIZE*RELOCATION_OPS)` bytes has consumed less than a second (`SUM(RELOCATION_TIME)=0`).

page size	pages used	pages free	relocation ops	relocation time
64	5910	0	2436	0
128	0	1	0	0
256	0	0	0	0
512	0	1	0	0
1024	0	0	0	0
2048	0	1	0	0
4096	0	1	0	0
8192	6169	0	5	0
16384	0	0	0	0

## 17.15.2 InnoDB INFORMATION\_SCHEMA Transaction and Locking Information

One `INFORMATION_SCHEMA` table and two Performance Schema tables enable you to monitor `InnoDB` transactions and diagnose potential locking problems:

- `INNODB_TRX`: This `INFORMATION_SCHEMA` table provides information about every transaction currently executing inside `InnoDB`, including the transaction state (for example, whether it is running or waiting for a lock), when the transaction started, and the particular SQL statement the transaction is executing.
- `data_locks`: This Performance Schema table contains a row for each held lock and each lock request that is blocked waiting for a held lock to be released:
  - There is one row for each held lock, whatever the state of the transaction that holds the lock (`INNODB_TRX.TRX_STATE` is `RUNNING`, `LOCK WAIT`, `ROLLING BACK` or `COMMITTING`).
  - Each transaction in `InnoDB` that is waiting for another transaction to release a lock (`INNODB_TRX.TRX_STATE` is `LOCK WAIT`) is blocked by exactly one blocking lock request. That blocking lock request is for a row or table lock held by another transaction in an incompatible mode.

A lock request always has a mode that is incompatible with the mode of the held lock that blocks the request (read vs. write, shared vs. exclusive).

The blocked transaction cannot proceed until the other transaction commits or rolls back, thereby releasing the requested lock. For every blocked transaction, `data_locks` contains one row that describes each lock the transaction has requested, and for which it is waiting.

- `data_lock_waits`: This Performance Schema table indicates which transactions are waiting for a given lock, or for which lock a given transaction is waiting. This table contains one or more rows for each blocked transaction, indicating the lock it has requested and any locks that are blocking that request. The `REQUESTING_ENGINE_LOCK_ID` value refers to the lock requested by a transaction, and the `BLOCKING_ENGINE_LOCK_ID` value refers to the lock (held by another transaction) that prevents the first transaction from proceeding. For any given blocked transaction, all rows in `data_lock_waits` have the same value for `REQUESTING_ENGINE_LOCK_ID` and different values for `BLOCKING_ENGINE_LOCK_ID`.

For more information about the preceding tables, see [Section 28.4.28, “The INFORMATION\\_SCHEMA INNODB\\_TRX Table”](#), [Section 29.12.13.1, “The data\\_locks Table”](#), and [Section 29.12.13.2, “The data\\_lock\\_waits Table”](#).

### 17.15.2.1 Using InnoDB Transaction and Locking Information

This section describes the use of locking information as exposed by the Performance Schema `data_locks` and `data_lock_waits` tables.

#### Identifying Blocking Transactions

It is sometimes helpful to identify which transaction blocks another. The tables that contain information about InnoDB transactions and data locks enable you to determine which transaction is waiting for another, and which resource is being requested. (For descriptions of these tables, see [Section 17.15.2, “InnoDB INFORMATION\\_SCHEMA Transaction and Locking Information”](#).)

Suppose that three sessions are running concurrently. Each session corresponds to a MySQL thread, and executes one transaction after another. Consider the state of the system when these sessions have issued the following statements, but none has yet committed its transaction:

- Session A:

```
BEGIN;
SELECT a FROM t FOR UPDATE;
SELECT SLEEP(100);
```

- Session B:

```
SELECT b FROM t FOR UPDATE;
```

- Session C:

```
SELECT c FROM t FOR UPDATE;
```

In this scenario, use the following query to see which transactions are waiting and which transactions are blocking them:

```
SELECT
 r.trx_id waiting_trx_id,
 r.trx_mysql_thread_id waiting_thread,
 r.trx_query waiting_query,
 b.trx_id blocking_trx_id,
 b.trx_mysql_thread_id blocking_thread,
 b.trx_query blocking_query
```

```
FROM performance_schema.data_lock_waits w
INNER JOIN information_schema.innodb_trx b
 ON b.trx_id = w.blocking_engine_transaction_id
INNER JOIN information_schema.innodb_trx r
 ON r.trx_id = w.requesting_engine_transaction_id;
```

Or, more simply, use the `sys` schema `innodb_lock_waits` view:

```
SELECT
 waiting_trx_id,
 waiting_pid,
 waiting_query,
 blocking_trx_id,
 blocking_pid,
 blocking_query
FROM sys.innodb_lock_waits;
```

If a NULL value is reported for the blocking query, see [Identifying a Blocking Query After the Issuing Session Becomes Idle](#).

waiting trx id	waiting thread	waiting query	blocking trx id	blocking thread	blocking query
A4	6	SELECT b FROM t FOR UPDATE	A3	5	SELECT SLEEP(100)
A5	7	SELECT c FROM t FOR UPDATE	A3	5	SELECT SLEEP(100)
A5	7	SELECT c FROM t FOR UPDATE	A4	6	SELECT b FROM t FOR UPDATE

In the preceding table, you can identify sessions by the “waiting query” or “blocking query” columns. As you can see:

- Session B (trx id [A4](#), thread [6](#)) and Session C (trx id [A5](#), thread [7](#)) are both waiting for Session A (trx id [A3](#), thread [5](#)).
- Session C is waiting for Session B as well as Session A.

You can see the underlying data in the `INFORMATION_SCHEMA INNODB_TRX` table and Performance Schema `data_locks` and `data_lock_waits` tables.

The following table shows some sample contents of the `INNODB_TRX` table.

trx id	trx state	trx started	trx requested lock id	trx wait started	trx weight	trx mysql thread id	trx query
A3	RUNNING	2008-01-15 16:44:54	NULL	NULL	2	5	SELECT SLEEP(100)
A4	LOCK WAIT	2008-01-15 16:45:09	A4:1:3:2	2008-01-15 16:45:09	2	6	SELECT b FROM t FOR UPDATE
A5	LOCK WAIT	2008-01-15 16:45:14	A5:1:3:2	2008-01-15 16:45:14	2	7	SELECT c FROM t FOR UPDATE

The following table shows some sample contents of the `data_locks` table.

lock id	lock trx id	lock mode	lock type	lock schema	lock table	lock index	lock data
A3:1:3:2	A3	X	RECORD	test	t	PRIMARY	0x0200
A4:1:3:2	A4	X	RECORD	test	t	PRIMARY	0x0200
A5:1:3:2	A5	X	RECORD	test	t	PRIMARY	0x0200

The following table shows some sample contents of the `data_lock_waits` table.

requesting trx id	requested lock id	blocking trx id	blocking lock id
A4	A4:1:3:2	A3	A3:1:3:2
A5	A5:1:3:2	A3	A3:1:3:2
A5	A5:1:3:2	A4	A4:1:3:2

## Identifying a Blocking Query After the Issuing Session Becomes Idle

When identifying blocking transactions, a NULL value is reported for the blocking query if the session that issued the query has become idle. In this case, use the following steps to determine the blocking query:

1. Identify the processlist ID of the blocking transaction. In the `sys.innodb_lock_waits` table, the processlist ID of the blocking transaction is the `blocking_pid` value.
2. Using the `blocking_pid`, query the MySQL Performance Schema `threads` table to determine the `THREAD_ID` of the blocking transaction. For example, if the `blocking_pid` is 6, issue this query:

```
SELECT THREAD_ID FROM performance_schema.threads WHERE PROCESSLIST_ID = 6;
```

3. Using the `THREAD_ID`, query the Performance Schema `events_statements_current` table to determine the last query executed by the thread. For example, if the `THREAD_ID` is 28, issue this query:

```
SELECT THREAD_ID, SQL_TEXT FROM performance_schema.events_statements_current
WHERE THREAD_ID = 28\G
```

4. If the last query executed by the thread is not enough information to determine why a lock is held, you can query the Performance Schema `events_statements_history` table to view the last 10 statements executed by the thread.

```
SELECT THREAD_ID, SQL_TEXT FROM performance_schema.events_statements_history
WHERE THREAD_ID = 28 ORDER BY EVENT_ID;
```

## Correlating InnoDB Transactions with MySQL Sessions

Sometimes it is useful to correlate internal InnoDB locking information with the session-level information maintained by MySQL. For example, you might like to know, for a given InnoDB transaction ID, the corresponding MySQL session ID and name of the session that may be holding a lock, and thus blocking other transactions.

The following output from the `INFORMATION_SCHEMA.INNODB_TRX` table and Performance Schema `data_locks` and `data_lock_waits` tables is taken from a somewhat loaded system. As can be seen, there are several transactions running.

The following `data_locks` and `data_lock_waits` tables show that:

- Transaction **77F** (executing an `INSERT`) is waiting for transactions **77E**, **77D**, and **77B** to commit.

- Transaction [77E](#) (executing an [INSERT](#)) is waiting for transactions [77D](#) and [77B](#) to commit.
- Transaction [77D](#) (executing an [INSERT](#)) is waiting for transaction [77B](#) to commit.
- Transaction [77B](#) (executing an [INSERT](#)) is waiting for transaction [77A](#) to commit.
- Transaction [77A](#) is running, currently executing [SELECT](#).
- Transaction [E56](#) (executing an [INSERT](#)) is waiting for transaction [E55](#) to commit.
- Transaction [E55](#) (executing an [INSERT](#)) is waiting for transaction [19C](#) to commit.
- Transaction [19C](#) is running, currently executing an [INSERT](#).

**Note**

There may be inconsistencies between queries shown in the [INFORMATION\\_SCHEMA PROCESSLIST](#) and [INNODB\\_TRX](#) tables. For an explanation, see [Section 17.15.2.3, “Persistence and Consistency of InnoDB Transaction and Locking Information”](#).

The following table shows the contents of the [PROCESSLIST](#) table for a system running a heavy [workload](#).

ID	USER	HOST	DB	COMMAND	TIME	STATE	INFO
384	root	localhost	test	Query	10	update	INSERT INTO t2 VALUES ...
257	root	localhost	test	Query	3	update	INSERT INTO t2 VALUES ...
130	root	localhost	test	Query	0	update	INSERT INTO t2 VALUES ...
61	root	localhost	test	Query	1	update	INSERT INTO t2 VALUES ...
8	root	localhost	test	Query	1	update	INSERT INTO t2 VALUES ...
4	root	localhost	test	Query	0	preparing	SELECT * FROM PROCESSLIST
2	root	localhost	test	Sleep	566		NULL

The following table shows the contents of the [INNODB\\_TRX](#) table for a system running a heavy [workload](#).

trx id	trx state	trx started	trx requested lock id	trx wait started	trx weight	trx mysql thread id	trx query
77F	LOCK WAIT	2008-01-15 13:10:16	77F	2008-01-15 13:10:16		876	INSERT INTO t09 (D, B, C) VALUES ...

trx id	trx state	trx started	trx requested lock id	trx wait started	trx weight	trx mysql thread id	trx query
77E	LOCK WAIT	2008-01-15 13:10:16	77E	2008-01-15 13:10:16	1	875	INSERT INTO t09 (D, B, C) VALUES ...
77D	LOCK WAIT	2008-01-15 13:10:16	77D	2008-01-15 13:10:16	1	874	INSERT INTO t09 (D, B, C) VALUES ...

### 17.15.2.2 InnoDB Lock and Lock-Wait Information

When a transaction updates a row in a table, or locks it with `SELECT FOR UPDATE`, InnoDB establishes a list or queue of locks on that row. Similarly, InnoDB maintains a list of locks on a table for table-level locks. If a second transaction wants to update a row or lock a table already locked by a prior transaction in an incompatible mode, InnoDB adds a lock request for the row to the corresponding queue. For a lock to be acquired by a transaction, all incompatible lock requests previously entered into the lock queue for that row or table must be removed (which occurs when the transactions holding or requesting those locks either commit or roll back).

A transaction may have any number of lock requests for different rows or tables. At any given time, a transaction may request a lock that is held by another transaction, in which case it is blocked by that other transaction. The requesting transaction must wait for the transaction that holds the blocking lock to commit or roll back. If a transaction is not waiting for a lock, it is in a `RUNNING` state. If a transaction is waiting for a lock, it is in a `LOCK WAIT` state. (The `INFORMATION_SCHEMA.INNODB_TRX` table indicates transaction state values.)

The Performance Schema `data_locks` table holds one or more rows for each `LOCK WAIT` transaction, indicating any lock requests that prevent its progress. This table also contains one row describing each lock in a queue of locks pending for a given row or table. The Performance Schema `data_lock_waits` table shows which locks already held by a transaction are blocking locks requested by other transactions.

### 17.15.2.3 Persistence and Consistency of InnoDB Transaction and Locking Information

The data exposed by the transaction and locking tables (`INFORMATION_SCHEMA.INNODB_TRX` table, Performance Schema `data_locks` and `data_lock_waits` tables) represents a glimpse into fast-

changing data. This is not like user tables, where the data changes only when application-initiated updates occur. The underlying data is internal system-managed data, and can change very quickly:

- Data might not be consistent between the `INNODB_TRX`, `data_locks`, and `data_lock_waits` tables.

The `data_locks` and `data_lock_waits` tables expose live data from the InnoDB storage engine, to provide lock information about the transactions in the `INNODB_TRX` table. Data retrieved from the lock tables exists when the `SELECT` is executed, but might be gone or changed by the time the query result is consumed by the client.

Joining `data_locks` with `data_lock_waits` can show rows in `data_lock_waits` that identify a parent row in `data_locks` that no longer exists or does not exist yet.

- Data in the transaction and locking tables might not be consistent with data in the `INFORMATION_SCHEMA.PROCESSLIST` table or Performance Schema `threads` table.

For example, you should be careful when comparing data in the InnoDB transaction and locking tables with data in the `PROCESSLIST` table. Even if you issue a single `SELECT` (joining `INNODB_TRX` and `PROCESSLIST`, for example), the content of those tables is generally not consistent. It is possible for `INNODB_TRX` to reference rows that are not present in `PROCESSLIST` or for the currently executing SQL query of a transaction shown in `INNODB_TRX.TRX_QUERY` to differ from the one in `PROCESSLIST.INFO`.

### 17.15.3 InnoDB INFORMATION\_SCHEMA Schema Object Tables

You can extract metadata about schema objects managed by InnoDB using InnoDB `INFORMATION_SCHEMA` tables. This information comes from the data dictionary. Traditionally, you would get this type of information using the techniques from [Section 17.17, “InnoDB Monitors”](#), setting up InnoDB monitors and parsing the output from the `SHOW ENGINE INNODB STATUS` statement. The InnoDB `INFORMATION_SCHEMA` table interface allows you to query this data using SQL.

InnoDB `INFORMATION_SCHEMA` schema object tables include the tables listed here:

- `INNODB_DATAFILES`
- `INNODB_TABLESTATS`
- `INNODB_FOREIGN`
- `INNODB_COLUMNS`
- `INNODB_INDEXES`
- `INNODB_FIELDS`
- `INNODB_TABLESPACES`
- `INNODB_TABLESPACES_BRIEF`
- `INNODB_FOREIGN_COLS`
- `INNODB_TABLES`

---

The table names are indicative of the type of data provided:

- `INNODB_TABLES` provides metadata about InnoDB tables.
- `INNODB_COLUMNS` provides metadata about InnoDB table columns.

- `INNODB_INDEXES` provides metadata about `InnoDB` indexes.
- `INNODB_FIELDS` provides metadata about the key columns (fields) of `InnoDB` indexes.
- `INNODB_TABLESTATS` provides a view of low-level status information about `InnoDB` tables that is derived from in-memory data structures.
- `INNODB_DATAFILES` provides data file path information for `InnoDB` file-per-table and general tablespaces.
- `INNODB_TABLESPACES` provides metadata about `InnoDB` file-per-table, general, and undo tablespaces.
- `INNODB_TABLESPACES_BRIEF` provides a subset of metadata about `InnoDB` tablespaces.
- `INNODB_FOREIGN` provides metadata about foreign keys defined on `InnoDB` tables.
- `INNODB_FOREIGN_COLS` provides metadata about the columns of foreign keys that are defined on `InnoDB` tables.

`InnoDB INFORMATION_SCHEMA` schema object tables can be joined together through fields such as `TABLE_ID`, `INDEX_ID`, and `SPACE`, allowing you to easily retrieve all available data for an object you want to study or monitor.

Refer to the `InnoDB INFORMATION_SCHEMA` documentation for information about the columns of each table.

### Example 17.2 InnoDB INFORMATION\_SCHEMA Schema Object Tables

This example uses a simple table (`t1`) with a single index (`i1`) to demonstrate the type of metadata found in the `InnoDB INFORMATION_SCHEMA` schema object tables.

1. Create a test database and table `t1`:

```
mysql> CREATE DATABASE test;

mysql> USE test;

mysql> CREATE TABLE t1 (
 col1 INT,
 col2 CHAR(10),
 col3 VARCHAR(10))
 ENGINE = InnoDB;

mysql> CREATE INDEX i1 ON t1(col1);
```

2. After creating the table `t1`, query `INNODB_TABLES` to locate the metadata for `test/t1`:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TABLES WHERE NAME='test/t1' \G
***** 1. row *****
 TABLE_ID: 71
 NAME: test/t1
 FLAG: 1
 N_COLS: 6
 SPACE: 57
 ROW_FORMAT: Compact
ZIP_PAGE_SIZE: 0
 INSTANT_COLS: 0
```

Table `t1` has a `TABLE_ID` of 71. The `FLAG` field provides bit level information about table format and storage characteristics. There are six columns, three of which are hidden columns created by `InnoDB` (`DB_ROW_ID`, `DB_TRX_ID`, and `DB_ROLL_PTR`). The ID of the table's `SPACE` is 57 (a value

of 0 would indicate that the table resides in the system tablespace). The `ROW_FORMAT` is `Compact`. `ZIP_PAGE_SIZE` only applies to tables with a `Compressed` row format. `INSTANT_COLS` shows number of columns in the table prior to adding the first instant column using `ALTER TABLE ... ADD COLUMN` with `ALGORITHM=INSTANT`.

- Using the `TABLE_ID` information from `INNODB_TABLES`, query the `INNODB_COLUMNS` table for information about the table's columns.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_COLUMNS where TABLE_ID = 71\G
***** 1. row *****
 TABLE_ID: 71
 NAME: col1
 POS: 0
 MTYPE: 6
 PRYPE: 1027
 LEN: 4
 HAS_DEFAULT: 0
DEFAULT_VALUE: NULL
***** 2. row *****
 TABLE_ID: 71
 NAME: col2
 POS: 1
 MTYPE: 2
 PRYPE: 524542
 LEN: 10
 HAS_DEFAULT: 0
DEFAULT_VALUE: NULL
***** 3. row *****
 TABLE_ID: 71
 NAME: col3
 POS: 2
 MTYPE: 1
 PRYPE: 524303
 LEN: 10
 HAS_DEFAULT: 0
DEFAULT_VALUE: NULL
```

In addition to the `TABLE_ID` and column `NAME`, `INNODB_COLUMNS` provides the ordinal position (`POS`) of each column (starting from 0 and incrementing sequentially), the column `MTYPE` or “main type” (6 = INT, 2 = CHAR, 1 = VARCHAR), the `PRYPE` or “precise type” (a binary value with bits that represent the MySQL data type, character set code, and nullability), and the column length (`LEN`). The `HAS_DEFAULT` and `DEFAULT_VALUE` columns only apply to columns added instantly using `ALTER TABLE ... ADD COLUMN` with `ALGORITHM=INSTANT`.

- Using the `TABLE_ID` information from `INNODB_TABLES` once again, query `INNODB_INDEXES` for information about the indexes associated with table `t1`.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_INDEXES WHERE TABLE_ID = 71 \G
***** 1. row *****
 INDEX_ID: 111
 NAME: GEN_CLUST_INDEX
 TABLE_ID: 71
 TYPE: 1
 N_FIELDS: 0
 PAGE_NO: 3
 SPACE: 57
MERGE_THRESHOLD: 50
***** 2. row *****
 INDEX_ID: 112
 NAME: i1
 TABLE_ID: 71
 TYPE: 0
 N_FIELDS: 1
 PAGE_NO: 4
```

```
SPACE: 57
MERGE_THRESHOLD: 50
```

`INNODB_INDEXES` returns data for two indexes. The first index is `GEN_CLUST_INDEX`, which is a clustered index created by `InnoDB` if the table does not have a user-defined clustered index. The second index (`i1`) is the user-defined secondary index.

The `INDEX_ID` is an identifier for the index that is unique across all databases in an instance. The `TABLE_ID` identifies the table that the index is associated with. The index `TYPE` value indicates the type of index (1 = Clustered Index, 0 = Secondary index). The `N_FIELDS` value is the number of fields that comprise the index. `PAGE_NO` is the root page number of the index B-tree, and `SPACE` is the ID of the tablespace where the index resides. A nonzero value indicates that the index does not reside in the system tablespace. `MERGE_THRESHOLD` defines a percentage threshold value for the amount of data in an index page. If the amount of data in an index page falls below the this value (the default is 50%) when a row is deleted or when a row is shortened by an update operation, `InnoDB` attempts to merge the index page with a neighboring index page.

- Using the `INDEX_ID` information from `INNODB_INDEXES`, query `INNODB_FIELDS` for information about the fields of index `i1`.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FIELDS where INDEX_ID = 112 \G
***** 1. row *****
INDEX_ID: 112
NAME: coll
POS: 0
```

`INNODB_FIELDS` provides the `NAME` of the indexed field and its ordinal position within the index. If the index (`i1`) had been defined on multiple fields, `INNODB_FIELDS` would provide metadata for each of the indexed fields.

- Using the `SPACE` information from `INNODB_TABLES`, query `INNODB_TABLESPACES` table for information about the table's tablespace.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TABLESPACES WHERE SPACE = 57 \G
***** 1. row *****
SPACE: 57
NAME: test/t1
FLAG: 16417
ROW_FORMAT: Dynamic
PAGE_SIZE: 16384
ZIP_PAGE_SIZE: 0
SPACE_TYPE: Single
FS_BLOCK_SIZE: 4096
FILE_SIZE: 114688
ALLOCATED_SIZE: 98304
AUTOEXTEND_SIZE: 0
SERVER_VERSION: 8.4.0
SPACE_VERSION: 1
ENCRYPTION: N
STATE: normal
```

In addition to the `SPACE` ID of the tablespace and the `NAME` of the associated table, `INNODB_TABLESPACES` provides tablespace `FLAG` data, which is bit level information about tablespace format and storage characteristics. Also provided are tablespace `ROW_FORMAT`, `PAGE_SIZE`, and several other tablespace metadata items.

- Using the `SPACE` information from `INNODB_TABLES` once again, query `INNODB_DATAFILES` for the location of the tablespace data file.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_DATAFILES WHERE SPACE = 57 \G
***** 1. row *****
```

```
SPACE: 57
PATH: ./test/t1.ibd
```

The datafile is located in the `test` directory under MySQL's `data` directory. If a `file-per-table` tablespace were created in a location outside the MySQL data directory using the `DATA DIRECTORY` clause of the `CREATE TABLE` statement, the tablespace `PATH` would be a fully qualified directory path.

- As a final step, insert a row into table `t1` (`TABLE_ID = 71`) and view the data in the `INNODB_TABLESTATS` table. The data in this table is used by the MySQL optimizer to calculate which index to use when querying an InnoDB table. This information is derived from in-memory data structures.

```
mysql> INSERT INTO t1 VALUES(5, 'abc', 'def');
Query OK, 1 row affected (0.06 sec)

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TABLESTATS where TABLE_ID = 71 \G
***** 1. row *****
 TABLE_ID: 71
 NAME: test/t1
 STATS_INITIALIZED: Initialized
 NUM_ROWS: 1
 CLUST_INDEX_SIZE: 1
 OTHER_INDEX_SIZE: 0
 MODIFIED_COUNTER: 1
 AUTOINC: 0
 REF_COUNT: 1
```

The `STATS_INITIALIZED` field indicates whether or not statistics have been collected for the table. `NUM_ROWS` is the current estimated number of rows in the table. The `CLUST_INDEX_SIZE` and `OTHER_INDEX_SIZE` fields report the number of pages on disk that store clustered and secondary indexes for the table, respectively. The `MODIFIED_COUNTER` value shows the number of rows modified by DML operations and cascade operations from foreign keys. The `AUTOINC` value is the next number to be issued for any autoincrement-based operation. There are no autoincrement columns defined on table `t1`, so the value is 0. The `REF_COUNT` value is a counter. When the counter reaches 0, it signifies that the table metadata can be evicted from the table cache.

### Example 17.3 Foreign Key INFORMATION\_SCHEMA Schema Object Tables

The `INNODB_FOREIGN` and `INNODB_FOREIGN_COLS` tables provide data about foreign key relationships. This example uses a parent table and child table with a foreign key relationship to demonstrate the data found in the `INNODB_FOREIGN` and `INNODB_FOREIGN_COLS` tables.

- Create the test database with parent and child tables:

```
mysql> CREATE DATABASE test;

mysql> USE test;

mysql> CREATE TABLE parent (id INT NOT NULL,
 PRIMARY KEY (id)) ENGINE=INNODB;

mysql> CREATE TABLE child (id INT, parent_id INT,
 -> INDEX par_ind (parent_id),
 -> CONSTRAINT fk1
 -> FOREIGN KEY (parent_id) REFERENCES parent(id)
 -> ON DELETE CASCADE) ENGINE=INNODB;
```

- After the parent and child tables are created, query `INNODB_FOREIGN` and locate the foreign key data for the `test/child` and `test/parent` foreign key relationship:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FOREIGN \G
***** 1. row *****
```

```

 ID: test/fk1
FOR_NAME: test/child
REF_NAME: test/parent
 N_COLS: 1
 TYPE: 1

```

Metadata includes the foreign key `ID` (`fk1`), which is named for the `CONSTRAINT` that was defined on the child table. The `FOR_NAME` is the name of the child table where the foreign key is defined. `REF_NAME` is the name of the parent table (the “referenced” table). `N_COLS` is the number of columns in the foreign key index. `TYPE` is a numerical value representing bit flags that provide additional information about the foreign key column. In this case, the `TYPE` value is 1, which indicates that the `ON DELETE CASCADE` option was specified for the foreign key. See the `INNODB_FOREIGN` table definition for more information about `TYPE` values.

- Using the foreign key `ID`, query `INNODB_FOREIGN_COLS` to view data about the columns of the foreign key.

```

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FOREIGN_COLS WHERE ID = 'test/fk1' \G
***** 1. row *****
 ID: test/fk1
FOR_COL_NAME: parent_id
REF_COL_NAME: id
 POS: 0

```

`FOR_COL_NAME` is the name of the foreign key column in the child table, and `REF_COL_NAME` is the name of the referenced column in the parent table. The `POS` value is the ordinal position of the key field within the foreign key index, starting at zero.

#### Example 17.4 Joining InnoDB INFORMATION\_SCHEMA Schema Object Tables

This example demonstrates joining three `InnoDB INFORMATION_SCHEMA` schema object tables (`INNODB_TABLES`, `INNODB_TABLESPACES`, and `INNODB_TABLESTATS`) to gather file format, row format, page size, and index size information about tables in the `employees` sample database.

The following table aliases are used to shorten the query string:

- `INFORMATION_SCHEMA.INNODB_TABLES: a`
- `INFORMATION_SCHEMA.INNODB_TABLESPACES: b`
- `INFORMATION_SCHEMA.INNODB_TABLESTATS: c`

An `IF()` control flow function is used to account for compressed tables. If a table is compressed, the index size is calculated using `ZIP_PAGE_SIZE` rather than `PAGE_SIZE`. `CLUST_INDEX_SIZE` and `OTHER_INDEX_SIZE`, which are reported in bytes, are divided by `1024*1024` to provide index sizes in megabytes (MBs). MB values are rounded to zero decimal spaces using the `ROUND()` function.

```

mysql> SELECT a.NAME, a.ROW_FORMAT,
 @page_size :=
 IF(a.ROW_FORMAT='Compressed',
 b.ZIP_PAGE_SIZE, b.PAGE_SIZE)
 AS page_size,
 ROUND((@page_size * c.CLUST_INDEX_SIZE)
 /(1024*1024)) AS pk_mb,
 ROUND((@page_size * c.OTHER_INDEX_SIZE)
 /(1024*1024)) AS secidx_mb
 FROM INFORMATION_SCHEMA.INNODB_TABLES a
 INNER JOIN INFORMATION_SCHEMA.INNODB_TABLESPACES b on a.NAME = b.NAME
 INNER JOIN INFORMATION_SCHEMA.INNODB_TABLESTATS c on b.NAME = c.NAME
 WHERE a.NAME LIKE 'employees/%'
 ORDER BY a.NAME DESC;

```

NAME	ROW_FORMAT	page_size	pk_mb	secidx_mb
employees/titles	Dynamic	16384	20	11
employees/salaries	Dynamic	16384	93	34
employees/employees	Dynamic	16384	15	0
employees/dept_manager	Dynamic	16384	0	0
employees/dept_emp	Dynamic	16384	12	10
employees/departments	Dynamic	16384	0	0

## 17.15.4 InnoDB INFORMATION\_SCHEMA FULLTEXT Index Tables

The following tables provide metadata for `FULLTEXT` indexes:

```
mysql> SHOW TABLES FROM INFORMATION_SCHEMA LIKE 'INNODB_FT%';
```

Tables_in_INFORMATION_SCHEMA (INNODB_FT%)
INNODB_FT_CONFIG
INNODB_FT_BEING_DELETED
INNODB_FT_DELETED
INNODB_FT_DEFAULT_STOPWORD
INNODB_FT_INDEX_TABLE
INNODB_FT_INDEX_CACHE

### Table Overview

- INNODB\_FT\_CONFIG:** Provides metadata about the `FULLTEXT` index and associated processing for an InnoDB table.
- INNODB\_FT\_BEING\_DELETED:** Provides a snapshot of the `INNODB_FT_DELETED` table; it is used only during an `OPTIMIZE TABLE` maintenance operation. When `OPTIMIZE TABLE` is run, the `INNODB_FT_BEING_DELETED` table is emptied, and `DOC_ID` values are removed from the `INNODB_FT_DELETED` table. Because the contents of `INNODB_FT_BEING_DELETED` typically have a short lifetime, this table has limited utility for monitoring or debugging. For information about running `OPTIMIZE TABLE` on tables with `FULLTEXT` indexes, see [Section 14.9.6, “Fine-Tuning MySQL Full-Text Search”](#).
- INNODB\_FT\_DELETED:** Stores rows that are deleted from the `FULLTEXT` index for an InnoDB table. To avoid expensive index reorganization during DML operations for an InnoDB `FULLTEXT` index, the information about newly deleted words is stored separately, filtered out of search results when you do a text search, and removed from the main search index only when you issue an `OPTIMIZE TABLE` statement for the InnoDB table.
- INNODB\_FT\_DEFAULT\_STOPWORD:** Holds a list of [stopwords](#) that are used by default when creating a `FULLTEXT` index on InnoDB tables.

For information about the `INNODB_FT_DEFAULT_STOPWORD` table, see [Section 14.9.4, “Full-Text Stopwords”](#).

- INNODB\_FT\_INDEX\_TABLE:** Provides information about the inverted index used to process text searches against the `FULLTEXT` index of an InnoDB table.
- INNODB\_FT\_INDEX\_CACHE:** Provides token information about newly inserted rows in a `FULLTEXT` index. To avoid expensive index reorganization during DML operations, the information about newly indexed words is stored separately, and combined with the main search index only when `OPTIMIZE TABLE` is run, when the server is shut down, or when the cache size exceeds a limit defined by the `innodb_ft_cache_size` or `innodb_ft_total_cache_size` system variable.

**Note**

With the exception of the `INNODB_FT_DEFAULT_STOPWORD` table, these tables are empty initially. Before querying any of them, set the value of the `innodb_ft_aux_table` system variable to the name (including the database name) of the table that contains the `FULLTEXT` index (for example, `test/articles`).

**Example 17.5 InnoDB FULLTEXT Index INFORMATION\_SCHEMA Tables**

This example uses a table with a `FULLTEXT` index to demonstrate the data contained in the `FULLTEXT` index `INFORMATION_SCHEMA` tables.

1. Create a table with a `FULLTEXT` index and insert some data:

```
mysql> CREATE TABLE articles (
 id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
 title VARCHAR(200),
 body TEXT,
 FULLTEXT (title,body)
) ENGINE=InnoDB;

mysql> INSERT INTO articles (title,body) VALUES
('MySQL Tutorial','DBMS stands for DataBase ...'),
('How To Use MySQL Well','After you went through a ...'),
('Optimizing MySQL','In this tutorial we show ...'),
('1001 MySQL Tricks','1. Never run mysqld as root. 2. ...'),
('MySQL vs. YourSQL','In the following database comparison ...'),
('MySQL Security','When configured properly, MySQL ...');
```

2. Set the `innodb_ft_aux_table` variable to the name of the table with the `FULLTEXT` index. If this variable is not set, the InnoDB `FULLTEXT` `INFORMATION_SCHEMA` tables are empty, with the exception of `INNODB_FT_DEFAULT_STOPWORD`.

```
mysql> SET GLOBAL innodb_ft_aux_table = 'test/articles';
```

3. Query the `INNODB_FT_INDEX_CACHE` table, which shows information about newly inserted rows in a `FULLTEXT` index. To avoid expensive index reorganization during DML operations, data for newly inserted rows remains in the `FULLTEXT` index cache until `OPTIMIZE TABLE` is run (or until the server is shut down or cache limits are exceeded).

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_CACHE LIMIT 5;
```

WORD	FIRST_DOC_ID	LAST_DOC_ID	DOC_COUNT	DOC_ID	POSITION
1001	5	5	1	5	0
after	3	3	1	3	22
comparison	6	6	1	6	44
configured	7	7	1	7	20
database	2	6	2	2	31

4. Enable the `innodb_optimize_fulltext_only` system variable and run `OPTIMIZE TABLE` on the table that contains the `FULLTEXT` index. This operation flushes the contents of the `FULLTEXT` index cache to the main `FULLTEXT` index. `innodb_optimize_fulltext_only` changes the way the `OPTIMIZE TABLE` statement operates on InnoDB tables, and is intended to be enabled temporarily, during maintenance operations on InnoDB tables with `FULLTEXT` indexes.

```
mysql> SET GLOBAL innodb_optimize_fulltext_only=ON;
```

```
mysql> OPTIMIZE TABLE articles;
```

Table	Op	Msg_type	Msg_text
test.articles	optimize	status	OK

- Query the `INNODB_FT_INDEX_TABLE` table to view information about data in the main `FULLTEXT` index, including information about the data that was just flushed from the `FULLTEXT` index cache.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_TABLE LIMIT 5;
```

WORD	FIRST_DOC_ID	LAST_DOC_ID	DOC_COUNT	DOC_ID	POSITION
1001	5	5	1	5	0
after	3	3	1	3	22
comparison	6	6	1	6	44
configured	7	7	1	7	20
database	2	6	2	2	31

The `INNODB_FT_INDEX_CACHE` table is now empty since the `OPTIMIZE TABLE` operation flushed the `FULLTEXT` index cache.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_CACHE LIMIT 5;
Empty set (0.00 sec)
```

- Delete some records from the `test/articles` table.

```
mysql> DELETE FROM test.articles WHERE id < 4;
```

- Query the `INNODB_FT_DELETED` table. This table records rows that are deleted from the `FULLTEXT` index. To avoid expensive index reorganization during DML operations, information about newly deleted records is stored separately, filtered out of search results when you do a text search, and removed from the main search index when you run `OPTIMIZE TABLE`.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_DELETED;
```

DOC_ID
2
3
4

- Run `OPTIMIZE TABLE` to remove the deleted records.

```
mysql> OPTIMIZE TABLE articles;
```

Table	Op	Msg_type	Msg_text
test.articles	optimize	status	OK

The `INNODB_FT_DELETED` table should now be empty.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_DELETED;
Empty set (0.00 sec)
```

9. Query the `INNODB_FT_CONFIG` table. This table contains metadata about the `FULLTEXT` index and related processing:

- `optimize_checkpoint_limit`: The number of seconds after which an `OPTIMIZE TABLE` run stops.
- `synced_doc_id`: The next `DOC_ID` to be issued.
- `stopword_table_name`: The `database/table` name for a user-defined stopwords table. The `VALUE` column is empty if there is no user-defined stopwords table.
- `use_stopword`: Indicates whether a stopwords table is used, which is defined when the `FULLTEXT` index is created.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_CONFIG;
+-----+-----+
| KEY | VALUE |
+-----+-----+
| optimize_checkpoint_limit | 180 |
| synced_doc_id | 8 |
| stopwords_table_name | |
| use_stopword | 1 |
+-----+-----+
```

10. Disable `innodb_optimize_fulltext_only`, since it is intended to be enabled only temporarily:

```
mysql> SET GLOBAL innodb_optimize_fulltext_only=OFF;
```

## 17.15.5 InnoDB INFORMATION\_SCHEMA Buffer Pool Tables

The `InnoDB INFORMATION_SCHEMA` buffer pool tables provide buffer pool status information and metadata about the pages within the `InnoDB` buffer pool.

The `InnoDB INFORMATION_SCHEMA` buffer pool tables include those listed below:

```
mysql> SHOW TABLES FROM INFORMATION_SCHEMA LIKE 'INNODB_BUFFER%';
+-----+-----+
| Tables_in_INFORMATION_SCHEMA (INNODB_BUFFER%) |
+-----+-----+
| INNODB_BUFFER_PAGE_LRU |
| INNODB_BUFFER_PAGE |
| INNODB_BUFFER_POOL_STATS |
+-----+-----+
```

### Table Overview

- `INNODB_BUFFER_PAGE`: Holds information about each page in the `InnoDB` buffer pool.
- `INNODB_BUFFER_PAGE_LRU`: Holds information about the pages in the `InnoDB` buffer pool, in particular how they are ordered in the LRU list that determines which pages to evict from the buffer pool when it becomes full. The `INNODB_BUFFER_PAGE_LRU` table has the same columns as the `INNODB_BUFFER_PAGE` table, except that the `INNODB_BUFFER_PAGE_LRU` table has an `LRU_POSITION` column instead of a `BLOCK_ID` column.
- `INNODB_BUFFER_POOL_STATS`: Provides buffer pool status information. Much of the same information is provided by `SHOW ENGINE INNODB STATUS` output, or may be obtained using `InnoDB` buffer pool server status variables.

### Warning

Querying the `INNODB_BUFFER_PAGE` or `INNODB_BUFFER_PAGE_LRU` table can affect performance. Do not query these tables on a production system unless you are aware of the performance impact and have determined it to be acceptable. To avoid impacting performance on a production system, reproduce the issue you want to investigate and query buffer pool statistics on a test instance.

### Example 17.6 Querying System Data in the `INNODB_BUFFER_PAGE` Table

This query provides an approximate count of pages that contain system data by excluding pages where the `TABLE_NAME` value is either `NULL` or includes a slash `/` or period `.` in the table name, which indicates a user-defined table.

```
mysql> SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
 WHERE TABLE_NAME IS NULL OR (INSTR(TABLE_NAME, '/') = 0 AND INSTR(TABLE_NAME, '.') = 0);
+-----+
| COUNT(*) |
+-----+
| 1516 |
+-----+
```

This query returns the approximate number of pages that contain system data, the total number of buffer pool pages, and an approximate percentage of pages that contain system data.

```
mysql> SELECT
 (SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
 WHERE TABLE_NAME IS NULL OR (INSTR(TABLE_NAME, '/') = 0 AND INSTR(TABLE_NAME, '.') = 0)
) AS system_pages,
 (
 SELECT COUNT(*)
 FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
) AS total_pages,
 (
 SELECT ROUND((system_pages/total_pages) * 100)
) AS system_page_percentage;
+-----+-----+-----+
| system_pages | total_pages | system_page_percentage |
+-----+-----+-----+
| 295 | 8192 | 4 |
+-----+-----+-----+
```

The type of system data in the buffer pool can be determined by querying the `PAGE_TYPE` value. For example, the following query returns eight distinct `PAGE_TYPE` values among the pages that contain system data:

```
mysql> SELECT DISTINCT PAGE_TYPE FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
 WHERE TABLE_NAME IS NULL OR (INSTR(TABLE_NAME, '/') = 0 AND INSTR(TABLE_NAME, '.') = 0);
+-----+
| PAGE_TYPE |
+-----+
| SYSTEM |
| IBUF_BITMAP |
| UNKNOWN |
| FILE_SPACE_HEADER |
| INODE |
| UNDO_LOG |
| ALLOCATED |
+-----+
```

### Example 17.7 Querying User Data in the `INNODB_BUFFER_PAGE` Table

This query provides an approximate count of pages containing user data by counting pages where the `TABLE_NAME` value is `NOT NULL` and `NOT LIKE '%INNODB_TABLES%'`.

```
mysql> SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
 WHERE TABLE_NAME IS NOT NULL AND TABLE_NAME NOT LIKE '%INNODB_TABLES%';
+-----+
| COUNT(*) |
+-----+
| 7897 |
+-----+
```

This query returns the approximate number of pages that contain user data, the total number of buffer pool pages, and an approximate percentage of pages that contain user data.

```
mysql> SELECT
 (SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
 WHERE TABLE_NAME IS NOT NULL AND (INSTR(TABLE_NAME, '/') > 0 OR INSTR(TABLE_NAME, '.') > 0)
) AS user_pages,
 (
 SELECT COUNT(*)
 FROM information_schema.INNODB_BUFFER_PAGE
) AS total_pages,
 (
 SELECT ROUND((user_pages/total_pages) * 100)
) AS user_page_percentage;
+-----+-----+-----+
| user_pages | total_pages | user_page_percentage |
+-----+-----+-----+
| 7897 | 8192 | 96 |
+-----+-----+-----+
```

This query identifies user-defined tables with pages in the buffer pool:

```
mysql> SELECT DISTINCT TABLE_NAME FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
 WHERE TABLE_NAME IS NOT NULL AND (INSTR(TABLE_NAME, '/') > 0 OR INSTR(TABLE_NAME, '.') > 0)
 AND TABLE_NAME NOT LIKE 'mysql`.`innodb_%';
+-----+
| TABLE_NAME |
+-----+
| `employees`.`salaries` |
| `employees`.`employees` |
+-----+
```

### Example 17.8 Querying Index Data in the INNODB\_BUFFER\_PAGE Table

For information about index pages, query the `INDEX_NAME` column using the name of the index. For example, the following query returns the number of pages and total data size of pages for the `emp_no` index that is defined on the `employees.salaries` table:

```
mysql> SELECT INDEX_NAME, COUNT(*) AS Pages,
 ROUND(SUM(IF(COMPRESSED_SIZE = 0, @@GLOBAL.innodb_page_size, COMPRESSED_SIZE))/1024/1024)
 AS 'Total Data (MB)'
FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
WHERE INDEX_NAME='emp_no' AND TABLE_NAME = '`employees`.`salaries`';
+-----+-----+-----+
| INDEX_NAME | Pages | Total Data (MB) |
+-----+-----+-----+
| emp_no | 1609 | 25 |
+-----+-----+-----+
```

This query returns the number of pages and total data size of pages for all indexes defined on the `employees.salaries` table:

```
mysql> SELECT INDEX_NAME, COUNT(*) AS Pages,
 ROUND(SUM(IF(COMPRESSED_SIZE = 0, @@GLOBAL.innodb_page_size, COMPRESSED_SIZE))/1024/1024)
 AS 'Total Data (MB)'
FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
```

```
WHERE TABLE_NAME = '`employees`.`salaries`'
GROUP BY INDEX_NAME;
```

INDEX_NAME	Pages	Total Data (MB)
emp_no	1608	25
PRIMARY	6086	95

### Example 17.9 Querying LRU\_POSITION Data in the INNODB\_BUFFER\_PAGE\_LRU Table

The `INNODB_BUFFER_PAGE_LRU` table holds information about the pages in the `InnoDB` buffer pool, in particular how they are ordered that determines which pages to evict from the buffer pool when it becomes full. The definition for this page is the same as for `INNODB_BUFFER_PAGE`, except this table has an `LRU_POSITION` column instead of a `BLOCK_ID` column.

This query counts the number of positions at a specific location in the LRU list occupied by pages of the `employees.employees` table.

```
mysql> SELECT COUNT(LRU_POSITION) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE_LRU
WHERE TABLE_NAME='`employees`.`employees`' AND LRU_POSITION < 3072;
```

COUNT(LRU_POSITION)
548

### Example 17.10 Querying the INNODB\_BUFFER\_POOL\_STATS Table

The `INNODB_BUFFER_POOL_STATS` table provides information similar to `SHOW ENGINE INNODB STATUS` and `InnoDB` buffer pool status variables.

```
mysql> SELECT * FROM information_schema.INNODB_BUFFER_POOL_STATS \G
***** 1. row *****
 POOL_ID: 0
 POOL_SIZE: 8192
 FREE_BUFFERS: 1
 DATABASE_PAGES: 8173
 OLD_DATABASE_PAGES: 3014
 MODIFIED_DATABASE_PAGES: 0
 PENDING_DECOMPRESS: 0
 PENDING_READS: 0
 PENDING_FLUSH_LRU: 0
 PENDING_FLUSH_LIST: 0
 PAGES_MADE_YOUNG: 15907
 PAGES_NOT_MADE_YOUNG: 3803101
 PAGES_MADE_YOUNG_RATE: 0
 PAGES_MADE_NOT_YOUNG_RATE: 0
 NUMBER_PAGES_READ: 3270
 NUMBER_PAGES_CREATED: 13176
 NUMBER_PAGES_WRITTEN: 15109
 PAGES_READ_RATE: 0
 PAGES_CREATE_RATE: 0
 PAGES_WRITTEN_RATE: 0
 NUMBER_PAGES_GET: 33069332
 HIT_RATE: 0
 YOUNG_MAKE_PER_THOUSAND_GETS: 0
 NOT_YOUNG_MAKE_PER_THOUSAND_GETS: 0
 NUMBER_PAGES_READ_AHEAD: 2713
 NUMBER_READ_AHEAD_EVICTED: 0
 READ_AHEAD_RATE: 0
 READ_AHEAD_EVICTED_RATE: 0
 LRU_IO_TOTAL: 0
```

```

LRU_IO_CURRENT: 0
UNCOMPRESS_TOTAL: 0
UNCOMPRESS_CURRENT: 0

```

For comparison, `SHOW ENGINE INNODB STATUS` output and InnoDB buffer pool status variable output is shown below, based on the same data set.

For more information about `SHOW ENGINE INNODB STATUS` output, see [Section 17.17.3, “InnoDB Standard Monitor and Lock Monitor Output”](#).

```

mysql> SHOW ENGINE INNODB STATUS\G
...

BUFFER POOL AND MEMORY

Total large memory allocated 137428992
Dictionary memory allocated 579084
Buffer pool size 8192
Free buffers 1
Database pages 8173
Old database pages 3014
Modified db pages 0
Pending reads 0
Pending writes: LRU 0, flush list 0, single page 0
Pages made young 15907, not young 3803101
0.00 youngs/s, 0.00 non-youngs/s
Pages read 3270, created 13176, written 15109
0.00 reads/s, 0.00 creates/s, 0.00 writes/s
No buffer pool page gets since the last printout
Pages read ahead 0.00/s, evicted without access 0.00/s, Random read ahead 0.00/s
LRU len: 8173, unzip_LRU len: 0
I/O sum[0]:cur[0], unzip sum[0]:cur[0]
...

```

For status variable descriptions, see [Section 7.1.10, “Server Status Variables”](#).

```

mysql> SHOW STATUS LIKE 'Innodb_buffer%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Innodb_buffer_pool_dump_status | not started |
| Innodb_buffer_pool_load_status | not started |
| Innodb_buffer_pool_resize_status | not started |
| Innodb_buffer_pool_pages_data | 8173 |
| Innodb_buffer_pool_bytes_data | 133906432 |
| Innodb_buffer_pool_pages_dirty | 0 |
| Innodb_buffer_pool_bytes_dirty | 0 |
| Innodb_buffer_pool_pages_flushed | 15109 |
| Innodb_buffer_pool_pages_free | 1 |
| Innodb_buffer_pool_pages_misc | 18 |
| Innodb_buffer_pool_pages_total | 8192 |
| Innodb_buffer_pool_read_ahead_rnd | 0 |
| Innodb_buffer_pool_read_ahead | 2713 |
| Innodb_buffer_pool_read_ahead_evicted | 0 |
| Innodb_buffer_pool_read_requests | 33069332 |
| Innodb_buffer_pool_reads | 558 |
| Innodb_buffer_pool_wait_free | 0 |
| Innodb_buffer_pool_write_requests | 11985961 |
+-----+-----+

```

## 17.15.6 InnoDB INFORMATION\_SCHEMA Metrics Table

The `INNODB_METRICS` table provides information about InnoDB performance and resource-related counters.

`INNODB_METRICS` table columns are shown below. For column descriptions, see [Section 28.4.21](#), “The `INFORMATION_SCHEMA INNODB_METRICS` Table”.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts" \G
***** 1. row *****
 NAME: dml_inserts
 SUBSYSTEM: dml
 COUNT: 46273
 MAX_COUNT: 46273
 MIN_COUNT: NULL
 AVG_COUNT: 492.2659574468085
 COUNT_RESET: 46273
MAX_COUNT_RESET: 46273
MIN_COUNT_RESET: NULL
AVG_COUNT_RESET: NULL
 TIME_ENABLED: 2014-11-28 16:07:53
 TIME_DISABLED: NULL
 TIME_ELAPSED: 94
 TIME_RESET: NULL
 STATUS: enabled
 TYPE: status_counter
 COMMENT: Number of rows inserted
```

## Enabling, Disabling, and Resetting Counters

You can enable, disable, and reset counters using the following variables:

- `innodb_monitor_enable`: Enables counters.

```
SET GLOBAL innodb_monitor_enable = [counter-name|module_name|pattern|all];
```

- `innodb_monitor_disable`: Disables counters.

```
SET GLOBAL innodb_monitor_disable = [counter-name|module_name|pattern|all];
```

- `innodb_monitor_reset`: Resets counter values to zero.

```
SET GLOBAL innodb_monitor_reset = [counter-name|module_name|pattern|all];
```

- `innodb_monitor_reset_all`: Resets all counter values. A counter must be disabled before using `innodb_monitor_reset_all`.

```
SET GLOBAL innodb_monitor_reset_all = [counter-name|module_name|pattern|all];
```

Counters and counter modules can also be enabled at startup using the MySQL server configuration file. For example, to enable the `log` module, `metadata_table_handles_opened` and `metadata_table_handles_closed` counters, enter the following line in the `[mysqld]` section of the MySQL server configuration file.

```
[mysqld]
innodb_monitor_enable = log,metadata_table_handles_opened,metadata_table_handles_closed
```

When enabling multiple counters or modules in a configuration file, specify the `innodb_monitor_enable` variable followed by counter and module names separated by a comma, as shown above. Only the `innodb_monitor_enable` variable can be used in a configuration file. The `innodb_monitor_disable` and `innodb_monitor_reset` variables are supported on the command line only.

### Note

Because each counter adds a degree of runtime overhead, use counters conservatively on production servers to diagnose specific issues or monitor specific functionality. A test or development server is recommended for more extensive use of counters.

## Counters

The list of available counters is subject to change. Query the Information Schema `INNODB_METRICS` table for counters available in your MySQL server version.

The counters enabled by default correspond to those shown in `SHOW ENGINE INNODB STATUS` output. Counters shown in `SHOW ENGINE INNODB STATUS` output are always enabled at a system level but can be disabled for the `INNODB_METRICS` table. Counter status is not persistent. Unless configured otherwise, counters revert to their default enabled or disabled status when the server is restarted.

If you run programs that would be affected by the addition or removal of counters, it is recommended that you review the releases notes and query the `INNODB_METRICS` table to identify those changes as part of your upgrade process.

```
mysql> SELECT name, subsystem, status FROM INFORMATION_SCHEMA.INNODB_METRICS ORDER BY NAME;
```

```

## Counter Modules

Each counter is associated with a particular module. Module names can be used to enable, disable, or reset all counters for a particular subsystem. For example, use `module_dml` to enable all counters associated with the `dml` subsystem.

```
mysql> SET GLOBAL innodb_monitor_enable = module_dml;

mysql> SELECT name, subsystem, status FROM INFORMATION_SCHEMA.INNODB_METRICS
 WHERE subsystem = 'dml';
```

name	subsystem	status
dml_reads	dml	enabled
dml_inserts	dml	enabled
dml_deletes	dml	enabled
dml_updates	dml	enabled

Module names can be used with `innodb_monitor_enable` and related variables.

Module names and corresponding `SUBSYSTEM` names are listed below.

- `module_adaptive_hash` (subsystem = `adaptive_hash_index`)
- `module_buffer` (subsystem = `buffer`)
- `module_buffer_page` (subsystem = `buffer_page_io`)
- `module_compress` (subsystem = `compression`)
- `module_ddl` (subsystem = `ddl`)
- `module_dml` (subsystem = `dml`)
- `module_file` (subsystem = `file_system`)
- `module_ibuf_system` (subsystem = `change_buffer`)
- `module_icp` (subsystem = `icp`)
- `module_index` (subsystem = `index`)
- `module_innodb` (subsystem = `innodb`)
- `module_lock` (subsystem = `lock`)
- `module_log` (subsystem = `log`)
- `module_metadata` (subsystem = `metadata`)
- `module_os` (subsystem = `os`)
- `module_purge` (subsystem = `purge`)
- `module_trx` (subsystem = `transaction`)
- `module_undo` (subsystem = `undo`)

**Example 17.11 Working with INNODB\_METRICS Table Counters**

This example demonstrates enabling, disabling, and resetting a counter, and querying counter data in the `INNODB_METRICS` table.

1. Create a simple InnoDB table:

```
mysql> USE test;
Database changed

mysql> CREATE TABLE t1 (c1 INT) ENGINE=INNODB;
Query OK, 0 rows affected (0.02 sec)
```

2. Enable the `dml_inserts` counter.

```
mysql> SET GLOBAL innodb_monitor_enable = dml_inserts;
Query OK, 0 rows affected (0.01 sec)
```

A description of the `dml_inserts` counter can be found in the `COMMENT` column of the `INNODB_METRICS` table:

```
mysql> SELECT NAME, COMMENT FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts";
+-----+-----+
| NAME | COMMENT |
+-----+-----+
| dml_inserts | Number of rows inserted |
+-----+-----+
```

3. Query the `INNODB_METRICS` table for the `dml_inserts` counter data. Because no DML operations have been performed, the counter values are zero or NULL. The `TIME_ENABLED` and `TIME_ELAPSED` values indicate when the counter was last enabled and how many seconds have elapsed since that time.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts" \G
***** 1. row *****
 NAME: dml_inserts
 SUBSYSTEM: dml
 COUNT: 0
 MAX_COUNT: 0
 MIN_COUNT: NULL
 AVG_COUNT: 0
 COUNT_RESET: 0
MAX_COUNT_RESET: 0
MIN_COUNT_RESET: NULL
AVG_COUNT_RESET: NULL
 TIME_ENABLED: 2014-12-04 14:18:28
 TIME_DISABLED: NULL
 TIME_ELAPSED: 28
 TIME_RESET: NULL
 STATUS: enabled
 TYPE: status_counter
 COMMENT: Number of rows inserted
```

4. Insert three rows of data into the table.

```
mysql> INSERT INTO t1 values(1);
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO t1 values(2);
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO t1 values(3);
Query OK, 1 row affected (0.00 sec)
```

5. Query the `INNODB_METRICS` table again for the `dml_inserts` counter data. A number of counter values have now incremented including `COUNT`, `MAX_COUNT`, `AVG_COUNT`, and `COUNT_RESET`. Refer to the `INNODB_METRICS` table definition for descriptions of these values.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts"\G
***** 1. row *****
 NAME: dml_inserts
 SUBSYSTEM: dml
 COUNT: 3
 MAX_COUNT: 3
 MIN_COUNT: NULL
 AVG_COUNT: 0.046153846153846156
 COUNT_RESET: 3
MAX_COUNT_RESET: 3
MIN_COUNT_RESET: NULL
AVG_COUNT_RESET: NULL
 TIME_ENABLED: 2014-12-04 14:18:28
 TIME_DISABLED: NULL
 TIME_ELAPSED: 65
 TIME_RESET: NULL
 STATUS: enabled
 TYPE: status_counter
 COMMENT: Number of rows inserted
```

6. Reset the `dml_inserts` counter and query the `INNODB_METRICS` table again for the `dml_inserts` counter data. The `%_RESET` values that were reported previously, such as `COUNT_RESET` and `MAX_RESET`, are set back to zero. Values such as `COUNT`, `MAX_COUNT`, and `AVG_COUNT`, which cumulatively collect data from the time the counter is enabled, are unaffected by the reset.

```
mysql> SET GLOBAL innodb_monitor_reset = dml_inserts;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts"\G
***** 1. row *****
 NAME: dml_inserts
 SUBSYSTEM: dml
 COUNT: 3
 MAX_COUNT: 3
 MIN_COUNT: NULL
 AVG_COUNT: 0.03529411764705882
 COUNT_RESET: 0
MAX_COUNT_RESET: 0
MIN_COUNT_RESET: NULL
AVG_COUNT_RESET: 0
 TIME_ENABLED: 2014-12-04 14:18:28
 TIME_DISABLED: NULL
 TIME_ELAPSED: 85
 TIME_RESET: 2014-12-04 14:19:44
 STATUS: enabled
 TYPE: status_counter
 COMMENT: Number of rows inserted
```

7. To reset all counter values, you must first disable the counter. Disabling the counter sets the `STATUS` value to `disabled`.

```
mysql> SET GLOBAL innodb_monitor_disable = dml_inserts;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts"\G
***** 1. row *****
 NAME: dml_inserts
 SUBSYSTEM: dml
 COUNT: 3
 MAX_COUNT: 3
 MIN_COUNT: NULL
```

```

 AVG_COUNT: 0.030612244897959183
 COUNT_RESET: 0
 MAX_COUNT_RESET: 0
 MIN_COUNT_RESET: NULL
 AVG_COUNT_RESET: 0
 TIME_ENABLED: 2014-12-04 14:18:28
 TIME_DISABLED: 2014-12-04 14:20:06
 TIME_ELAPSED: 98
 TIME_RESET: NULL
 STATUS: disabled
 TYPE: status_counter
 COMMENT: Number of rows inserted

```

**Note**

Wildcard match is supported for counter and module names. For example, instead of specifying the full `dml_inserts` counter name, you can specify `dml_i%`. You can also enable, disable, or reset multiple counters or modules at once using a wildcard match. For example, specify `dml_%` to enable, disable, or reset all counters that begin with `dml_`.

8. After the counter is disabled, you can reset all counter values using the `innodb_monitor_reset_all` option. All values are set to zero or NULL.

```

mysql> SET GLOBAL innodb_monitor_reset_all = dml_inserts;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts"\G
***** 1. row *****
 NAME: dml_inserts
 SUBSYSTEM: dml
 COUNT: 0
 MAX_COUNT: NULL
 MIN_COUNT: NULL
 AVG_COUNT: NULL
 COUNT_RESET: 0
 MAX_COUNT_RESET: NULL
 MIN_COUNT_RESET: NULL
 AVG_COUNT_RESET: NULL
 TIME_ENABLED: NULL
 TIME_DISABLED: NULL
 TIME_ELAPSED: NULL
 TIME_RESET: NULL
 STATUS: disabled
 TYPE: status_counter
 COMMENT: Number of rows inserted

```

## 17.15.7 InnoDB INFORMATION\_SCHEMA Temporary Table Info Table

`INNODB_TEMP_TABLE_INFO` provides information about user-created InnoDB temporary tables that are active in the InnoDB instance. It does not provide information about internal InnoDB temporary tables used by the optimizer.

```

mysql> SHOW TABLES FROM INFORMATION_SCHEMA LIKE 'INNODB_TEMP%';
+-----+
| Tables_in_INFORMATION_SCHEMA (INNODB_TEMP%) |
+-----+
| INNODB_TEMP_TABLE_INFO |
+-----+

```

For the table definition, see [Section 28.4.27, “The INFORMATION\\_SCHEMA INNODB\\_TEMP\\_TABLE\\_INFO Table”](#).

**Example 17.12 INNODB\_TEMP\_TABLE\_INFO**

This example demonstrates characteristics of the `INNODB_TEMP_TABLE_INFO` table.

1. Create a simple InnoDB temporary table:

```
mysql> CREATE TEMPORARY TABLE t1 (c1 INT PRIMARY KEY) ENGINE=INNODB;
```

2. Query `INNODB_TEMP_TABLE_INFO` to view the temporary table metadata.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TEMP_TABLE_INFO\G
***** 1. row *****
 TABLE_ID: 194
 NAME: #sql7a79_1_0
 N_COLS: 4
 SPACE: 182
```

The `TABLE_ID` is a unique identifier for the temporary table. The `NAME` column displays the system-generated name for the temporary table, which is prefixed with “#sql”. The number of columns (`N_COLS`) is 4 rather than 1 because InnoDB always creates three hidden table columns (`DB_ROW_ID`, `DB_TRX_ID`, and `DB_ROLL_PTR`).

3. Restart MySQL and query `INNODB_TEMP_TABLE_INFO`.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TEMP_TABLE_INFO\G
```

An empty set is returned because `INNODB_TEMP_TABLE_INFO` and its data are not persisted to disk when the server is shut down.

4. Create a new temporary table.

```
mysql> CREATE TEMPORARY TABLE t1 (c1 INT PRIMARY KEY) ENGINE=INNODB;
```

5. Query `INNODB_TEMP_TABLE_INFO` to view the temporary table metadata.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TEMP_TABLE_INFO\G
***** 1. row *****
 TABLE_ID: 196
 NAME: #sql7b0e_1_0
 N_COLS: 4
 SPACE: 184
```

The `SPACE` ID may be different because it is dynamically generated when the server is started.

## 17.15.8 Retrieving InnoDB Tablespace Metadata from INFORMATION\_SCHEMA.FILES

The Information Schema `FILES` table provides metadata about all InnoDB tablespace types including [file-per-table tablespaces](#), [general tablespaces](#), the [system tablespace](#), [temporary table tablespaces](#), and [undo tablespaces](#) (if present).

This section provides InnoDB-specific usage examples. For more information about data provided by the Information Schema `FILES` table, see [Section 28.3.15, “The INFORMATION\\_SCHEMA FILES Table”](#).

### Note

The `INNODB_TABLESPACES` and `INNODB_DATAFILES` tables also provide metadata about InnoDB tablespaces, but data is limited to file-per-table, general, and undo tablespaces.

This query retrieves metadata about the [InnoDB](#) system tablespace from fields of the Information Schema [FILES](#) table that are pertinent to [InnoDB](#) tablespaces. [FILES](#) columns that are not relevant to [InnoDB](#) always return [NULL](#), and are excluded from the query.

```
mysql> SELECT FILE_ID, FILE_NAME, FILE_TYPE, TABLESPACE_NAME, FREE_EXTENTS,
-> TOTAL_EXTENTS, EXTENT_SIZE, INITIAL_SIZE, MAXIMUM_SIZE, AUTOEXTEND_SIZE, DATA_FREE, STATUS ENGINE
-> FROM INFORMATION_SCHEMA.FILES WHERE TABLESPACE_NAME LIKE 'innodb_system' \G
***** 1. row *****
 FILE_ID: 0
 FILE_NAME: ./ibdata1
 FILE_TYPE: TABLESPACE
TABLESPACE_NAME: innodb_system
 FREE_EXTENTS: 0
 TOTAL_EXTENTS: 12
 EXTENT_SIZE: 1048576
 INITIAL_SIZE: 12582912
 MAXIMUM_SIZE: NULL
 AUTOEXTEND_SIZE: 67108864
 DATA_FREE: 4194304
 ENGINE: NORMAL
```

This query retrieves the [FILE\\_ID](#) (equivalent to the space ID) and the [FILE\\_NAME](#) (which includes path information) for [InnoDB](#) file-per-table and general tablespaces. File-per-table and general tablespaces have a [.ibd](#) file extension.

```
mysql> SELECT FILE_ID, FILE_NAME FROM INFORMATION_SCHEMA.FILES
-> WHERE FILE_NAME LIKE '%.ibd%' ORDER BY FILE_ID;
+-----+-----+
| FILE_ID | FILE_NAME |
+-----+-----+
| 2 | ./mysql/plugin.ibd |
| 3 | ./mysql/servers.ibd |
| 4 | ./mysql/help_topic.ibd |
| 5 | ./mysql/help_category.ibd |
| 6 | ./mysql/help_relation.ibd |
| 7 | ./mysql/help_keyword.ibd |
| 8 | ./mysql/time_zone_name.ibd |
| 9 | ./mysql/time_zone.ibd |
| 10 | ./mysql/time_zone_transition.ibd |
| 11 | ./mysql/time_zone_transition_type.ibd |
| 12 | ./mysql/time_zone_leap_second.ibd |
| 13 | ./mysql/innodb_table_stats.ibd |
| 14 | ./mysql/innodb_index_stats.ibd |
| 15 | ./mysql/slave_relay_log_info.ibd |
| 16 | ./mysql/slave_master_info.ibd |
| 17 | ./mysql/slave_worker_info.ibd |
| 18 | ./mysql/gtid_executed.ibd |
| 19 | ./mysql/server_cost.ibd |
| 20 | ./mysql/engine_cost.ibd |
| 21 | ./sys/sys_config.ibd |
| 23 | ./test/t1.ibd |
| 26 | /home/user/test/test/t2.ibd |
+-----+-----+
```

This query retrieves the [FILE\\_ID](#) and [FILE\\_NAME](#) for the [InnoDB](#) global temporary tablespace. Global temporary tablespace file names are prefixed by [ibtmp](#).

```
mysql> SELECT FILE_ID, FILE_NAME FROM INFORMATION_SCHEMA.FILES
-> WHERE FILE_NAME LIKE '%ibtmp%';
+-----+-----+
| FILE_ID | FILE_NAME |
+-----+-----+
| 22 | ./ibtmp1 |
+-----+-----+
```

Similarly, InnoDB undo tablespace file names are prefixed by `undo`. The following query returns the `FILE_ID` and `FILE_NAME` for InnoDB undo tablespaces.

```
mysql> SELECT FILE_ID, FILE_NAME FROM INFORMATION_SCHEMA.FILES
WHERE FILE_NAME LIKE '%undo%';
```

## 17.16 InnoDB Integration with MySQL Performance Schema

This section provides a brief introduction to InnoDB integration with Performance Schema. For comprehensive Performance Schema documentation, see [Chapter 29, MySQL Performance Schema](#).

You can profile certain internal InnoDB operations using the MySQL [Performance Schema feature](#). This type of tuning is primarily for expert users who evaluate optimization strategies to overcome performance bottlenecks. DBAs can also use this feature for capacity planning, to see whether their typical workload encounters any performance bottlenecks with a particular combination of CPU, RAM, and disk storage; and if so, to judge whether performance can be improved by increasing the capacity of some part of the system.

To use this feature to examine InnoDB performance:

- You must be generally familiar with how to use the [Performance Schema feature](#). For example, you should know how to enable instruments and consumers, and how to query `performance_schema` tables to retrieve data. For an introductory overview, see [Section 29.1, “Performance Schema Quick Start”](#).
- You should be familiar with Performance Schema instruments that are available for InnoDB. To view InnoDB-related instruments, you can query the `setup_instruments` table for instrument names that contain `'innodb'`.

```
mysql> SELECT *
FROM performance_schema.setup_instruments
WHERE NAME LIKE '%innodb%';
```

NAME	ENABLED	TIMED
wait/synch/mutex/innodb/commit_cond_mutex	NO	NO
wait/synch/mutex/innodb/innobase_share_mutex	NO	NO
wait/synch/mutex/innodb/autoinc_mutex	NO	NO
wait/synch/mutex/innodb/buf_pool_mutex	NO	NO
wait/synch/mutex/innodb/buf_pool_zip_mutex	NO	NO
wait/synch/mutex/innodb/cache_last_read_mutex	NO	NO
wait/synch/mutex/innodb/dict_foreign_err_mutex	NO	NO
wait/synch/mutex/innodb/dict_sys_mutex	NO	NO
wait/synch/mutex/innodb/recalc_pool_mutex	NO	NO
...		
wait/io/file/innodb/innodb_data_file	YES	YES
wait/io/file/innodb/innodb_log_file	YES	YES
wait/io/file/innodb/innodb_temp_file	YES	YES
stage/innodb/alter table (end)	YES	YES
stage/innodb/alter table (flush)	YES	YES
stage/innodb/alter table (insert)	YES	YES
stage/innodb/alter table (log apply index)	YES	YES
stage/innodb/alter table (log apply table)	YES	YES
stage/innodb/alter table (merge sort)	YES	YES
stage/innodb/alter table (read PK and internal sort)	YES	YES
stage/innodb/buffer pool load	YES	YES
memory/innodb/buf_buf_pool	NO	NO
memory/innodb/dict_stats_bg_recalc_pool_t	NO	NO
memory/innodb/dict_stats_index_map_t	NO	NO
memory/innodb/dict_stats_n_diff_on_level	NO	NO
memory/innodb/other	NO	NO
memory/innodb/row_log_buf	NO	NO
memory/innodb/row_merge_sort	NO	NO
memory/innodb/std	NO	NO

```

| memory/innodb/sync_debug_latches | NO | NO |
| memory/innodb/trx_sys_t::rw_trx_ids | NO | NO |
...
+-----+-----+-----+
155 rows in set (0.00 sec)

```

For additional information about the instrumented [InnoDB](#) objects, you can query Performance Schema [instances tables](#), which provide additional information about instrumented objects. Instance tables relevant to [InnoDB](#) include:

- The [mutex\\_instances](#) table
- The [rwlock\\_instances](#) table
- The [cond\\_instances](#) table
- The [file\\_instances](#) table

#### Note

Mutexes and RW-locks related to the [InnoDB](#) buffer pool are not included in this coverage; the same applies to the output of the `SHOW ENGINE INNODB MUTEX` statement.

For example, to view information about instrumented [InnoDB](#) file objects seen by the Performance Schema when executing file I/O instrumentation, you might issue the following query:

```

mysql> SELECT *
 FROM performance_schema.file_instances
 WHERE EVENT_NAME LIKE '%innodb%'\G
***** 1. row *****
FILE_NAME: /home/dtprice/mysql-9.1/data/ibdata1
EVENT_NAME: wait/io/file/innodb/innodb_data_file
OPEN_COUNT: 3
***** 2. row *****
FILE_NAME: /home/dtprice/mysql-9.1/data/#ib_16384_0.dblwr
EVENT_NAME: wait/io/file/innodb/innodb_dblwr_file
OPEN_COUNT: 2
***** 3. row *****
FILE_NAME: /home/dtprice/mysql-9.1/data/#ib_16384_1.dblwr
EVENT_NAME: wait/io/file/mysql-9.1/innodb_dblwr_file
OPEN_COUNT: 2
...

```

- You should be familiar with [performance\\_schema](#) tables that store [InnoDB](#) event data. Tables relevant to [InnoDB](#)-related events include:
  - The [Wait Event](#) tables, which store wait events.
  - The [Summary](#) tables, which provide aggregated information for terminated events over time. Summary tables include [file I/O summary tables](#), which aggregate information about I/O operations.
  - [Stage Event](#) tables, which store event data for [InnoDB ALTER TABLE](#) and buffer pool load operations. For more information, see [Section 17.16.1, “Monitoring ALTER TABLE Progress for InnoDB Tables Using Performance Schema”](#), and [Monitoring Buffer Pool Load Progress Using Performance Schema](#).

If you are only interested in [InnoDB](#)-related objects, use the clause `WHERE EVENT_NAME LIKE '%innodb%'` or `WHERE NAME LIKE '%innodb%'` (as required) when querying these tables.

## 17.16.1 Monitoring ALTER TABLE Progress for InnoDB Tables Using Performance Schema

You can monitor `ALTER TABLE` progress for InnoDB tables using [Performance Schema](#).

There are seven stage events that represent different phases of `ALTER TABLE`. Each stage event reports a running total of `WORK_COMPLETED` and `WORK_ESTIMATED` for the overall `ALTER TABLE` operation as it progresses through its different phases. `WORK_ESTIMATED` is calculated using a formula that takes into account all of the work that `ALTER TABLE` performs, and may be revised during `ALTER TABLE` processing. `WORK_COMPLETED` and `WORK_ESTIMATED` values are an abstract representation of all of the work performed by `ALTER TABLE`.

In order of occurrence, `ALTER TABLE` stage events include:

- `stage/innodb/alter table (read PK and internal sort)`: This stage is active when `ALTER TABLE` is in the reading-primary-key phase. It starts with `WORK_COMPLETED=0` and `WORK_ESTIMATED` set to the estimated number of pages in the primary key. When the stage is completed, `WORK_ESTIMATED` is updated to the actual number of pages in the primary key.
- `stage/innodb/alter table (merge sort)`: This stage is repeated for each index added by the `ALTER TABLE` operation.
- `stage/innodb/alter table (insert)`: This stage is repeated for each index added by the `ALTER TABLE` operation.
- `stage/innodb/alter table (log apply index)`: This stage includes the application of DML log generated while `ALTER TABLE` was running.
- `stage/innodb/alter table (flush)`: Before this stage begins, `WORK_ESTIMATED` is updated with a more accurate estimate, based on the length of the flush list.
- `stage/innodb/alter table (log apply table)`: This stage includes the application of concurrent DML log generated while `ALTER TABLE` was running. The duration of this phase depends on the extent of table changes. This phase is instant if no concurrent DML was run on the table.
- `stage/innodb/alter table (end)`: Includes any remaining work that appeared after the flush phase, such as reapplying DML that was executed on the table while `ALTER TABLE` was running.

### Note

InnoDB `ALTER TABLE` stage events do not currently account for the addition of spatial indexes.

## ALTER TABLE Monitoring Example Using Performance Schema

The following example demonstrates how to enable the `stage/innodb/alter table%` stage event instruments and related consumer tables to monitor `ALTER TABLE` progress. For information about Performance Schema stage event instruments and related consumers, see [Section 29.12.5, “Performance Schema Stage Event Tables”](#).

1. Enable the `stage/innodb/alter%` instruments:

```
mysql> UPDATE performance_schema.setup_instruments
 SET ENABLED = 'YES'
 WHERE NAME LIKE 'stage/innodb/alter%';
Query OK, 7 rows affected (0.00 sec)
Rows matched: 7 Changed: 7 Warnings: 0
```

2. Enable the stage event consumer tables, which include `events_stages_current`, `events_stages_history`, and `events_stages_history_long`.

```
mysql> UPDATE performance_schema.setup_consumers
 SET ENABLED = 'YES'
 WHERE NAME LIKE '%stages%';
Query OK, 3 rows affected (0.00 sec)
Rows matched: 3 Changed: 3 Warnings: 0
```

3. Run an `ALTER TABLE` operation. In this example, a `middle_name` column is added to the `employees` table of the `employees` sample database.

```
mysql> ALTER TABLE employees.employees ADD COLUMN middle_name varchar(14) AFTER first_name;
Query OK, 0 rows affected (9.27 sec)
Records: 0 Duplicates: 0 Warnings: 0
```

4. Check the progress of the `ALTER TABLE` operation by querying the Performance Schema `events_stages_current` table. The stage event shown differs depending on which `ALTER TABLE` phase is currently in progress. The `WORK_COMPLETED` column shows the work completed. The `WORK_ESTIMATED` column provides an estimate of the remaining work.

```
mysql> SELECT EVENT_NAME, WORK_COMPLETED, WORK_ESTIMATED
 FROM performance_schema.events_stages_current;
+-----+-----+-----+
| EVENT_NAME | WORK_COMPLETED | WORK_ESTIMATED |
+-----+-----+-----+
| stage/innodb/alter table (read PK and internal sort) | 280 | 1245 |
+-----+-----+-----+
1 row in set (0.01 sec)
```

The `events_stages_current` table returns an empty set if the `ALTER TABLE` operation has completed. In this case, you can check the `events_stages_history` table to view event data for the completed operation. For example:

```
mysql> SELECT EVENT_NAME, WORK_COMPLETED, WORK_ESTIMATED
 FROM performance_schema.events_stages_history;
+-----+-----+-----+
| EVENT_NAME | WORK_COMPLETED | WORK_ESTIMATED |
+-----+-----+-----+
| stage/innodb/alter table (read PK and internal sort) | 886 | 1213 |
| stage/innodb/alter table (flush) | 1213 | 1213 |
| stage/innodb/alter table (log apply table) | 1597 | 1597 |
| stage/innodb/alter table (end) | 1597 | 1597 |
| stage/innodb/alter table (log apply table) | 1981 | 1981 |
+-----+-----+-----+
5 rows in set (0.00 sec)
```

As shown above, the `WORK_ESTIMATED` value was revised during `ALTER TABLE` processing. The estimated work after completion of the initial stage is 1213. When `ALTER TABLE` processing completed, `WORK_ESTIMATED` was set to the actual value, which is 1981.

## 17.16.2 Monitoring InnoDB Mutex Waits Using Performance Schema

A mutex is a synchronization mechanism used in the code to enforce that only one thread at a given time can have access to a common resource. When two or more threads executing in the server need to access the same resource, the threads compete against each other. The first thread to obtain a lock on the mutex causes the other threads to wait until the lock is released.

For InnoDB mutexes that are instrumented, mutex waits can be monitored using [Performance Schema](#). Wait event data collected in Performance Schema tables can help identify mutexes with the most waits or the greatest total wait time, for example.

The following example demonstrates how to enable [InnoDB](#) mutex wait instruments, how to enable associated consumers, and how to query wait event data.

1. To view available [InnoDB](#) mutex wait instruments, query the Performance Schema [setup\\_instruments](#) table. All [InnoDB](#) mutex wait instruments are disabled by default.

```
mysql> SELECT *
 FROM performance_schema.setup_instruments
 WHERE NAME LIKE '%wait/synch/mutex/innodb%';
```

NAME	ENABLED	TIMED
wait/synch/mutex/innodb/commit_cond_mutex	NO	NO
wait/synch/mutex/innodb/innobase_share_mutex	NO	NO
wait/synch/mutex/innodb/autoinc_mutex	NO	NO
wait/synch/mutex/innodb/autoinc_persisted_mutex	NO	NO
wait/synch/mutex/innodb/buf_pool_flush_state_mutex	NO	NO
wait/synch/mutex/innodb/buf_pool_LRU_list_mutex	NO	NO
wait/synch/mutex/innodb/buf_pool_free_list_mutex	NO	NO
wait/synch/mutex/innodb/buf_pool_zip_free_mutex	NO	NO
wait/synch/mutex/innodb/buf_pool_zip_hash_mutex	NO	NO
wait/synch/mutex/innodb/buf_pool_zip_mutex	NO	NO
wait/synch/mutex/innodb/cache_last_read_mutex	NO	NO
wait/synch/mutex/innodb/dict_foreign_err_mutex	NO	NO
wait/synch/mutex/innodb/dict_persist_dirty_tables_mutex	NO	NO
wait/synch/mutex/innodb/dict_sys_mutex	NO	NO
wait/synch/mutex/innodb/recalc_pool_mutex	NO	NO
wait/synch/mutex/innodb/fil_system_mutex	NO	NO
wait/synch/mutex/innodb/flush_list_mutex	NO	NO
wait/synch/mutex/innodb/fts_bg_threads_mutex	NO	NO
wait/synch/mutex/innodb/fts_delete_mutex	NO	NO
wait/synch/mutex/innodb/fts_optimize_mutex	NO	NO
wait/synch/mutex/innodb/fts_doc_id_mutex	NO	NO
wait/synch/mutex/innodb/log_flush_order_mutex	NO	NO
wait/synch/mutex/innodb/hash_table_mutex	NO	NO
wait/synch/mutex/innodb/ibuf_bitmap_mutex	NO	NO
wait/synch/mutex/innodb/ibuf_mutex	NO	NO
wait/synch/mutex/innodb/ibuf_pessimistic_insert_mutex	NO	NO
wait/synch/mutex/innodb/log_sys_mutex	NO	NO
wait/synch/mutex/innodb/log_sys_write_mutex	NO	NO
wait/synch/mutex/innodb/mutex_list_mutex	NO	NO
wait/synch/mutex/innodb/page_zip_stat_per_index_mutex	NO	NO
wait/synch/mutex/innodb/purge_sys_pq_mutex	NO	NO
wait/synch/mutex/innodb/recv_sys_mutex	NO	NO
wait/synch/mutex/innodb/recv_writer_mutex	NO	NO
wait/synch/mutex/innodb/redo_rseg_mutex	NO	NO
wait/synch/mutex/innodb/noredoreseg_mutex	NO	NO
wait/synch/mutex/innodb/rw_lock_list_mutex	NO	NO
wait/synch/mutex/innodb/rw_lock_mutex	NO	NO
wait/synch/mutex/innodb/srv_dict_tmpfile_mutex	NO	NO
wait/synch/mutex/innodb/srv_innodb_monitor_mutex	NO	NO
wait/synch/mutex/innodb/srv_misc_tmpfile_mutex	NO	NO
wait/synch/mutex/innodb/srv_monitor_file_mutex	NO	NO
wait/synch/mutex/innodb/buf_dblwr_mutex	NO	NO
wait/synch/mutex/innodb/trx_undo_mutex	NO	NO
wait/synch/mutex/innodb/trx_pool_mutex	NO	NO
wait/synch/mutex/innodb/trx_pool_manager_mutex	NO	NO
wait/synch/mutex/innodb/srv_sys_mutex	NO	NO
wait/synch/mutex/innodb/lock_mutex	NO	NO
wait/synch/mutex/innodb/lock_wait_mutex	NO	NO
wait/synch/mutex/innodb/trx_mutex	NO	NO
wait/synch/mutex/innodb/srv_threads_mutex	NO	NO
wait/synch/mutex/innodb/rtr_active_mutex	NO	NO
wait/synch/mutex/innodb/rtr_match_mutex	NO	NO
wait/synch/mutex/innodb/rtr_path_mutex	NO	NO
wait/synch/mutex/innodb/rtr_ssn_mutex	NO	NO

wait/synch/mutex/innodb/trx_sys_mutex	NO	NO
wait/synch/mutex/innodb/zip_pad_mutex	NO	NO
wait/synch/mutex/innodb/master_key_id_mutex	NO	NO

- Some InnoDB mutex instances are created at server startup and are only instrumented if the associated instrument is also enabled at server startup. To ensure that all InnoDB mutex instances are instrumented and enabled, add the following `performance-schema-instrument` rule to your MySQL configuration file:

```
performance-schema-instrument='wait/synch/mutex/innodb/%=ON'
```

If you do not require wait event data for all InnoDB mutexes, you can disable specific instruments by adding additional `performance-schema-instrument` rules to your MySQL configuration file. For example, to disable InnoDB mutex wait event instruments related to full-text search, add the following rule:

```
performance-schema-instrument='wait/synch/mutex/innodb/fts%=OFF'
```

#### Note

Rules with a longer prefix such as `wait/synch/mutex/innodb/fts%` take precedence over rules with shorter prefixes such as `wait/synch/mutex/innodb/%`.

After adding the `performance-schema-instrument` rules to your configuration file, restart the server. All the InnoDB mutexes except for those related to full text search are enabled. To verify, query the `setup_instruments` table. The `ENABLED` and `TIMED` columns should be set to `YES` for the instruments that you enabled.

```
mysql> SELECT *
FROM performance_schema.setup_instruments
WHERE NAME LIKE '%wait/synch/mutex/innodb%';
```

NAME	ENABLED	TIMED
wait/synch/mutex/innodb/commit_cond_mutex	YES	YES
wait/synch/mutex/innodb/innobase_share_mutex	YES	YES
wait/synch/mutex/innodb/autoinc_mutex	YES	YES
...		
wait/synch/mutex/innodb/master_key_id_mutex	YES	YES

49 rows in set (0.00 sec)

- Enable wait event consumers by updating the `setup_consumers` table. Wait event consumers are disabled by default.

```
mysql> UPDATE performance_schema.setup_consumers
SET enabled = 'YES'
WHERE name like 'events_waits%';
Query OK, 3 rows affected (0.00 sec)
Rows matched: 3 Changed: 3 Warnings: 0
```

You can verify that wait event consumers are enabled by querying the `setup_consumers` table. The `events_waits_current`, `events_waits_history`, and `events_waits_history_long` consumers should be enabled.

```
mysql> SELECT * FROM performance_schema.setup_consumers;
```

NAME	ENABLED
events_stages_current	NO

events_stages_history	NO
events_stages_history_long	NO
events_statements_current	YES
events_statements_history	YES
events_statements_history_long	NO
events_transactions_current	YES
events_transactions_history	YES
events_transactions_history_long	NO
events_waits_current	YES
events_waits_history	YES
events_waits_history_long	YES
global_instrumentation	YES
thread_instrumentation	YES
statements_digest	YES

15 rows in set (0.00 sec)

4. Once instruments and consumers are enabled, run the workload that you want to monitor. In this example, the `mysqlslap` load emulation client is used to simulate a workload.

```
$> ./mysqlslap --auto-generate-sql --concurrency=100 --iterations=10
 --number-of-queries=1000 --number-char-cols=6 --number-int-cols=6;
```

5. Query the wait event data. In this example, wait event data is queried from the `events_waits_summary_global_by_event_name` table which aggregates data found in the `events_waits_current`, `events_waits_history`, and `events_waits_history_long` tables. Data is summarized by event name (`EVENT_NAME`), which is the name of the instrument that produced the event. Summarized data includes:

- `COUNT_STAR`

The number of summarized wait events.

- `SUM_TIMER_WAIT`

The total wait time of the summarized timed wait events.

- `MIN_TIMER_WAIT`

The minimum wait time of the summarized timed wait events.

- `AVG_TIMER_WAIT`

The average wait time of the summarized timed wait events.

- `MAX_TIMER_WAIT`

The maximum wait time of the summarized timed wait events.

The following query returns the instrument name (`EVENT_NAME`), the number of wait events (`COUNT_STAR`), and the total wait time for the events for that instrument (`SUM_TIMER_WAIT`). Because waits are timed in picoseconds (trillionths of a second) by default, wait times are divided by 1000000000 to show wait times in milliseconds. Data is presented in descending order, by the number of summarized wait events (`COUNT_STAR`). You can adjust the `ORDER BY` clause to order the data by total wait time.

```
mysql> SELECT EVENT_NAME, COUNT_STAR, SUM_TIMER_WAIT/1000000000 SUM_TIMER_WAIT_MS
FROM performance_schema.events_waits_summary_global_by_event_name
WHERE SUM_TIMER_WAIT > 0 AND EVENT_NAME LIKE 'wait/synch/mutex/innodb/%'
ORDER BY COUNT_STAR DESC;
```

EVENT_NAME	COUNT_STAR	SUM_TIMER_WAIT_MS
wait/synch/mutex/innodb/trx_mutex	201111	23.4719
wait/synch/mutex/innodb/fil_system_mutex	62244	9.6426
wait/synch/mutex/innodb/redo_rseg_mutex	48238	3.1135
wait/synch/mutex/innodb/log_sys_mutex	46113	2.0434
wait/synch/mutex/innodb/trx_sys_mutex	35134	1068.1588
wait/synch/mutex/innodb/lock_mutex	34872	1039.2589
wait/synch/mutex/innodb/log_sys_write_mutex	17805	1526.0490
wait/synch/mutex/innodb/dict_sys_mutex	14912	1606.7348
wait/synch/mutex/innodb/trx_undo_mutex	10634	1.1424
wait/synch/mutex/innodb/rw_lock_list_mutex	8538	0.1960
wait/synch/mutex/innodb/buf_pool_free_list_mutex	5961	0.6473
wait/synch/mutex/innodb/trx_pool_mutex	4885	8821.7496
wait/synch/mutex/innodb/buf_pool_LRU_list_mutex	4364	0.2077
wait/synch/mutex/innodb/innobase_share_mutex	3212	0.2650
wait/synch/mutex/innodb/flush_list_mutex	3178	0.2349
wait/synch/mutex/innodb/trx_pool_manager_mutex	2495	0.1310
wait/synch/mutex/innodb/buf_pool_flush_state_mutex	1318	0.2161
wait/synch/mutex/innodb/log_flush_order_mutex	1250	0.0893
wait/synch/mutex/innodb/buf_dblwr_mutex	951	0.0918
wait/synch/mutex/innodb/recalc_pool_mutex	670	0.0942
wait/synch/mutex/innodb/dict_persist_dirty_tables_mutex	345	0.0414
wait/synch/mutex/innodb/lock_wait_mutex	303	0.1565
wait/synch/mutex/innodb/autoinc_mutex	196	0.0213
wait/synch/mutex/innodb/autoinc_persisted_mutex	196	0.0175
wait/synch/mutex/innodb/purge_sys_pq_mutex	117	0.0308
wait/synch/mutex/innodb/srv_sys_mutex	94	0.0077
wait/synch/mutex/innodb/ibuf_mutex	22	0.0086
wait/synch/mutex/innodb/recv_sys_mutex	12	0.0008
wait/synch/mutex/innodb/srv_innodb_monitor_mutex	4	0.0009
wait/synch/mutex/innodb/recv_writer_mutex	1	0.0005

### Note

The preceding result set includes wait event data produced during the startup process. To exclude this data, you can truncate the [events\\_waits\\_summary\\_global\\_by\\_event\\_name](#) table immediately after startup and before running your workload. However, the truncate operation itself may produce a negligible amount wait event data.

```
mysql> TRUNCATE performance_schema.events_waits_summary_global_by_event_name;
```

## 17.17 InnoDB Monitors

[InnoDB](#) monitors provide information about the [InnoDB](#) internal state. This information is useful for performance tuning.

### 17.17.1 InnoDB Monitor Types

There are two types of [InnoDB](#) monitor:

- The standard [InnoDB](#) Monitor displays the following types of information:
  - Work done by the main background thread
  - Semaphore waits
  - Data about the most recent foreign key and deadlock errors
  - Lock waits for transactions

- Table and record locks held by active transactions
- Pending I/O operations and related statistics
- Insert buffer and adaptive hash index statistics
- Redo log data
- Buffer pool statistics
- Row operation data
- The [InnoDB Lock Monitor](#) prints additional lock information as part of the standard [InnoDB Monitor](#) output.

## 17.17.2 Enabling InnoDB Monitors

When [InnoDB](#) monitors are enabled for periodic output, [InnoDB](#) writes the output to [mysqld](#) server standard error output ([stderr](#)) every 15 seconds, approximately.

[InnoDB](#) sends the monitor output to [stderr](#) rather than to [stdout](#) or fixed-size memory buffers to avoid potential buffer overflows.

On Windows, [stderr](#) is directed to the default log file unless configured otherwise. If you want to direct the output to the console window rather than to the error log, start the server from a command prompt in a console window with the `--console` option. For more information, see [Default Error Log Destination on Windows](#).

On Unix and Unix-like systems, [stderr](#) is typically directed to the terminal unless configured otherwise. For more information, see [Default Error Log Destination on Unix and Unix-Like Systems](#).

[InnoDB](#) monitors should only be enabled when you actually want to see monitor information because output generation causes some performance decrement. Also, if monitor output is directed to the error log, the log may become quite large if you forget to disable the monitor later.

### Note

To assist with troubleshooting, [InnoDB](#) temporarily enables standard [InnoDB Monitor](#) output under certain conditions. For more information, see [Section 17.20, “InnoDB Troubleshooting”](#).

[InnoDB](#) monitor output begins with a header containing a timestamp and the monitor name. For example:

```
=====
2014-10-16 18:37:29 0x7fc2a95c1700 INNODB MONITOR OUTPUT
=====
```

The header for the standard [InnoDB Monitor](#) (`INNODB MONITOR OUTPUT`) is also used for the Lock Monitor because the latter produces the same output with the addition of extra lock information.

The `innodb_status_output` and `innodb_status_output_locks` system variables are used to enable the standard [InnoDB Monitor](#) and [InnoDB Lock Monitor](#).

The `PROCESS` privilege is required to enable or disable [InnoDB Monitors](#).

## Enabling the Standard InnoDB Monitor

Enable the standard [InnoDB Monitor](#) by setting the `innodb_status_output` system variable to `ON`.

```
SET GLOBAL innodb_status_output=ON;
```

To disable the standard InnoDB Monitor, set `innodb_status_output` to `OFF`.

When you shut down the server, the `innodb_status_output` variable is set to the default `OFF` value.

## Enabling the InnoDB Lock Monitor

InnoDB Lock Monitor data is printed with the InnoDB Standard Monitor output. Both the InnoDB Standard Monitor and InnoDB Lock Monitor must be enabled to have InnoDB Lock Monitor data printed periodically.

To enable the InnoDB Lock Monitor, set the `innodb_status_output_locks` system variable to `ON`. Both the InnoDB standard Monitor and InnoDB Lock Monitor must be enabled to have InnoDB Lock Monitor data printed periodically:

```
SET GLOBAL innodb_status_output=ON;
SET GLOBAL innodb_status_output_locks=ON;
```

To disable the InnoDB Lock Monitor, set `innodb_status_output_locks` to `OFF`. Set `innodb_status_output` to `OFF` to also disable the InnoDB Standard Monitor.

When you shut down the server, the `innodb_status_output` and `innodb_status_output_locks` variables are set to the default `OFF` value.

### Note

To enable the InnoDB Lock Monitor for `SHOW ENGINE INNODB STATUS` output, you are only required to enable `innodb_status_output_locks`.

## Obtaining Standard InnoDB Monitor Output On Demand

As an alternative to enabling the standard InnoDB Monitor for periodic output, you can obtain standard InnoDB Monitor output on demand using the `SHOW ENGINE INNODB STATUS` SQL statement, which fetches the output to your client program. If you are using the `mysql` interactive client, the output is more readable if you replace the usual semicolon statement terminator with `\G`:

```
mysql> SHOW ENGINE INNODB STATUS\G
```

`SHOW ENGINE INNODB STATUS` output also includes InnoDB Lock Monitor data if the InnoDB Lock Monitor is enabled.

## Directing Standard InnoDB Monitor Output to a Status File

Standard InnoDB Monitor output can be enabled and directed to a status file by specifying the `--innodb-status-file` option at startup. When this option is used, InnoDB creates a file named `innodb_status.pid` in the data directory and writes output to it every 15 seconds, approximately.

InnoDB removes the status file when the server is shut down normally. If an abnormal shutdown occurs, the status file may have to be removed manually.

The `--innodb-status-file` option is intended for temporary use, as output generation can affect performance, and the `innodb_status.pid` file can become quite large over time.

## 17.17.3 InnoDB Standard Monitor and Lock Monitor Output

The Lock Monitor is the same as the Standard Monitor except that it includes additional lock information. Enabling either monitor for periodic output turns on the same output stream, but the stream includes extra information if the Lock Monitor is enabled. For example, if you enable the Standard Monitor and Lock Monitor, that turns on a single output stream. The stream includes extra lock information until you disable the Lock Monitor.

Standard Monitor output is limited to 1MB when produced using the `SHOW ENGINE INNODB STATUS` statement. This limit does not apply to output written to server standard error output (`stderr`).

Example Standard Monitor output:

```
mysql> SHOW ENGINE INNODB STATUS\G
***** 1. row *****
Type: InnoDB
Name:
Status:
=====
2018-04-12 15:14:08 0x7f971c063700 INNODB MONITOR OUTPUT
=====
Per second averages calculated from the last 4 seconds

END OF INNODB MONITOR OUTPUT
=====

```

## Standard Monitor Output Sections

For a description of each metric reported by the Standard Monitor, refer to the [Metrics](#) chapter in the [Oracle Enterprise Manager for MySQL Database User's Guide](#).

- [Status](#)

This section shows the timestamp, the monitor name, and the number of seconds that per-second averages are based on. The number of seconds is the elapsed time between the current time and the last time [InnoDB](#) Monitor output was printed.

- [BACKGROUND THREAD](#)

The [srv\\_master\\_thread](#) lines shows work done by the main background thread.

- [SEMAPHORES](#)

This section reports threads waiting for a semaphore and statistics on how many times threads have needed a spin or a wait on a mutex or a rw-lock semaphore. A large number of threads waiting for semaphores may be a result of disk I/O, or contention problems inside [InnoDB](#). Contention can be due to heavy parallelism of queries or problems in operating system thread scheduling. Setting the [innodb\\_thread\\_concurrency](#) system variable smaller than the default value might help in such situations. The [Spin rounds per wait](#) line shows the number of spinlock rounds per OS wait for a mutex.

Mutex metrics are reported by [SHOW ENGINE INNODB MUTEX](#).

- [LATEST FOREIGN KEY ERROR](#)

This section provides information about the most recent foreign key constraint error. It is not present if no such error has occurred. The contents include the statement that failed as well as information about the constraint that failed and the referenced and referencing tables.

- [LATEST DETECTED DEADLOCK](#)

This section provides information about the most recent deadlock. It is not present if no deadlock has occurred. The contents show which transactions are involved, the statement each was attempting to execute, the locks they have and need, and which transaction [InnoDB](#) decided to roll back to break the deadlock. The lock modes reported in this section are explained in [Section 17.7.1, “InnoDB Locking”](#).

- [TRANSACTIONS](#)

If this section reports lock waits, your applications might have lock contention. The output can also help to trace the reasons for transaction deadlocks.

- [FILE I/O](#)

This section provides information about threads that [InnoDB](#) uses to perform various types of I/O. The first few of these are dedicated to general [InnoDB](#) processing. The contents also display information for pending I/O operations and statistics for I/O performance.

The number of these threads are controlled by the [innodb\\_read\\_io\\_threads](#) and [innodb\\_write\\_io\\_threads](#) parameters. See [Section 17.14, “InnoDB Startup Options and System Variables”](#).

- [INSERT BUFFER AND ADAPTIVE HASH INDEX](#)

This section shows the status of the [InnoDB](#) insert buffer (also referred to as the [change buffer](#)) and the adaptive hash index.

For related information, see [Section 17.5.2, “Change Buffer”](#), and [Section 17.5.3, “Adaptive Hash Index”](#).

- [LOG](#)

This section displays information about the [InnoDB](#) log. The contents include the current log sequence number, how far the log has been flushed to disk, and the position at which [InnoDB](#) last took a checkpoint. (See [Section 17.11.3, “InnoDB Checkpoints”](#).) The section also displays information about pending writes and write performance statistics.

- [BUFFER POOL AND MEMORY](#)

This section gives you statistics on pages read and written. You can calculate from these numbers how many data file I/O operations your queries currently are doing.

For buffer pool statistics descriptions, see [Monitoring the Buffer Pool Using the InnoDB Standard Monitor](#). For additional information about the operation of the buffer pool, see [Section 17.5.1, “Buffer Pool”](#).

- [ROW OPERATIONS](#)

This section shows what the main thread is doing, including the number and performance rate for each type of row operation.

## 17.18 InnoDB Backup and Recovery

This section covers topics related to [InnoDB](#) backup and recovery.

- For information about backup techniques applicable to [InnoDB](#), see [Section 17.18.1, “InnoDB Backup”](#).
- For information about point-in-time recovery, recovery from disk failure or corruption, and how [InnoDB](#) performs crash recovery, see [Section 17.18.2, “InnoDB Recovery”](#).

### 17.18.1 InnoDB Backup

The key to safe database management is making regular backups. Depending on your data volume, number of MySQL servers, and database workload, you can use these backup techniques, alone or in combination: [hot backup](#) with *MySQL Enterprise Backup*; [cold backup](#) by copying files while the MySQL server is shut down; [logical backup](#) with `mysqldump` for smaller data volumes or to record the structure of schema objects. Hot and cold backups are [physical backups](#) that copy actual data files, which can be used directly by the `mysql` server for faster restore.

Using *MySQL Enterprise Backup* is the recommended method for backing up [InnoDB](#) data.

#### Note

[InnoDB](#) does not support databases that are restored using third-party backup tools.

### Hot Backups

The `mysqlbackup` command, part of the MySQL Enterprise Backup component, lets you back up a running MySQL instance, including [InnoDB](#) tables, with minimal disruption to operations while producing a consistent snapshot of the database. When `mysqlbackup` is copying [InnoDB](#) tables, reads and writes to [InnoDB](#) tables can continue. MySQL Enterprise Backup can also create compressed backup files, and

back up subsets of tables and databases. In conjunction with the MySQL binary log, users can perform point-in-time recovery. MySQL Enterprise Backup is part of the MySQL Enterprise subscription. For more details, see [Section 32.1, “MySQL Enterprise Backup Overview”](#).

## Cold Backups

If you can shut down the MySQL server, you can make a physical backup that consists of all files used by InnoDB to manage its tables. Use the following procedure:

1. Perform a [slow shutdown](#) of the MySQL server and make sure that it stops without errors.
2. Copy all InnoDB data files (`ibdata` files and `.ibd` files) into a safe place.
3. Copy all InnoDB redo log files (`#ib_redoN` files) to a safe place.
4. Copy your `my.cnf` configuration file or files to a safe place.

## Logical Backups Using `mysqldump`

In addition to physical backups, it is recommended that you regularly create logical backups by dumping your tables using `mysqldump`. A binary file might be corrupted without you noticing it. Dumped tables are stored into text files that are human-readable, so spotting table corruption becomes easier. Also, because the format is simpler, the chance for serious data corruption is smaller. `mysqldump` also has a `--single-transaction` option for making a consistent snapshot without locking out other clients. See [Section 9.3.1, “Establishing a Backup Policy”](#).

Replication works with InnoDB tables, so you can use MySQL replication capabilities to keep a copy of your database at database sites requiring high availability. See [Section 17.19, “InnoDB and MySQL Replication”](#).

## 17.18.2 InnoDB Recovery

This section describes InnoDB recovery. Topics include:

- [Point-in-Time Recovery](#)
- [Recovery from Data Corruption or Disk Failure](#)
- [InnoDB Crash Recovery](#)
- [Tablespace Discovery During Crash Recovery](#)

### Point-in-Time Recovery

To recover an InnoDB database to the present from the time at which the physical backup was made, you must run MySQL server with binary logging enabled, even before taking the backup. To achieve point-in-time recovery after restoring a backup, you can apply changes from the binary log that occurred after the backup was made. See [Section 9.5, “Point-in-Time \(Incremental\) Recovery”](#).

### Recovery from Data Corruption or Disk Failure

If your database becomes corrupted or disk failure occurs, you must perform the recovery using a backup. In the case of corruption, first find a backup that is not corrupted. After restoring the base backup, do a point-in-time recovery from the binary log files using `mysqlbinlog` and `mysql` to restore the changes that occurred after the backup was made.

In some cases of database corruption, it is enough to dump, drop, and re-create one or a few corrupt tables. You can use the `CHECK TABLE` statement to check whether a table is corrupt, although `CHECK TABLE` naturally cannot detect every possible kind of corruption.

In some cases, apparent database page corruption is actually due to the operating system corrupting its own file cache, and the data on disk may be okay. It is best to try restarting the computer first. Doing so may eliminate errors that appeared to be database page corruption. If MySQL still has trouble starting because of InnoDB consistency problems, see [Section 17.20.3, “Forcing InnoDB Recovery”](#) for steps to start the instance in recovery mode, which permits you to dump the data.

## InnoDB Crash Recovery

To recover from an unexpected MySQL server exit, the only requirement is to restart the MySQL server. InnoDB automatically checks the logs and performs a roll-forward of the database to the present. InnoDB automatically rolls back uncommitted transactions that were present at the time of the crash.

InnoDB crash recovery consists of several steps:

- **Tablespace discovery**

Tablespace discovery is the process that InnoDB uses to identify tablespaces that require redo log application. See [Tablespace Discovery During Crash Recovery](#).

- **Redo log application**

Redo log application is performed during initialization, before accepting any connections. If all changes are flushed from the [buffer pool](#) to the [tablespaces](#) (`ibdata*` and `*.ibd` files) at the time of the shutdown or crash, redo log application is skipped. InnoDB also skips redo log application if redo log files are missing at startup.

- The current maximum auto-increment counter value is written to the redo log each time the value changes, which makes it crash-safe. During recovery, InnoDB scans the redo log to collect counter value changes and applies the changes to the in-memory table object.

For more information about how InnoDB handles auto-increment values, see [Section 17.6.1.6, “AUTO\\_INCREMENT Handling in InnoDB”](#), and [InnoDB AUTO\\_INCREMENT Counter Initialization](#).

- When encountering index tree corruption, InnoDB writes a corruption flag to the redo log, which makes the corruption flag crash-safe. InnoDB also writes in-memory corruption flag data to an engine-private system table on each checkpoint. During recovery, InnoDB reads corruption flags from both locations and merges results before marking in-memory table and index objects as corrupt.
- Removing redo logs to speed up recovery is not recommended, even if some data loss is acceptable. Removing redo logs should only be considered after a clean shutdown, with `innodb_fast_shutdown` set to 0 or 1.
- **Roll back of incomplete transactions**

Incomplete transactions are any transactions that were active at the time of unexpected exit or [fast shutdown](#). The time it takes to roll back an incomplete transaction can be three or four times the amount of time a transaction is active before it is interrupted, depending on server load.

You cannot cancel transactions that are being rolled back. In extreme cases, when rolling back transactions is expected to take an exceptionally long time, it may be faster to start InnoDB with an `innodb_force_recovery` setting of 3 or greater. See [Section 17.20.3, “Forcing InnoDB Recovery”](#).

- **Change buffer merge**

Applying changes from the change buffer (part of the [system tablespace](#)) to leaf pages of secondary indexes, as the index pages are read to the buffer pool.

- **Purge**

Deleting delete-marked records that are no longer visible to active transactions.

The steps that follow redo log application do not depend on the redo log (other than for logging the writes) and are performed in parallel with normal processing. Of these, only rollback of incomplete transactions is special to crash recovery. The insert buffer merge and the purge are performed during normal processing.

After redo log application, [InnoDB](#) attempts to accept connections as early as possible, to reduce downtime. As part of crash recovery, [InnoDB](#) rolls back transactions that were not committed or in [XA PREPARE](#) state when the server exited. The rollback is performed by a background thread, executed in parallel with transactions from new connections. Until the rollback operation is completed, new connections may encounter locking conflicts with recovered transactions.

In most situations, even if the MySQL server was killed unexpectedly in the middle of heavy activity, the recovery process happens automatically and no action is required of the DBA. If a hardware failure or severe system error corrupted [InnoDB](#) data, MySQL might refuse to start. In this case, see [Section 17.20.3, “Forcing InnoDB Recovery”](#).

For information about the binary log and [InnoDB](#) crash recovery, see [Section 7.4.4, “The Binary Log”](#).

## Tablespace Discovery During Crash Recovery

If, during recovery, [InnoDB](#) encounters redo logs written since the last checkpoint, the redo logs must be applied to affected tablespaces. The process that identifies affected tablespaces during recovery is referred to as *tablespace discovery*.

Tablespace discovery relies on the [innodb\\_directories](#) setting, which defines the directories to scan at startup for tablespace files. The [innodb\\_directories](#) default setting is NULL, but the directories defined by [innodb\\_data\\_home\\_dir](#), [innodb\\_undo\\_directory](#), and [datadir](#) are always appended to the [innodb\\_directories](#) argument value when InnoDB builds a list of directories to scan at startup. These directories are appended regardless of whether an [innodb\\_directories](#) setting is specified explicitly. Tablespace files defined with an absolute path or that reside outside of the directories appended to the [innodb\\_directories](#) setting should be added to the [innodb\\_directories](#) setting. Recovery is terminated if any tablespace file referenced in a redo log has not been discovered previously.

## 17.19 InnoDB and MySQL Replication

It is possible to use replication in a way where the storage engine on the replica is not the same as the storage engine on the source. For example, you can replicate modifications to an [InnoDB](#) table on the source to a [MyISAM](#) table on the replica. For more information see, [Section 19.4.4, “Using Replication with Different Source and Replica Storage Engines”](#).

For information about setting up a replica, see [Section 19.1.2.6, “Setting Up Replicas”](#), and [Section 19.1.2.5, “Choosing a Method for Data Snapshots”](#). To make a new replica without taking down the source or an existing replica, use the [MySQL Enterprise Backup](#) product.

Transactions that fail on the source do not affect replication. MySQL replication is based on the binary log where MySQL writes SQL statements that modify data. A transaction that fails (for example, because of a foreign key violation, or because it is rolled back) is not written to the binary log, so it is not sent to replicas. See [Section 15.3.1, “START TRANSACTION, COMMIT, and ROLLBACK Statements”](#).

**Replication and CASCADE.** Cascading actions for [InnoDB](#) tables on the source are executed on the replica *only* if the tables sharing the foreign key relation use [InnoDB](#) on both the source and replica. This is true whether you are using statement-based or row-based replication. Suppose that you have started replication, and then create two tables on the source, where [InnoDB](#) is defined as the default storage engine, using the following `CREATE TABLE` statements:

```
CREATE TABLE fc1 (
 i INT PRIMARY KEY,
 j INT
);

CREATE TABLE fc2 (
 m INT PRIMARY KEY,
 n INT,
 FOREIGN KEY ni (n) REFERENCES fc1 (i)
 ON DELETE CASCADE
);
```

If the replica has [MyISAM](#) defined as the default storage engine, the same tables are created on the replica, but they use the [MyISAM](#) storage engine, and the `FOREIGN KEY` option is ignored. Now we insert some rows into the tables on the source:

```
source> INSERT INTO fc1 VALUES (1, 1), (2, 2);
Query OK, 2 rows affected (0.09 sec)
Records: 2 Duplicates: 0 Warnings: 0

source> INSERT INTO fc2 VALUES (1, 1), (2, 2), (3, 1);
Query OK, 3 rows affected (0.19 sec)
Records: 3 Duplicates: 0 Warnings: 0
```

At this point, on both the source and the replica, table `fc1` contains 2 rows, and table `fc2` contains 3 rows, as shown here:

```
source> SELECT * FROM fc1;
+----+-----+
| i | j |
+----+-----+
| 1 | 1 |
| 2 | 2 |
+----+-----+
2 rows in set (0.00 sec)

source> SELECT * FROM fc2;
+----+-----+
| m | n |
+----+-----+
| 1 | 1 |
| 2 | 2 |
| 3 | 1 |
+----+-----+
3 rows in set (0.00 sec)

replica> SELECT * FROM fc1;
+----+-----+
| i | j |
+----+-----+
| 1 | 1 |
| 2 | 2 |
+----+-----+
2 rows in set (0.00 sec)

replica> SELECT * FROM fc2;
+----+-----+
| m | n |
+----+-----+
```

```

| 1 | 1 |
| 2 | 2 |
| 3 | 1 |
+----+-----+
3 rows in set (0.00 sec)

```

Now suppose that you perform the following `DELETE` statement on the source:

```

source> DELETE FROM fc1 WHERE i=1;
Query OK, 1 row affected (0.09 sec)

```

Due to the cascade, table `fc2` on the source now contains only 1 row:

```

source> SELECT * FROM fc2;
+----+-----+
| m | n |
+----+-----+
| 2 | 2 |
+----+-----+
1 row in set (0.00 sec)

```

However, the cascade does not propagate on the replica because on the replica the `DELETE` for `fc1` deletes no rows from `fc2`. The replica's copy of `fc2` still contains all of the rows that were originally inserted:

```

replica> SELECT * FROM fc2;
+----+-----+
| m | n |
+----+-----+
| 1 | 1 |
| 3 | 1 |
| 2 | 2 |
+----+-----+
3 rows in set (0.00 sec)

```

This difference is due to the fact that the cascading deletes are handled internally by the `InnoDB` storage engine, which means that none of the changes are logged.

## 17.20 InnoDB Troubleshooting

The following general guidelines apply to troubleshooting `InnoDB` problems:

- When an operation fails or you suspect a bug, look at the MySQL server error log (see [Section 7.4.2, “The Error Log”](#)). [Server Error Message Reference](#) provides troubleshooting information for some of the common `InnoDB`-specific errors that you may encounter.
- If the failure is related to a [deadlock](#), run with the `innodb_print_all_deadlocks` option enabled so that details about each deadlock are printed to the MySQL server error log. For information about deadlocks, see [Section 17.7.5, “Deadlocks in InnoDB”](#).
- If the issue is related to the `InnoDB` data dictionary, see [Section 17.20.4, “Troubleshooting InnoDB Data Dictionary Operations”](#).
- When troubleshooting, it is usually best to run the MySQL server from the command prompt, rather than through `mysqld_safe` or as a Windows service. You can then see what `mysqld` prints to the console, and so have a better grasp of what is going on. On Windows, start `mysqld` with the `--console` option to direct the output to the console window.
- Enable the `InnoDB` Monitors to obtain information about a problem (see [Section 17.17, “InnoDB Monitors”](#)). If the problem is performance-related, or your server appears to be hung, you should enable

the standard Monitor to print information about the internal state of [InnoDB](#). If the problem is with locks, enable the Lock Monitor. If the problem is with table creation, tablespaces, or data dictionary operations, refer to the [InnoDB Information Schema system tables](#) to examine contents of the [InnoDB](#) internal data dictionary.

[InnoDB](#) temporarily enables standard [InnoDB](#) Monitor output under the following conditions:

- A long semaphore wait
- [InnoDB](#) cannot find free blocks in the buffer pool
- Over 67% of the buffer pool is occupied by lock heaps or the adaptive hash index
- If you suspect that a table is corrupt, run `CHECK TABLE` on that table.

## 17.20.1 Troubleshooting InnoDB I/O Problems

The troubleshooting steps for [InnoDB](#) I/O problems depend on when the problem occurs: during startup of the MySQL server, or during normal operations when a DML or DDL statement fails due to problems at the file system level.

### Initialization Problems

If something goes wrong when [InnoDB](#) attempts to initialize its tablespace or its log files, delete all files created by [InnoDB](#): all `ibdata` files and all redo log files (`#ib_redoN` files). If you created any [InnoDB](#) tables, also delete any `.ibd` files from the MySQL database directories. Then try initializing [InnoDB](#) again. For easiest troubleshooting, start the MySQL server from a command prompt so that you see what is happening.

### Runtime Problems

If [InnoDB](#) prints an operating system error during a file operation, usually the problem has one of the following solutions:

- Make sure the [InnoDB](#) data file directory and the [InnoDB](#) log directory exist.
- Make sure `mysqld` has access rights to create files in those directories.
- Make sure `mysqld` can read the proper `my.cnf` or `my.ini` option file, so that it starts with the options that you specified.
- Make sure the disk is not full and you are not exceeding any disk quota.
- Make sure that the names you specify for subdirectories and data files do not clash.
- Doublecheck the syntax of the `innodb_data_home_dir` and `innodb_data_file_path` values. In particular, any `MAX` value in the `innodb_data_file_path` option is a hard limit, and exceeding that limit causes a fatal error.

## 17.20.2 Troubleshooting Recovery Failures

Checkpoints and advancing the checkpoint LSN are not permitted until redo log recovery is complete and data dictionary dynamic metadata (`srv_dict_metadata`) is transferred to data dictionary table (`dict_table_t`) objects. Should the redo log run out of space during recovery or after recovery (but before data dictionary dynamic metadata is transferred to data dictionary table objects) as a result of this change, an `innodb_force_recovery` restart may be required, starting with at least the

`SRV_FORCE_NO_IBUF_MERGE` setting or, in case that fails, the `SRV_FORCE_NO_LOG_REDO` setting. If an `innodb_force_recovery` restart fails in this scenario, recovery from backup may be necessary.

### 17.20.3 Forcing InnoDB Recovery

To investigate database page corruption, you might dump your tables from the database with `SELECT ... INTO OUTFILE`. Usually, most of the data obtained in this way is intact. Serious corruption might cause `SELECT * FROM tbl_name` statements or InnoDB background operations to unexpectedly exit or assert, or even cause InnoDB roll-forward recovery to crash. In such cases, you can use the `innodb_force_recovery` option to force the InnoDB storage engine to start up while preventing background operations from running, so that you can dump your tables. For example, you can add the following line to the `[mysqld]` section of your option file before restarting the server:

```
[mysqld]
innodb_force_recovery = 1
```

For information about using option files, see [Section 6.2.2.2, “Using Option Files”](#).

#### Warning

Only set `innodb_force_recovery` to a value greater than 0 in an emergency situation, so that you can start InnoDB and dump your tables. Before doing so, ensure that you have a backup copy of your database in case you need to recreate it. Values of 4 or greater can permanently corrupt data files. Only use an `innodb_force_recovery` setting of 4 or greater on a production server instance after you have successfully tested the setting on a separate physical copy of your database. When forcing InnoDB recovery, you should always start with `innodb_force_recovery=1` and only increase the value incrementally, as necessary.

`innodb_force_recovery` is 0 by default (normal startup without forced recovery). The permissible nonzero values for `innodb_force_recovery` are 1 to 6. A larger value includes the functionality of lesser values. For example, a value of 3 includes all of the functionality of values 1 and 2.

If you are able to dump your tables with an `innodb_force_recovery` value of 3 or less, then you are relatively safe that only some data on corrupt individual pages is lost. A value of 4 or greater is considered dangerous because data files can be permanently corrupted. A value of 6 is considered drastic because database pages are left in an obsolete state, which in turn may introduce more corruption into [B-trees](#) and other database structures.

As a safety measure, InnoDB prevents `INSERT`, `UPDATE`, or `DELETE` operations when `innodb_force_recovery` is greater than 0. An `innodb_force_recovery` setting of 4 or greater places InnoDB in read-only mode.

- 1 (`SRV_FORCE_IGNORE_CORRUPT`)

Lets the server run even if it detects a corrupt [page](#). Tries to make `SELECT * FROM tbl_name` jump over corrupt index records and pages, which helps in dumping tables.

- 2 (`SRV_FORCE_NO_BACKGROUND`)

Prevents the [master thread](#) and any [purge threads](#) from running. If an unexpected exit would occur during the [purge](#) operation, this recovery value prevents it.

- 3 (`SRV_FORCE_NO_TRX_UNDO`)

Does not run transaction [rollbacks](#) after [crash recovery](#).

- 4 (SRV\_FORCE\_NO\_IBUF\_MERGE)

Prevents [insert buffer](#) merge operations. If they would cause a crash, does not do them. Does not calculate table [statistics](#). This value can permanently corrupt data files. After using this value, be prepared to drop and recreate all secondary indexes. Sets [InnoDB](#) to read-only.

- 5 (SRV\_FORCE\_NO\_UNDO\_LOG\_SCAN)

Does not look at [undo logs](#) when starting the database: [InnoDB](#) treats even incomplete transactions as committed. This value can permanently corrupt data files. Sets [InnoDB](#) to read-only.

- 6 (SRV\_FORCE\_NO\_LOG\_REDO)

Does not do the [redo log](#) roll-forward in connection with recovery. This value can permanently corrupt data files. Leaves database pages in an obsolete state, which in turn may introduce more corruption into B-trees and other database structures. Sets [InnoDB](#) to read-only.

You can [SELECT](#) from tables to dump them. With an [innodb\\_force\\_recovery](#) value of 3 or less you can [DROP](#) or [CREATE](#) tables. [DROP TABLE](#) is also supported with an [innodb\\_force\\_recovery](#) value greater than 3. [DROP TABLE](#) is not permitted with an [innodb\\_force\\_recovery](#) value greater than 4.

If you know that a given table is causing an unexpected exit on rollback, you can drop it. If you encounter a runaway rollback caused by a failing mass import or [ALTER TABLE](#), you can kill the [mysqld](#) process and set [innodb\\_force\\_recovery](#) to 3 to bring the database up without the rollback, and then [DROP](#) the table that is causing the runaway rollback.

If corruption within the table data prevents you from dumping the entire table contents, a query with an [ORDER BY primary\\_key DESC](#) clause might be able to dump the portion of the table after the corrupted part.

If a high [innodb\\_force\\_recovery](#) value is required to start [InnoDB](#), there may be corrupted data structures that could cause complex queries (queries containing [WHERE](#), [ORDER BY](#), or other clauses) to fail. In this case, you may only be able to run basic [SELECT \\* FROM t](#) queries.

## 17.20.4 Troubleshooting InnoDB Data Dictionary Operations

Information about table definitions is stored in the [InnoDB data dictionary](#). If you move data files around, dictionary data can become inconsistent.

If a data dictionary corruption or consistency issue prevents you from starting [InnoDB](#), see [Section 17.20.3, “Forcing InnoDB Recovery”](#) for information about manual recovery.

### Cannot Open Datafile

With [innodb\\_file\\_per\\_table](#) enabled (the default), the following messages may appear at startup if a [file-per-table](#) tablespace file ([.ibd](#) file) is missing:

```
[ERROR] InnoDB: Operating system error number 2 in a file operation.
[ERROR] InnoDB: The error means the system cannot find the path specified.
[ERROR] InnoDB: Cannot open datafile for read-only: './test/t1.ibd' OS error: 71
[Warning] InnoDB: Ignoring tablespace `test/t1` because it could not be opened.
```

To address these messages, issue [DROP TABLE](#) statement to remove data about the missing table from the data dictionary.

### Restoring Orphan File-Per-Table ibd Files

This procedure describes how to restore orphan [file-per-table .ibd](#) files to another MySQL instance. You might use this procedure if the system tablespace is lost or unrecoverable and you want to restore [.ibd](#) file backups on a new MySQL instance.

The procedure is not supported for [general tablespace .ibd](#) files.

The procedure assumes that you only have [.ibd](#) file backups, you are recovering to the same version of MySQL that initially created the orphan [.ibd](#) files, and that [.ibd](#) file backups are clean. See [Section 17.6.1.4, “Moving or Copying InnoDB Tables”](#) for information about creating clean backups.

Table import limitations outlined in [Section 17.6.1.3, “Importing InnoDB Tables”](#) are applicable to this procedure.

1. On the new MySQL instance, recreate the table in a database of the same name.

```
mysql> CREATE DATABASE sakila;

mysql> USE sakila;

mysql> CREATE TABLE actor (
-> actor_id SMALLINT UNSIGNED NOT NULL AUTO_INCREMENT,
-> first_name VARCHAR(45) NOT NULL,
-> last_name VARCHAR(45) NOT NULL,
-> last_update TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
-> PRIMARY KEY (actor_id),
-> KEY idx_actor_last_name (last_name)
->)ENGINE=InnoDB DEFAULT CHARSET=utf8mb4;
```

2. Discard the tablespace of the newly created table.

```
mysql> ALTER TABLE sakila.actor DISCARD TABLESPACE;
```

3. Copy the orphan [.ibd](#) file from your backup directory to the new database directory.

```
$> cp /backup_directory/actor.ibd path/to/mysql-5.7/data/sakila/
```

4. Ensure that the [.ibd](#) file has the necessary file permissions.
5. Import the orphan [.ibd](#) file. A warning is issued indicating that [InnoDB](#) is attempting to import the file without schema verification.

```
mysql> ALTER TABLE sakila.actor IMPORT TABLESPACE; SHOW WARNINGS;
Query OK, 0 rows affected, 1 warning (0.15 sec)

Warning | 1810 | InnoDB: IO Read error: (2, No such file or directory)
Error opening './sakila/actor.cfg', will attempt to import
without schema verification
```

6. Query the table to verify that the [.ibd](#) file was successfully restored.

```
mysql> SELECT COUNT(*) FROM sakila.actor;
+-----+
| count(*) |
+-----+
| 200 |
+-----+
```

## 17.20.5 InnoDB Error Handling

The following items describe how [InnoDB](#) performs error handling. [InnoDB](#) sometimes rolls back only the statement that failed, other times it rolls back the entire transaction.

- If you run out of file space in a [tablespace](#), a MySQL `Table is full` error occurs and [InnoDB](#) rolls back the SQL statement.
- A transaction [deadlock](#) causes [InnoDB](#) to [roll back](#) the entire [transaction](#). Retry the entire transaction when this happens.

A lock wait timeout causes [InnoDB](#) to roll back the current statement (the statement that was waiting for the lock and encountered the timeout). To have the entire transaction roll back, start the server with `--innodb-rollback-on-timeout` enabled. Retry the statement if using the default behavior, or the entire transaction if `--innodb-rollback-on-timeout` is enabled.

Both deadlocks and lock wait timeouts are normal on busy servers and it is necessary for applications to be aware that they may happen and handle them by retrying. You can make them less likely by doing as little work as possible between the first change to data during a transaction and the commit, so the locks are held for the shortest possible time and for the smallest possible number of rows. Sometimes splitting work between different transactions may be practical and helpful.

- A duplicate-key error rolls back the SQL statement, if you have not specified the [IGNORE](#) option in your statement.
- A [row too long error](#) rolls back the SQL statement.
- Other errors are mostly detected by the MySQL layer of code (above the [InnoDB](#) storage engine level), and they roll back the corresponding SQL statement. Locks are not released in a rollback of a single SQL statement.

During implicit rollbacks, as well as during the execution of an explicit [ROLLBACK](#) SQL statement, [SHOW PROCESSLIST](#) displays [Rolling back](#) in the [State](#) column for the relevant connection.

## 17.21 InnoDB Limits

This section describes limits for [InnoDB](#) tables, indexes, tablespaces, and other aspects of the [InnoDB](#) storage engine.

- A table can contain a maximum of 1017 columns. Virtual generated columns are included in this limit.
- A table can contain a maximum of 64 [secondary indexes](#).
- The index key prefix length limit is 3072 bytes for [InnoDB](#) tables that use [DYNAMIC](#) or [COMPRESSED](#) row format.

The index key prefix length limit is 767 bytes for [InnoDB](#) tables that use the [REDUNDANT](#) or [COMPACT](#) row format. For example, you might hit this limit with a [column prefix](#) index of more than 191 characters on a [TEXT](#) or [VARCHAR](#) column, assuming a [utf8mb4](#) character set and the maximum of 4 bytes for each character.

Attempting to use an index key prefix length that exceeds the limit returns an error.

If you reduce the [InnoDB page size](#) to 8KB or 4KB by specifying the `innodb_page_size` option when creating the MySQL instance, the maximum length of the index key is lowered proportionally, based on the limit of 3072 bytes for a 16KB page size. That is, the maximum index key length is 1536 bytes when the page size is 8KB, and 768 bytes when the page size is 4KB.

The limits that apply to index key prefixes also apply to full-column index keys.

- A maximum of 16 columns is permitted for multicolumn indexes. Exceeding the limit returns an error.

```
ERROR 1070 (42000): Too many key parts specified; max 16 parts allowed
```

- The maximum row size, excluding any variable-length columns that are stored off-page, is slightly less than half of a page for 4KB, 8KB, 16KB, and 32KB page sizes. For example, the maximum row size for the default `innodb_page_size` of 16KB is about 8000 bytes. However, for an InnoDB page size of 64KB, the maximum row size is approximately 16000 bytes. `LONGBLOB` and `LONGTEXT` columns must be less than 4GB, and the total row size, including `BLOB` and `TEXT` columns, must be less than 4GB.

If a row is less than half a page long, all of it is stored locally within the page. If it exceeds half a page, variable-length columns are chosen for external off-page storage until the row fits within half a page, as described in [Section 17.11.2, “File Space Management”](#).

- Although InnoDB supports row sizes larger than 65,535 bytes internally, MySQL itself imposes a row-size limit of 65,535 for the combined size of all columns. See [Section 10.4.7, “Limits on Table Column Count and Row Size”](#).
- The maximum table or tablespace size is impacted by the server's file system, which can impose a maximum file size that is smaller than the internal 64 TiB size limit defined by InnoDB. For example, the `ext4` file system on Linux has a maximum file size of 16 TiB, so the maximum table or tablespace size becomes 16 TiB instead of 64 TiB. Another example is the `FAT32` file system, which has a maximum file size of 4 GB.

If you require a larger system tablespace, configure it using several smaller data files rather than one large data file, or distribute table data across file-per-table and general tablespace data files.

- The combined maximum size for InnoDB log files is 512GB.
- The minimum tablespace size is slightly larger than 10MB. The maximum tablespace size depends on the InnoDB page size.

**Table 17.26 InnoDB Maximum Tablespace Size**

InnoDB Page Size	Maximum Tablespace Size
4KB	16TB
8KB	32TB
16KB	64TB
32KB	128TB
64KB	256TB

The maximum tablespace size is also the maximum size for a table.

- An InnoDB instance supports up to  $2^{32}$  (4294967296) tablespaces, with a small number of those tablespaces reserved for undo and temporary tables.
- Shared tablespaces support up to  $2^{32}$  (4294967296) tables.
- The path of a tablespace file, including the file name, cannot exceed the `MAX_PATH` limit on Windows. Prior to Windows 10, the `MAX_PATH` limit is 260 characters. As of Windows 10, version 1607, `MAX_PATH` limitations are removed from common Win32 file and directory functions, but you must enable the new behavior.
- For limits associated with concurrent read-write transactions, see [Section 17.6.6, “Undo Logs”](#).

## 17.22 InnoDB Restrictions and Limitations

This section describes restrictions and limitations of the [InnoDB](#) storage engine.

- You cannot create a table with a column name that matches the name of an internal [InnoDB](#) column (including [DB\\_ROW\\_ID](#), [DB\\_TRX\\_ID](#), and [DB\\_ROLL\\_PTR](#). This restriction applies to use of the names in any lettercase.

```
mysql> CREATE TABLE t1 (c1 INT, db_row_id INT) ENGINE=INNODB;
ERROR 1166 (42000): Incorrect column name 'db_row_id'
```

- [SHOW TABLE STATUS](#) does not provide accurate statistics for [InnoDB](#) tables except for the physical size reserved by the table. The row count is only a rough estimate used in SQL optimization.
- [InnoDB](#) does not keep an internal count of rows in a table because concurrent transactions might “see” different numbers of rows at the same time. Consequently, [SELECT COUNT\(\\*\)](#) statements only count rows visible to the current transaction.

For information about how [InnoDB](#) processes [SELECT COUNT\(\\*\)](#) statements, refer to the [COUNT\(\)](#) description in [Section 14.19.1, “Aggregate Function Descriptions”](#).

- [ROW\\_FORMAT=COMPRESSED](#) is unsupported for page sizes greater than 16KB.
- A MySQL instance using a particular [InnoDB](#) page size ([innodb\\_page\\_size](#)) cannot use data files or log files from an instance that uses a different page size.
- For limitations associated with importing tables using the *Transportable Tablespaces* feature, see [Table Import Limitations](#).
- For limitations associated with online DDL, see [Section 17.12.8, “Online DDL Limitations”](#).
- For limitations associated with general tablespaces, see [General Tablespace Limitations](#).
- For limitations associated with data-at-rest encryption, see [Encryption Limitations](#).

18.11.1	Pluggable Storage Engine Architecture .....	3551
18.11.2	The Common Database Server Layer .....	3551

Storage engines are MySQL components that handle the SQL operations for different table types. [InnoDB](#) is the default and most general-purpose storage engine, and Oracle recommends using it for tables except for specialized use cases. (The [CREATE TABLE](#) statement in MySQL 9.1 creates [InnoDB](#) tables by default.)

MySQL Server uses a pluggable storage engine architecture that enables storage engines to be loaded into and unloaded from a running MySQL server.

To determine which storage engines your server supports, use the [SHOW ENGINES](#) statement. The value in the [Support](#) column indicates whether an engine can be used. A value of [YES](#), [NO](#), or [DEFAULT](#) indicates that an engine is available, not available, or available and currently set as the default storage engine.

```
mysql> SHOW ENGINES\G
***** 1. row *****
 Engine: PERFORMANCE_SCHEMA
 Support: YES
 Comment: Performance Schema
Transactions: NO
 XA: NO
 Savepoints: NO
***** 2. row *****
 Engine: InnoDB
 Support: DEFAULT
```

```
 Comment: Supports transactions, row-level locking, and foreign keys
Transactions: YES
 XA: YES
Savepoints: YES
***** 3. row *****
 Engine: MRG_MYISAM
 Support: YES
 Comment: Collection of identical MyISAM tables
Transactions: NO
 XA: NO
Savepoints: NO
***** 4. row *****
 Engine: BLACKHOLE
 Support: YES
 Comment: /dev/null storage engine (anything you write to it disappears)
Transactions: NO
 XA: NO
Savepoints: NO
***** 5. row *****
 Engine: MyISAM
 Support: YES
 Comment: MyISAM storage engine
Transactions: NO
 XA: NO
Savepoints: NO
...

```

This chapter covers use cases for special-purpose MySQL storage engines. It does not cover the default [InnoDB](#) storage engine or the [NDB](#) storage engine which are covered in [Chapter 17, The InnoDB Storage Engine](#) and [Chapter 25, MySQL NDB Cluster 9.1](#). For advanced users, it also contains a description of the pluggable storage engine architecture (see [Section 18.11, “Overview of MySQL Storage Engine Architecture”](#)).

For information about features offered in commercial MySQL Server binaries, see [MySQL Editions](#), on the MySQL website. The storage engines available might depend on which edition of MySQL you are using.

For answers to commonly asked questions about MySQL storage engines, see [Section A.2, “MySQL 9.1 FAQ: Storage Engines”](#).

## MySQL 9.1 Supported Storage Engines

- **InnoDB**: The default storage engine in MySQL 9.1. [InnoDB](#) is a transaction-safe (ACID compliant) storage engine for MySQL that has commit, rollback, and crash-recovery capabilities to protect user data. [InnoDB](#) row-level locking (without escalation to coarser granularity locks) and Oracle-style consistent nonlocking reads increase multi-user concurrency and performance. [InnoDB](#) stores user data in clustered indexes to reduce I/O for common queries based on primary keys. To maintain data integrity, [InnoDB](#) also supports [FOREIGN KEY](#) referential-integrity constraints. For more information about [InnoDB](#), see [Chapter 17, The InnoDB Storage Engine](#).
- **MyISAM**: These tables have a small footprint. [Table-level locking](#) limits the performance in read/write workloads, so it is often used in read-only or read-mostly workloads in Web and data warehousing configurations.
- **Memory**: Stores all data in RAM, for fast access in environments that require quick lookups of non-critical data. This engine was formerly known as the [HEAP](#) engine. Its use cases are decreasing; [InnoDB](#) with its buffer pool memory area provides a general-purpose and durable way to keep most or all data in memory, and [NDBCLUSTER](#) provides fast key-value lookups for huge distributed data sets.
- **CSV**: Its tables are really text files with comma-separated values. CSV tables let you import or dump data in CSV format, to exchange data with scripts and applications that read and write that same format.

Because CSV tables are not indexed, you typically keep the data in [InnoDB](#) tables during normal operation, and only use CSV tables during the import or export stage.

- [Archive](#): These compact, unindexed tables are intended for storing and retrieving large amounts of seldom-referenced historical, archived, or security audit information.
- [Blackhole](#): The Blackhole storage engine accepts but does not store data, similar to the Unix `/dev/null` device. Queries always return an empty set. These tables can be used in replication configurations where DML statements are sent to replica servers, but the source server does not keep its own copy of the data.
- [NDB](#) (also known as [NDBCLUSTER](#)): This clustered database engine is particularly suited for applications that require the highest possible degree of uptime and availability.
- [Merge](#): Enables a MySQL DBA or developer to logically group a series of identical [MyISAM](#) tables and reference them as one object. Good for VLDB environments such as data warehousing.
- [Federated](#): Offers the ability to link separate MySQL servers to create one logical database from many physical servers. Very good for distributed or data mart environments.
- [Example](#): This engine serves as an example in the MySQL source code that illustrates how to begin writing new storage engines. It is primarily of interest to developers. The storage engine is a “stub” that does nothing. You can create tables with this engine, but no data can be stored in them or retrieved from them.

You are not restricted to using the same storage engine for an entire server or schema. You can specify the storage engine for any table. For example, an application might use mostly [InnoDB](#) tables, with one [CSV](#) table for exporting data to a spreadsheet and a few [MEMORY](#) tables for temporary workspaces.

### Choosing a Storage Engine

The various storage engines provided with MySQL are designed with different use cases in mind. The following table provides an overview of some storage engines provided with MySQL, with clarifying notes following the table.

**Table 18.1 Storage Engines Feature Summary**

Feature	MyISAM	Memory	InnoDB	Archive	NDB
B-tree indexes	Yes	Yes	Yes	No	No
Backup/point-in-time recovery (note 1)	Yes	Yes	Yes	Yes	Yes
Cluster database support	No	No	No	No	Yes
Clustered indexes	No	No	Yes	No	No
Compressed data	Yes (note 2)	No	Yes	Yes	No
Data caches	No	N/A	Yes	No	Yes
Encrypted data	Yes (note 3)	Yes (note 3)	Yes (note 4)	Yes (note 3)	Yes (note 5)
Foreign key support	No	No	Yes	No	Yes

Feature	MyISAM	Memory	InnoDB	Archive	NDB
Full-text search indexes	Yes	No	Yes (note 6)	No	No
Geospatial data type support	Yes	No	Yes	Yes	Yes
Geospatial indexing support	Yes	No	Yes (note 7)	No	No
Hash indexes	No	Yes	No (note 8)	No	Yes
Index caches	Yes	N/A	Yes	No	Yes
Locking granularity	Table	Table	Row	Row	Row
MVCC	No	No	Yes	No	No
Replication support (note 1)	Yes	Limited (note 9)	Yes	Yes	Yes
Storage limits	256TB	RAM	64TB	None	384EB
T-tree indexes	No	No	No	No	Yes
Transactions	No	No	Yes	No	Yes
Update statistics for data dictionary	Yes	Yes	Yes	Yes	Yes

**Notes:**

1. Implemented in the server, rather than in the storage engine.
2. Compressed MyISAM tables are supported only when using the compressed row format. Tables using the compressed row format with MyISAM are read only.
3. Implemented in the server via encryption functions.
4. Implemented in the server via encryption functions; In MySQL 5.7 and later, data-at-rest encryption is supported.
5. Implemented in the server via encryption functions; encrypted NDB backups as of NDB 8.0.22; transparent NDB file system encryption supported in NDB 8.0.29 and later.
6. Support for FULLTEXT indexes is available in MySQL 5.6 and later.
7. Support for geospatial indexing is available in MySQL 5.7 and later.
8. InnoDB utilizes hash indexes internally for its Adaptive Hash Index feature.
9. See the discussion later in this section.

## 18.1 Setting the Storage Engine

When you create a new table, you can specify which storage engine to use by adding an [ENGINE](#) table option to the [CREATE TABLE](#) statement:

```
-- ENGINE=INNODB not needed unless you have set a different
-- default storage engine.
```

```
CREATE TABLE t1 (i INT) ENGINE = INNODB;
-- Simple table definitions can be switched from one to another.
CREATE TABLE t2 (i INT) ENGINE = CSV;
CREATE TABLE t3 (i INT) ENGINE = MEMORY;
```

When you omit the `ENGINE` option, the default storage engine is used. The default engine is `InnoDB` in MySQL 9.1. You can specify the default engine by using the `--default-storage-engine` server startup option, or by setting the `default-storage-engine` option in the `my.cnf` configuration file.

You can set the default storage engine for the current session by setting the `default_storage_engine` variable:

```
SET default_storage_engine=NDBCLUSTER;
```

The storage engine for `TEMPORARY` tables created with `CREATE TEMPORARY TABLE` can be set separately from the engine for permanent tables by setting the `default_tmp_storage_engine`, either at startup or at runtime.

To convert a table from one storage engine to another, use an `ALTER TABLE` statement that indicates the new engine:

```
ALTER TABLE t ENGINE = InnoDB;
```

See [Section 15.1.20, “CREATE TABLE Statement”](#), and [Section 15.1.9, “ALTER TABLE Statement”](#).

If you try to use a storage engine that is not compiled in or that is compiled in but deactivated, MySQL instead creates a table using the default storage engine. For example, in a replication setup, perhaps your source server uses `InnoDB` tables for maximum safety, but the replica servers use other storage engines for speed at the expense of durability or concurrency.

By default, a warning is generated whenever `CREATE TABLE` or `ALTER TABLE` cannot use the default storage engine. To prevent confusing, unintended behavior if the desired engine is unavailable, enable the `NO_ENGINE_SUBSTITUTION` SQL mode. If the desired engine is unavailable, this setting produces an error instead of a warning, and the table is not created or altered. See [Section 7.1.11, “Server SQL Modes”](#).

MySQL may store a table's index and data in one or more other files, depending on the storage engine. Table and column definitions are stored in the MySQL data dictionary. Individual storage engines create any additional files required for the tables that they manage. If a table name contains special characters, the names for the table files contain encoded versions of those characters as described in [Section 11.2.4, “Mapping of Identifiers to File Names”](#).

## 18.2 The MyISAM Storage Engine

`MyISAM` is based on the older (and no longer available) `ISAM` storage engine but has many useful extensions.

**Table 18.2 MyISAM Storage Engine Features**

Feature	Support
<b>B-tree indexes</b>	Yes
<b>Backup/point-in-time recovery</b> (Implemented in the server, rather than in the storage engine.)	Yes
<b>Cluster database support</b>	No
<b>Clustered indexes</b>	No

Feature	Support
<b>Compressed data</b>	Yes (Compressed MyISAM tables are supported only when using the compressed row format. Tables using the compressed row format with MyISAM are read only.)
<b>Data caches</b>	No
<b>Encrypted data</b>	Yes (Implemented in the server via encryption functions.)
<b>Foreign key support</b>	No
<b>Full-text search indexes</b>	Yes
<b>Geospatial data type support</b>	Yes
<b>Geospatial indexing support</b>	Yes
<b>Hash indexes</b>	No
<b>Index caches</b>	Yes
<b>Locking granularity</b>	Table
<b>MVCC</b>	No
<b>Replication support</b> (Implemented in the server, rather than in the storage engine.)	Yes
<b>Storage limits</b>	256TB
<b>T-tree indexes</b>	No
<b>Transactions</b>	No
<b>Update statistics for data dictionary</b>	Yes

Each [MyISAM](#) table is stored on disk in two files. The files have names that begin with the table name and have an extension to indicate the file type. The data file has an [.MYD](#) ([MYData](#)) extension. The index file has an [.MYI](#) ([MYIndex](#)) extension. The table definition is stored in the MySQL data dictionary.

To specify explicitly that you want a [MyISAM](#) table, indicate that with an [ENGINE](#) table option:

```
CREATE TABLE t (i INT) ENGINE = MYISAM;
```

In MySQL 9.1, it is normally necessary to use [ENGINE](#) to specify the [MyISAM](#) storage engine because [InnoDB](#) is the default engine.

You can check or repair [MyISAM](#) tables with the [mysqlcheck](#) client or [myisamchk](#) utility. You can also compress [MyISAM](#) tables with [myisampack](#) to take up much less space. See [Section 6.5.3, “mysqlcheck — A Table Maintenance Program”](#), [Section 6.6.4, “myisamchk — MyISAM Table-Maintenance Utility”](#), and [Section 6.6.6, “myisampack — Generate Compressed, Read-Only MyISAM Tables”](#).

In MySQL 9.1, the [MyISAM](#) storage engine provides no partitioning support. *Partitioned [MyISAM](#) tables created in previous versions of MySQL cannot be used in MySQL 9.1.* For more information, see [Section 26.6.2, “Partitioning Limitations Relating to Storage Engines”](#). For help with upgrading such tables so that they can be used in MySQL 9.1, see [Section 3.5, “Changes in MySQL 9.1”](#).

[MyISAM](#) tables have the following characteristics:

- All data values are stored with the low byte first. This makes the data machine and operating system independent. The only requirements for binary portability are that the machine uses two's-complement signed integers and IEEE floating-point format. These requirements are widely used among mainstream

machines. Binary compatibility might not be applicable to embedded systems, which sometimes have peculiar processors.

There is no significant speed penalty for storing data low byte first; the bytes in a table row normally are unaligned and it takes little more processing to read an unaligned byte in order than in reverse order. Also, the code in the server that fetches column values is not time critical compared to other code.

- All numeric key values are stored with the high byte first to permit better index compression.
- Large files (up to 63-bit file length) are supported on file systems and operating systems that support large files.
- There is a limit of  $(2^{32})^2$  (1.844E+19) rows in a [MyISAM](#) table.
- The maximum number of indexes per [MyISAM](#) table is 64.

The maximum number of columns per index is 16.

- The maximum key length is 1000 bytes. This can also be changed by changing the source and recompiling. For the case of a key longer than 250 bytes, a larger key block size than the default of 1024 bytes is used.
- When rows are inserted in sorted order (as when you are using an [AUTO\\_INCREMENT](#) column), the index tree is split so that the high node only contains one key. This improves space utilization in the index tree.
- Internal handling of one [AUTO\\_INCREMENT](#) column per table is supported. [MyISAM](#) automatically updates this column for [INSERT](#) and [UPDATE](#) operations. This makes [AUTO\\_INCREMENT](#) columns faster (at least 10%). Values at the top of the sequence are not reused after being deleted. (When an [AUTO\\_INCREMENT](#) column is defined as the last column of a multiple-column index, reuse of values deleted from the top of a sequence does occur.) The [AUTO\\_INCREMENT](#) value can be reset with [ALTER TABLE](#) or [myisamchk](#).
- Dynamic-sized rows are much less fragmented when mixing deletes with updates and inserts. This is done by automatically combining adjacent deleted blocks and by extending blocks if the next block is deleted.
- [MyISAM](#) supports concurrent inserts: If a table has no free blocks in the middle of the data file, you can [INSERT](#) new rows into it at the same time that other threads are reading from the table. A free block can occur as a result of deleting rows or an update of a dynamic length row with more data than its current contents. When all free blocks are used up (filled in), future inserts become concurrent again. See [Section 10.11.3, “Concurrent Inserts”](#).
- You can put the data file and index file in different directories on different physical devices to get more speed with the [DATA DIRECTORY](#) and [INDEX DIRECTORY](#) table options to [CREATE TABLE](#). See [Section 15.1.20, “CREATE TABLE Statement”](#).
- [BLOB](#) and [TEXT](#) columns can be indexed.
- [NULL](#) values are permitted in indexed columns. This takes 0 to 1 bytes per key.
- Each character column can have a different character set. See [Chapter 12, Character Sets, Collations, Unicode](#).
- There is a flag in the [MyISAM](#) index file that indicates whether the table was closed correctly. If [mysqld](#) is started with the [myisam\\_recover\\_options](#) system variable set, [MyISAM](#) tables are automatically checked when opened, and are repaired if the table wasn't closed properly.

- `myisamchk` marks tables as checked if you run it with the `--update-state` option. `myisamchk --fast` checks only those tables that don't have this mark.
- `myisamchk --analyze` stores statistics for portions of keys, as well as for entire keys.
- `myisampack` can pack `BLOB` and `VARCHAR` columns.

`MyISAM` also supports the following features:

- Support for a true `VARCHAR` type; a `VARCHAR` column starts with a length stored in one or two bytes.
- Tables with `VARCHAR` columns may have fixed or dynamic row length.
- The sum of the lengths of the `VARCHAR` and `CHAR` columns in a table may be up to 64KB.
- Arbitrary length `UNIQUE` constraints.

## Additional Resources

- A forum dedicated to the `MyISAM` storage engine is available at <https://forums.mysql.com/list.php?21>.

### 18.2.1 MyISAM Startup Options

The following options to `mysqld` can be used to change the behavior of `MyISAM` tables. For additional information, see [Section 7.1.7, “Server Command Options”](#).

**Table 18.3 MyISAM Option and Variable Reference**

Name	Cmd-Line	Option File	System Var	Status Var	Var Scope	Dynamic
<code>bulk_insert_buffer_size</code>	Yes	Yes	Yes		Both	Yes

<code>tmp_table_size</code>	Yes	Yes	Yes		Both	Yes

The following system variables affect the behavior of `MyISAM` tables. For additional information, see [Section 7.1.8, “Server System Variables”](#).

- `bulk_insert_buffer_size`

The size of the tree cache used in bulk insert optimization.

**Note**

This is a limit *per thread*!

- `delay_key_write=ALL`

Don't flush key buffers between writes for any [MyISAM](#) table.

**Note**

If you do this, you should not access [MyISAM](#) tables from another program (such as from another MySQL server or with `myisamchk`) when the tables are in use. Doing so risks index corruption. Using `--external-locking` does not eliminate this risk.

- `myisam_max_sort_file_size`

The maximum size of the temporary file that MySQL is permitted to use while re-creating a [MyISAM](#) index (during `REPAIR TABLE`, `ALTER TABLE`, or `LOAD DATA`). If the file size would be larger than this value, the index is created using the key cache instead, which is slower. The value is given in bytes.

- `myisam_recover_options=mode`

Set the mode for automatic recovery of crashed [MyISAM](#) tables.

- `myisam_sort_buffer_size`

Set the size of the buffer used when recovering tables.

Automatic recovery is activated if you start `mysqld` with the `myisam_recover_options` system variable set. In this case, when the server opens a [MyISAM](#) table, it checks whether the table is marked as crashed or whether the open count variable for the table is not 0 and you are running the server with external locking disabled. If either of these conditions is true, the following happens:

- The server checks the table for errors.
- If the server finds an error, it tries to do a fast table repair (with sorting and without re-creating the data file).
- If the repair fails because of an error in the data file (for example, a duplicate-key error), the server tries again, this time re-creating the data file.
- If the repair still fails, the server tries once more with the old repair option method (write row by row without sorting). This method should be able to repair any type of error and has low disk space requirements.

If the recovery wouldn't be able to recover all rows from previously completed statements and you didn't specify `FORCE` in the value of the `myisam_recover_options` system variable, automatic repair aborts with an error message in the error log:

```
Error: Couldn't repair table: test.g00pages
```

If you specify `FORCE`, a warning like this is written instead:

```
Warning: Found 344 of 354 rows when repairing ./test/g00pages
```

If the automatic recovery value includes `BACKUP`, the recovery process creates files with names of the form `tbl_name-datetime.BAK`. You should have a `cron` script that automatically moves these files from the database directories to backup media.

## 18.2.2 Space Needed for Keys

`MyISAM` tables use B-tree indexes. You can roughly calculate the size for the index file as  $(key\_length + 4) / 0.67$ , summed over all keys. This is for the worst case when all keys are inserted in sorted order and the table doesn't have any compressed keys.

String indexes are space compressed. If the first index part is a string, it is also prefix compressed. Space compression makes the index file smaller than the worst-case figure if a string column has a lot of trailing space or is a `VARCHAR` column that is not always used to the full length. Prefix compression is used on keys that start with a string. Prefix compression helps if there are many strings with an identical prefix.

In `MyISAM` tables, you can also prefix compress numbers by specifying the `PACK_KEYS=1` table option when you create the table. Numbers are stored with the high byte first, so this helps when you have many integer keys that have an identical prefix.

## 18.2.3 MyISAM Table Storage Formats

`MyISAM` supports three different storage formats. Two of them, fixed and dynamic format, are chosen automatically depending on the type of columns you are using. The third, compressed format, can be created only with the `myisampack` utility (see [Section 6.6.6, “myisampack — Generate Compressed, Read-Only MyISAM Tables”](#)).

When you use `CREATE TABLE` or `ALTER TABLE` for a table that has no `BLOB` or `TEXT` columns, you can force the table format to `FIXED` or `DYNAMIC` with the `ROW_FORMAT` table option.

See [Section 15.1.20, “CREATE TABLE Statement”](#), for information about `ROW_FORMAT`.

You can decompress (unpack) compressed `MyISAM` tables using `myisamchk --unpack`; see [Section 6.6.4, “myisamchk — MyISAM Table-Maintenance Utility”](#), for more information.

### 18.2.3.1 Static (Fixed-Length) Table Characteristics

Static format is the default for `MyISAM` tables. It is used when the table contains no variable-length columns (`VARCHAR`, `VARBINARY`, `BLOB`, or `TEXT`). Each row is stored using a fixed number of bytes.

Of the three `MyISAM` storage formats, static format is the simplest and most secure (least subject to corruption). It is also the fastest of the on-disk formats due to the ease with which rows in the data file can be found on disk: To look up a row based on a row number in the index, multiply the row number by the row length to calculate the row position. Also, when scanning a table, it is very easy to read a constant number of rows with each disk read operation.

The security is evidenced if your computer crashes while the MySQL server is writing to a fixed-format `MyISAM` file. In this case, `myisamchk` can easily determine where each row starts and ends, so it can usually reclaim all rows except the partially written one. `MyISAM` table indexes can always be reconstructed based on the data rows.

#### Note

Fixed-length row format is available only for tables having no `BLOB` or `TEXT` columns. Creating a table having such columns with an explicit `ROW_FORMAT` clause does not raise an error or warning; the format specification is ignored.

Static-format tables have these characteristics:

- `CHAR` and `VARCHAR` columns are space-padded to the specified column width, although the column type is not altered. `BINARY` and `VARBINARY` columns are padded with `0x00` bytes to the column width.
- `NULL` columns require additional space in the row to record whether their values are `NULL`. Each `NULL` column takes one bit extra, rounded up to the nearest byte.
- Very quick.
- Easy to cache.
- Easy to reconstruct after a crash, because rows are located in fixed positions.
- Reorganization is unnecessary unless you delete a huge number of rows and want to return free disk space to the operating system. To do this, use `OPTIMIZE TABLE` or `myisamchk -r`.
- Usually require more disk space than dynamic-format tables.
- The expected row length in bytes for static-sized rows is calculated using the following expression:

```
row length = 1
 + (sum of column lengths)
 + (number of NULL columns + delete_flag + 7)/8
 + (number of variable-length columns)
```

`delete_flag` is 1 for tables with static row format. Static tables use a bit in the row record for a flag that indicates whether the row has been deleted. `delete_flag` is 0 for dynamic tables because the flag is stored in the dynamic row header.

### 18.2.3.2 Dynamic Table Characteristics

Dynamic storage format is used if a `MyISAM` table contains any variable-length columns (`VARCHAR`, `VARBINARY`, `BLOB`, or `TEXT`), or if the table was created with the `ROW_FORMAT=DYNAMIC` table option.

Dynamic format is a little more complex than static format because each row has a header that indicates how long it is. A row can become fragmented (stored in noncontiguous pieces) when it is made longer as a result of an update.

You can use `OPTIMIZE TABLE` or `myisamchk -r` to defragment a table. If you have fixed-length columns that you access or change frequently in a table that also contains some variable-length columns, it might be a good idea to move the variable-length columns to other tables just to avoid fragmentation.

Dynamic-format tables have these characteristics:

- All string columns are dynamic except those with a length less than four.
- Each row is preceded by a bitmap that indicates which columns contain the empty string (for string columns) or zero (for numeric columns). This does not include columns that contain `NULL` values. If a string column has a length of zero after trailing space removal, or a numeric column has a value of zero, it is marked in the bitmap and not saved to disk. Nonempty strings are saved as a length byte plus the string contents.
- `NULL` columns require additional space in the row to record whether their values are `NULL`. Each `NULL` column takes one bit extra, rounded up to the nearest byte.
- Much less disk space usually is required than for fixed-length tables.

- Each row uses only as much space as is required. However, if a row becomes larger, it is split into as many pieces as are required, resulting in row fragmentation. For example, if you update a row with information that extends the row length, the row becomes fragmented. In this case, you may have to run `OPTIMIZE TABLE` or `myisamchk -r` from time to time to improve performance. Use `myisamchk -ei` to obtain table statistics.
- More difficult than static-format tables to reconstruct after a crash, because rows may be fragmented into many pieces and links (fragments) may be missing.
- The expected row length for dynamic-sized rows is calculated using the following expression:

```

3
+ (number of columns + 7) / 8
+ (number of char columns)
+ (packed size of numeric columns)
+ (length of strings)
+ (number of NULL columns + 7) / 8

```

There is a penalty of 6 bytes for each link. A dynamic row is linked whenever an update causes an enlargement of the row. Each new link is at least 20 bytes, so the next enlargement probably goes in the same link. If not, another link is created. You can find the number of links using `myisamchk -ed`. All links may be removed with `OPTIMIZE TABLE` or `myisamchk -r`.

### 18.2.3.3 Compressed Table Characteristics

Compressed storage format is a read-only format that is generated with the `myisampack` tool. Compressed tables can be uncompressed with `myisamchk`.

Compressed tables have the following characteristics:

- Compressed tables take very little disk space. This minimizes disk usage, which is helpful when using slow disks (such as CD-ROMs).
- Each row is compressed separately, so there is very little access overhead. The header for a row takes up one to three bytes depending on the biggest row in the table. Each column is compressed differently. There is usually a different Huffman tree for each column. Some of the compression types are:
  - Suffix space compression.
  - Prefix space compression.
  - Numbers with a value of zero are stored using one bit.
  - If values in an integer column have a small range, the column is stored using the smallest possible type. For example, a `BIGINT` column (eight bytes) can be stored as a `TINYINT` column (one byte) if all its values are in the range from `-128` to `127`.
  - If a column has only a small set of possible values, the data type is converted to `ENUM`.
  - A column may use any combination of the preceding compression types.
- Can be used for fixed-length or dynamic-length rows.

#### Note

While a compressed table is read only, and you cannot therefore update or add rows in the table, DDL (Data Definition Language) operations are still valid. For example, you may still use `DROP` to drop the table, and `TRUNCATE TABLE` to empty the table.

## 18.2.4 MyISAM Table Problems

The file format that MySQL uses to store data has been extensively tested, but there are always circumstances that may cause database tables to become corrupted. The following discussion describes how this can happen and how to handle it.

### 18.2.4.1 Corrupted MyISAM Tables

Even though the [MyISAM](#) table format is very reliable (all changes to a table made by an SQL statement are written before the statement returns), you can still get corrupted tables if any of the following events occur:

- The `mysqld` process is killed in the middle of a write.
- An unexpected computer shutdown occurs (for example, the computer is turned off).
- Hardware failures.
- You are using an external program (such as `myisamchk`) to modify a table that is being modified by the server at the same time.
- A software bug in the MySQL or [MyISAM](#) code.

Typical symptoms of a corrupt table are:

- You get the following error while selecting data from the table:

```
Incorrect key file for table: '...'. Try to repair it
```

- Queries don't find rows in the table or return incomplete results.

You can check the health of a [MyISAM](#) table using the `CHECK TABLE` statement, and repair a corrupted [MyISAM](#) table with `REPAIR TABLE`. When `mysqld` is not running, you can also check or repair a table with the `myisamchk` command. See [Section 15.7.3.2, “CHECK TABLE Statement”](#), [Section 15.7.3.5, “REPAIR TABLE Statement”](#), and [Section 6.6.4, “myisamchk — MyISAM Table-Maintenance Utility”](#).

If your tables become corrupted frequently, you should try to determine why this is happening. The most important thing to know is whether the table became corrupted as a result of an unexpected server exit. You can verify this easily by looking for a recent `restarted mysqld` message in the error log. If there is such a message, it is likely that table corruption is a result of the server dying. Otherwise, corruption may have occurred during normal operation. This is a bug. You should try to create a reproducible test case that demonstrates the problem. See [Section B.3.3.3, “What to Do If MySQL Keeps Crashing”](#), and [Section 7.9, “Debugging MySQL”](#).

### 18.2.4.2 Problems from Tables Not Being Closed Properly

Each [MyISAM](#) index file (`.MYI` file) has a counter in the header that can be used to check whether a table has been closed properly. If you get the following warning from `CHECK TABLE` or `myisamchk`, it means that this counter has gone out of sync:

```
clients are using or haven't closed the table properly
```

This warning doesn't necessarily mean that the table is corrupted, but you should at least check the table.

The counter works as follows:

- The first time a table is updated in MySQL, a counter in the header of the index files is incremented.

- The counter is not changed during further updates.
- When the last instance of a table is closed (because a `FLUSH TABLES` operation was performed or because there is no room in the table cache), the counter is decremented if the table has been updated at any point.
- When you repair the table or check the table and it is found to be okay, the counter is reset to zero.
- To avoid problems with interaction with other processes that might check the table, the counter is not decremented on close if it was zero.

In other words, the counter can become incorrect only under these conditions:

- A `MyISAM` table is copied without first issuing `LOCK TABLES` and `FLUSH TABLES`.
- MySQL has crashed between an update and the final close. (The table may still be okay because MySQL always issues writes for everything between each statement.)
- A table was modified by `myisamchk --recover` or `myisamchk --update-state` at the same time that it was in use by `mysqld`.
- Multiple `mysqld` servers are using the table and one server performed a `REPAIR TABLE` or `CHECK TABLE` on the table while it was in use by another server. In this setup, it is safe to use `CHECK TABLE`, although you might get the warning from other servers. However, `REPAIR TABLE` should be avoided because when one server replaces the data file with a new one, this is not known to the other servers.

In general, it is a bad idea to share a data directory among multiple servers. See [Section 7.8, “Running Multiple MySQL Instances on One Machine”](#), for additional discussion.

## 18.3 The MEMORY Storage Engine

The `MEMORY` storage engine (formerly known as `HEAP`) creates special-purpose tables with contents that are stored in memory. Because the data is vulnerable to crashes, hardware issues, or power outages, only use these tables as temporary work areas or read-only caches for data pulled from other tables.

**Table 18.4 MEMORY Storage Engine Features**

Feature	Support
<b>B-tree indexes</b>	Yes
<b>Backup/point-in-time recovery</b> (Implemented in the server, rather than in the storage engine.)	Yes
<b>Cluster database support</b>	No
<b>Clustered indexes</b>	No
<b>Compressed data</b>	No
<b>Data caches</b>	N/A
<b>Encrypted data</b>	Yes (Implemented in the server via encryption functions.)
<b>Foreign key support</b>	No
<b>Full-text search indexes</b>	No
<b>Geospatial data type support</b>	No
<b>Geospatial indexing support</b>	No
<b>Hash indexes</b>	Yes

Feature	Support
Index caches	N/A
Locking granularity	Table
MVCC	No
Replication support (Implemented in the server, rather than in the storage engine.)	Limited (See the discussion later in this section.)
Storage limits	RAM
T-tree indexes	No
Transactions	No
Update statistics for data dictionary	Yes

- [Managing Memory Use](#)
- [Additional Resources](#)

## When to Use MEMORY or NDB Cluster

Developers looking to deploy applications that use the [MEMORY](#) storage engine for important, highly available, or frequently updated data should consider whether NDB Cluster is a better choice. A typical use case for the [MEMORY](#) engine involves these characteristics:

- Operations involving transient, non-critical data such as session management or caching. When the MySQL server halts or restarts, the data in [MEMORY](#) tables is lost.
- In-memory storage for fast access and low latency. Data volume can fit entirely in memory without causing the operating system to swap out virtual memory pages.
- A read-only or read-mostly data access pattern (limited updates).

NDB Cluster offers the same features as the [MEMORY](#) engine with higher performance levels, and provides additional features not available with [MEMORY](#):

- Row-level locking and multiple-thread operation for low contention between clients.
- Scalability even with statement mixes that include writes.
- Optional disk-backed operation for data durability.

- Shared-nothing architecture and multiple-host operation with no single point of failure, enabling 99.999% availability.
- Automatic data distribution across nodes; application developers need not craft custom sharding or partitioning solutions.
- Support for variable-length data types (including `BLOB` and `TEXT`) not supported by `MEMORY`.

## Partitioning

`MEMORY` tables cannot be partitioned.

## Performance Characteristics

`MEMORY` performance is constrained by contention resulting from single-thread execution and table lock overhead when processing updates. This limits scalability when load increases, particularly for statement mixes that include writes.

Despite the in-memory processing for `MEMORY` tables, they are not necessarily faster than `InnoDB` tables on a busy server, for general-purpose queries, or under a read/write workload. In particular, the table locking involved with performing updates can slow down concurrent usage of `MEMORY` tables from multiple sessions.

Depending on the kinds of queries performed on a `MEMORY` table, you might create indexes as either the default hash data structure (for looking up single values based on a unique key), or a general-purpose B-tree data structure (for all kinds of queries involving equality, inequality, or range operators such as less than or greater than). The following sections illustrate the syntax for creating both kinds of indexes. A common performance issue is using the default hash indexes in workloads where B-tree indexes are more efficient.

## Characteristics of MEMORY Tables

The `MEMORY` storage engine does not create any files on disk. The table definition is stored in the MySQL data dictionary.

`MEMORY` tables have the following characteristics:

- Space for `MEMORY` tables is allocated in small blocks. Tables use 100% dynamic hashing for inserts. No overflow area or extra key space is needed. No extra space is needed for free lists. Deleted rows are put in a linked list and are reused when you insert new data into the table. `MEMORY` tables also have none of the problems commonly associated with deletes plus inserts in hashed tables.
- `MEMORY` tables use a fixed-length row-storage format. Variable-length types such as `VARCHAR` are stored using a fixed length.
- `MEMORY` tables cannot contain `BLOB` or `TEXT` columns.
- `MEMORY` includes support for `AUTO_INCREMENT` columns.
- Non-`TEMPORARY MEMORY` tables are shared among all clients, just like any other non-`TEMPORARY` table.

## DDL Operations for MEMORY Tables

To create a `MEMORY` table, specify the clause `ENGINE=MEMORY` on the `CREATE TABLE` statement.

```
CREATE TABLE t (i INT) ENGINE = MEMORY;
```

As indicated by the engine name, **MEMORY** tables are stored in memory. They use hash indexes by default, which makes them very fast for single-value lookups, and very useful for creating temporary tables. However, when the server shuts down, all rows stored in **MEMORY** tables are lost. The tables themselves continue to exist because their definitions are stored in the MySQL data dictionary, but they are empty when the server restarts.

This example shows how you might create, use, and remove a **MEMORY** table:

```
mysql> CREATE TABLE test ENGINE=MEMORY
 SELECT ip,SUM(downloads) AS down
 FROM log_table GROUP BY ip;

mysql> SELECT COUNT(ip),AVG(down) FROM test;

mysql> DROP TABLE test;
```

The maximum size of **MEMORY** tables is limited by the `max_heap_table_size` system variable, which has a default value of 16MB. To enforce different size limits for **MEMORY** tables, change the value of this variable. The value in effect for **CREATE TABLE**, or a subsequent **ALTER TABLE** or **TRUNCATE TABLE**, is the value used for the life of the table. A server restart also sets the maximum size of existing **MEMORY** tables to the global `max_heap_table_size` value. You can set the size for individual tables as described later in this section.

## Indexes

The **MEMORY** storage engine supports both **HASH** and **BTREE** indexes. You can specify one or the other for a given index by adding a **USING** clause as shown here:

```
CREATE TABLE lookup
 (id INT, INDEX USING HASH (id))
 ENGINE = MEMORY;
CREATE TABLE lookup
 (id INT, INDEX USING BTREE (id))
 ENGINE = MEMORY;
```

For general characteristics of B-tree and hash indexes, see [Section 10.3.1, “How MySQL Uses Indexes”](#).

**MEMORY** tables can have up to 64 indexes per table, 16 columns per index and a maximum key length of 3072 bytes.

If a **MEMORY** table hash index has a high degree of key duplication (many index entries containing the same value), updates to the table that affect key values and all deletes are significantly slower. The degree of this slowdown is proportional to the degree of duplication (or, inversely proportional to the index cardinality). You can use a **BTREE** index to avoid this problem.

**MEMORY** tables can have nonunique keys. (This is an uncommon feature for implementations of hash indexes.)

Columns that are indexed can contain **NULL** values.

## User-Created and Temporary Tables

**MEMORY** table contents are stored in memory, which is a property that **MEMORY** tables share with internal temporary tables that the server creates on the fly while processing queries. However, the two types of tables differ in that **MEMORY** tables are not subject to storage conversion, whereas internal temporary tables are:

- If an internal temporary table becomes too large, the server automatically converts it to on-disk storage, as described in [Section 10.4.4, “Internal Temporary Table Use in MySQL”](#).

- User-created `MEMORY` tables are never converted to disk tables.

## Loading Data

To populate a `MEMORY` table when the MySQL server starts, you can use the `init_file` system variable. For example, you can put statements such as `INSERT INTO ... SELECT` or `LOAD DATA` into a file to load the table from a persistent data source, and use `init_file` to name the file. See [Section 7.1.8, “Server System Variables”](#), and [Section 15.2.9, “LOAD DATA Statement”](#).

## MEMORY Tables and Replication

When a replication source server shuts down and restarts, its `MEMORY` tables become empty. To replicate this effect to replicas, the first time that the source uses a given `MEMORY` table after startup, it logs an event that notifies replicas that the table must be emptied by writing a `TRUNCATE TABLE` statement for that table to the binary log. When a replica server shuts down and restarts, its `MEMORY` tables also become empty, and it writes a `TRUNCATE TABLE` statement to its own binary log, which is passed on to any downstream replicas.

When you use `MEMORY` tables in a replication topology, in some situations, the table on the source and the table on the replica can differ. For information on handling each of these situations to prevent stale reads or errors, see [Section 19.5.1.22, “Replication and MEMORY Tables”](#).

## Managing Memory Use

The server needs sufficient memory to maintain all `MEMORY` tables that are in use at the same time.

Memory is not reclaimed if you delete individual rows from a `MEMORY` table. Memory is reclaimed only when the entire table is deleted. Memory that was previously used for deleted rows is re-used for new rows within the same table. To free all the memory used by a `MEMORY` table when you no longer require its contents, execute `DELETE` or `TRUNCATE TABLE` to remove all rows, or remove the table altogether using `DROP TABLE`. To free up the memory used by deleted rows, use `ALTER TABLE ENGINE=MEMORY` to force a table rebuild.

The memory needed for one row in a `MEMORY` table is calculated using the following expression:

```
SUM_OVER_ALL_BTREE_KEYS(max_length_of_key + sizeof(char*) * 4)
+ SUM_OVER_ALL_HASH_KEYS(sizeof(char*) * 2)
+ ALIGN(length_of_row+1, sizeof(char*))
```

`ALIGN()` represents a round-up factor to cause the row length to be an exact multiple of the `char` pointer size. `sizeof(char*)` is 4 on 32-bit machines and 8 on 64-bit machines.

As mentioned earlier, the `max_heap_table_size` system variable sets the limit on the maximum size of `MEMORY` tables. To control the maximum size for individual tables, set the session value of this variable before creating each table. (Do not change the global `max_heap_table_size` value unless you intend the value to be used for `MEMORY` tables created by all clients.) The following example creates two `MEMORY` tables, with a maximum size of 1MB and 2MB, respectively:

```
mysql> SET max_heap_table_size = 1024*1024;
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t1 (id INT, UNIQUE(id)) ENGINE = MEMORY;
Query OK, 0 rows affected (0.01 sec)

mysql> SET max_heap_table_size = 1024*1024*2;
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t2 (id INT, UNIQUE(id)) ENGINE = MEMORY;
Query OK, 0 rows affected (0.00 sec)
```

Both tables revert to the server's global `max_heap_table_size` value if the server restarts.

You can also specify a `MAX_ROWS` table option in `CREATE TABLE` statements for `MEMORY` tables to provide a hint about the number of rows you plan to store in them. This does not enable the table to grow beyond the `max_heap_table_size` value, which still acts as a constraint on maximum table size. For maximum flexibility in being able to use `MAX_ROWS`, set `max_heap_table_size` at least as high as the value to which you want each `MEMORY` table to be able to grow.

## Additional Resources

A forum dedicated to the `MEMORY` storage engine is available at <https://forums.mysql.com/list.php?92>.

## 18.4 The CSV Storage Engine

The `CSV` storage engine stores data in text files using comma-separated values format.

The `CSV` storage engine is always compiled into the MySQL server.

To examine the source for the `CSV` engine, look in the `storage/csv` directory of a MySQL source distribution.

When you create a `CSV` table, the server creates a plain text data file having a name that begins with the table name and has a `.CSV` extension. When you store data into the table, the storage engine saves it into the data file in comma-separated values format.

```
mysql> CREATE TABLE test (i INT NOT NULL, c CHAR(10) NOT NULL)
-> ENGINE = CSV;
Query OK, 0 rows affected (0.06 sec)

mysql> INSERT INTO test
-> VALUES ROW(1,'record one'), ROW(2,'record two');
Query OK, 2 rows affected (0.05 sec)
Records: 2 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM test;
+-----+
| i | c |
+-----+
| 1 | record one |
| 2 | record two |
+-----+
2 rows in set (0.00 sec)
```

Creating a `CSV` table also creates a corresponding metafile that stores the state of the table and the number of rows that exist in the table. The name of this file is the same as the name of the table with the extension `CSM`.

If you examine the `test.CSV` file in the database directory created by executing the preceding statements, its contents should look like this:

```
"1","record one"
"2","record two"
```

This format can be read, and even written, by spreadsheet applications such as Microsoft Excel.

### 18.4.1 Repairing and Checking CSV Tables

The `CSV` storage engine supports the `CHECK TABLE` and `REPAIR TABLE` statements to verify and, if possible, repair a damaged `CSV` table.

When running the `CHECK TABLE` statement, the `CSV` file is checked for validity by looking for the correct field separators, escaped fields (matching or missing quotation marks), the correct number of fields compared to the table definition and the existence of a corresponding `CSV` metafile. The first invalid row discovered causes an error. Checking a valid table produces output like that shown here:

```
mysql> CHECK TABLE csvtest;
+-----+-----+-----+-----+
| Table | Op | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.csvtest | check | status | OK |
+-----+-----+-----+-----+
```

A check on a corrupted table returns a fault such as

```
mysql> CHECK TABLE csvtest;
+-----+-----+-----+-----+
| Table | Op | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.csvtest | check | error | Corrupt |
+-----+-----+-----+-----+
```

To repair a table, use `REPAIR TABLE`, which copies as many valid rows from the existing `CSV` data as possible, and then replaces the existing `CSV` file with the recovered rows. Any rows beyond the corrupted data are lost.

```
mysql> REPAIR TABLE csvtest;
+-----+-----+-----+-----+
| Table | Op | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.csvtest | repair | status | OK |
+-----+-----+-----+-----+
```

### Warning

During repair, only the rows from the `CSV` file up to the first damaged row are copied to the new table. All other rows from the first damaged row to the end of the table are removed, even valid rows.

## 18.4.2 CSV Limitations

The `CSV` storage engine does not support indexing.

The `CSV` storage engine does not support partitioning.

All tables that you create using the `CSV` storage engine must have the `NOT NULL` attribute on all columns.

## 18.5 The ARCHIVE Storage Engine

The `ARCHIVE` storage engine produces special-purpose tables that store large amounts of unindexed data in a very small footprint.

**Table 18.5 ARCHIVE Storage Engine Features**

Feature	Support
<b>B-tree indexes</b>	No
<b>Backup/point-in-time recovery</b> (Implemented in the server, rather than in the storage engine.)	Yes
<b>Cluster database support</b>	No

Feature	Support
Clustered indexes	No
Compressed data	Yes
Data caches	No
Encrypted data	Yes (Implemented in the server via encryption functions.)
Foreign key support	No
Full-text search indexes	No
Geospatial data type support	Yes
Geospatial indexing support	No
Hash indexes	No
Index caches	No
Locking granularity	Row
MVCC	No
Replication support (Implemented in the server, rather than in the storage engine.)	Yes
Storage limits	None
T-tree indexes	No
Transactions	No
Update statistics for data dictionary	Yes

The [ARCHIVE](#) storage engine is included in MySQL binary distributions. To enable this storage engine if you build MySQL from source, invoke [CMake](#) with the `-DWITH_ARCHIVE_STORAGE_ENGINE` option.

To examine the source for the [ARCHIVE](#) engine, look in the `storage/archive` directory of a MySQL source distribution.

You can check whether the [ARCHIVE](#) storage engine is available with the `SHOW ENGINES` statement.

When you create an [ARCHIVE](#) table, the storage engine creates files with names that begin with the table name. The data file has an extension of `.ARZ`. An `.ARN` file may appear during optimization operations.

The [ARCHIVE](#) engine supports `INSERT`, `REPLACE`, and `SELECT`, but not `DELETE` or `UPDATE`. It does support `ORDER BY` operations, `BLOB` columns, and spatial data types (see [Section 13.4.1, “Spatial Data Types”](#)). Geographic spatial reference systems are not supported. The [ARCHIVE](#) engine uses row-level locking.

The [ARCHIVE](#) engine supports the `AUTO_INCREMENT` column attribute. The `AUTO_INCREMENT` column can have either a unique or nonunique index. Attempting to create an index on any other column results in an error. The [ARCHIVE](#) engine also supports the `AUTO_INCREMENT` table option in `CREATE TABLE` statements to specify the initial sequence value for a new table or reset the sequence value for an existing table, respectively.

[ARCHIVE](#) does not support inserting a value into an `AUTO_INCREMENT` column less than the current maximum column value. Attempts to do so result in an `ER_DUP_KEY` error.

The [ARCHIVE](#) engine ignores `BLOB` columns if they are not requested and scans past them while reading.

The [ARCHIVE](#) storage engine does not support partitioning.

**Storage:** Rows are compressed as they are inserted. The `ARCHIVE` engine uses `zlib` lossless data compression (see <http://www.zlib.net/>). You can use `OPTIMIZE TABLE` to analyze the table and pack it into a smaller format (for a reason to use `OPTIMIZE TABLE`, see later in this section). The engine also supports `CHECK TABLE`. There are several types of insertions that are used:

- An `INSERT` statement just pushes rows into a compression buffer, and that buffer flushes as necessary. The insertion into the buffer is protected by a lock. A `SELECT` forces a flush to occur.
- A bulk insert is visible only after it completes, unless other inserts occur at the same time, in which case it can be seen partially. A `SELECT` never causes a flush of a bulk insert unless a normal insert occurs while it is loading.

**Retrieval:** On retrieval, rows are uncompressed on demand; there is no row cache. A `SELECT` operation performs a complete table scan: When a `SELECT` occurs, it finds out how many rows are currently available and reads that number of rows. `SELECT` is performed as a consistent read. Note that lots of `SELECT` statements during insertion can deteriorate the compression, unless only bulk inserts are used. To achieve better compression, you can use `OPTIMIZE TABLE` or `REPAIR TABLE`. The number of rows in `ARCHIVE` tables reported by `SHOW TABLE STATUS` is always accurate. See [Section 15.7.3.4, “OPTIMIZE TABLE Statement”](#), [Section 15.7.3.5, “REPAIR TABLE Statement”](#), and [Section 15.7.7.37, “SHOW TABLE STATUS Statement”](#).

## Additional Resources

- A forum dedicated to the `ARCHIVE` storage engine is available at <https://forums.mysql.com/list.php?112>.

## 18.6 The BLACKHOLE Storage Engine

The `BLACKHOLE` storage engine acts as a “black hole” that accepts data but throws it away and does not store it. Retrievals always return an empty result:

```
mysql> CREATE TABLE test(i INT, c CHAR(10)) ENGINE = BLACKHOLE;
Query OK, 0 rows affected (0.03 sec)

mysql> INSERT INTO test VALUES(1,'record one'),(2,'record two');
Query OK, 2 rows affected (0.00 sec)
Records: 2 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM test;
Empty set (0.00 sec)
```

To enable the `BLACKHOLE` storage engine if you build MySQL from source, invoke `CMake` with the `-DWITH_BLACKHOLE_STORAGE_ENGINE` option.

To examine the source for the `BLACKHOLE` engine, look in the `sql` directory of a MySQL source distribution.

When you create a `BLACKHOLE` table, the server creates the table definition in the global data dictionary. There are no files associated with the table.

The `BLACKHOLE` storage engine supports all kinds of indexes. That is, you can include index declarations in the table definition.

The maximum key length is 3072 bytes.

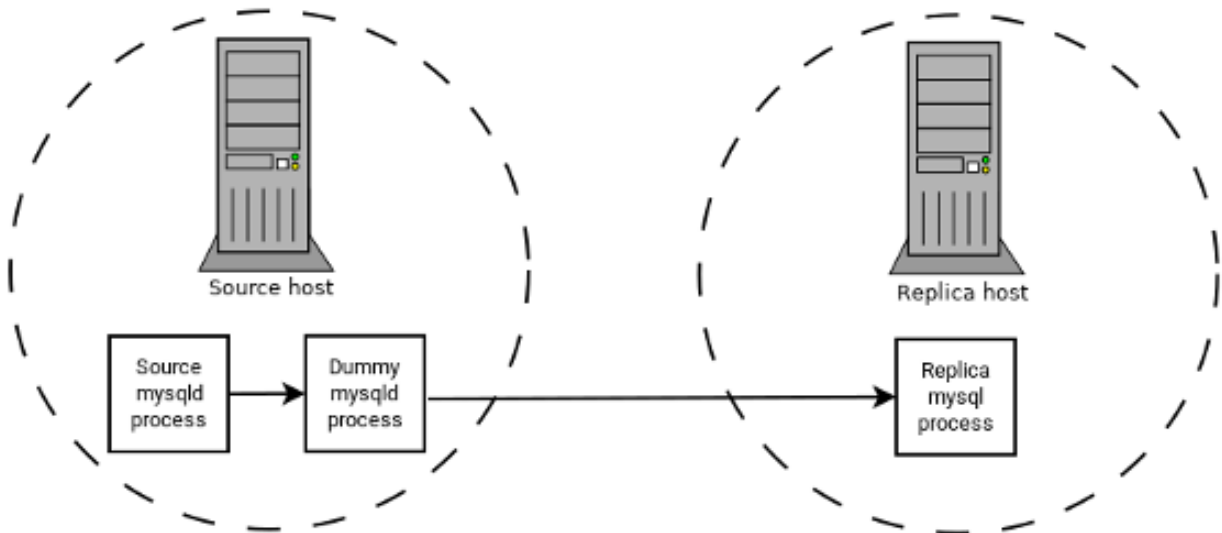

The `BLACKHOLE` storage engine does not support partitioning.

You can check whether the `BLACKHOLE` storage engine is available with the `SHOW ENGINES` statement.

Inserts into a `BLACKHOLE` table do not store any data, but if statement based binary logging is enabled, the SQL statements are logged and replicated to replica servers. This can be useful as a repeater or filter mechanism.

Suppose that your application requires replica-side filtering rules, but transferring all binary log data to the replica first results in too much traffic. In such a case, it is possible to set up on the replication source server a “dummy” replica process whose default storage engine is `BLACKHOLE`, depicted as follows:

**Figure 18.1 Replication using `BLACKHOLE` for Filtering**

The source writes to its binary log. The “dummy” `mysql` process acts as a replica, applying the desired combination of `replicate-do-*` and `replicate-ignore-*` rules, and writes a new, filtered binary log of its own. (See [Section 19.1.6, “Replication and Binary Logging Options and Variables”](#).) This filtered log is provided to the replica.

The dummy process does not actually store any data, so there is little processing overhead incurred by running the additional `mysql` process on the replication source server. This type of setup can be repeated with additional replicas.

`INSERT` triggers for `BLACKHOLE` tables work as expected. However, because the `BLACKHOLE` table does not actually store any data, `UPDATE` and `DELETE` triggers are not activated: The `FOR EACH ROW` clause in the trigger definition does not apply because there are no rows.

Other possible uses for the `BLACKHOLE` storage engine include:

- Verification of dump file syntax.
- Measurement of the overhead from binary logging, by comparing performance using `BLACKHOLE` with and without binary logging enabled.
- `BLACKHOLE` is essentially a “no-op” storage engine, so it could be used for finding performance bottlenecks not related to the storage engine itself.

The `BLACKHOLE` engine is transaction-aware, in the sense that committed transactions are written to the binary log and rolled-back transactions are not.

## Blackhole Engine and Auto Increment Columns

The `BLACKHOLE` engine is a no-op engine. Any operations performed on a table using `BLACKHOLE` have no effect. This should be borne in mind when considering the behavior of primary key columns that auto increment. The engine does not automatically increment field values, and does not retain auto increment field state. This has important implications in replication.

Consider the following replication scenario where all three of the following conditions apply:

1. On a source server there is a blackhole table with an auto increment field that is a primary key.
2. On a replica the same table exists but using the MyISAM engine.
3. Inserts are performed into the source's table without explicitly setting the auto increment value in the `INSERT` statement itself or through using a `SET INSERT_ID` statement.

In this scenario replication fails with a duplicate entry error on the primary key column.

In statement based replication, the value of `INSERT_ID` in the context event is always the same. Replication therefore fails due to trying insert a row with a duplicate value for a primary key column.

In row based replication, the value that the engine returns for the row always be the same for each insert. This results in the replica attempting to replay two insert log entries using the same value for the primary key column, and so replication fails.

## Column Filtering

When using row-based replication, (`binlog_format=ROW`), a replica where the last columns are missing from a table is supported, as described in the section [Section 19.5.1.9, “Replication with Differing Table Definitions on Source and Replica”](#).

This filtering works on the replica side, that is, the columns are copied to the replica before they are filtered out. There are at least two cases where it is not desirable to copy the columns to the replica:

1. If the data is confidential, so the replica server should not have access to it.
2. If the source has many replicas, filtering before sending to the replicas may reduce network traffic.

Source column filtering can be achieved using the `BLACKHOLE` engine. This is carried out in a way similar to how source table filtering is achieved - by using the `BLACKHOLE` engine and the `--replicate-do-table` or `--replicate-ignore-table` option.

The setup for the source is:

```
CREATE TABLE t1 (public_col_1, ..., public_col_N,
 secret_col_1, ..., secret_col_M) ENGINE=MyISAM;
```

The setup for the trusted replica is:

```
CREATE TABLE t1 (public_col_1, ..., public_col_N) ENGINE=BLACKHOLE;
```

The setup for the untrusted replica is:

```
CREATE TABLE t1 (public_col_1, ..., public_col_N) ENGINE=MyISAM;
```

## 18.7 The MERGE Storage Engine

The `MERGE` storage engine, also known as the `MRG_MyISAM` engine, is a collection of identical `MyISAM` tables that can be used as one. “Identical” means that all tables have identical column data types and index information. You cannot merge `MyISAM` tables in which the columns are listed in a different order,

do not have exactly the same data types in corresponding columns, or have the indexes in different order. However, any or all of the `MyISAM` tables can be compressed with `myisampack`. See [Section 6.6.6, “myisampack — Generate Compressed, Read-Only MyISAM Tables”](#). Differences between tables such as these do not matter:

- Names of corresponding columns and indexes can differ.
- Comments for tables, columns, and indexes can differ.
- Table options such as `AVG_ROW_LENGTH`, `MAX_ROWS`, or `PACK_KEYS` can differ.

An alternative to a `MERGE` table is a partitioned table, which stores partitions of a single table in separate files and enables some operations to be performed more efficiently. For more information, see [Chapter 26, Partitioning](#).

When you create a `MERGE` table, MySQL creates a `.MRG` file on disk that contains the names of the underlying `MyISAM` tables that should be used as one. The table format of the `MERGE` table is stored in the MySQL data dictionary. The underlying tables do not have to be in the same database as the `MERGE` table.

You can use `SELECT`, `DELETE`, `UPDATE`, and `INSERT` on `MERGE` tables. You must have `SELECT`, `DELETE`, and `UPDATE` privileges on the `MyISAM` tables that you map to a `MERGE` table.

#### Note

The use of `MERGE` tables entails the following security issue: If a user has access to `MyISAM` table `t`, that user can create a `MERGE` table `m` that accesses `t`. However, if the user's privileges on `t` are subsequently revoked, the user can continue to access `t` by doing so through `m`.

Use of `DROP TABLE` with a `MERGE` table drops only the `MERGE` specification. The underlying tables are not affected.

To create a `MERGE` table, you must specify a `UNION=(list-of-tables)` option that indicates which `MyISAM` tables to use. You can optionally specify an `INSERT_METHOD` option to control how inserts into the `MERGE` table take place. Use a value of `FIRST` or `LAST` to cause inserts to be made in the first or last underlying table, respectively. If you specify no `INSERT_METHOD` option or if you specify it with a value of `NO`, inserts into the `MERGE` table are not permitted and attempts to do so result in an error.

The following example shows how to create a `MERGE` table:

```
mysql> CREATE TABLE t1 (
-> a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
-> message CHAR(20)) ENGINE=MyISAM;
mysql> CREATE TABLE t2 (
-> a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
-> message CHAR(20)) ENGINE=MyISAM;
mysql> INSERT INTO t1 (message) VALUES ('Testing'),('table'),('t1');
mysql> INSERT INTO t2 (message) VALUES ('Testing'),('table'),('t2');
mysql> CREATE TABLE total (
-> a INT NOT NULL AUTO_INCREMENT,
-> message CHAR(20), INDEX(a))
-> ENGINE=MERGE UNION=(t1,t2) INSERT_METHOD=LAST;
```

Column `a` is indexed as a `PRIMARY KEY` in the underlying `MyISAM` tables, but not in the `MERGE` table. There it is indexed but not as a `PRIMARY KEY` because a `MERGE` table cannot enforce uniqueness over the set of underlying tables. (Similarly, a column with a `UNIQUE` index in the underlying tables should be indexed in the `MERGE` table but not as a `UNIQUE` index.)

After creating the `MERGE` table, you can use it to issue queries that operate on the group of tables as a whole:

```
mysql> SELECT * FROM total;
```

a   message	
1	Testing
2	table
3	t1
1	Testing
2	table
3	t2

To remap a [MERGE](#) table to a different collection of [MyISAM](#) tables, you can use one of the following methods:

- [DROP](#) the [MERGE](#) table and re-create it.
- Use [ALTER TABLE \*tbl\\_name\* UNION=\(...\)](#) to change the list of underlying tables.

It is also possible to use [ALTER TABLE ... UNION=\(\)](#) (that is, with an empty [UNION](#) clause) to remove all of the underlying tables. However, in this case, the table is effectively empty and inserts fail because there is no underlying table to take new rows. Such a table might be useful as a template for creating new [MERGE](#) tables with [CREATE TABLE ... LIKE](#).

The underlying table definitions and indexes must conform closely to the definition of the [MERGE](#) table. Conformance is checked when a table that is part of a [MERGE](#) table is opened, not when the [MERGE](#) table is created. If any table fails the conformance checks, the operation that triggered the opening of the table fails. This means that changes to the definitions of tables within a [MERGE](#) may cause a failure when the [MERGE](#) table is accessed. The conformance checks applied to each table are:

- The underlying table and the [MERGE](#) table must have the same number of columns.
- The column order in the underlying table and the [MERGE](#) table must match.
- Additionally, the specification for each corresponding column in the parent [MERGE](#) table and the underlying tables are compared and must satisfy these checks:
  - The column type in the underlying table and the [MERGE](#) table must be equal.
  - The column length in the underlying table and the [MERGE](#) table must be equal.
  - The column of the underlying table and the [MERGE](#) table can be [NULL](#).
- The underlying table must have at least as many indexes as the [MERGE](#) table. The underlying table may have more indexes than the [MERGE](#) table, but cannot have fewer.

#### Note

A known issue exists where indexes on the same columns must be in identical order, in both the [MERGE](#) table and the underlying [MyISAM](#) table. See Bug #33653.

Each index must satisfy these checks:

- The index type of the underlying table and the [MERGE](#) table must be the same.
- The number of index parts (that is, multiple columns within a compound index) in the index definition for the underlying table and the [MERGE](#) table must be the same.
- For each index part:

- Index part lengths must be equal.
- Index part types must be equal.
- Index part languages must be equal.
- Check whether index parts can be `NULL`.

If a `MERGE` table cannot be opened or used because of a problem with an underlying table, `CHECK TABLE` displays information about which table caused the problem.

## Additional Resources

- A forum dedicated to the `MERGE` storage engine is available at <https://forums.mysql.com/list.php?93>.

### 18.7.1 MERGE Table Advantages and Disadvantages

`MERGE` tables can help you solve the following problems:

- Easily manage a set of log tables. For example, you can put data from different months into separate tables, compress some of them with `myisampack`, and then create a `MERGE` table to use them as one.
- Obtain more speed. You can split a large read-only table based on some criteria, and then put individual tables on different disks. A `MERGE` table structured this way could be much faster than using a single large table.
- Perform more efficient searches. If you know exactly what you are looking for, you can search in just one of the underlying tables for some queries and use a `MERGE` table for others. You can even have many different `MERGE` tables that use overlapping sets of tables.
- Perform more efficient repairs. It is easier to repair individual smaller tables that are mapped to a `MERGE` table than to repair a single large table.
- Instantly map many tables as one. A `MERGE` table need not maintain an index of its own because it uses the indexes of the individual tables. As a result, `MERGE` table collections are *very* fast to create or remap. (You must still specify the index definitions when you create a `MERGE` table, even though no indexes are created.)
- If you have a set of tables from which you create a large table on demand, you can instead create a `MERGE` table from them on demand. This is much faster and saves a lot of disk space.
- Exceed the file size limit for the operating system. Each `MyISAM` table is bound by this limit, but a collection of `MyISAM` tables is not.
- You can create an alias or synonym for a `MyISAM` table by defining a `MERGE` table that maps to that single table. There should be no really notable performance impact from doing this (only a couple of indirect calls and `memcpy( )` calls for each read).

The disadvantages of `MERGE` tables are:

- You can use only identical `MyISAM` tables for a `MERGE` table.
- Some `MyISAM` features are unavailable in `MERGE` tables. For example, you cannot create `FULLTEXT` indexes on `MERGE` tables. (You can create `FULLTEXT` indexes on the underlying `MyISAM` tables, but you cannot search the `MERGE` table with a full-text search.)

- If the `MERGE` table is nontemporary, all underlying `MyISAM` tables must be nontemporary. If the `MERGE` table is temporary, the `MyISAM` tables can be any mix of temporary and nontemporary.
- `MERGE` tables use more file descriptors than `MyISAM` tables. If 10 clients are using a `MERGE` table that maps to 10 tables, the server uses  $(10 \times 10) + 10$  file descriptors. (10 data file descriptors for each of the 10 clients, and 10 index file descriptors shared among the clients.)
- Index reads are slower. When you read an index, the `MERGE` storage engine needs to issue a read on all underlying tables to check which one most closely matches a given index value. To read the next index value, the `MERGE` storage engine needs to search the read buffers to find the next value. Only when one index buffer is used up does the storage engine need to read the next index block. This makes `MERGE` indexes much slower on `eq_ref` searches, but not much slower on `ref` searches. For more information about `eq_ref` and `ref`, see [Section 15.8.2, “EXPLAIN Statement”](#).

## 18.7.2 MERGE Table Problems

The following are known problems with `MERGE` tables:

- `MERGE` child tables are locked through the parent table. If the parent is temporary, it is not locked, and thus the child tables are also not locked; this means that parallel use of the underlying `MyISAM` tables corrupts them.
- If you use `ALTER TABLE` to change a `MERGE` table to another storage engine, the mapping to the underlying tables is lost. Instead, the rows from the underlying `MyISAM` tables are copied into the altered table, which then uses the specified storage engine.
- The `INSERT_METHOD` table option for a `MERGE` table indicates which underlying `MyISAM` table to use for inserts into the `MERGE` table. However, use of the `AUTO_INCREMENT` table option for that `MyISAM` table has no effect for inserts into the `MERGE` table until at least one row has been inserted directly into the `MyISAM` table.
- A `MERGE` table cannot maintain uniqueness constraints over the entire table. When you perform an `INSERT`, the data goes into the first or last `MyISAM` table (as determined by the `INSERT_METHOD` option). MySQL ensures that unique key values remain unique within that `MyISAM` table, but not over all the underlying tables in the collection.
- Because the `MERGE` engine cannot enforce uniqueness over the set of underlying tables, `REPLACE` does not work as expected. The two key facts are:
  - `REPLACE` can detect unique key violations only in the underlying table to which it is going to write (which is determined by the `INSERT_METHOD` option). This differs from violations in the `MERGE` table itself.
  - If `REPLACE` detects a unique key violation, it changes only the corresponding row in the underlying table it is writing to; that is, the first or last table, as determined by the `INSERT_METHOD` option.

Similar considerations apply for `INSERT ... ON DUPLICATE KEY UPDATE`.

- `MERGE` tables do not support partitioning. That is, you cannot partition a `MERGE` table, nor can any of a `MERGE` table's underlying `MyISAM` tables be partitioned.
- You should not use `ANALYZE TABLE`, `REPAIR TABLE`, `OPTIMIZE TABLE`, `ALTER TABLE`, `DROP TABLE`, `DELETE` without a `WHERE` clause, or `TRUNCATE TABLE` on any of the tables that are mapped into an open `MERGE` table. If you do so, the `MERGE` table may still refer to the original table and yield unexpected results. To work around this problem, ensure that no `MERGE` tables remain open by issuing a `FLUSH TABLES` statement prior to performing any of the named operations.

The unexpected results include the possibility that the operation on the `MERGE` table reports table corruption. If this occurs after one of the named operations on the underlying `MyISAM` tables, the corruption message is spurious. To deal with this, issue a `FLUSH TABLES` statement after modifying the `MyISAM` tables.

- `DROP TABLE` on a table that is in use by a `MERGE` table does not work on Windows because the `MERGE` storage engine's table mapping is hidden from the upper layer of MySQL. Windows does not permit open files to be deleted, so you first must flush all `MERGE` tables (with `FLUSH TABLES`) or drop the `MERGE` table before dropping the table.
- The definition of the `MyISAM` tables and the `MERGE` table are checked when the tables are accessed (for example, as part of a `SELECT` or `INSERT` statement). The checks ensure that the definitions of the tables and the parent `MERGE` table definition match by comparing column order, types, sizes and associated indexes. If there is a difference between the tables, an error is returned and the statement fails. Because these checks take place when the tables are opened, any changes to the definition of a single table, including column changes, column ordering, and engine alterations cause the statement to fail.
- The order of indexes in the `MERGE` table and its underlying tables should be the same. If you use `ALTER TABLE` to add a `UNIQUE` index to a table used in a `MERGE` table, and then use `ALTER TABLE` to add a nonunique index on the `MERGE` table, the index ordering is different for the tables if there was already a nonunique index in the underlying table. (This happens because `ALTER TABLE` puts `UNIQUE` indexes before nonunique indexes to facilitate rapid detection of duplicate keys.) Consequently, queries on tables with such indexes may return unexpected results.
- If you encounter an error message similar to `ERROR 1017 (HY000): Can't find file: 'tbl_name.MRG' (errno: 2)`, it generally indicates that some of the underlying tables do not use the `MyISAM` storage engine. Confirm that all of these tables are `MyISAM`.
- The maximum number of rows in a `MERGE` table is  $2^{64}$  (~1.844E+19; the same as for a `MyISAM` table). It is not possible to merge multiple `MyISAM` tables into a single `MERGE` table that would have more than this number of rows.
- Use of underlying `MyISAM` tables of differing row formats with a parent `MERGE` table is currently known to fail. See Bug #32364.
- You cannot change the union list of a nontemporary `MERGE` table when `LOCK TABLES` is in effect. The following does *not* work:

```
CREATE TABLE m1 ... ENGINE=MRG_MYISAM ...;
LOCK TABLES t1 WRITE, t2 WRITE, m1 WRITE;
ALTER TABLE m1 ... UNION=(t1,t2) ...;
```

However, you can do this with a temporary `MERGE` table.

- You cannot create a `MERGE` table with `CREATE ... SELECT`, neither as a temporary `MERGE` table, nor as a nontemporary `MERGE` table. For example:

```
CREATE TABLE m1 ... ENGINE=MRG_MYISAM ... SELECT ...;
```

Attempts to do this result in an error: `tbl_name` is not `BASE TABLE`.

- In some cases, differing `PACK_KEYS` table option values among the `MERGE` and underlying tables cause unexpected results if the underlying tables contain `CHAR` or `BINARY` columns. As a workaround, use `ALTER TABLE` to ensure that all involved tables have the same `PACK_KEYS` value. (Bug #50646)

## 18.8 The FEDERATED Storage Engine

The **FEDERATED** storage engine lets you access data from a remote MySQL database without using replication or cluster technology. Querying a local **FEDERATED** table automatically pulls the data from the remote (federated) tables. No data is stored on the local tables.

To include the **FEDERATED** storage engine if you build MySQL from source, invoke **CMake** with the `-DWITH_FEDERATED_STORAGE_ENGINE` option.

The **FEDERATED** storage engine is not enabled by default in the running server; to enable **FEDERATED**, you must start the MySQL server binary using the `--federated` option.

To examine the source for the **FEDERATED** engine, look in the `storage/federated` directory of a MySQL source distribution.

## 18.8.1 FEDERATED Storage Engine Overview

When you create a table using one of the standard storage engines (such as **MyISAM**, **CSV** or **InnoDB**), the table consists of the table definition and the associated data. When you create a **FEDERATED** table, the table definition is the same, but the physical storage of the data is handled on a remote server.

A **FEDERATED** table consists of two elements:

- A *remote server* with a database table, which in turn consists of the table definition (stored in the MySQL data dictionary) and the associated table. The table type of the remote table may be any type supported by the remote `mysqld` server, including **MyISAM** or **InnoDB**.
- A *local server* with a database table, where the table definition matches that of the corresponding table on the remote server. The table definition is stored in the data dictionary. There is no data file on the local server. Instead, the table definition includes a connection string that points to the remote table.

When executing queries and statements on a **FEDERATED** table on the local server, the operations that would normally insert, update or delete information from a local data file are instead sent to the remote server for execution, where they update the data file on the remote server or return matching rows from the remote server.

The basic structure of a **FEDERATED** table setup is shown in [Figure 18.2, “FEDERATED Table Structure”](#).

**Figure 18.2 FEDERATED Table Structure**

When a client issues an SQL statement that refers to a [FEDERATED](#) table, the flow of information between the local server (where the SQL statement is executed) and the remote server (where the data is physically stored) is as follows:

1. The storage engine looks through each column that the [FEDERATED](#) table has and constructs an appropriate SQL statement that refers to the remote table.
2. The statement is sent to the remote server using the MySQL client API.
3. The remote server processes the statement and the local server retrieves any result that the statement produces (an affected-rows count or a result set).
4. If the statement produces a result set, each column is converted to internal storage engine format that the [FEDERATED](#) engine expects and can use to display the result to the client that issued the original statement.

The local server communicates with the remote server using MySQL client C API functions. It invokes `mysql_real_query()` to send the statement. To read a result set, it uses `mysql_store_result()` and fetches rows one at a time using `mysql_fetch_row()`.

## 18.8.2 How to Create FEDERATED Tables

To create a [FEDERATED](#) table you should follow these steps:

1. Create the table on the remote server. Alternatively, make a note of the table definition of an existing table, perhaps using the `SHOW CREATE TABLE` statement.
2. Create the table on the local server with an identical table definition, but adding the connection information that links the local table to the remote table.

For example, you could create the following table on the remote server:

```
CREATE TABLE test_table (
 id INT(20) NOT NULL AUTO_INCREMENT,
 name VARCHAR(32) NOT NULL DEFAULT '',
 other INT(20) NOT NULL DEFAULT '0',
 PRIMARY KEY (id),
 INDEX name (name),
 INDEX other_key (other)
)
ENGINE=MyISAM
DEFAULT CHARSET=utf8mb4;
```

To create the local table that is federated to the remote table, there are two options available. You can either create the local table and specify the connection string (containing the server name, login, password) to be used to connect to the remote table using the [CONNECTION](#), or you can use an existing connection that you have previously created using the [CREATE SERVER](#) statement.

### Important

When you create the local table it *must* have an identical field definition to the remote table.

### Note

You can improve the performance of a [FEDERATED](#) table by adding indexes to the table on the host. The optimization occurs because the query sent to the remote server includes the contents of the [WHERE](#) clause and is sent to the remote server and subsequently executed locally. This reduces the network traffic that would otherwise request the entire table from the server for local processing.

### 18.8.2.1 Creating a FEDERATED Table Using CONNECTION

To use the first method, you must specify the `CONNECTION` string after the engine type in a `CREATE TABLE` statement. For example:

```
CREATE TABLE federated_table (
 id INT(20) NOT NULL AUTO_INCREMENT,
 name VARCHAR(32) NOT NULL DEFAULT '',
 other INT(20) NOT NULL DEFAULT '0',
 PRIMARY KEY (id),
 INDEX name (name),
 INDEX other_key (other)
)
ENGINE=FEDERATED
DEFAULT CHARSET=utf8mb4
CONNECTION='mysql://fed_user@remote_host:9306/federated/test_table';
```

#### Note

`CONNECTION` replaces the `COMMENT` used in some previous versions of MySQL.

The `CONNECTION` string contains the information required to connect to the remote server containing the table in which the data physically resides. The connection string specifies the server name, login credentials, port number and database/table information. In the example, the remote table is on the server `remote_host`, using port 9306. The name and port number should match the host name (or IP address) and port number of the remote MySQL server instance you want to use as your remote table.

The format of the connection string is as follows:

```
scheme://user_name[:password]@host_name[:port_num]/db_name/tbl_name
```

Where:

- `scheme`: A recognized connection protocol. Only `mysql` is supported as the `scheme` value at this point.
- `user_name`: The user name for the connection. This user must have been created on the remote server, and must have suitable privileges to perform the required actions (`SELECT`, `INSERT`, `UPDATE`, and so forth) on the remote table.
- `password`: (Optional) The corresponding password for `user_name`.
- `host_name`: The host name or IP address of the remote server.
- `port_num`: (Optional) The port number for the remote server. The default is 3306.
- `db_name`: The name of the database holding the remote table.
- `tbl_name`: The name of the remote table. The name of the local and the remote table do not have to match.

Sample connection strings:

```
CONNECTION='mysql://username:password@hostname:port/database/tablename'
CONNECTION='mysql://username@hostname/database/tablename'
CONNECTION='mysql://username:password@hostname/database/tablename'
```

### 18.8.2.2 Creating a FEDERATED Table Using CREATE SERVER

If you are creating a number of `FEDERATED` tables on the same server, or if you want to simplify the process of creating `FEDERATED` tables, you can use the `CREATE SERVER` statement to define the server connection parameters, just as you would with the `CONNECTION` string.

The format of the `CREATE SERVER` statement is:

```
CREATE SERVER
server_name
FOREIGN DATA WRAPPER wrapper_name
OPTIONS (option [, option] ...)
```

The `server_name` is used in the connection string when creating a new `FEDERATED` table.

For example, to create a server connection identical to the `CONNECTION` string:

```
CONNECTION='mysql://fed_user@remote_host:9306/federated/test_table';
```

You would use the following statement:

```
CREATE SERVER fedlink
FOREIGN DATA WRAPPER mysql
OPTIONS (USER 'fed_user', HOST 'remote_host', PORT 9306, DATABASE 'federated');
```

To create a `FEDERATED` table that uses this connection, you still use the `CONNECTION` keyword, but specify the name you used in the `CREATE SERVER` statement.

```
CREATE TABLE test_table (
 id INT(20) NOT NULL AUTO_INCREMENT,
 name VARCHAR(32) NOT NULL DEFAULT '',
 other INT(20) NOT NULL DEFAULT '0',
 PRIMARY KEY (id),
 INDEX name (name),
 INDEX other_key (other)
)
ENGINE=FEDERATED
DEFAULT CHARSET=utf8mb4
CONNECTION='fedlink/test_table';
```

The connection name in this example contains the name of the connection (`fedlink`) and the name of the table (`test_table`) to link to, separated by a slash. If you specify only the connection name without a table name, the table name of the local table is used instead.

For more information on `CREATE SERVER`, see [Section 15.1.18, “CREATE SERVER Statement”](#).

The `CREATE SERVER` statement accepts the same arguments as the `CONNECTION` string. The `CREATE SERVER` statement updates the rows in the `mysql.servers` table. See the following table for information on the correspondence between parameters in a connection string, options in the `CREATE SERVER` statement, and the columns in the `mysql.servers` table. For reference, the format of the `CONNECTION` string is as follows:

```
scheme://user_name[:password]@host_name[:port_num]/db_name/tbl_name
```

Description	CONNECTION string	CREATE SERVER option	mysql.servers column
Connection scheme	<code>scheme</code>	<code>wrapper_name</code>	Wrapper
Remote user	<code>user_name</code>	USER	Username
Remote password	<code>password</code>	PASSWORD	Password
Remote host	<code>host_name</code>	HOST	Host
Remote port	<code>port_num</code>	PORT	Port
Remote database	<code>db_name</code>	DATABASE	Db

## 18.8.3 FEDERATED Storage Engine Notes and Tips

You should be aware of the following points when using the `FEDERATED` storage engine:

- `FEDERATED` tables may be replicated to other replicas, but you must ensure that the replica servers are able to use the user/password combination that is defined in the `CONNECTION` string (or the row in the `mysql.servers` table) to connect to the remote server.

The following items indicate features that the `FEDERATED` storage engine does and does not support:

- The remote server must be a MySQL server.
- The remote table that a `FEDERATED` table points to *must* exist before you try to access the table through the `FEDERATED` table.
- It is possible for one `FEDERATED` table to point to another, but you must be careful not to create a loop.
- A `FEDERATED` table does not support indexes in the usual sense; because access to the table data is handled remotely, it is actually the remote table that makes use of indexes. This means that, for a query that cannot use any indexes and so requires a full table scan, the server fetches all rows from the remote table and filters them locally. This occurs regardless of any `WHERE` or `LIMIT` used with this `SELECT` statement; these clauses are applied locally to the returned rows.

Queries that fail to use indexes can thus cause poor performance and network overload. In addition, since returned rows must be stored in memory, such a query can also lead to the local server swapping, or even hanging.

- Care should be taken when creating a `FEDERATED` table since the index definition from an equivalent `MyISAM` or other table may not be supported. For example, creating a `FEDERATED` table fails if the table uses an index prefix on any `VARCHAR`, `TEXT` or `BLOB` columns. The following definition using `MyISAM` is valid:

```
CREATE TABLE `T1` (
 `A` VARCHAR(100),
 UNIQUE KEY(`A`(30))
) ENGINE=MYISAM;
```

The key prefix in this example is incompatible with the `FEDERATED` engine, and the equivalent statement fails:

```
CREATE TABLE `T1` (
 `A` VARCHAR(100),
 UNIQUE KEY(`A`(30))
) ENGINE=FEDERATED
 CONNECTION='MYSQL://127.0.0.1:3306/TEST/T1';
```

If possible, you should try to separate the column and index definition when creating tables on both the remote server and the local server to avoid these index issues.

- Internally, the implementation uses `SELECT`, `INSERT`, `UPDATE`, and `DELETE`, but not `HANDLER`.
- The `FEDERATED` storage engine supports `SELECT`, `INSERT`, `UPDATE`, `DELETE`, `TRUNCATE TABLE`, and indexes. It does not support `ALTER TABLE`, or any Data Definition Language statements that directly affect the structure of the table, other than `DROP TABLE`. The current implementation does not use prepared statements.
- `FEDERATED` accepts `INSERT ... ON DUPLICATE KEY UPDATE` statements, but if a duplicate-key violation occurs, the statement fails with an error.

- Transactions are not supported.
- **FEDERATED** performs bulk-insert handling such that multiple rows are sent to the remote table in a batch, which improves performance. Also, if the remote table is transactional, it enables the remote storage engine to perform statement rollback properly should an error occur. This capability has the following limitations:
  - The size of the insert cannot exceed the maximum packet size between servers. If the insert exceeds this size, it is broken into multiple packets and the rollback problem can occur.
  - Bulk-insert handling does not occur for `INSERT ... ON DUPLICATE KEY UPDATE`.
- There is no way for the **FEDERATED** engine to know if the remote table has changed. The reason for this is that this table must work like a data file that would never be written to by anything other than the database system. The integrity of the data in the local table could be breached if there was any change to the remote database.
- When using a **CONNECTION** string, you cannot use an '@' character in the password. You can get round this limitation by using the `CREATE SERVER` statement to create a server connection.
- The `insert_id` and `timestamp` options are not propagated to the data provider.
- Any `DROP TABLE` statement issued against a **FEDERATED** table drops only the local table, not the remote table.
- User-defined partitioning is not supported for **FEDERATED** tables.

## 18.8.4 FEDERATED Storage Engine Resources

The following additional resources are available for the **FEDERATED** storage engine:

- A forum dedicated to the **FEDERATED** storage engine is available at <https://forums.mysql.com/list.php?105>.

## 18.9 The EXAMPLE Storage Engine

The **EXAMPLE** storage engine is a stub engine that does nothing. Its purpose is to serve as an example in the MySQL source code that illustrates how to begin writing new storage engines. As such, it is primarily of interest to developers.

To enable the **EXAMPLE** storage engine if you build MySQL from source, invoke **CMake** with the `-DWITH_EXAMPLE_STORAGE_ENGINE` option.

To examine the source for the **EXAMPLE** engine, look in the `storage/example` directory of a MySQL source distribution.

When you create an **EXAMPLE** table, no files are created. No data can be stored into the table. Retrievals return an empty result.

```
mysql> CREATE TABLE test (i INT) ENGINE = EXAMPLE;
Query OK, 0 rows affected (0.78 sec)

mysql> INSERT INTO test VALUES ROW(1), ROW(2), ROW(3);
ERROR 1031 (HY000): Table storage engine for 'test' doesn't »
 have this option

mysql> SELECT * FROM test;
Empty set (0.31 sec)
```

The **EXAMPLE** storage engine does not support indexing.

The [EXAMPLE](#) storage engine does not support partitioning.

## 18.10 Other Storage Engines

Other storage engines may be available from third parties and community members that have used the Custom Storage Engine interface.

Third party engines are not supported by MySQL. For further information, documentation, installation guides, bug reporting or for any help or assistance with these engines, please contact the developer of the engine directly.

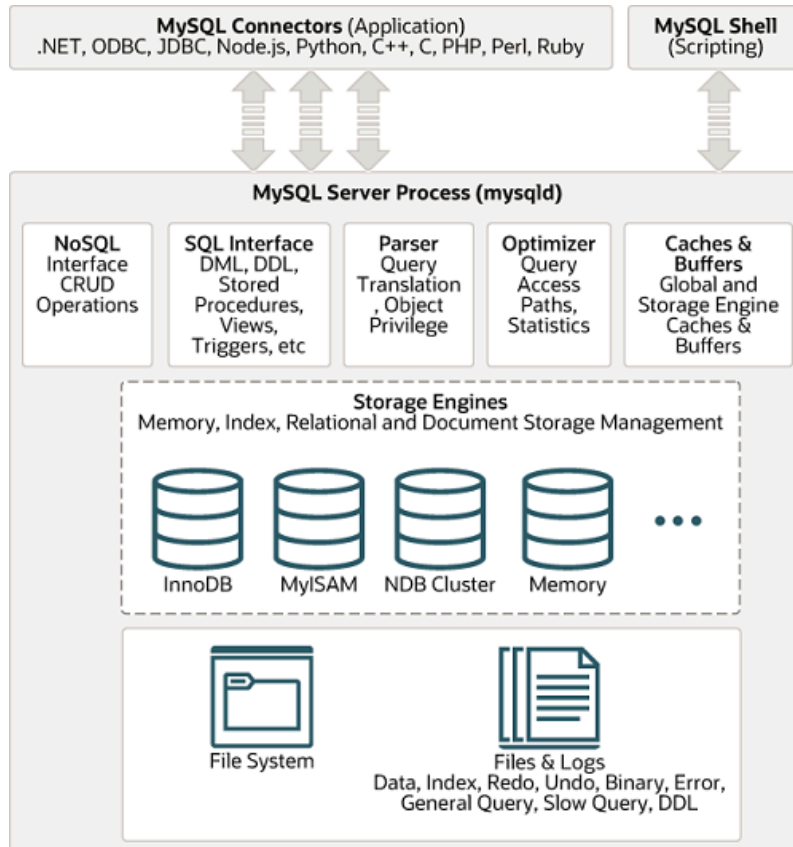

For more information on developing a customer storage engine that can be used with the Pluggable Storage Engine Architecture, see [MySQL Internals: Writing a Custom Storage Engine](#).

## 18.11 Overview of MySQL Storage Engine Architecture

The MySQL pluggable storage engine architecture enables a database professional to select a specialized storage engine for a particular application need while being completely shielded from the need to manage any specific application coding requirements. The MySQL server architecture isolates the application programmer and DBA from all of the low-level implementation details at the storage level, providing a consistent and easy application model and API. Thus, although there are different capabilities across different storage engines, the application is shielded from these differences.

The MySQL pluggable storage engine architecture is shown in [Figure 18.3, “MySQL Architecture with Pluggable Storage Engines”](#).

**Figure 18.3 MySQL Architecture with Pluggable Storage Engines**

The pluggable storage engine architecture provides a standard set of management and support services that are common among all underlying storage engines. The storage engines themselves are the components of the database server that actually perform actions on the underlying data that is maintained at the physical server level.

This efficient and modular architecture provides huge benefits for those wishing to specifically target a particular application need—such as data warehousing, transaction processing, or high availability situations—while enjoying the advantage of utilizing a set of interfaces and services that are independent of any one storage engine.

The application programmer and DBA interact with the MySQL database through Connector APIs and service layers that are above the storage engines. If application changes bring about requirements that demand the underlying storage engine change, or that one or more storage engines be added to support new needs, no significant coding or process changes are required to make things work. The MySQL server architecture shields the application from the underlying complexity of the storage engine by presenting a consistent and easy-to-use API that applies across storage engines.

## 18.11.1 Pluggable Storage Engine Architecture

MySQL Server uses a pluggable storage engine architecture that enables storage engines to be loaded into and unloaded from a running MySQL server.

### Plugging in a Storage Engine

Before a storage engine can be used, the storage engine plugin shared library must be loaded into MySQL using the `INSTALL PLUGIN` statement. For example, if the `EXAMPLE` engine plugin is named `example` and the shared library is named `ha_example.so`, you load it with the following statement:

```
INSTALL PLUGIN example SONAME 'ha_example.so';
```

To install a pluggable storage engine, the plugin file must be located in the MySQL plugin directory, and the user issuing the `INSTALL PLUGIN` statement must have `INSERT` privilege for the `mysql.plugin` table.

The shared library must be located in the MySQL server plugin directory, the location of which is given by the `plugin_dir` system variable.

### Unplugging a Storage Engine

To unplug a storage engine, use the `UNINSTALL PLUGIN` statement:

```
UNINSTALL PLUGIN example;
```

If you unplug a storage engine that is needed by existing tables, those tables become inaccessible, but are still present on disk (where applicable). Ensure that there are no tables using a storage engine before you unplug the storage engine.

## 18.11.2 The Common Database Server Layer

A MySQL pluggable storage engine is the component in the MySQL database server that is responsible for performing the actual data I/O operations for a database as well as enabling and enforcing certain feature sets that target a specific application need. A major benefit of using specific storage engines is that you are only delivered the features needed for a particular application, and therefore you have less system overhead in the database, with the end result being more efficient and higher database performance. This is one of the reasons that MySQL has always been known to have such high performance, matching or beating proprietary monolithic databases in industry standard benchmarks.

From a technical perspective, what are some of the unique supporting infrastructure components that are in a storage engine? Some of the key feature differentiations include:

- *Concurrency*: Some applications have more granular lock requirements (such as row-level locks) than others. Choosing the right locking strategy can reduce overhead and therefore improve overall performance. This area also includes support for capabilities such as multi-version concurrency control or “snapshot” read.
- *Transaction Support*: Not every application needs transactions, but for those that do, there are very well defined requirements such as ACID compliance and more.
- *Referential Integrity*: The need to have the server enforce relational database referential integrity through DDL defined foreign keys.
- *Physical Storage*: This involves everything from the overall page size for tables and indexes as well as the format used for storing data to physical disk.
- *Index Support*: Different application scenarios tend to benefit from different index strategies. Each storage engine generally has its own indexing methods, although some (such as B-tree indexes) are common to nearly all engines.
- *Memory Caches*: Different applications respond better to some memory caching strategies than others, so although some memory caches are common to all storage engines (such as those used for user connections), others are uniquely defined only when a particular storage engine is put in play.
- *Performance Aids*: This includes multiple I/O threads for parallel operations, thread concurrency, database checkpointing, bulk insert handling, and more.
- *Miscellaneous Target Features*: This may include support for geospatial operations, security restrictions for certain data manipulation operations, and other similar features.

Each set of the pluggable storage engine infrastructure components are designed to offer a selective set of benefits for a particular application. Conversely, avoiding a set of component features helps reduce unnecessary overhead. It stands to reason that understanding a particular application's set of requirements and selecting the proper MySQL storage engine can have a dramatic impact on overall system efficiency and performance.

Replication enables data from one MySQL database server (known as a source) to be copied to one or more MySQL database servers (known as replicas). Replication is asynchronous by default; replicas do not need to be connected permanently to receive updates from a source. Depending on the configuration, you can replicate all databases, selected databases, or even selected tables within a database.

Advantages of replication in MySQL include:

- Scale-out solutions - spreading the load among multiple replicas to improve performance. In this environment, all writes and updates must take place on the source server. Reads, however, may take place on one or more replicas. This model can improve the performance of writes (since the source

---

is dedicated to updates), while dramatically increasing read speed across an increasing number of replicas.

- Data security - because the replica can pause the replication process, it is possible to run backup services on the replica without corrupting the corresponding source data.
- Analytics - live data can be created on the source, while the analysis of the information can take place on the replica without affecting the performance of the source.
- Long-distance data distribution - you can use replication to create a local copy of data for a remote site to use, without permanent access to the source.

For information on how to use replication in such scenarios, see [Section 19.4, “Replication Solutions”](#).

MySQL 9.1 supports different methods of replication. The traditional method is based on replicating events from the source's binary log, and requires the log files and positions in them to be synchronized between source and replica. The newer method based on *global transaction identifiers* (GTIDs) is transactional and therefore does not require working with log files or positions within these files, which greatly simplifies many common replication tasks. Replication using GTIDs guarantees consistency between source and replica as long as all transactions committed on the source have also been applied on the replica. For more information about GTIDs and GTID-based replication in MySQL, see [Section 19.1.3, “Replication with Global Transaction Identifiers”](#). For information on using binary log file position based replication, see [Section 19.1, “Configuring Replication”](#).

Replication in MySQL supports different types of synchronization. The original type of synchronization is one-way, asynchronous replication, in which one server acts as the source, while one or more other servers act as replicas. This is in contrast to the *synchronous* replication which is a characteristic of NDB Cluster (see [Chapter 25, MySQL NDB Cluster 9.1](#)). In MySQL 9.1, semisynchronous replication is supported in addition to the built-in asynchronous replication. With semisynchronous replication, a commit performed on the source blocks before returning to the session that performed the transaction until at least one replica acknowledges that it has received and logged the events for the transaction; see [Section 19.4.10, “Semisynchronous Replication”](#). MySQL 9.1 also supports delayed replication such that a replica deliberately lags behind the source by at least a specified amount of time; see [Section 19.4.11, “Delayed Replication”](#). For scenarios where *synchronous* replication is required, use NDB Cluster (see [Chapter 25, MySQL NDB Cluster 9.1](#)).

There are a number of solutions available for setting up replication between servers, and the best method to use depends on the presence of data and the engine types you are using. For more information on the available options, see [Section 19.1.2, “Setting Up Binary Log File Position Based Replication”](#).

There are two core types of replication format, Statement Based Replication (SBR), which replicates entire SQL statements, and Row Based Replication (RBR), which replicates only the changed rows. You can also use a third variety, Mixed Based Replication (MBR). For more information on the different replication formats, see [Section 19.2.1, “Replication Formats”](#).

Replication is controlled through a number of different options and variables. For more information, see [Section 19.1.6, “Replication and Binary Logging Options and Variables”](#). Additional security measures can be applied to a replication topology, as described in [Section 19.3, “Replication Security”](#).

You can use replication to solve a number of different problems, including performance, supporting the backup of different databases, and as part of a larger solution to alleviate system failures. For information on how to address these issues, see [Section 19.4, “Replication Solutions”](#).

For notes and tips on how different data types and statements are treated during replication, including details of replication features, version compatibility, upgrades, and potential problems and their resolution,

see [Section 19.5, “Replication Notes and Tips”](#). For answers to some questions often asked by those who are new to MySQL Replication, see [Section A.14, “MySQL 9.1 FAQ: Replication”](#).

For detailed information on the implementation of replication, how replication works, the process and contents of the binary log, background threads and the rules used to decide how statements are recorded and replicated, see [Section 19.2, “Replication Implementation”](#).

## 19.1 Configuring Replication

This section describes how to configure the different types of replication available in MySQL and includes the setup and configuration required for a replication environment, including step-by-step instructions for creating a new replication environment. The major components of this section are:

- For a guide to setting up two or more servers for replication using binary log file positions, [Section 19.1.2, “Setting Up Binary Log File Position Based Replication”](#), deals with the configuration of the servers and provides methods for copying data between the source and replicas.
- For a guide to setting up two or more servers for replication using GTID transactions, [Section 19.1.3, “Replication with Global Transaction Identifiers”](#), deals with the configuration of the servers.
- Events in the binary log are recorded using a number of formats. These are referred to as statement-based replication (SBR) or row-based replication (RBR). A third type, mixed-format replication (MIXED), uses SBR or RBR replication automatically to take advantage of the benefits of both SBR and RBR formats when appropriate. The different formats are discussed in [Section 19.2.1, “Replication Formats”](#).
- Detailed information on the different configuration options and variables that apply to replication is provided in [Section 19.1.6, “Replication and Binary Logging Options and Variables”](#).
- Once started, the replication process should require little administration or monitoring. However, for advice on common tasks that you may want to execute, see [Section 19.1.7, “Common Replication Administration Tasks”](#).

### 19.1.1 Binary Log File Position Based Replication Configuration Overview

This section describes replication between MySQL servers based on the binary log file position method, where the MySQL instance operating as the source (where the database changes take place) writes updates and changes as “events” to the binary log. The information in the binary log is stored in different logging formats according to the database changes being recorded. Replicas are configured to read the binary log from the source and to execute the events in the binary log on the replica's local database.

Each replica receives a copy of the entire contents of the binary log. It is the responsibility of the replica to decide which statements in the binary log should be executed. Unless you specify otherwise, all events in the source's binary log are executed on the replica. If required, you can configure the replica to process only events that apply to particular databases or tables.

#### Important

You cannot configure the source to log only certain events.

Each replica keeps a record of the binary log coordinates: the file name and position within the file that it has read and processed from the source. This means that multiple replicas can be connected to the source and executing different parts of the same binary log. Because the replicas control this process, individual replicas can be connected and disconnected from the server without affecting the source's operation. Also, because each replica records the current position within the binary log, it is possible for replicas to be disconnected, reconnect and then resume processing.

The source and each replica must be configured with a unique ID (using the `server_id` system variable). In addition, each replica must be configured with information about the source's host name, log file name, and position within that file. These details can be controlled from within a MySQL session using a `CHANGE REPLICATION SOURCE TO` statement on the replica. The details are stored within the replica's connection metadata repository (see [Section 19.2.4, “Relay Log and Replication Metadata Repositories”](#)).

## 19.1.2 Setting Up Binary Log File Position Based Replication

This section describes how to set up a MySQL server to use binary log file position based replication. There are a number of different methods for setting up replication, and the exact method to use depends on how you are setting up replication, and whether you already have data in the database on the source that you want to replicate.

### Tip

To deploy multiple instances of MySQL, you can use [InnoDB Cluster](#) which enables you to easily administer a group of MySQL server instances in [MySQL Shell](#). InnoDB Cluster wraps MySQL Group Replication in a programmatic environment that enables you easily deploy a cluster of MySQL instances to achieve high availability. In addition, InnoDB Cluster interfaces seamlessly with [MySQL Router](#), which enables your applications to connect to the cluster without writing your own failover process. For similar use cases that do not require high availability, however, you can use [InnoDB ReplicaSet](#). Installation instructions for MySQL Shell can be found [here](#).

There are some generic tasks that are common to all setups:

- On the source, you must ensure that binary logging is enabled, and configure a unique server ID. This might require a server restart. See [Section 19.1.2.1, “Setting the Replication Source Configuration”](#).
- On each replica that you want to connect to the source, you must configure a unique server ID. This might require a server restart. See [Section 19.1.2.2, “Setting the Replica Configuration”](#).
- Optionally, create a separate user for your replicas to use during authentication with the source when reading the binary log for replication. See [Section 19.1.2.3, “Creating a User for Replication”](#).
- Before creating a data snapshot or starting the replication process, on the source you should record the current position in the binary log. You need this information when configuring the replica so that the replica knows where within the binary log to start executing events. See [Section 19.1.2.4, “Obtaining the Replication Source Binary Log Coordinates”](#).
- If you already have data on the source and want to use it to synchronize the replica, you need to create a data snapshot to copy the data to the replica. The storage engine you are using has an impact on how you create the snapshot. When you are using [MyISAM](#), you must stop processing statements on the source to obtain a read-lock, then obtain its current binary log coordinates and dump its data, before permitting the source to continue executing statements. If you do not stop the execution of statements, the data dump and the source status information become mismatched, resulting in inconsistent or corrupted databases on the replicas. For more information on replicating a [MyISAM](#) source, see [Section 19.1.2.4, “Obtaining the Replication Source Binary Log Coordinates”](#). If you are using [InnoDB](#), you do not need a read-lock and a transaction that is long enough to transfer the data snapshot is sufficient. For more information, see [Section 17.19, “InnoDB and MySQL Replication”](#).
- Configure the replica with settings for connecting to the source, such as the host name, login credentials, and binary log file name and position. See [Section 19.1.2.7, “Setting the Source Configuration on the Replica”](#).

- Implement replication-specific security measures on the sources and replicas as appropriate for your system. See [Section 19.3, “Replication Security”](#).

**Note**

Certain steps within the setup process require the [SUPER](#) privilege. If you do not have this privilege, it might not be possible to enable replication.

After configuring the basic options, select your scenario:

- To set up replication for a fresh installation of a source and replicas that contain no data, see [Setting Up Replication with New Source and Replicas](#).
- To set up replication of a new source using the data from an existing MySQL server, see [Setting Up Replication with Existing Data](#).
- To add replicas to an existing replication environment, see [Section 19.1.2.8, “Adding Replicas to a Replication Environment”](#).

Before administering MySQL replication servers, read this entire chapter and try all statements mentioned in [Section 15.4.1, “SQL Statements for Controlling Source Servers”](#), and [Section 15.4.2, “SQL Statements for Controlling Replica Servers”](#). Also familiarize yourself with the replication startup options described in [Section 19.1.6, “Replication and Binary Logging Options and Variables”](#).

### 19.1.2.1 Setting the Replication Source Configuration

To configure a source to use binary log file position based replication, you must ensure that binary logging is enabled, and establish a unique server ID.

Each server within a replication topology must be configured with a unique server ID, which you can specify using the [server\\_id](#) system variable. This server ID is used to identify individual servers within the replication topology, and must be a positive integer between 1 and  $(2^{32})-1$ . The default [server\\_id](#) value is 1; you can change this at runtime by issuing a statement like this one:

```
SET GLOBAL server_id = 2;
```

Organization and selection of the server IDs is arbitrary, as long as each server ID is different from every other server ID in use by any other server in the replication topology. Note that if a value of 0 was set previously for the server ID, you must restart the server to initialize the source with your new nonzero server ID. Otherwise, a server restart is not needed when you change the server ID, unless you make other configuration changes that require it.

Binary logging is required on the source because the binary log is the basis for replicating changes from the source to its replicas. Binary logging is enabled by default (the [log\\_bin](#) system variable is set to ON). The [--log-bin](#) option tells the server what base name to use for binary log files. It is recommended that you specify this option to give the binary log files a non-default base name, so that if the host name changes, you can easily continue to use the same binary log file names (see [Section B.3.7, “Known Issues in MySQL”](#)). If binary logging was previously disabled on the source using the [--skip-log-bin](#) option, you must restart the server without this option to enable it.

**Note**

The following options also have an impact on the source:

- For the greatest possible durability and consistency in a replication setup using [InnoDB](#) with transactions, you should use

`innodb_flush_log_at_trx_commit=1` and `sync_binlog=1` in the source's `my.cnf` file.

- Ensure that the `skip_networking` system variable is not enabled on the source. If networking has been disabled, the replica cannot communicate with the source and replication fails.

### 19.1.2.2 Setting the Replica Configuration

Each replica must have a unique server ID, as specified by the `server_id` system variable. If you are setting up multiple replicas, each one must have a unique `server_id` value that differs from that of the source and from any of the other replicas. If the replica's server ID is not already set, or the current value conflicts with the value that you have chosen for the source or another replica, you must change it.

The default `server_id` value is 1. You can change the `server_id` value dynamically by issuing a statement like this:

```
SET GLOBAL server_id = 21;
```

Note that a value of 0 for the server ID prevents a replica from connecting to a source. If that server ID value (which was the default in earlier releases) was set previously, you must restart the server to initialize the replica with your new nonzero server ID. Otherwise, a server restart is not needed when you change the server ID, unless you make other configuration changes that require it. For example, if binary logging was disabled on the server and you want it enabled for your replica, a server restart is required to enable this.

If you are shutting down the replica server, you can edit the `[mysqld]` section of the configuration file to specify a unique server ID. For example:

```
[mysqld]
server-id=21
```

Binary logging is enabled by default on all servers. A replica is not required to have binary logging enabled for replication to take place. However, binary logging on a replica means that the replica's binary log can be used for data backups and crash recovery. Replicas that have binary logging enabled can also be used as part of a more complex replication topology. For example, you might want to set up replication servers using this chained arrangement:

```
A -> B -> C
```

Here, **A** serves as the source for the replica **B**, and **B** serves as the source for the replica **C**. For this to work, **B** must be both a source *and* a replica. Updates received from **A** must be logged by **B** to its binary log, in order to be passed on to **C**. In addition to binary logging, this replication topology requires the system variable `log_replica_updates` to be enabled. With replica updates enabled, the replica writes updates that are received from a source and performed by the replica's SQL thread to the replica's own binary log. `log_replica_updates` is enabled by default.

If you need to disable binary logging or replica update logging on a replica, you can do this by specifying the `--skip-log-bin` and `--log-replica-updates=OFF` options for the replica. If you decide to re-enable these features on the replica, remove the relevant options and restart the server.

### 19.1.2.3 Creating a User for Replication

Each replica connects to the source using a MySQL user name and password, so there must be a user account on the source that the replica can use to connect. The user name is specified by the

`SOURCE_USER` option of the `CHANGE REPLICATION SOURCE TO` statement when you set up a replica. Any account can be used for this operation, providing it has been granted the `REPLICATION SLAVE` privilege. You can choose to create a different account for each replica, or connect to the source using the same account for each replica.

Although you do not have to create an account specifically for replication, you should be aware that the replication user name and password are stored in plain text in the replica's connection metadata repository `mysql.slave_master_info` (see [Section 19.2.4.2, “Replication Metadata Repositories”](#)). Therefore, you may want to create a separate account that has privileges only for the replication process, to minimize the possibility of compromise to other accounts.

To create a new account, use `CREATE USER`. To grant this account the privileges required for replication, use the `GRANT` statement. If you create an account solely for the purposes of replication, that account needs only the `REPLICATION SLAVE` privilege. For example, to set up a new user, `repl`, that can connect for replication from any host within the `example.com` domain, issue these statements on the source:

```
mysql> CREATE USER 'repl'@'%example.com' IDENTIFIED BY 'password';
mysql> GRANT REPLICATION SLAVE ON *.* TO 'repl'@'%example.com';
```

See [Section 15.7.1, “Account Management Statements”](#), for more information on statements for manipulation of user accounts.

#### Important

To connect to the source using a user account that authenticates with the `caching_sha2_password` plugin, you must either set up a secure connection as described in [Section 19.3.1, “Setting Up Replication to Use Encrypted Connections”](#), or enable the unencrypted connection to support password exchange using an RSA key pair. The `caching_sha2_password` authentication plugin is the default for new users (see [Section 8.4.1.1, “Caching SHA-2 Pluggable Authentication”](#)). If the user account that you create or use for replication (as specified by the `SOURCE_USER` option) uses this authentication plugin, and you are not using a secure connection, you must enable RSA key pair-based password exchange for a successful connection.

### 19.1.2.4 Obtaining the Replication Source Binary Log Coordinates

To configure the replica to start the replication process at the correct point, you need to note the source's current coordinates within its binary log.

#### Warning

This procedure uses `FLUSH TABLES WITH READ LOCK`, which blocks `COMMIT` operations for `InnoDB` tables.

If you are planning to shut down the source to create a data snapshot, you can optionally skip this procedure and instead store a copy of the binary log index file along with the data snapshot. In that situation, the source creates a new binary log file on restart. The source binary log coordinates where the replica must start the replication process are therefore the start of that new file, which is the next binary log file on the source following after the files that are listed in the copied binary log index file.

To obtain the source binary log coordinates, follow these steps:

1. Start a session on the source by connecting to it with the command-line client, and flush all tables and block write statements by executing the `FLUSH TABLES WITH READ LOCK` statement:

```
mysql> FLUSH TABLES WITH READ LOCK;
```

### Warning

Leave the client from which you issued the `FLUSH TABLES` statement running so that the read lock remains in effect. If you exit the client, the lock is released.

2. In a different session on the source, use the `SHOW BINARY LOG STATUS` statement to determine the current binary log file name and position:

```
mysql> SHOW BINARY LOG STATUS\G
***** 1. row *****
 File: mysql-bin.000003
 Position: 73
 Binlog_Do_DB: test
 Binlog_Ignore_DB: manual, mysql
Executed_Gtid_Set: 3E11FA47-71CA-11E1-9E33-C80AA9429562:1-5
1 row in set (0.00 sec)
```

The `File` column shows the name of the log file and the `Position` column shows the position within the file. In this example, the binary log file is `mysql-bin.000003` and the position is 73. Record these values. You need them later when you are setting up the replica. They represent the replication coordinates at which the replica should begin processing new updates from the source.

If the source has been running previously with binary logging disabled, the log file name and position values displayed by `SHOW BINARY LOG STATUS` or `mysqldump --source-data` are empty. In that case, the values that you need to use later when specifying the source's binary log file and position are the empty string ( `' '` ) and 4.

You now have the information you need to enable the replica to start reading from the source's binary log in the correct place to start replication.

The next step depends on whether you have existing data on the source. Choose one of the following options:

- If you have existing data that needs to be synchronized with the replica before you start replication, leave the client running so that the lock remains in place. This prevents any further changes being made, so that the data copied to the replica is in synchrony with the source. Proceed to [Section 19.1.2.5, “Choosing a Method for Data Snapshots”](#).
- If you are setting up a new source and replica combination, you can exit the first session to release the read lock. See [Setting Up Replication with New Source and Replicas](#) for how to proceed.

## 19.1.2.5 Choosing a Method for Data Snapshots

If the source database contains existing data it is necessary to copy this data to each replica. There are different ways to dump the data from the source database. The following sections describe possible options.

To select the appropriate method of dumping the database, choose between these options:

- Use the `mysqldump` tool to create a dump of all the databases you want to replicate. This is the recommended method, especially when using `InnoDB`.
- If your database is stored in binary portable files, you can copy the raw data files to a replica. This can be more efficient than using `mysqldump` and importing the file on each replica, because it skips the overhead of updating indexes as the `INSERT` statements are replayed. With storage engines such as `InnoDB` this is not recommended.

- Use MySQL Server's clone plugin to transfer all the data from an existing replica to a clone. For instructions to use this method, see [Section 7.6.7.7, “Cloning for Replication”](#).

#### Tip

To deploy multiple instances of MySQL, you can use [InnoDB Cluster](#) which enables you to easily administer a group of MySQL server instances in [MySQL Shell](#). InnoDB Cluster wraps MySQL Group Replication in a programmatic environment that enables you easily deploy a cluster of MySQL instances to achieve high availability. In addition, InnoDB Cluster interfaces seamlessly with [MySQL Router](#), which enables your applications to connect to the cluster without writing your own failover process. For similar use cases that do not require high availability, however, you can use [InnoDB ReplicaSet](#). Installation instructions for MySQL Shell can be found [here](#).

## Creating a Data Snapshot Using mysqldump

To create a snapshot of the data in an existing source database, use the [mysqldump](#) tool. Once the data dump has been completed, import this data into the replica before starting the replication process.

The following example dumps all databases to a file named `dbdump.db`, and includes the `--source-data` option which automatically appends the `CHANGE REPLICATION SOURCE TO` statement required on the replica to start the replication process:

```
$> mysqldump --all-databases --source-data > dbdump.db
```

#### Note

If you do not use `--source-data`, then it is necessary to lock all tables in a separate session manually. See [Section 19.1.2.4, “Obtaining the Replication Source Binary Log Coordinates”](#).

It is possible to exclude certain databases from the dump using the [mysqldump](#) tool. If you want to choose which databases to include in the dump, do not use `--all-databases`. Choose one of these options:

- Exclude all the tables in the database using `--ignore-table` option.
- Name only those databases which you want dumped using the `--databases` option.

#### Note

By default, if GTIDs are in use on the source (`gtid_mode=ON`), [mysqldump](#) includes the GTIDs from the `gtid_executed` set on the source in the dump output to add them to the `gtid_purged` set on the replica. If you are dumping only specific databases or tables, it is important to note that the value that is included by [mysqldump](#) includes the GTIDs of all transactions in the `gtid_executed` set on the source, even those that changed suppressed parts of the database, or other databases on the server that were not included in the partial dump. Check the description for [mysqldump's --set-gtid-purged](#) option to find the outcome of the default behavior for the MySQL Server versions you are using, and how to change the behavior if this outcome is not suitable for your situation.

For more information, see [Section 6.5.4, “mysqldump — A Database Backup Program”](#).

To import the data, either copy the dump file to the replica, or access the file from the source when connecting remotely to the replica.

## Creating a Data Snapshot Using Raw Data Files

This section describes how to create a data snapshot using the raw files which make up the database. Employing this method with a table using a storage engine that has complex caching or logging algorithms requires extra steps to produce a perfect “point in time” snapshot: the initial copy command could leave out cache information and logging updates, even if you have acquired a global read lock. How the storage engine responds to this depends on its crash recovery abilities.

If you use [InnoDB](#) tables, you can use the [mysqlbackup](#) command from the MySQL Enterprise Backup component to produce a consistent snapshot. This command records the log name and offset corresponding to the snapshot to be used on the replica. MySQL Enterprise Backup is a commercial product that is included as part of a MySQL Enterprise subscription. See [Section 32.1, “MySQL Enterprise Backup Overview”](#) for detailed information.

This method also does not work reliably if the source and replica have different values for [ft\\_stopword\\_file](#), [ft\\_min\\_word\\_len](#), or [ft\\_max\\_word\\_len](#) and you are copying tables having full-text indexes.

Assuming the above exceptions do not apply to your database, use the [cold backup](#) technique to obtain a reliable binary snapshot of [InnoDB](#) tables: do a [slow shutdown](#) of the MySQL Server, then copy the data files manually.

To create a raw data snapshot of [MyISAM](#) tables when your MySQL data files exist on a single file system, you can use standard file copy tools such as [cp](#) or [copy](#), a remote copy tool such as [scp](#) or [rsync](#), an archiving tool such as [zip](#) or [tar](#), or a file system snapshot tool such as [dump](#). If you are replicating only certain databases, copy only those files that relate to those tables. For [InnoDB](#), all tables in all databases are stored in the [system tablespace](#) files, unless you have the [innodb\\_file\\_per\\_table](#) option enabled.

The following files are not required for replication:

- Files relating to the [mysql](#) database.
- The replica's connection metadata repository file [master.info](#), if used; the use of this file is now deprecated (see [Section 19.2.4, “Relay Log and Replication Metadata Repositories”](#)).
- The source's binary log files, with the exception of the binary log index file if you are going to use this to locate the source binary log coordinates for the replica.
- Any relay log files.

Depending on whether you are using [InnoDB](#) tables or not, choose one of the following:

If you are using [InnoDB](#) tables, and also to get the most consistent results with a raw data snapshot, shut down the source server during the process, as follows:

1. Acquire a read lock and get the source's status. See [Section 19.1.2.4, “Obtaining the Replication Source Binary Log Coordinates”](#).
2. In a separate session, shut down the source server:

```
$> mysqladmin shutdown
```

3. Make a copy of the MySQL data files. The following examples show common ways to do this. You need to choose only one of them:

```
$> tar cf /tmp/db.tar ./data
```

```
$> zip -r /tmp/db.zip ./data
$> rsync --recursive ./data /tmp/dbdata
```

4. Restart the source server.

If you are not using [InnoDB](#) tables, you can get a snapshot of the system from a source without shutting down the server as described in the following steps:

1. Acquire a read lock and get the source's status. See [Section 19.1.2.4, “Obtaining the Replication Source Binary Log Coordinates”](#).
2. Make a copy of the MySQL data files. The following examples show common ways to do this. You need to choose only one of them:

```
$> tar cf /tmp/db.tar ./data
$> zip -r /tmp/db.zip ./data
$> rsync --recursive ./data /tmp/dbdata
```

3. In the client where you acquired the read lock, release the lock:

```
mysql> UNLOCK TABLES;
```

Once you have created the archive or copy of the database, copy the files to each replica before starting the replication process.

### 19.1.2.6 Setting Up Replicas

The following sections describe how to set up replicas. Before you proceed, ensure that you have:

- Configured the source with the necessary configuration properties. See [Section 19.1.2.1, “Setting the Replication Source Configuration”](#).
- Obtained the source status information, or a copy of the source's binary log index file made during a shutdown for the data snapshot. See [Section 19.1.2.4, “Obtaining the Replication Source Binary Log Coordinates”](#).
- On the source, released the read lock:

```
mysql> UNLOCK TABLES;
```

- On the replica, edited the MySQL configuration. See [Section 19.1.2.2, “Setting the Replica Configuration”](#).

The next steps depend on whether you have existing data to import to the replica or not. See [Section 19.1.2.5, “Choosing a Method for Data Snapshots”](#) for more information. Choose one of the following:

- If you do not have a snapshot of a database to import, see [Setting Up Replication with New Source and Replicas](#).
- If you have a snapshot of a database to import, see [Setting Up Replication with Existing Data](#).

### Setting Up Replication with New Source and Replicas

When there is no snapshot of a previous database to import, configure the replica to start replication from the new source.

To set up replication between a source and a new replica:

1. Start up the replica.
2. Execute a `CHANGE REPLICATION SOURCE TO` statement on the replica to set the source configuration. See [Section 19.1.2.7, “Setting the Source Configuration on the Replica”](#).

Perform these replica setup steps on each replica.

This method can also be used if you are setting up new servers but have an existing dump of the databases from a different server that you want to load into your replication configuration. By loading the data into a new source, the data is automatically replicated to the replicas.

If you are setting up a new replication environment using the data from a different existing database server to create a new source, run the dump file generated from that server on the new source. The database updates are automatically propagated to the replicas:

```
$> mysql -h source < fulldb.dump
```

## Setting Up Replication with Existing Data

When setting up replication with existing data, transfer the snapshot from the source to the replica before starting replication. The process for importing data to the replica depends on how you created the snapshot of data on the source.

### Tip

To deploy multiple instances of MySQL, you can use [InnoDB Cluster](#) which enables you to easily administer a group of MySQL server instances in [MySQL Shell](#). InnoDB Cluster wraps MySQL Group Replication in a programmatic environment that enables you easily deploy a cluster of MySQL instances to achieve high availability. In addition, InnoDB Cluster interfaces seamlessly with [MySQL Router](#), which enables your applications to connect to the cluster without writing your own failover process. For similar use cases that do not require high availability, however, you can use [InnoDB ReplicaSet](#). Installation instructions for MySQL Shell can be found [here](#).

### Note

If the replication source server or existing replica that you are copying to create the new replica has any scheduled events, ensure that these are disabled on the new replica before you start it. If an event runs on the new replica that has already run on the source, the duplicated operation causes an error. The Event Scheduler is controlled by the `event_scheduler` system variable (default `ON`), so events that are active on the original server run by default when the new replica starts up. To stop all events from running on the new replica, set the `event_scheduler` system variable to `OFF` or `DISABLED` on the new replica. Alternatively, you can use the `ALTER EVENT` statement to set individual events to `DISABLE` or `DISABLE ON REPLICA` to prevent them from running on the new replica. You can list the events on a server using the `SHOW` statement or the Information Schema `EVENTS` table. For more information, see [Section 19.5.1.16, “Replication of Invoked Features”](#).

As an alternative to creating a new replica in this way, MySQL Server's clone plugin can be used to transfer all the data and replication settings from an existing replica to a clone. For instructions to use this method, see [Section 7.6.7.7, “Cloning for Replication”](#).

Follow this procedure to set up replication with existing data:

1. If you used MySQL Server's clone plugin to create a clone from an existing replica (see [Section 7.6.7.7, "Cloning for Replication"](#)), the data is already transferred. Otherwise, import the data to the replica using one of the following methods.

- a. If you used `mysqldump`, start the replica server, ensuring that replication does not start by starting the server with `--skip-replica-start`. Then import the dump file:

```
$> mysql < fulldb.dump
```

- b. If you created a snapshot using the raw data files, extract the data files into your replica's data directory. For example:

```
$> tar xvf dbdump.tar
```

You may need to set permissions and ownership on the files so that the replica server can access and modify them. Then start the replica server, ensuring that replication does not start by using `--skip-replica-start`.

2. Configure the replica with the replication coordinates from the source. This tells the replica the binary log file and position within the file where replication needs to start. Also, configure the replica with the login credentials and host name of the source. For more information on the `CHANGE REPLICATION SOURCE TO` statement required, see [Section 19.1.2.7, "Setting the Source Configuration on the Replica"](#).
3. Start the replication threads by issuing a `START REPLICATION` statement.

After you have performed this procedure, the replica connects to the source and replicates any updates that have occurred on the source since the snapshot was taken. Error messages are issued to the replica's error log if it is not able to replicate for any reason.

The replica uses information logged in its connection metadata repository and applier metadata repository to keep track of how much of the source's binary log it has processed. By default, these repositories are tables named `slave_master_info` and `slave_relay_log_info` in the `mysql` database. Do *not* remove or edit these tables unless you know exactly what you are doing and fully understand the implications. Even in that case, it is preferred that you use the `CHANGE REPLICATION SOURCE TO` statement to change replication parameters. The replica uses the values specified in the statement to update the replication metadata repositories automatically. See [Section 19.2.4, "Relay Log and Replication Metadata Repositories"](#), for more information.

#### Note

The contents of the replica's connection metadata repository override some of the server options specified on the command line or in `my.cnf`. See [Section 19.1.6, "Replication and Binary Logging Options and Variables"](#), for more details.

A single snapshot of the source suffices for multiple replicas. To set up additional replicas, use the same source snapshot and follow the replica portion of the procedure just described.

### 19.1.2.7 Setting the Source Configuration on the Replica

To set up the replica to communicate with the source for replication, configure the replica with the necessary connection information. To do this, on the replica, execute the following `CHANGE REPLICATION SOURCE TO` statement, replacing the option values with the actual values relevant to your system:

```
mysql> CHANGE REPLICATION SOURCE TO
-> SOURCE_HOST='source_host_name',
-> SOURCE_USER='replication_user_name',
```

```
-> SOURCE_PASSWORD='replication_password',
-> SOURCE_LOG_FILE='recorded_log_file_name',
-> SOURCE_LOG_POS=recorded_log_position;
```

## Note

Replication cannot use Unix socket files. You must be able to connect to the source MySQL server using TCP/IP.

The `CHANGE REPLICATION SOURCE TO` statement has other options as well. For example, it is possible to set up secure replication using SSL. For a full list of options, and information about the maximum permissible length for the string-valued options, see [Section 15.4.2.2, “CHANGE REPLICATION SOURCE TO Statement”](#).

## Important

As noted in [Section 19.1.2.3, “Creating a User for Replication”](#), if you are not using a secure connection and the user account named in the `SOURCE_USER` option authenticates with the `caching_sha2_password` plugin (the default in MySQL 9.1), you must specify the `SOURCE_PUBLIC_KEY_PATH` or `GET_SOURCE_PUBLIC_KEY` option in the `CHANGE REPLICATION SOURCE TO` statement to enable RSA key pair-based password exchange.

## 19.1.2.8 Adding Replicas to a Replication Environment

You can add another replica to an existing replication configuration without stopping the source server. To do this, you can set up the new replica by copying the data directory of an existing replica, and giving the new replica a different server ID (which is user-specified) and server UUID (which is generated at startup).

## Note

If the replication source server or existing replica that you are copying to create the new replica has any scheduled events, ensure that these are disabled on the new replica before you start it. If an event runs on the new replica that has already run on the source, the duplicated operation causes an error. The Event Scheduler is controlled by the `event_scheduler` system variable, which defaults to `ON`, so events that are active on the original server run by default when the new replica starts up. To stop all events from running on the new replica, set the `event_scheduler` system variable to `OFF` or `DISABLED` on the new replica. Alternatively, you can use the `ALTER EVENT` statement to set individual events to `DISABLE` or `DISABLE ON REPLICA` to prevent them from running on the new replica. You can list the events on a server using the `SHOW` statement or the Information Schema `EVENTS` table. For more information, see [Section 19.5.1.16, “Replication of Invoked Features”](#).

As an alternative to creating a new replica in this way, MySQL Server's clone plugin can be used to transfer all the data and replication settings from an existing replica to a clone. For instructions to use this method, see [Section 7.6.7.7, “Cloning for Replication”](#).

To duplicate an existing replica without cloning, follow these steps:

1. Stop the existing replica and record the replica status information, particularly the source binary log file and relay log file positions. You can view the replica status either in the Performance Schema replication tables (see [Section 29.12.11, “Performance Schema Replication Tables”](#)), or by issuing `SHOW REPLICATION STATUS` as follows:

```
mysql> STOP REPLICA;
mysql> SHOW REPLICA STATUS\G
```

2. Shut down the existing replica:

```
$> mysqladmin shutdown
```

3. Copy the data directory from the existing replica to the new replica, including the log files and relay log files. You can do this by creating an archive using `tar` or `WinZip`, or by performing a direct copy using a tool such as `cp` or `rsync`.

### Important

- Before copying, verify that all the files relating to the existing replica actually are stored in the data directory. For example, the `InnoDB` system tablespace, undo tablespace, and redo log might be stored in an alternative location. `InnoDB` tablespace files and file-per-table tablespaces might have been created in other directories. The binary logs and relay logs for the replica might be in their own directories outside the data directory. Check through the system variables that are set for the existing replica and look for any alternative paths that have been specified. If you find any, copy these directories over as well.
- During copying, if files have been used for the replication metadata repositories (see [Section 19.2.4, “Relay Log and Replication Metadata Repositories”](#)), ensure that you also copy these files from the existing replica to the new replica. If tables have been used for the repositories (the default, the tables are in the data directory).
- After copying, delete the `auto.cnf` file from the copy of the data directory on the new replica, so that the new replica is started with a different generated server UUID. The server UUID must be unique.

A common problem that is encountered when adding new replicas is that the new replica fails with a series of warning and error messages like these:

```
071118 16:44:10 [Warning] Neither --relay-log nor --relay-log-index were used; so
replication may break when this MySQL server acts as a replica and has his hostname
changed!! Please use '--relay-log=new_replica_hostname-relay-bin' to avoid this problem.
071118 16:44:10 [ERROR] Failed to open the relay log './old_replica_hostname-relay-bin.003525'
(relay_log_pos 22940879)
071118 16:44:10 [ERROR] Could not find target log during relay log initialization
071118 16:44:10 [ERROR] Failed to initialize the master info structure
```

This situation can occur if the `relay_log` system variable is not specified, as the relay log files contain the host name as part of their file names. This is also true of the relay log index file if the `relay_log_index` system variable is not used. For more information about these variables, see [Section 19.1.6, “Replication and Binary Logging Options and Variables”](#).

To avoid this problem, use the same value for `relay_log` on the new replica that was used on the existing replica. If this option was not set explicitly on the existing replica, use `existing_replica_hostname-relay-bin`. If this is not possible, copy the existing replica's relay log index file to the new replica and set the `relay_log_index` system variable on the new replica to match what was used on the existing replica. If this option was not set explicitly on the existing replica, use `existing_replica_hostname-relay-bin.index`. Alternatively, if you have already tried to start the new replica after following the remaining steps in this section and have encountered errors like those described previously, then perform the following steps:

- a. If you have not already done so, issue `STOP REPLICATION` on the new replica.  
  
If you have already started the existing replica again, issue `STOP REPLICATION` on the existing replica as well.
  - b. Copy the contents of the existing replica's relay log index file into the new replica's relay log index file, making sure to overwrite any content already in the file.
  - c. Proceed with the remaining steps in this section.
4. When copying is complete, restart the existing replica.
  5. On the new replica, edit the configuration and give the new replica a unique server ID (using the `server_id` system variable) that is not used by the source or any of the existing replicas.
  6. Start the new replica server, ensuring that replication does not start yet by specifying `--skip-replica-start`. Use the Performance Schema replication tables or issue `SHOW REPLICATION STATUS` to confirm that the new replica has the correct settings when compared with the existing replica. Also display the server ID and server UUID and verify that these are correct and unique for the new replica.
  7. Start the replica threads by issuing a `START REPLICATION` statement. The new replica now uses the information in its connection metadata repository to start the replication process.

### 19.1.3 Replication with Global Transaction Identifiers

This section explains transaction-based replication using *global transaction identifiers* (GTIDs). When using GTIDs, each transaction can be identified and tracked as it is committed on the originating server and applied by any replicas; this means that it is not necessary when using GTIDs to refer to log files or positions within those files when starting a new replica or failing over to a new source, which greatly simplifies these tasks. Because GTID-based replication is completely transaction-based, it is simple to determine whether sources and replicas are consistent; as long as all transactions committed on a source are also committed on a replica, consistency between the two is guaranteed. You can use either statement-based or row-based replication with GTIDs (see [Section 19.2.1, “Replication Formats”](#)); however, for best results, we recommend that you use the row-based format.

GTIDs are always preserved between source and replica. This means that you can always determine the source for any transaction applied on any replica by examining its binary log. In addition, once a transaction with a given GTID is committed on a given server, any subsequent transaction having the same GTID is ignored by that server. Thus, a transaction committed on the source can be applied no more than once on the replica, which helps to guarantee consistency.

This section discusses the following topics:

- How GTIDs are defined and created, and how they are represented in a MySQL server (see [Section 19.1.3.1, “GTID Format and Storage”](#)).
- The life cycle of a GTID (see [Section 19.1.3.2, “GTID Life Cycle”](#)).
- The auto-positioning function for synchronizing a replica and source that use GTIDs (see [Section 19.1.3.3, “GTID Auto-Positioning”](#)).
- A general procedure for setting up and starting GTID-based replication (see [Section 19.1.3.4, “Setting Up Replication Using GTIDs”](#)).
- Suggested methods for provisioning new replication servers when using GTIDs (see [Section 19.1.3.5, “Using GTIDs for Failover and Scaleout”](#)).

- Restrictions and limitations that you should be aware of when using GTID-based replication (see [Section 19.1.3.7, “Restrictions on Replication with GTIDs”](#)).
- Stored functions that you can use to work with GTIDs (see [Section 19.1.3.8, “Stored Function Examples to Manipulate GTIDs”](#)).

For information about MySQL Server options and variables relating to GTID-based replication, see [Section 19.1.6.5, “Global Transaction ID System Variables”](#). See also [Section 14.18.2, “Functions Used with Global Transaction Identifiers \(GTIDs\)”](#), which describes SQL functions supported by MySQL 9.1 for use with GTIDs.

### 19.1.3.1 GTID Format and Storage

A global transaction identifier (GTID) is a unique identifier created and associated with each transaction committed on the server of origin (the source). This identifier is unique not only to the server on which it originated, but is unique across all servers in a given replication topology.

GTID assignment distinguishes between client transactions, which are committed on the source, and replicated transactions, which are reproduced on a replica. When a client transaction is committed on the source, it is assigned a new GTID, provided that the transaction was written to the binary log. Client transactions are guaranteed to have monotonically increasing GTIDs without gaps between the generated numbers. If a client transaction is not written to the binary log (for example, because the transaction was filtered out, or the transaction was read-only), it is not assigned a GTID on the server of origin.

Replicated transactions retain the same GTID that was assigned to the transaction on the server of origin. The GTID is present before the replicated transaction begins to execute, and is persisted even if the replicated transaction is not written to the binary log on the replica, or is filtered out on the replica. The `mysql.gtid_executed` system table is used to preserve the assigned GTIDs of all the transactions applied on a MySQL server, except those that are stored in a currently active binary log file.

The auto-skip function for GTIDs means that a transaction committed on the source can be applied no more than once on the replica, which helps to guarantee consistency. Once a transaction with a given GTID has been committed on a given server, any attempt to execute a subsequent transaction with the same GTID is ignored by that server. No error is raised, and no statement in the transaction is executed.

If a transaction with a given GTID has started to execute on a server, but has not yet committed or rolled back, any attempt to start a concurrent transaction on the server with the same GTID blocks. The server neither begins to execute the concurrent transaction nor returns control to the client. Once the first attempt at the transaction commits or rolls back, concurrent sessions that were blocking on the same GTID may proceed. If the first attempt rolled back, one concurrent session proceeds to attempt the transaction, and any other concurrent sessions that were blocking on the same GTID remain blocked. If the first attempt committed, all the concurrent sessions stop being blocked, and auto-skip all the statements of the transaction.

A GTID is represented as a pair of coordinates, separated by a colon character (:), as shown here:

```
GTID = source_id:transaction_id
```

The *source\_id* identifies the originating server. Normally, the source's `server_uuid` is used for this purpose. The *transaction\_id* is a sequence number determined by the order in which the transaction was committed on the source. For example, the first transaction to be committed has `1` as its *transaction\_id*, and the tenth transaction to be committed on the same originating server is assigned a *transaction\_id* of `10`. It is not possible for a transaction to have `0` as a sequence number in a GTID. For example, the twenty-third transaction to be committed originally on the server with the UUID `3E11FA47-71CA-11E1-9E33-C80AA9429562` has this GTID:

```
3E11FA47-71CA-11E1-9E33-C80AA9429562:23
```

The upper limit for sequence numbers for GTIDs on a server instance is the number of non-negative values for a signed 64-bit integer ( $2^{63} - 1$ , or 9223372036854775807). If the server runs out of GTIDs, it takes the action specified by `binlog_error_action`. A warning message is issued when the server instance is approaching the limit.

MySQL 9.1 also supports tagged GTIDs. A tagged GTID consists of three parts, separated by colon characters, as shown here:

```
GTID = source_id:tag:transaction_id
```

In this case, the `source_id` and `transaction_id` are as defined previously. The `tag` is a user-defined string used to identify a specific group of transactions; see the description of the `gtid_next` system variable for permitted syntax. *Example:* the one-hundred-seventeenth transaction to be committed originally on the server with the UUID `ed102faf-eb00-11eb-8f20-0c5415bfaa1d` and the tag `Domain_1` has this GTID:

```
ed102faf-eb00-11eb-8f20-0c5415bfaa1d:Domain_1:117
```

The GTID for a transaction is shown in the output from `mysqlbinlog`, and it is used to identify an individual transaction in the Performance Schema replication status tables, for example, `replication_applier_status_by_worker`. The value stored by the `gtid_next` system variable (`@@GLOBAL.gtid_next`) is a single GTID.

## GTID Sets

A GTID set is a set comprising one or more single GTIDs or ranges of GTIDs. GTID sets are used in a MySQL server in several ways. For example, the values stored by the `gtid_executed` and `gtid_purged` system variables are GTID sets. The `START REPLICA` options `UNTIL SQL_BEFORE_GTIDS` and `UNTIL SQL_AFTER_GTIDS` can be used to make a replica process transactions only up to the first GTID in a GTID set, or stop after the last GTID in a GTID set. The built-in functions `GTID_SUBSET()` and `GTID_SUBTRACT()` require GTID sets as input.

A range of GTIDs originating from the same server can be collapsed into a single expression, as shown here:

```
3E11FA47-71CA-11E1-9E33-C80AA9429562:1-5
```

The above example represents the first through fifth transactions originating on the MySQL server whose `server_uuid` is `3E11FA47-71CA-11E1-9E33-C80AA9429562`. Multiple single GTIDs or ranges of GTIDs originating from the same server can also be included in a single expression, with the GTIDs or ranges separated by colons, as in the following example:

```
3E11FA47-71CA-11E1-9E33-C80AA9429562:1-3:11:47-49
```

A GTID set can include any combination of single GTIDs and ranges of GTIDs, and it can include GTIDs originating from different servers. This example shows the GTID set stored in the `gtid_executed` system variable (`@@GLOBAL.gtid_executed`) of a replica that has applied transactions from more than one source:

```
2174B383-5441-11E8-B90A-C80AA9429562:1-3, 24DA167-0C0C-11E8-8442-00059A3C7B00:1-19
```

When GTID sets are returned from server variables, UUIDs are in alphabetical order, and numeric intervals are merged and in ascending order.

When constructing a GTID set, a user-defined tag is treated as part of the UUID. This means that multiple GTIDs originating from the same server and having the same tag can be included in a single expression, as shown in this example:

```
3E11FA47-71CA-11E1-9E33-C80AA9429562:Domain_1:1-3:11:47-49
```

GTIDs originating from the same server but having different tags are treated in a manner similar to those originating from different servers, like this:

```
3E11FA47-71CA-11E1-9E33-C80AA9429562:Domain_1:1-3:15-21, 3E11FA47-71CA-11E1-9E33-C80AA9429562:Domain_2:8-5
```

The complete syntax for a GTID set is as follows:

```
gtid_set:
 uuid_set [, uuid_set] ...
 | ''

uuid_set:
 uuid:[tag:]interval[:interval]...

uuid:
 hhhhhhhh-hhhh-hhhh-hhhh-hhhhhhhhhhhh

h:
 [0-9|A-F]

tag:
 [a-z_][a-z0-9_]{0,31}

interval:
 m[-n]

 (m >= 1; n > m)
```

## mysql.gtid\_executed Table

GTIDs are stored in a table named `gtid_executed`, in the `mysql` database. A row in this table contains, for each GTID or set of GTIDs that it represents, the UUID of the originating server, the user-defined tag (if there is one), and the starting and ending transaction IDs of the set; for a row referencing only a single GTID, these last two values are the same.

The `mysql.gtid_executed` table is created (if it does not already exist) when MySQL Server is installed or upgraded, using a `CREATE TABLE` statement similar to that shown here:

```
CREATE TABLE gtid_executed (
 source_uuid CHAR(36) NOT NULL,
 interval_start BIGINT NOT NULL,
 interval_end BIGINT NOT NULL,
 gtid_tag CHAR(32) NOT NULL,
 PRIMARY KEY (source_uuid, gtid_tag, interval_start)
);
```

### Warning

As with other MySQL system tables, do not attempt to create or modify this table yourself.

The `mysql.gtid_executed` table is provided for internal use by the MySQL server. It enables a replica to use GTIDs when binary logging is disabled on the replica, and it enables retention of the GTID state when the binary logs have been lost. Note that the `mysql.gtid_executed` table is cleared if you issue `RESET BINARY LOGS AND GTIDS`.

GTIDs are stored in the `mysql.gtid_executed` table only when `gtid_mode` is `ON` or `ON_PERMISSIVE`. If binary logging is disabled (`log_bin` is `OFF`), or if `log_replica_updates` is disabled, the server stores

the GTID belonging to each transaction together with the transaction in the buffer when the transaction is committed, and the background thread adds the contents of the buffer periodically as one or more entries to the `mysql.gtid_executed` table. In addition, the table is compressed periodically at a user-configurable rate, as described in [mysql.gtid\\_executed Table Compression](#).

If binary logging is enabled (`log_bin` is `ON`), for the `InnoDB` storage engine only, the server updates the `mysql.gtid_executed` table in the same way as when binary logging or replica update logging is disabled, storing the GTID for each transaction at transaction commit time. For other storage engines, the server updates the `mysql.gtid_executed` table only when the binary log is rotated or the server is shut down. At these times, the server writes GTIDs for all transactions that were written into the previous binary log into the `mysql.gtid_executed` table.

If the `mysql.gtid_executed` table cannot be accessed for writes, and the binary log file is rotated for any reason other than reaching the maximum file size (`max_binlog_size`), the current binary log file continues to be used. An error message is returned to the client that requested the rotation, and a warning is logged on the server. If the `mysql.gtid_executed` table cannot be accessed for writes and `max_binlog_size` is reached, the server responds according to its `binlog_error_action` setting. If `IGNORE_ERROR` is set, an error is logged on the server and binary logging is halted, or if `ABORT_SERVER` is set, the server shuts down.

## mysql.gtid\_executed Table Compression

Over the course of time, the `mysql.gtid_executed` table can become filled with many rows referring to individual GTIDs that originate on the same server, have the same GTID tag (if any), and whose transaction IDs make up a range, similar to what is shown here:

source_uuid	interval_start	interval_end	gtid_tag
3E11FA47-71CA-11E1-9E33-C80AA9429562	31	31	Domain_1
3E11FA47-71CA-11E1-9E33-C80AA9429562	32	32	Domain_1
3E11FA47-71CA-11E1-9E33-C80AA9429562	33	33	Domain_1
3E11FA47-71CA-11E1-9E33-C80AA9429562	34	34	Domain_1
3E11FA47-71CA-11E1-9E33-C80AA9429562	35	35	Domain_1
3E11FA47-71CA-11E1-9E33-C80AA9429562	36	36	Domain_2
3E11FA47-71CA-11E1-9E33-C80AA9429562	37	37	Domain_2
3E11FA47-71CA-11E1-9E33-C80AA9429562	38	38	Domain_2
3E11FA47-71CA-11E1-9E33-C80AA9429562	39	39	Domain_2
3E11FA47-71CA-11E1-9E33-C80AA9429562	40	40	Domain_1
3E11FA47-71CA-11E1-9E33-C80AA9429562	41	41	Domain_1
3E11FA47-71CA-11E1-9E33-C80AA9429562	42	42	Domain_1
3E11FA47-71CA-11E1-9E33-C80AA9429562	43	43	Domain_1
3E11FA47-71CA-11E1-9E33-C80AA9429562	44	44	Domain_2
3E11FA47-71CA-11E1-9E33-C80AA9429562	45	45	Domain_2
3E11FA47-71CA-11E1-9E33-C80AA9429562	46	46	Domain_2
3E11FA47-71CA-11E1-9E33-C80AA9429562	47	47	Domain_1
3E11FA47-71CA-11E1-9E33-C80AA9429562	48	48	Domain_1
...			

To save space, the MySQL server can compress the `mysql.gtid_executed` table periodically by replacing each such set of rows with a single row that spans the entire interval of transaction identifiers, like this:

source_uuid	interval_start	interval_end	gtid_tag
3E11FA47-71CA-11E1-9E33-C80AA9429562	31	35	Domain_1
3E11FA47-71CA-11E1-9E33-C80AA9429562	36	39	Domain_2
3E11FA47-71CA-11E1-9E33-C80AA9429562	40	43	Domain_1
3E11FA47-71CA-11E1-9E33-C80AA9429562	44	46	Domain_2
3E11FA47-71CA-11E1-9E33-C80AA9429562	47	48	Domain_1

...

The server can carry out compression using a dedicated foreground thread named `thread/sql/compress_gtid_table`. This thread is not listed in the output of `SHOW PROCESSLIST`, but it can be viewed as a row in the `threads` table, as shown here:

```
mysql> SELECT * FROM performance_schema.threads WHERE NAME LIKE '%gtid%'\G
***** 1. row *****
 THREAD_ID: 26
 NAME: thread/sql/compress_gtid_table
 TYPE: FOREGROUND
 PROCESSLIST_ID: 1
PROCESSLIST_USER: NULL
PROCESSLIST_HOST: NULL
 PROCESSLIST_DB: NULL
PROCESSLIST_COMMAND: Daemon
PROCESSLIST_TIME: 1509
PROCESSLIST_STATE: Suspending
PROCESSLIST_INFO: NULL
 PARENT_THREAD_ID: 1
 ROLE: NULL
 INSTRUMENTED: YES
 HISTORY: YES
CONNECTION_TYPE: NULL
 THREAD_OS_ID: 18677
```

When binary logging is enabled on the server, this compression method is not used, and instead the `mysql.gtid_executed` table is compressed on each binary log rotation. However, when binary logging is disabled on the server, the `thread/sql/compress_gtid_table` thread sleeps until a specified number of transactions have been executed, then wakes up to perform compression of the `mysql.gtid_executed` table. It then sleeps until the same number of transactions have taken place, then wakes up to perform the compression again, repeating this loop indefinitely. The number of transactions that elapse before the table is compressed, and thus the compression rate, is controlled by the value of the `gtid_executed_compression_period` system variable. Setting that value to 0 means that the thread never wakes up, meaning that this explicit compression method is not used. Instead, compression occurs implicitly as required.

InnoDB transactions are written to the `mysql.gtid_executed` table by a process separate from that used for transactions involving storage engines other than InnoDB. This process is controlled by a different thread, `innodb/clone_gtid_thread`. This GTID persister thread collects GTIDs in groups, flushes them to the `mysql.gtid_executed` table, then compresses the table. If the server has a mix of InnoDB transactions and non-InnoDB transactions, which are written to the `mysql.gtid_executed` table individually, the compression carried out by the `compress_gtid_table` thread interferes with the work of the GTID persister thread and can slow it significantly. For this reason, it is recommended that you set `gtid_executed_compression_period` to 0, so that the `compress_gtid_table` thread is never activated.

The default value for `gtid_executed_compression_period` is 0, and all transactions regardless of storage engine are written to the `mysql.gtid_executed` table by the GTID persister thread.

When a server instance is started, if `gtid_executed_compression_period` is set to a nonzero value and the `thread/sql/compress_gtid_table` thread is launched, in most server configurations, explicit compression is performed for the `mysql.gtid_executed` table. Compression is triggered by the thread launch.

### 19.1.3.2 GTID Life Cycle

The life cycle of a GTID consists of the following steps:

1. A transaction is executed and committed on the source. This client transaction is assigned a GTID composed of the source's UUID and the smallest nonzero transaction sequence number not yet used on this server. The GTID is written to the source's binary log (immediately preceding the transaction itself in the log). If a client transaction is not written to the binary log (for example, because the transaction was filtered out, or the transaction was read-only), it is not assigned a GTID.
2. If a GTID was assigned for the transaction, the GTID is persisted atomically at commit time by writing it to the binary log at the beginning of the transaction (as a `Gtid_log_event`). Whenever the binary log is rotated or the server is shut down, the server writes GTIDs for all transactions that were written into the previous binary log file into the `mysql.gtid_executed` table.
3. If a GTID was assigned for the transaction, the GTID is externalized non-atomically (very shortly after the transaction is committed) by adding it to the set of GTIDs in the `gtid_executed` system variable (`@@GLOBAL.gtid_executed`). This GTID set contains a representation of the set of all committed GTID transactions, and it is used in replication as a token that represents the server state. With binary logging enabled (as required for the source), the set of GTIDs in the `gtid_executed` system variable is a complete record of the transactions applied, but the `mysql.gtid_executed` table is not, because the most recent history is still in the current binary log file.
4. After the binary log data is transmitted to the replica and stored in the replica's relay log (using established mechanisms for this process, see [Section 19.2, "Replication Implementation"](#), for details), the replica reads the GTID and sets the value of its `gtid_next` system variable as this GTID. This tells the replica that the next transaction must be logged using this GTID. It is important to note that the replica sets `gtid_next` in a session context.
5. The replica verifies that no thread has yet taken ownership of the GTID in `gtid_next` in order to process the transaction. By reading and checking the replicated transaction's GTID first, before processing the transaction itself, the replica guarantees not only that no previous transaction having this GTID has been applied on the replica, but also that no other session has already read this GTID but has not yet committed the associated transaction. So if multiple clients attempt to apply the same transaction concurrently, the server resolves this by letting only one of them execute. The `gtid_owned` system variable (`@@GLOBAL.gtid_owned`) for the replica shows each GTID that is currently in use and the ID of the thread that owns it. If the GTID has already been used, no error is raised, and the auto-skip function is used to ignore the transaction.
6. If the GTID has not been used, the replica applies the replicated transaction. Because `gtid_next` is set to the GTID already assigned by the source, the replica does not attempt to generate a new GTID for this transaction, but instead uses the GTID stored in `gtid_next`.
7. If binary logging is enabled on the replica, the GTID is persisted atomically at commit time by writing it to the binary log at the beginning of the transaction (as a `Gtid_log_event`). Whenever the binary log is rotated or the server is shut down, the server writes GTIDs for all transactions that were written into the previous binary log file into the `mysql.gtid_executed` table.
8. If binary logging is disabled on the replica, the GTID is persisted atomically by writing it directly into the `mysql.gtid_executed` table. MySQL appends a statement to the transaction to insert the GTID into the table. This operation is atomic for DDL statements as well as for DML statements. In this situation, the `mysql.gtid_executed` table is a complete record of the transactions applied on the replica.
9. Very shortly after the replicated transaction is committed on the replica, the GTID is externalized non-atomically by adding it to the set of GTIDs in the `gtid_executed` system variable (`@@GLOBAL.gtid_executed`) for the replica. As for the source, this GTID set contains a representation of the set of all committed GTID transactions. If binary logging is disabled on the replica, the `mysql.gtid_executed` table is also a complete record of the transactions applied on the replica. If binary logging is enabled on the replica, meaning that some GTIDs are only recorded in the binary log, the set of GTIDs in the `gtid_executed` system variable is the only complete record.

Client transactions that are completely filtered out on the source are not assigned a GTID, therefore they are not added to the set of transactions in the `gtid_executed` system variable, or added to the `mysql.gtid_executed` table. However, the GTIDs of replicated transactions that are completely filtered out on the replica are persisted. If binary logging is enabled on the replica, the filtered-out transaction is written to the binary log as a `Gtid_log_event` followed by an empty transaction containing only `BEGIN` and `COMMIT` statements. If binary logging is disabled, the GTID of the filtered-out transaction is written to the `mysql.gtid_executed` table. Preserving the GTIDs for filtered-out transactions ensures that the `mysql.gtid_executed` table and the set of GTIDs in the `gtid_executed` system variable can be compressed. It also ensures that the filtered-out transactions are not retrieved again if the replica reconnects to the source, as explained in [Section 19.1.3.3, “GTID Auto-Positioning”](#).

On a multithreaded replica (with `replica_parallel_workers > 0`), transactions can be applied in parallel, so replicated transactions can commit out of order (unless `replica_preserve_commit_order = 1`). When that happens, the set of GTIDs in the `gtid_executed` system variable contains multiple GTID ranges with gaps between them. (On a source or a single-threaded replica, there are monotonically increasing GTIDs without gaps between the numbers.) Gaps on multithreaded replicas only occur among the most recently applied transactions, and are filled in as replication progresses. When replication threads are stopped cleanly using the `STOP REPLICATION` statement, ongoing transactions are applied so that the gaps are filled in. In the event of a shutdown such as a server failure or the use of the `KILL` statement to stop replication threads, the gaps might remain.

## What changes are assigned a GTID?

The typical scenario is that the server generates a new GTID for a committed transaction. However, GTIDs can also be assigned to other changes besides transactions, and in some cases a single transaction can be assigned multiple GTIDs.

Every database change (DDL or DML) that is written to the binary log is assigned a GTID. This includes changes that are autocommitted, and changes that are committed using `BEGIN` and `COMMIT` or `START TRANSACTION` statements. A GTID is also assigned to the creation, alteration, or deletion of a database, and of a non-table database object such as a procedure, function, trigger, event, view, user, role, or grant.

Non-transactional updates as well as transactional updates are assigned GTIDs. In addition, for a non-transactional update, if a disk write failure occurs while attempting to write to the binary log cache and a gap is therefore created in the binary log, the resulting incident log event is assigned a GTID.

When a table is automatically dropped by a generated statement in the binary log, a GTID is assigned to the statement. Temporary tables are dropped automatically when a replica begins to apply events from a source that has just been started, and when statement-based replication is in use (`binlog_format=STATEMENT`) and a user session that has open temporary tables disconnects. Tables that use the `MEMORY` storage engine are deleted automatically the first time they are accessed after the server is started, because rows might have been lost during the shutdown.

When a transaction is not written to the binary log on the server of origin, the server does not assign a GTID to it. This includes transactions that are rolled back and transactions that are executed while binary logging is disabled on the server of origin, either globally (with `--skip-log-bin` specified in the server's configuration) or for the session (`SET @@SESSION.sql_log_bin = 0`). This also includes no-op transactions when row-based replication is in use (`binlog_format=ROW`).

XA transactions are assigned separate GTIDs for the `XA PREPARE` phase of the transaction and the `XA COMMIT` or `XA ROLLBACK` phase of the transaction. XA transactions are persistently prepared so that users can commit them or roll them back in the case of a failure (which in a replication topology might include a failover to another server). The two parts of the transaction are therefore replicated separately, so they must have their own GTIDs, even though a non-XA transaction that is rolled back would not have a GTID.

In the following special cases, a single statement can generate multiple transactions, and therefore be assigned multiple GTIDs:

- A stored procedure is invoked that commits multiple transactions. One GTID is generated for each transaction that the procedure commits.
- A multi-table `DROP TABLE` statement drops tables of different types. Multiple GTIDs can be generated if any of the tables use storage engines that do not support atomic DDL, or if any of the tables are temporary tables.
- A `CREATE TABLE ... SELECT` statement is issued when row-based replication is in use (`binlog_format=ROW`). One GTID is generated for the `CREATE TABLE` action and one GTID is generated for the row-insert actions.

## The `gtid_next` System Variable

By default, for new transactions committed in user sessions, the server automatically generates and assigns a new GTID. When the transaction is applied on a replica, the GTID from the server of origin is preserved. You can change this behavior by setting the session value of the `gtid_next` system variable:

- When `gtid_next` is set to `AUTOMATIC` (the default) and a transaction is committed and written to the binary log, the server automatically generates and assigns a new GTID. If a transaction is rolled back or not written to the binary log for another reason, the server does not generate and assign a GTID.
- If you set `gtid_next` to `AUTOMATIC:TAG`, a new GTID including the specified tag is assigned to each new transaction.
- If you set `gtid_next` to a valid GTID (consisting of a UUID, an optional tag, and a transaction sequence number, separated by a colon), the server assigns that GTID to your transaction. This GTID is assigned and added to `gtid_executed` even when the transaction is not written to the binary log, or when the transaction is empty.

Note that after you set `gtid_next` to a specific GTID (in either `UUID:NUMBER` or `UUID:TAG:NUMBER` format), and the transaction has been committed or rolled back, an explicit `SET @@SESSION.gtid_next` statement must be issued before any other statement. You can use this to set the GTID value back to `AUTOMATIC` if you do not want to assign any more GTIDs explicitly.

When replication applier threads apply replicated transactions, they use this technique, setting `@@SESSION.gtid_next` explicitly to the GTID of the replicated transaction as assigned on the server of origin. This means the GTID from the server of origin is retained, rather than a new GTID being generated and assigned by the replica. It also means the GTID is added to `gtid_executed` on the replica even when binary logging or replica update logging is disabled on the replica, or when the transaction is a no-op or is filtered out on the replica.

It is possible for a client to simulate a replicated transaction by setting `@@SESSION.gtid_next` to a specific GTID before executing the transaction. This technique is used by `mysqlbinlog` to generate a dump of the binary log that the client can replay to preserve GTIDs. A simulated replicated transaction committed through a client is completely equivalent to a replicated transaction committed through a replication applier thread, and they cannot be distinguished after the fact.

## The `gtid_purged` System Variable

The set of GTIDs in the `gtid_purged` system variable (`@@GLOBAL.gtid_purged`) contains the GTIDs of all the transactions that have been committed on the server, but that do not exist in any binary log file on the server. `gtid_purged` is a subset of `gtid_executed`. The following categories of GTIDs are in `gtid_purged`:

- GTIDs of replicated transactions that were committed with binary logging disabled on the replica.
- GTIDs of transactions that were written to a binary log file that has now been purged.
- GTIDs that were added explicitly to the set by the statement `SET @@GLOBAL.gtid_purged`.

You can change the value of `gtid_purged` in order to record on the server that the transactions in a certain GTID set have been applied, although they do not exist in any binary log on the server. When you add GTIDs to `gtid_purged`, they are also added to `gtid_executed`. An example use case for this action is when you are restoring a backup of one or more databases on a server, but you do not have the relevant binary logs containing the transactions on the server. You can also choose whether to replace the whole GTID set in `gtid_purged` with a specified GTID set, or to add a specified GTID set to the GTIDs already in `gtid_purged`. For details of how to do this, see the description for `gtid_purged`.

The sets of GTIDs in the `gtid_executed` and `gtid_purged` system variables are initialized when the server starts. Every binary log file begins with the event `Previous_gtid_log_event`, which contains the set of GTIDs in all previous binary log files (composed from the GTIDs in the preceding file's `Previous_gtid_log_event`, and the GTIDs of every `Gtid_log_event` in the preceding file itself). The contents of `Previous_gtid_log_event` in the oldest and most recent binary log files are used to compute the `gtid_executed` and `gtid_purged` sets at server startup:

- `gtid_executed` is computed as the union of the GTIDs in `Previous_gtid_log_event` in the most recent binary log file, the GTIDs of transactions in that binary log file, and the GTIDs stored in the `mysql.gtid_executed` table. This GTID set contains all the GTIDs that have been used (or added explicitly to `gtid_purged`) on the server, whether or not they are currently in a binary log file on the server. It does not include the GTIDs for transactions that are currently being processed on the server (`@@GLOBAL.gtid_owned`).
- `gtid_purged` is computed by first adding the GTIDs in `Previous_gtid_log_event` in the most recent binary log file and the GTIDs of transactions in that binary log file. This step gives the set of GTIDs that are currently, or were once, recorded in a binary log on the server (`gtids_in_binlog`). Next, the GTIDs in `Previous_gtid_log_event` in the oldest binary log file are subtracted from `gtids_in_binlog`. This step gives the set of GTIDs that are currently recorded in a binary log on the server (`gtids_in_binlog_not_purged`). Finally, `gtids_in_binlog_not_purged` is subtracted from `gtid_executed`. The result is the set of GTIDs that have been used on the server, but are not currently recorded in a binary log file on the server, and this result is used to initialize `gtid_purged`.

## Resetting the GTID Execution History

If you need to reset the GTID execution history on a server, use the `RESET BINARY LOGS AND GTIDS` statement. You might need to do this after carrying out test queries to verify a replication setup on new GTID-enabled servers, or when you want to join a new server to a replication group but it contains some unwanted local transactions that are not accepted by Group Replication.

### Warning

Use `RESET BINARY LOGS AND GTIDS` with caution to avoid losing any wanted GTID execution history and binary log files.

Before issuing `RESET BINARY LOGS AND GTIDS`, ensure that you have backups of the server's binary log files and binary log index file, if any, and obtain and save the GTID set held in the global value of the `gtid_executed` system variable (for example, by issuing a `SELECT @@GLOBAL.gtid_executed` statement and saving the results). If you are removing unwanted transactions from that GTID set, use `mysqlbinlog` to examine the contents of the transactions to ensure that they have no value, contain no data that must be saved or replicated, and did not result in data changes on the server.

When you issue `RESET BINARY LOGS AND GTIDS`, the following reset operations are carried out:

- The value of the `gtid_purged` system variable is set to an empty string ('').
- The global value (but not the session value) of the `gtid_executed` system variable is set to an empty string.
- The `mysql.gtid_executed` table is cleared (see [mysql.gtid\\_executed Table](#)).
- If the server has binary logging enabled, the existing binary log files are deleted and the binary log index file is cleared.

Note that `RESET BINARY LOGS AND GTIDS` is the method to reset the GTID execution history even if the server is a replica where binary logging is disabled. `RESET REPLICAS` has no effect on the GTID execution history.

### 19.1.3.3 GTID Auto-Positioning

GTIDs replace the file-offset pairs previously required to determine points for starting, stopping, or resuming the flow of data between source and replica. When GTIDs are in use, all the information that the replica needs for synchronizing with the source is obtained directly from the replication data stream.

To start a replica using GTID-based replication, you need to enable the `SOURCE_AUTO_POSITION` option in the `CHANGE REPLICATION SOURCE TO` statement. The alternative `SOURCE_LOG_FILE` and `SOURCE_LOG_POS` options specify the name of the log file and the starting position within the file, but with GTIDs the replica does not need this nonlocal data. For full instructions to configure and start sources and replicas using GTID-based replication, see [Section 19.1.3.4, “Setting Up Replication Using GTIDs”](#).

The `SOURCE_AUTO_POSITION` option is disabled by default. If multi-source replication is enabled on the replica, you need to set the option for each applicable replication channel. Disabling the `SOURCE_AUTO_POSITION` option again causes the replica to revert to file-based replication; this means that, when `GTID_ONLY=ON`, some positions may be marked as invalid, in which case you must also specify both `SOURCE_LOG_FILE` and `SOURCE_LOG_POS` when disabling `SOURCE_AUTO_POSITION`.

When a replica has GTIDs enabled (`GTID_MODE=ON`, `ON_PERMISSIVE`, or `OFF_PERMISSIVE`) and the `SOURCE_AUTO_POSITION` option enabled, auto-positioning is activated for connection to the source. The source must have `GTID_MODE=ON` set in order for the connection to succeed. In the initial handshake, the replica sends a GTID set containing the transactions that it has already received, committed, or both. This GTID set is equal to the union of the set of GTIDs in the `gtid_executed` system variable (`@@GLOBAL.gtid_executed`), and the set of GTIDs recorded in the Performance Schema `replication_connection_status` table as received transactions (the result of the statement `SELECT RECEIVED_TRANSACTION_SET FROM PERFORMANCE_SCHEMA.replication_connection_status`).

The source responds by sending all transactions recorded in its binary log whose GTID is not included in the GTID set sent by the replica. To do this, the source first identifies the appropriate binary log file to begin working with, by checking the `Previous_gtid_log_event` in the header of each of its binary log files, starting with the most recent. When the source finds the first `Previous_gtid_log_event` which contains no transactions that the replica is missing, it begins with that binary log file. This method is efficient and only takes a significant amount of time if the replica is behind the source by a large number of binary log files. The source then reads the transactions in that binary log file and subsequent files up to the current one, sending the transactions with GTIDs that the replica is missing, and skipping the transactions that were in the GTID set sent by the replica. The elapsed time until the replica receives the first missing transaction depends on its offset in the binary log file. This exchange ensures that the source only sends the transactions with a GTID that the replica has not already received or committed. If the replica receives

transactions from more than one source, as in the case of a diamond topology, the auto-skip function ensures that the transactions are not applied twice.

If any of the transactions that should be sent by the source have been purged from the source's binary log, or added to the set of GTIDs in the `gtid_purged` system variable by another method, the source sends the error `ER_SOURCE_HAS_PURGED_REQUIRED_GTIDS` to the replica, and replication does not start. The GTIDs of the missing purged transactions are identified and listed in the source's error log in the warning message `ER_FOUND_MISSING_GTIDS`. The replica cannot recover automatically from this error because parts of the transaction history that are needed to catch up with the source have been purged. Attempting to reconnect without the `SOURCE_AUTO_POSITION` option enabled only results in the loss of the purged transactions on the replica. The correct approach to recover from this situation is for the replica to replicate the missing transactions listed in the `ER_FOUND_MISSING_GTIDS` message from another source, or for the replica to be replaced by a new replica created from a more recent backup. Consider revising the binary log expiration period (`binlog_expire_logs_seconds`) on the source to ensure that the situation does not occur again.

If during the exchange of transactions it is found that the replica has received or committed transactions with the source's UUID in the GTID, but the source itself does not have a record of them, the source sends the error `ER_REPLICA_HAS_MORE_GTIDS_THAN_SOURCE` to the replica and replication does not start. This situation can occur if a source that does not have `sync_binlog=1` set experiences a power failure or operating system crash, and loses committed transactions that have not yet been synchronized to the binary log file, but have been received by the replica. The source and replica can diverge if any clients commit transactions on the source after it is restarted, which can lead to the situation where the source and replica are using the same GTID for different transactions. The correct approach to recover from this situation is to check manually whether the source and replica have diverged. If the same GTID is now in use for different transactions, you either need to perform manual conflict resolution for individual transactions as required, or remove either the source or the replica from the replication topology. If the issue is only missing transactions on the source, you can make the source into a replica instead, allow it to catch up with the other servers in the replication topology, and then make it a source again if needed.

For a multi-source replica in a diamond topology (where the replica replicates from two or more sources, which in turn replicate from a common source), when GTID-based replication is in use, ensure that any replication filters or other channel configuration are identical on all channels on the multi-source replica. With GTID-based replication, filters are applied only to the transaction data, and GTIDs are not filtered out. This happens so that a replica's GTID set stays consistent with the source's, meaning GTID auto-positioning can be used without re-acquiring filtered out transactions each time. In the case where the downstream replica is multi-source and receives the same transaction from multiple sources in a diamond topology, the downstream replica now has multiple versions of the transaction, and the result depends on which channel applies the transaction first. The second channel to attempt it skips the transaction using GTID auto-skip, because the transaction's GTID was added to the `gtid_executed` set by the first channel. With identical filtering on the channels, there is no problem because all versions of the transaction contain the same data, so the results are the same. However, with different filtering on the channels, the database can become inconsistent and replication can hang.

### 19.1.3.4 Setting Up Replication Using GTIDs

This section describes a process for configuring and starting GTID-based replication in MySQL 9.1. This is a “cold start” procedure that assumes either that you are starting the source server for the first time, or that it is possible to stop it; for information about provisioning replicas using GTIDs from a running source server, see [Section 19.1.3.5, “Using GTIDs for Failover and Scaleout”](#). For information about changing GTID mode on servers online, see [Section 19.1.4, “Changing GTID Mode on Online Servers”](#).

The key steps in this startup process for the simplest possible GTID replication topology, consisting of one source and one replica, are as follows:

1. If replication is already running, synchronize both servers by making them read-only.
2. Stop both servers.
3. Restart both servers with GTIDs enabled and the correct options configured.

The `mysqld` options necessary to start the servers as described are discussed in the example that follows later in this section.

4. Instruct the replica to use the source as the replication data source and to use auto-positioning. The SQL statements needed to accomplish this step are described in the example that follows later in this section.
5. Take a new backup. Binary logs containing transactions without GTIDs cannot be used on servers where GTIDs are enabled, so backups taken before this point cannot be used with your new configuration.
6. Start the replica, then disable read-only mode on both servers, so that they can accept updates.

In the following example, two servers are already running as source and replica, using MySQL's binary log position-based replication protocol. If you are starting with new servers, see [Section 19.1.2.3, “Creating a User for Replication”](#) for information about adding a specific user for replication connections and [Section 19.1.2.1, “Setting the Replication Source Configuration”](#) for information about setting the `server_id` variable. The following examples show how to store `mysqld` startup options in server's option file, see [Section 6.2.2.2, “Using Option Files”](#) for more information. Alternatively you can use startup options when running `mysqld`.

Most of the steps that follow require the use of the MySQL `root` account or another MySQL user account that has the `SUPER` privilege. `mysqladmin shutdown` requires either the `SUPER` privilege or the `SHUTDOWN` privilege.

**Step 1: Synchronize the servers.** This step is only required when working with servers which are already replicating without using GTIDs. For new servers proceed to Step 3. Make the servers read-only by setting the `read_only` system variable to `ON` on each server by issuing the following:

```
mysql> SET @@GLOBAL.read_only = ON;
```

Wait for all ongoing transactions to commit or roll back. Then, allow the replica to catch up with the source. *It is extremely important that you make sure the replica has processed all updates before continuing.*

If you use binary logs for anything other than replication, for example to do point in time backup and restore, wait until you do not need the old binary logs containing transactions without GTIDs. Ideally, wait for the server to purge all binary logs, and wait for any existing backup to expire.

#### Important

It is important to understand that logs containing transactions without GTIDs cannot be used on servers where GTIDs are enabled. Before proceeding, you must be sure that transactions without GTIDs do not exist anywhere in the topology.

**Step 2: Stop both servers.** Stop each server using `mysqladmin` as shown here, where `username` is the user name for a MySQL user having sufficient privileges to shut down the server:

```
$> mysqladmin -username -p shutdown
```

Then supply this user's password at the prompt.

**Step 3: Start both servers with GTIDs enabled.** To enable GTID-based replication, each server must be started with GTID mode enabled by setting the `gtid_mode` variable to `ON`, and with the

`enforce_gtid_consistency` variable enabled to ensure that only statements which are safe for GTID-based replication are logged. For example:

```
gtid_mode=ON
enforce-gtid-consistency=ON
```

Start each replica with `--skip-replica-start`. For more information on GTID related options and variables, see [Section 19.1.6.5, “Global Transaction ID System Variables”](#).

It is not mandatory to have binary logging enabled in order to use GTIDs when using the [mysql.gtid\\_executed Table](#). Source servers must always have binary logging enabled in order to be able to replicate. However, replica servers can use GTIDs but without binary logging. If you need to disable binary logging on a replica server, you can do this by specifying the `--skip-log-bin` and `--log-replica-updates=OFF` options for the replica.

**Step 4: Configure the replica to use GTID-based auto-positioning.** Tell the replica to use the source with GTID based transactions as the replication data source, and to use GTID-based auto-positioning rather than file-based positioning. Issue a `CHANGE REPLICATION SOURCE TO` on the replica, including the `SOURCE_AUTO_POSITION` option in the statement to tell the replica that the source's transactions are identified by GTIDs.

You may also need to supply appropriate values for the source's host name and port number as well as the user name and password for a replication user account which can be used by the replica to connect to the source; if these have already been set prior to Step 1 and no further changes need to be made, the corresponding options can safely be omitted from the statement shown here.

```
mysql> CHANGE REPLICATION SOURCE TO
> SOURCE_HOST = host,
> SOURCE_PORT = port,
> SOURCE_USER = user,
> SOURCE_PASSWORD = password,
> SOURCE_AUTO_POSITION = 1;
```

**Step 5: Take a new backup.** Existing backups that were made before you enabled GTIDs can no longer be used on these servers now that you have enabled GTIDs. Take a new backup at this point, so that you are not left without a usable backup.

For instance, you can execute `FLUSH LOGS` on the server where you are taking backups. Then either explicitly take a backup or wait for the next iteration of any periodic backup routine you may have set up.

**Step 6: Start the replica and disable read-only mode.** Start the replica like this:

```
mysql> START REPLICA;
```

The following step is only necessary if you configured a server to be read-only in Step 1. To allow the server to begin accepting updates again, issue the following statement:

```
mysql> SET @@GLOBAL.read_only = OFF;
```

GTID-based replication should now be running, and you can begin (or resume) activity on the source as before. [Section 19.1.3.5, “Using GTIDs for Failover and Scaleout”](#), discusses creation of new replicas when using GTIDs.

### 19.1.3.5 Using GTIDs for Failover and Scaleout

There are a number of techniques when using MySQL Replication with Global Transaction Identifiers (GTIDs) for provisioning a new replica which can then be used for scaleout, being promoted to source as necessary for failover. This section describes the following techniques:

- [Simple replication](#)
- [Copying data and transactions to the replica](#)
- [Injecting empty transactions](#)
- [Excluding transactions with `gtid\_purged`](#)
- [Restoring GTID mode replicas](#)

Global transaction identifiers were added to MySQL Replication for the purpose of simplifying in general management of the replication data flow and of failover activities in particular. Each identifier uniquely identifies a set of binary log events that together make up a transaction. GTIDs play a key role in applying changes to the database: the server automatically skips any transaction having an identifier which the server recognizes as one that it has processed before. This behavior is critical for automatic replication positioning and correct failover.

The mapping between identifiers and sets of events comprising a given transaction is captured in the binary log. This poses some challenges when provisioning a new server with data from another existing server. To reproduce the identifier set on the new server, it is necessary to copy the identifiers from the old server to the new one, and to preserve the relationship between the identifiers and the actual events. This is necessary for restoring a replica that is immediately available as a candidate to become a new source on failover or switchover.

**Simple replication.** The easiest way to reproduce all identifiers and transactions on a new server is to make the new server into the replica of a source that has the entire execution history, and enable global transaction identifiers on both servers. See [Section 19.1.3.4, “Setting Up Replication Using GTIDs”](#), for more information.

Once replication is started, the new server copies the entire binary log from the source and thus obtains all information about all GTIDs.

This method is simple and effective, but requires the replica to read the binary log from the source; it can sometimes take a comparatively long time for the new replica to catch up with the source, so this method is not suitable for fast failover or restoring from backup. This section explains how to avoid fetching all of the execution history from the source by copying binary log files to the new server.

**Copying data and transactions to the replica.** Executing the entire transaction history can be time-consuming when the source server has processed a large number of transactions previously, and this can represent a major bottleneck when setting up a new replica. To eliminate this requirement, a snapshot of the data set, the binary logs and the global transaction information the source server contains can be imported to the new replica. The server where the snapshot is taken can be either the source or one of its replicas, but you must ensure that the server has processed all required transactions before copying the data.

There are several variants of this method, the difference being in the manner in which data dumps and transactions from binary logs are transferred to the replica, as outlined here:

#### Data Set

1. Create a dump file using `mysqldump` on the source server. Set the `mysqldump` option `--source-data` to 1, to include a `CHANGE REPLICATION SOURCE TO` statement with binary logging information. Set the `--set-gtid-purged` option to `AUTO` (the default) or `ON`, to include information about executed transactions in the dump. Then use the `mysql` client to import the dump file on the target server.

2. Alternatively, create a data snapshot of the source server using raw data files, then copy these files to the target server, following the instructions in [Section 19.1.2.5, “Choosing a Method for Data Snapshots”](#). If you use `InnoDB` tables, you can use the `mysqlbackup` command from the MySQL Enterprise Backup component to produce a consistent snapshot. This command records the log name and offset corresponding to the snapshot to be used on the replica. MySQL Enterprise Backup is a commercial product that is included as part of a MySQL Enterprise subscription. See [Section 32.1, “MySQL Enterprise Backup Overview”](#) for detailed information.
3. Alternatively, stop both the source and target servers, copy the contents of the source's data directory to the new replica's data directory, then restart the replica. If you use this method, the replica must be configured for GTID-based replication, in other words with `gtid_mode=ON`. For instructions and important information for this method, see [Section 19.1.2.8, “Adding Replicas to a Replication Environment”](#).

#### Transaction History

If the source server has a complete transaction history in its binary logs (that is, the GTID set `@@GLOBAL.gtid_purged` is empty), you can use these methods.

1. Import the binary logs from the source server to the new replica using `mysqlbinlog`, with the `--read-from-remote-server` and `--read-from-remote-source` options.
2. Alternatively, copy the source server's binary log files to the replica. You can make copies from the replica using `mysqlbinlog` with the `--read-from-remote-server` and `--raw` options. These can be read into the replica by using `mysqlbinlog > file` (without the `--raw` option) to export the binary log files to SQL files, then passing these files to the `mysql` client for processing. Ensure that all of the binary log files are processed using a single `mysql` process, rather than multiple connections. For example:

```
$> mysqlbinlog copied-binlog.000001 copied-binlog.000002 | mysql -u root
```

For more information, see [Section 6.6.9.3, “Using mysqlbinlog to Back Up Binary Log Files”](#).

This method has the advantage that a new server is available almost immediately; only those transactions that were committed while the snapshot or dump file was being replayed still need to be obtained from the existing source. This means that the replica's availability is not instantaneous, but only a relatively short amount of time should be required for the replica to catch up with these few remaining transactions.

Copying over binary logs to the target server in advance is usually faster than reading the entire transaction execution history from the source in real time. However, it may not always be feasible to move these files to the target when required, due to size or other considerations. The two remaining methods for provisioning a new replica discussed in this section use other means to transfer information about transactions to the new replica.

**Injecting empty transactions.** The source's global `gtid_executed` variable contains the set of all transactions executed on the source. Rather than copy the binary logs when taking a snapshot to provision

a new server, you can instead note the content of `gtid_executed` on the server from which the snapshot was taken. Before adding the new server to the replication chain, simply commit an empty transaction on the new server for each transaction identifier contained in the source's `gtid_executed`, like this:

```
SET GTID_NEXT='aaa-bbb-ccc-ddd:N';

BEGIN;
COMMIT;

SET GTID_NEXT='AUTOMATIC';
```

Once all transaction identifiers have been reinstated in this way using empty transactions, you must flush and purge the replica's binary logs, as shown here, where `N` is the nonzero suffix of the current binary log file name:

```
FLUSH LOGS;
PURGE BINARY LOGS TO 'source-bin.00000N';
```

You should do this to prevent this server from flooding the replication stream with false transactions in the event that it is later promoted to the source. (The `FLUSH LOGS` statement forces the creation of a new binary log file; `PURGE BINARY LOGS` purges the empty transactions, but retains their identifiers.)

This method creates a server that is essentially a snapshot, but in time is able to become a source as its binary log history converges with that of the replication stream (that is, as it catches up with the source or sources). This outcome is similar in effect to that obtained using the remaining provisioning method, which we discuss in the next few paragraphs.

**Excluding transactions with `gtid_purged`.** The source's global `gtid_purged` variable contains the set of all transactions that have been purged from the source's binary log. As with the method discussed previously (see [Injecting empty transactions](#)), you can record the value of `gtid_executed` on the server from which the snapshot was taken (in place of copying the binary logs to the new server). Unlike the previous method, there is no need to commit empty transactions (or to issue `PURGE BINARY LOGS`); instead, you can set `gtid_purged` on the replica directly, based on the value of `gtid_executed` on the server from which the backup or snapshot was taken.

As with the method using empty transactions, this method creates a server that is functionally a snapshot, but in time is able to become a source as its binary log history converges with that of the source and other replicas.

**Restoring GTID mode replicas.** When restoring a replica in a GTID based replication setup that has encountered an error, injecting an empty transaction may not solve the problem because an event does not have a GTID.

Use `mysqlbinlog` to find the next transaction, which is probably the first transaction in the next log file after the event. Copy everything up to the `COMMIT` for that transaction, being sure to include the `SET @@SESSION.gtid_next`. Even if you are not using row-based replication, you can still run binary log row events in the command line client.

Stop the replica and run the transaction you copied. The `mysqlbinlog` output sets the delimiter to `/*! */;`, so set it back to the default, like this:

```
mysql> DELIMITER ;
```

Restart replication from the correct position automatically:

```
mysql> SET gtid_next=AUTOMATIC;
mysql> RESET REPLICATION;
```

```
mysql> START REPLICA;
```

### 19.1.3.6 Replication From a Source Without GTIDs to a Replica With GTIDs

You can set up replication channels to assign a GTID to replicated transactions that do not already have one. This feature enables replication from a source server that does not have GTIDs enabled and does not use GTID-based replication, to a replica that has GTIDs enabled. If it is possible to enable GTIDs on the replication source server, as described in [Section 19.1.4, “Changing GTID Mode on Online Servers”](#), use that approach instead. This feature is designed for replication source servers where you cannot enable GTIDs. Note that as is standard for MySQL replication, this feature does not support replication from MySQL source servers earlier than the previous release series, so MySQL 9.0 is the earliest supported source for a MySQL 9.1 replica.

You can enable GTID assignment on a replication channel using the `ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS` option of the `CHANGE REPLICATION SOURCE TO` statement. `LOCAL` assigns a GTID including the replica's own UUID (the `server_uuid` setting). `uuid` assigns a GTID including the specified UUID, such as the `server_uuid` setting for the replication source server. Using a nonlocal UUID lets you differentiate between transactions that originated on the replica and transactions that originated on the source, and for a multi-source replica, between transactions that originated on different sources. If any of the transactions sent by the source do have a GTID already, that GTID is retained.

#### Important

A replica set up with `ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS` on any channel cannot be promoted to replace the replication source server in the event that failover is required, and a backup taken from the replica cannot be used to restore the replication source server. The same restriction applies to replacing or restoring other replicas that use `ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS` on any channel.

The replica must have `gtid_mode=ON` set, and this cannot be changed afterwards, unless you set `ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS=OFF`. If the replica server is started without GTIDs enabled and with `ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS` set for any replication channels, the settings are not changed, but a warning message is written to the error log explaining how to change the situation.

For a multi-source replica, you can have a mix of channels that use `ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS`, and channels that do not. Channels specific to Group Replication cannot use `ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS`, but an asynchronous replication channel for another source on a server instance that is a Group Replication group member can do so. For a channel on a Group Replication group member, do not specify the Group Replication group name as the UUID for creating the GTIDs.

Using `ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS` on a replication channel is not the same as introducing GTID-based replication for the channel. The GTID set (`gtid_executed`) from a replica set up with `ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS` should not be transferred to another server or compared with another server's `gtid_executed` set. The GTIDs that are assigned to the anonymous transactions, and the UUID you choose for them, only have significance for that replica's own use. The exception to this is any downstream replicas of the replica where you enabled `ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS`, and any servers that were created from a backup of that replica.

If you set up any downstream replicas, these servers do not have `ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS` enabled. Only the replica that

is receiving transactions directly from the non-GTID source server needs to have `ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS` set on the relevant replication channel. Among that replica and its downstream replicas, you can compare GTID sets, fail over from one replica to another, and use backups to create additional replicas, as you would in any GTID-based replication topology. `ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS` is used where transactions are received from a non-GTID server outside this group.

A replication channel using `ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS` has the following behavior differences to GTID-based replication:

- GTIDs are assigned to the replicated transactions when they are applied (unless they already had a GTID). A GTID would normally be assigned on the replication source server when the transaction is committed, and sent to the replica along with the transaction. On a multi-threaded replica, this means the order of the GTIDs does not necessarily match the order of the transactions, even if `replica_preserve_commit_order = 1`.
- The `SOURCE_LOG_FILE` and `SOURCE_LOG_POS` options of the `CHANGE REPLICATION SOURCE TO` statement are used to position the replication I/O (receiver) thread, rather than the `SOURCE_AUTO_POSITION` option.
- The `SET GLOBAL sql_replica_skip_counter` statement is used to skip transactions on a replication channel set up with `ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS`, rather than the method of committing empty transactions. For instructions, see [Section 19.1.7.3, “Skipping Transactions”](#).
- The `UNTIL SQL_BEFORE_GTIDS` and `UNTIL SQL_AFTER_GTIDS` options of the `START REPLICATION` statement cannot be used for the channel.
- The function `WAIT_FOR_EXECUTED_GTID_SET( )` works across the server and can be used to wait for any downstream replicas of the server that have `ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS` enabled. To wait for the channel with `ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS` enabled to catch up with the source, which does not use GTIDs, use the `SOURCE_POS_WAIT( )` function.

The Performance Schema `replication_applier_configuration` table shows whether GTIDs are assigned to anonymous transactions on a replication channel, what the UUID is, and whether it is the UUID of the replica server (`LOCAL`) or a user-specified UUID (`UUID`). The information is also recorded in the applier metadata repository. A `RESET REPLICATION ALL` statement resets the `ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS` setting, but a `RESET REPLICATION` statement does not.

### 19.1.3.7 Restrictions on Replication with GTIDs

Because GTID-based replication is dependent on transactions, some features otherwise available in MySQL are not supported when using it. This section provides information about restrictions on and limitations of replication with GTIDs.

**Updates involving nontransactional storage engines.** When using GTIDs, updates to tables using nontransactional storage engines such as `MyISAM` cannot be made in the same statement or transaction as updates to tables using transactional storage engines such as `InnoDB`.

This restriction is due to the fact that updates to tables that use a nontransactional storage engine mixed with updates to tables that use a transactional storage engine within the same transaction can result in multiple GTIDs being assigned to the same transaction.

Such problems can also occur when the source and the replica use different storage engines for their respective versions of the same table, where one storage engine is transactional and the other is not. Also

be aware that triggers that are defined to operate on nontransactional tables can be the cause of these problems.

In any of the cases just mentioned, the one-to-one correspondence between transactions and GTIDs is broken, with the result that GTID-based replication cannot function correctly.

**CREATE TABLE ... SELECT statements.** For storage engines which support atomic DDL, `CREATE TABLE ... SELECT` is recorded in the binary log as one transaction. For more information, see [Section 15.1.1, “Atomic Data Definition Statement Support”](#).

**Temporary tables.** If `binlog_format` is set to `STATEMENT`, `CREATE TEMPORARY TABLE` and `DROP TEMPORARY TABLE` statements cannot be used inside transactions, procedures, functions, and triggers when GTIDs are in use on the server (that is, when the `enforce_gtid_consistency` system variable is set to `ON`). They can be used outside these contexts when GTIDs are in use, provided that `autocommit=1` is set. When `binlog_format` is set to `ROW` or `MIXED`, `CREATE TEMPORARY TABLE` and `DROP TEMPORARY TABLE` statements are allowed inside a transaction, procedure, function, or trigger when GTIDs are in use. The statements are not written to the binary log and are therefore not replicated to replicas. The use of row-based replication means that the replicas remain in sync without the need to replicate temporary tables. If the removal of these statements from a transaction results in an empty transaction, the transaction is not written to the binary log.

**Preventing execution of unsupported statements.** To prevent execution of statements that would cause GTID-based replication to fail, all servers must be started with the `--enforce-gtid-consistency` option when enabling GTIDs. This causes statements of any of the types discussed previously in this section to fail with an error.

Note that `--enforce-gtid-consistency` only takes effect if binary logging takes place for a statement. If binary logging is disabled on the server, or if statements are not written to the binary log because they are removed by a filter, GTID consistency is not checked or enforced for the statements that are not logged.

For information about other required startup options when enabling GTIDs, see [Section 19.1.3.4, “Setting Up Replication Using GTIDs”](#).

**Skipping transactions.** `sql_replica_skip_counter` is not available when using GTID-based replication. If you need to skip transactions, use the value of the source's `gtid_executed` variable instead. If you have enabled GTID assignment on a replication channel using the `ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS` option of the `CHANGE REPLICATION SOURCE TO` statement, `sql_replica_skip_counter` is available. For more information, see [Section 19.1.7.3, “Skipping Transactions”](#).

**Ignoring servers.** `IGNORE_SERVER_IDS` cannot be used with `CHANGE REPLICATION SOURCE TO` when using GTIDs, because transactions that have already been applied are automatically ignored. Before starting GTID-based replication, check for and clear all ignored server ID lists that have previously been set on the servers involved. The `SHOW REPLICA STATUS` statement, which can be issued for individual channels, displays the list of ignored server IDs if there is one. If there is no list, the `Replicate_Ignore_Server_Ids` field is blank. If the list of ignored server IDs is not empty, you can clear it with `CHANGE REPLICATION SOURCE TO ... IGNORE_SERVER_IDS=()` (in other words, with an empty list of server IDs to be ignored).

### 19.1.3.8 Stored Function Examples to Manipulate GTIDs

This section provides examples of stored functions (see [Chapter 27, \*Stored Objects\*](#)) which you can create using some of the built-in functions provided by MySQL for use with GTID-based replication, listed here:

- `GTID_SUBSET()`: Shows whether one GTID set is a subset of another.
- `GTID_SUBTRACT()`: Returns the GTIDs from one GTID set that are not in another.
- `WAIT_FOR_EXECUTED_GTID_SET()`: Waits until all transactions in a given GTID set have been executed.

See [Section 14.18.2, “Functions Used with Global Transaction Identifiers \(GTIDs\)”](#), more more information about the functions just listed.

Note that in these stored functions, the delimiter command has been used to change the MySQL statement delimiter to a vertical bar, like this:

```
mysql> delimiter |
```

All of the stored functions shown in this section take string representations of GTID sets as arguments, so GTID sets must always be quoted when used with them.

This function returns nonzero (true) if two GTID sets are the same set, even if they are not formatted in the same way:

```
CREATE FUNCTION GTID_IS_EQUAL(gs1 LONGTEXT, gs2 LONGTEXT)
 RETURNS INT
 RETURN GTID_SUBSET(gs1, gs2) AND GTID_SUBSET(gs2, gs1)
|
```

This function returns nonzero (true) if two GTID sets are disjoint:

```
CREATE FUNCTION GTID_IS_DISJOINT(gs1 LONGTEXT, gs2 LONGTEXT)
 RETURNS INT
 RETURN GTID_SUBSET(gs1, GTID_SUBTRACT(gs1, gs2))
|
```

This function returns nonzero (true) if two GTID sets are disjoint and `sum` is their union:

```
CREATE FUNCTION GTID_IS_DISJOINT_UNION(gs1 LONGTEXT, gs2 LONGTEXT, sum LONGTEXT)
 RETURNS INT
 RETURN GTID_IS_EQUAL(GTID_SUBTRACT(sum, gs1), gs2) AND
 GTID_IS_EQUAL(GTID_SUBTRACT(sum, gs2), gs1)
|
```

This function returns a normalized form of the GTID set, in all uppercase, with no whitespace and no duplicates, with UUIDs in alphabetic order and intervals in numeric order:

```
CREATE FUNCTION GTID_NORMIMIZE(gs LONGTEXT)
 RETURNS LONGTEXT
 RETURN GTID_SUBTRACT(gs, '')
|
```

This function returns the union of two GTID sets:

```
CREATE FUNCTION GTID_UNION(gs1 LONGTEXT, gs2 LONGTEXT)
 RETURNS LONGTEXT
 RETURN GTID_NORMIMIZE(CONCAT(gs1, ',', gs2))
|
```

This function returns the intersection of two GTID sets.

```
CREATE FUNCTION GTID_INTERSECTION(gs1 LONGTEXT, gs2 LONGTEXT)
 RETURNS LONGTEXT
```

```
RETURN GTID_SUBTRACT(gs1, GTID_SUBTRACT(gs1, gs2))
```

This function returns the symmetric difference between two GTID sets, that is, the GTIDs that exist in `gs1` but not in `gs2`, as well as the GTIDs that exist in `gs2` but not in `gs1`.

```
CREATE FUNCTION GTID_SYMMETRIC_DIFFERENCE(gs1 LONGTEXT, gs2 LONGTEXT)
RETURNS LONGTEXT
RETURN GTID_SUBTRACT(CONCAT(gs1, ',', gs2), GTID_INTERSECTION(gs1, gs2))
```

This function removes from a GTID set all the GTIDs with the specified origin, and returns the remaining GTIDs, if any. The UUID is the identifier used by the server where the transaction originated, which is normally the value of `server_uuid`.

```
CREATE FUNCTION GTID_SUBTRACT_UUID(gs LONGTEXT, uuid TEXT)
RETURNS LONGTEXT
RETURN GTID_SUBTRACT(gs, CONCAT(UUID, ':1-', (1 << 63) - 2))
```

This function acts as the reverse of the previous one; it returns only those GTIDs from the GTID set that originate from the server with the specified identifier (UUID).

```
CREATE FUNCTION GTID_INTERSECTION_WITH_UUID(gs LONGTEXT, uuid TEXT)
RETURNS LONGTEXT
RETURN GTID_SUBTRACT(gs, GTID_SUBTRACT_UUID(gs, uuid))
```

### Example 19.1 Verifying that a replica is up to date

The built-in functions `GTID_SUBSET()` and `GTID_SUBTRACT()` can be used to check that a replica has applied at least every transaction that a source has applied.

To perform this check with `GTID_SUBSET()`, execute the following statement on the replica:

```
SELECT GTID_SUBSET(source_gtid_executed, replica_gtid_executed);
```

If the returns value is 0 (false), this means that some GTIDs in `source_gtid_executed` are not present in `replica_gtid_executed`, and that the replica has not yet applied transactions that were applied on the source, which means that the replica is not up to date.

To perform the same check with `GTID_SUBTRACT()`, execute the following statement on the replica:

```
SELECT GTID_SUBTRACT(source_gtid_executed, replica_gtid_executed);
```

This statement returns any GTIDs that are in `source_gtid_executed` but not in `replica_gtid_executed`. If any GTIDs are returned, the source has applied some transactions that the replica has not applied, and the replica is therefore not up to date.

### Example 19.2 Backup and restore scenario

The stored functions `GTID_IS_EQUAL()`, `GTID_IS_DISJOINT()`, and `GTID_IS_DISJOINT_UNION()` can be used to verify backup and restore operations involving multiple databases and servers. In this example scenario, `server1` contains database `db1`, and `server2` contains database `db2`. The goal is to copy database `db2` to `server1`, and the result on `server1` should be the union of the two databases. The procedure used is to back up `server2` using `mysqldump`, then to restore this backup on `server1`.

Provided that `mysqldump` was run with `--set-gtid-purged` set to `ON` or `AUTO` (the default), the output contains a `SET @@GLOBAL.gtid_purged` statement which adds the `gtid_executed` set from `server2` to the `gtid_purged` set on `server1`. `gtid_purged` contains the GTIDs of all the transactions that have been committed on a given server but which do not exist in any binary log file on the server. When database `db2` is copied to `server1`, the GTIDs of the transactions committed on `server2`, which are not in the binary log files on `server1`, must be added to `gtid_purged` for `server1` to make the set complete.

The stored functions can be used to assist with the following steps in this scenario:

- Use `GTID_IS_EQUAL()` to verify that the backup operation computed the correct GTID set for the `SET @@GLOBAL.gtid_purged` statement. On `server2`, extract that statement from the `mysqldump` output, and store the GTID set into a local variable, such as `$gtid_purged_set`. Then execute the following statement:

```
server2> SELECT GTID_IS_EQUAL($gtid_purged_set, @@GLOBAL.gtid_executed);
```

If the result is 1, the two GTID sets are equal, and the set has been computed correctly.

- Use `GTID_IS_DISJOINT()` to verify that the GTID set in the `mysqldump` output does not overlap with the `gtid_executed` set on `server1`. Having identical GTIDs present on both servers causes errors when copying database `db2` to `server1`. To check, on `server1`, extract and store `gtid_purged` from the output into a local variable as done previously, then execute the following statement:

```
server1> SELECT GTID_IS_DISJOINT($gtid_purged_set, @@GLOBAL.gtid_executed);
```

If the result is 1, there is no overlap between the two GTID sets, so no duplicate GTIDs are present.

- Use `GTID_IS_DISJOINT_UNION()` to verify that the restore operation resulted in the correct GTID state on `server1`. Before restoring the backup, on `server1`, obtain the existing `gtid_executed` set by executing the following statement:

```
server1> SELECT @@GLOBAL.gtid_executed;
```

Store the result in a local variable `$original_gtid_executed`, as well as the set from `gtid_purged` in another local variable as described previously. When the backup from `server2` has been restored onto `server1`, execute the following statement to verify the GTID state:

```
server1> SELECT
-> GTID_IS_DISJOINT_UNION($original_gtid_executed,
-> $gtid_purged_set,
-> @@GLOBAL.gtid_executed);
```

If the result is 1, the stored function has verified that the original `gtid_executed` set from `server1` (`$original_gtid_executed`) and the `gtid_purged` set that was added from `server2` (`$gtid_purged_set`) have no overlap, and that the updated `gtid_executed` set on `server1` now consists of the previous `gtid_executed` set from `server1` plus the `gtid_purged` set from `server2`, which is the desired result. Ensure that this check is carried out before any further transactions take place on `server1`, otherwise the new transactions in `gtid_executed` cause it to fail.

### Example 19.3 Selecting the most up-to-date replica for manual failover

The stored function `GTID_UNION()` can be used to identify the most up-to-date replica from a set of replicas, in order to perform a manual failover operation after a source server has stopped unexpectedly. If some of the replicas are experiencing replication lag, this stored function can be used to compute the most up-to-date replica without waiting for all the replicas to apply their existing relay logs, and therefore to minimize the failover time. The function can return the union of `gtid_executed` on each replica with the set of transactions received by the replica, which is recorded in the Performance Schema

`replication_connection_status` table. You can compare these results to find which replica's record of transactions is the most up to date, even if not all of the transactions have been committed yet.

On each replica, compute the complete record of transactions by issuing the following statement:

```
SELECT GTID_UNION(RECEIVED_TRANSACTION_SET, @@GLOBAL.gtid_executed)
FROM performance_schema.replication_connection_status
WHERE channel_name = 'name';
```

You can then compare the results from each replica to see which one has the most up-to-date record of transactions, and use this replica as the new source.

#### Example 19.4 Checking for extraneous transactions on a replica

The stored function `GTID_SUBTRACT_UUID()` can be used to check whether a replica has received transactions that did not originate from its designated source or sources. If it has, there might be an issue with your replication setup, or with a proxy, router, or load balancer. This function works by removing from a GTID set all the GTIDs from a specified originating server, and returning the remaining GTIDs, if any.

For a replica with a single source, issue the following statement, giving the identifier of the originating source, which is normally the same as `server_uuid`:

```
SELECT GTID_SUBTRACT_UUID(@@GLOBAL.gtid_executed, server_uuid_of_source);
```

If the result is not empty, the transactions returned are extra transactions that did not originate from the designated source.

For a replica in a multisource topology, include the server UUID of each source in the function call, like this:

```
SELECT
 GTID_SUBTRACT_UUID(GTID_SUBTRACT_UUID(@@GLOBAL.gtid_executed,
 server_uuid_of_source_1),
 server_uuid_of_source_2);
```

If the result is not empty, the transactions returned are extra transactions that did not originate from any of the designated sources.

#### Example 19.5 Verifying that a server in a replication topology is read-only

The stored function `GTID_INTERSECTION_WITH_UUID()` can be used to verify that a server has not originated any GTIDs and is in a read-only state. The function returns only those GTIDs from the GTID set that originate from the server with the specified identifier. If any of the transactions listed in `gtid_executed` from this server use the server's own identifier, the server itself originated those transactions. You can issue the following statement on the server to check:

```
SELECT GTID_INTERSECTION_WITH_UUID(@@GLOBAL.gtid_executed, my_server_uuid);
```

#### Example 19.6 Validating an additional replica in multisource replication

The stored function `GTID_INTERSECTION_WITH_UUID()` can be used to find out if a replica attached to a multisource replication setup has applied all the transactions originating from one particular source. In this scenario, `source1` and `source2` are both sources and replicas and replicate to each other. `source2` also has its own replica. The replica also receives and applies transactions from `source1` if `source2` is configured with `log_replica_updates=ON`, but it does not do so if `source2` uses

`log_replica_updates=OFF`. Whichever the case, we currently want only to find out if the replica is up to date with `source2`. In this situation, `GTID_INTERSECTION_WITH_UUID()` can be used to identify the transactions that `source2` originated, discarding the transactions that `source2` has replicated from `source1`. The built-in function `GTID_SUBSET()` can then be used to compare the result with the `gtid_executed` set on the replica. If the replica is up to date with `source2`, the `gtid_executed` set on the replica contains all the transactions in the intersection set (the transactions that originated from `source2`).

To carry out this check, store the values of `gtid_executed` and the server UUID from `source2` and the value of `gtid_executed` from the replica into user variables as follows:

```
source2> SELECT @@GLOBAL.gtid_executed INTO @source2_gtid_executed;

source2> SELECT @@GLOBAL.server_uuid INTO @source2_server_uuid;

replica> SELECT @@GLOBAL.gtid_executed INTO @replica_gtid_executed;
```

Then use `GTID_INTERSECTION_WITH_UUID()` and `GTID_SUBSET()` with these variables as input, as follows:

```
SELECT
 GTID_SUBSET(
 GTID_INTERSECTION_WITH_UUID(@source2_gtid_executed,
 @source2_server_uuid),
 @replica_gtid_executed);
```

The server identifier from `source2` (`@source2_server_uuid`) is used with `GTID_INTERSECTION_WITH_UUID()` to identify and return only those GTIDs from the set of GTIDs that originated on `source2`, omitting those that originated on `source1`. The resulting GTID set is then compared with the set of all executed GTIDs on the replica, using `GTID_SUBSET()`. If this statement returns nonzero (true), all the identified GTIDs from `source2` (the first set input) are also found in `gtid_executed` from the replica, meaning that the replica has received and executed all the transactions that originated from `source2`.

## 19.1.4 Changing GTID Mode on Online Servers

This section describes how to change the mode of replication from and to GTID mode without having to take the server offline.

### 19.1.4.1 Replication Mode Concepts

Before setting the replication mode of an online server, it is important to understand some key concepts of replication. This section explains these concepts and is essential reading before attempting to modify the replication mode of an online server.

The modes of replication available in MySQL rely on different techniques for identifying logged transactions. The types of transactions used by replication are listed here:

- A GTID transaction is identified by a global transaction identifier (GTID) which takes one of two forms: `UUID:NUMBER` or `UUID:TAG:NUMBER`. Every GTID transaction in the binary log is preceded by a `Gtid_log_event`. A GTID transaction can be addressed either by its GTID, or by the name of the file in which it is logged and its position within that file.
- An anonymous transaction has no GTID; MySQL 9.1 ensures that every anonymous transaction in a log is preceded by an `Anonymous_gtid_log_event`. (In old versions of MySQL, an anonymous

transaction was not preceded by any particular event.) An anonymous transaction can be addressed by file name and position only.

When using GTIDs you can take advantage of GTID auto-positioning and automatic failover, and use `WAIT_FOR_EXECUTED_GTID_SET()`, `session_track_gtids`, and Performance Schema tables to monitor replicated transactions (see [Section 29.12.11, “Performance Schema Replication Tables”](#)).

A transaction in a relay log from a source running a previous version of MySQL might not be preceded by any particular event, but after being replayed and recorded in the replica's binary log, it is preceded with an `Anonymous_gtid_log_event`.

To change the replication mode online, it is necessary to set the `gtid_mode` and `enforce_gtid_consistency` variables using an account that has privileges sufficient to set global system variables; see [Section 7.1.9.1, “System Variable Privileges”](#). Permitted values for `gtid_mode` are listed here, in order, with their meanings:

- **OFF**: Only anonymous transactions can be replicated.
- **OFF\_PERMISSIVE**: New transactions are anonymous; replicated transactions may be either GTID or anonymous.
- **ON\_PERMISSIVE**: New transactions use GTIDs; replicated transactions may be either GTID or anonymous.
- **ON**: All transaction must have GTIDs; anonymous transactions cannot be replicated.

It is possible to have servers using anonymous and servers using GTID transactions in the same replication topology. For example, a source where `gtid_mode=ON` can replicate to a replica where `gtid_mode=ON_PERMISSIVE`.

Replication from a source using `gtid_mode=ON` provides the ability to use GTID auto-positioning, configured using the `SOURCE_AUTO_POSITION` option of the `CHANGE REPLICATION SOURCE TO` statement. The replication topology in use has an impact on whether it is possible to enable auto-positioning or not, since this feature relies on GTIDs and is not compatible with anonymous transactions. It is strongly recommended to ensure there are no anonymous transactions remaining in the topology before enabling auto-positioning; see [Section 19.1.4.2, “Enabling GTID Transactions Online”](#).

Valid combinations of `gtid_mode` and auto-positioning on source and replica are shown in the next table. The meaning of each entry is as follows:

- **Y**: The values of `gtid_mode` on the source and on the replica are compatible.
- **N**: The values of `gtid_mode` on the source and on the replica are not compatible.
- **\***: Auto-positioning can be used with this combination of values.

**Table 19.1 Valid Combinations of Source and Replica `gtid_mode`**

<code>gtid_mode</code>	Source <b>OFF</b>	Source <b>OFF_PERMISSIVE</b>	Source <b>ON_PERMISSIVE</b>	Source <b>ON</b>
Replica <b>OFF</b>	Y	Y	N	N
Replica <b>OFF_PERMISSIVE</b>	Y	Y	Y	Y*
Replica <b>ON_PERMISSIVE</b>	Y	Y	Y	Y*

<code>gtid_mode</code>	Source OFF	Source OFF_PERMISSIVE	Source ON_PERMISSIVE	Source ON
Replica ON	N	N	Y	Y*

The current value of `gtid_mode` also affects `gtid_next`. The next table shows the behavior of the server for combinations of different values of `gtid_mode` and `gtid_next`. The meaning of each entry is as follows:

- **ANONYMOUS**: Generate an anonymous transaction.
- **Error**: Generate an error, and do not execute `SET GTID_NEXT`.
- **UUID:NUMBER**: Generate a GTID with the specified UUID:NUMBER.
- **UUID:TAG:NUMBER**: Generate a GTID with the specified UUID:TAG:NUMBER.
- **New GTID**: Generate a GTID with an automatically generated number.

**Table 19.2 Valid Combinations of `gtid_mode` and `gtid_next`**

	<code>gtid_next = AUTOMATIC (binary log on)</code>	<code>gtid_next = AUTOMATIC (binary log off)</code>	<code>gtid_next = AUTOMATIC: &lt;TAG&gt;</code>	<code>gtid_next = ANONYMOUS</code>	<code>gtid_next = &lt;UUID&gt;:&lt;NUMBER&gt;</code>	<code>gtid_next = &lt;UUID&gt;:&lt;TAG&gt;:&lt;NUMBER&gt;</code>
<code>gtid_mode = OFF</code>	ANONYMOUS	ANONYMOUS	Error	ANONYMOUS	Error	Error
<code>gtid_mode = OFF_PERMISSIVE</code>	ANONYMOUS	ANONYMOUS	Error	ANONYMOUS	<UUID>:<NUMBER>	<UUID>:<TAG>:<NUMBER>
<code>gtid_mode = ON_PERMISSIVE</code>	New GTID	ANONYMOUS	New GTID	ANONYMOUS	<UUID>:<NUMBER>	<UUID>:<TAG>:<NUMBER>
<code>gtid_mode = ON</code>	New GTID	ANONYMOUS	New GTID	Error	<UUID>:<NUMBER>	<UUID>:<TAG>:<NUMBER>

When binary logging is not in use and `gtid_next` is **AUTOMATIC**, then no GTID is generated.

#### 19.1.4.2 Enabling GTID Transactions Online

This section describes how to enable GTID transactions, and optionally auto-positioning, on servers that are already online and using anonymous transactions. This procedure does not require taking the server offline and is suited to use in production. However, if you have the possibility to take the servers offline when enabling GTID transactions that process is easier.

You can set up replication channels to assign GTIDs to replicated transactions that do not already have any. This feature enables replication from a source server that does not use GTID-based replication, to a replica that does. If it is possible to enable GTIDs on the replication source server, as described in this procedure, use this approach instead. Assigning GTIDs is designed for replication source servers where you cannot enable GTIDs. For more information on this option, see [Section 19.1.3.6, “Replication From a Source Without GTIDs to a Replica With GTIDs”](#).

Before you start, ensure that `gtid_mode` is **OFF** on all servers.

The following procedure can be paused at any time and later resumed where it was, or reversed by jumping to the corresponding step of [Section 19.1.4.3, “Disabling GTID Transactions Online”](#), the online

procedure to disable GTIDs. This makes the procedure fault-tolerant because any unrelated issues that may appear in the middle of the procedure can be handled as usual, and then the procedure continued where it was left off.

To enable GTID transactions, you must complete each of the following steps before continuing to the next one.

1. On each server, execute the following statement:

```
SET @@GLOBAL.enforce_gtid_consistency = WARN;
```

Let the server run for a while with your normal workload and monitor the logs. If this step causes any warnings in the log, adjust your application so that it only uses GTID-compatible features and does not generate any warnings.

2. On each server, execute this statement:

```
SET @@GLOBAL.enforce_gtid_consistency = ON;
```

3. On each server, execute the following statement:

```
SET @@GLOBAL.gtid_mode = OFF_PERMISSIVE;
```

The order in which the servers execute this statement makes no difference, but all servers must do so before beginning the next step.

4. On each server, execute the following statement:

```
SET @@GLOBAL.gtid_mode = ON_PERMISSIVE;
```

As in the previous step, it makes no difference which server executes the statement first, as long as each server does so before proceeding further.

5. On each server, wait until `Ongoing_anonymous_transaction_count` is 0. You can check its value using a `SHOW STATUS` statement, like this:

```
mysql> SHOW STATUS LIKE 'Ongoing%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Ongoing_anonymous_transaction_count | 0 |
+-----+-----+
1 row in set (0.00 sec)
```

On a replica, it is theoretically possible that this is 0 and then a nonzero value again. This is not a problem, as long as it is 0 at least once.

6. Wait for all transactions generated up to the previous step to replicate to all servers. You can do this without stopping updates; what matters is that all anonymous transactions are replicated before proceeding further.

See [Section 19.1.4.4, “Verifying Replication of Anonymous Transactions”](#) for one method of checking that all anonymous transactions have replicated to all servers.

7. If you use binary logs for anything other than replication, such as point-in-time backup and restore, wait until you no longer need the old binary logs containing transactions without GTIDs.

For instance, after all transactions have been replicated, you can execute `FLUSH LOGS` on the server where you are taking backups. Then either explicitly take a backup or wait for the next iteration of any periodic backup routine you may have set up.

Ideally, you should wait for the server to purge all binary logs that existed when the previous step was completed, and for any backup taken before then to expire.

Keep in mind that binary logs containing anonymous transactions (that is, transactions without GTIDs) cannot be used following the next step, after which, you must make sure that no transactions without GTIDs remain uncommitted on any server.

8. On each server, execute this statement:

```
SET @@GLOBAL.GTID_MODE = ON;
```

9. On each server, add `gtid-mode=ON` and `enforce-gtid-consistency=ON` to `my.cnf`. This guarantees that GTIDs are used for all transactions which have not already been processed. To start using the GTID protocol so that you can later perform automatic failover, execute the the next set of statements on each replica. If you use multi-source replication, do this for each channel, including the `FOR CHANNEL channel` clause:

```
STOP REPLICA [FOR CHANNEL 'channel'];

CHANGE REPLICATION SOURCE TO SOURCE_AUTO_POSITION = 1 [FOR CHANNEL 'channel'];

START REPLICA [FOR CHANNEL 'channel'];
```

### 19.1.4.3 Disabling GTID Transactions Online

This section describes how to disable GTID transactions on servers that are already online. This procedure does not require taking the server offline and is suited to use in production. However, if you have the possibility to take the servers offline when disabling GTIDs mode that process is easier.

The process is similar to enabling GTID transactions while the server is online, but reversing the steps. The only thing that differs is the point at which you wait for logged transactions to replicate.

Before starting, all servers must meet the following conditions:

- All servers have `gtid_mode` set to `ON`.
- The `--replicate-same-server-id` option is not set on any server. You cannot disable GTID transactions if this option is set together with the `--log-replica-updates` option (default) and binary logging is enabled (also the default). Without GTIDs, this combination of options causes infinite loops in circular replication.

1. Execute the following statements on each replica, and if you are using multi-source replication, do so for each channel, including the `FOR CHANNEL` clause when using multi-source replication:

```
STOP REPLICA [FOR CHANNEL 'channel'];

CHANGE REPLICATION SOURCE TO
 SOURCE_AUTO_POSITION = 0,
 SOURCE_LOG_FILE = 'file',
 SOURCE_LOG_POS = position
 [FOR CHANNEL 'channel'];

START REPLICA [FOR CHANNEL 'channel'];
```

You can obtain the values for `file` and `position` from the `relay_source_log_file` and `exec_source_log_position` columns in the output of `SHOW REPLICA STATUS`. The `file` and `channel` names are strings; both of these must be quoted when used in the `STOP REPLICA`, `CHANGE REPLICATION SOURCE TO`, and `START REPLICA` statements.

2. On each server, execute the following statement:

```
SET @@global.gtid_mode = ON_PERMISSIVE;
```

3. On each server, execute the following statement:

```
SET @@global.gtid_mode = OFF_PERMISSIVE;
```

4. On each server, wait until the global value of `gtid_owned` is equal to the empty string. This can be checked using the statement shown here:

```
SELECT @@global.gtid_owned;
```

On a replica, it is theoretically possible that this is empty and then becomes nonempty again. This is not a problem; it suffices that the value is empty at least once.

5. Wait for all transactions that currently exist in any binary log to be committed on all replicas. See [Section 19.1.4.4, “Verifying Replication of Anonymous Transactions”](#), for one method of checking that all anonymous transactions have replicated to all servers.
6. If you use binary logs for anything other than replication—for example, to perform point-in-time backup or restore—wait until you no longer need any old binary logs containing GTID transactions.

For instance, after the previous step has completed, you can execute `FLUSH LOGS` on the server where you are taking the backup. Then, either take a backup manually, or wait for the next iteration of any periodic backup routine you may have set up.

Ideally, you should wait for the server to purge all binary logs that existed when step 5 was completed, and for any backup taken before then to expire.

You should keep in mind that logs containing GTID transactions cannot be used after the next step. For this reason, before proceeding further, you must be sure that no uncommitted GTID transactions exist anywhere in the topology.

7. On each server, execute the following statement:

```
SET @@global.gtid_mode = OFF;
```

8. On each server, set `gtid_mode=OFF` in `my.cnf`.

Optionally, you can also set `enforce_gtid_consistency=OFF`. After doing so, you should add `enforce_gtid_consistency=OFF` to your configuration file.

If you want to downgrade to an earlier version of MySQL, you can do so now, using the normal downgrade procedure.

#### 19.1.4.4 Verifying Replication of Anonymous Transactions

This section explains how to monitor a replication topology and verify that all anonymous transactions have been replicated. This is helpful when changing the replication mode online as you can verify that it is safe to change to GTID transactions.

There are several possible ways to wait for transactions to replicate:

The simplest method, which works regardless of your topology but relies on timing is as follows: If you are sure that the replica never lags more than *N* seconds, wait any period of time that is longer than *N* seconds, which you consider safe for your deployment.

A safer method, in the sense that it does not depend on timing, if you only have a source with one or more replicas, is to perform the following two steps:

1. On the source, execute this statement:

```
SHOW BINARY LOG STATUS;
```

Make a note of the values displayed in the `File` and `Position` columns of the output.

2. On each replica, use the file and position information from the source to perform the statement shown here:

```
SELECT SOURCE_POS_WAIT(file, position);
```

If you have a source and multiple levels of replicas (that is, replicas of replicas), repeat the second step on each level, starting from the source, then on all of its replicas, then on all of the replicas of these replicas, and so on.

If you employ a circular replication topology where multiple servers may have write clients, perform the second step for each source-replica connection, until you have completed the full circle. Repeat this process so that you complete the full circle twice.

For example, if there are three servers A, B, and C, replicating in a circle, so that A replicates to B, B replicates to C, and C replicates to A, do as follows, in the order shown:

- Perform Step 1 on A, and Step 2 on B.
- Perform Step 1 on B, and Step 2 on C.
- Perform Step 1 on C, and Step 2 on A.
- Perform Step 1 on A, and Step 2 on B.
- Perform Step 1 on B, and Step 2 on C.
- Perform Step 1 on C, and Step 2 on A.

### 19.1.5 MySQL Multi-Source Replication

Multi-source replication in MySQL 9.1 enables a replica to receive transactions from multiple immediate sources in parallel. In a multi-source replication topology, a replica creates a replication channel for each source that it should receive transactions from. For more information on how replication channels function, see [Section 19.2.2, “Replication Channels”](#).

You might choose to implement multi-source replication to achieve goals like these:

- Backing up multiple servers to a single server.
- Merging table shards.
- Consolidating data from multiple servers to a single server.

Multi-source replication does not implement any conflict detection or resolution when applying transactions, and those tasks are left to the application if required.

#### Note

Each channel on a multi-source replica must replicate from a different source. You cannot set up multiple replication channels from a single replica to a single source. This is because the server IDs of replicas must be unique in a replication topology. The source distinguishes replicas only by their server IDs, not by the names of the

replication channels, so it cannot recognize different replication channels from the same replica.

A multi-source replica can also be set up as a multi-threaded replica, by setting the system variable `replica_parallel_workers` to a value greater than 0. When you do this on a multi-source replica, each channel on the replica has the specified number of applier threads, plus a coordinator thread to manage them. You cannot configure the number of applier threads for individual channels.

MySQL 9.1 also supports replication filters on specific replication channels with multi-source replicas. Channel specific replication filters can be used when the same database or table is present on multiple sources, and you only need the replica to replicate it from one source. For GTID-based replication, if the same transaction might arrive from multiple sources (such as in a diamond topology), you must ensure the filtering setup is the same on all channels. For more information, see [Section 19.2.5.4, “Replication Channel Based Filters”](#).

This section provides tutorials on how to configure sources and replicas for multi-source replication, how to start, stop and reset multi-source replicas, and how to monitor multi-source replication.

### 19.1.5.1 Configuring Multi-Source Replication

A multi-source replication topology requires at least two sources and one replica configured. In these tutorials, we assume that you have two sources `source1` and `source2`, and a replica `replicahost`. The replica replicates one database from each of the sources, `db1` from `source1` and `db2` from `source2`.

Sources in a multi-source replication topology can be configured to use either GTID-based replication, or binary log position-based replication. See [Section 19.1.3.4, “Setting Up Replication Using GTIDs”](#) for how to configure a source using GTID-based replication. See [Section 19.1.2.1, “Setting the Replication Source Configuration”](#) for how to configure a source using file position based replication.

Replicas in a multi-source replication topology require `TABLE` repositories for the replica's connection metadata repository and applier metadata repository, which are the default in MySQL 9.1. Multi-source replication is not compatible with the deprecated alternative file repositories.

Create a suitable user account on all the sources that the replica can use to connect. You can use the same account on all the sources, or a different account on each. If you create an account solely for the purposes of replication, that account needs only the `REPLICATION SLAVE` privilege. For example, to set up a new user, `ted`, that can connect from the replica `replicahost`, use the `mysql` client to issue these statements on each of the sources:

```
mysql> CREATE USER 'ted'@'replicahost' IDENTIFIED BY 'password';
mysql> GRANT REPLICATION SLAVE ON *.* TO 'ted'@'replicahost';
```

For more information about the default authentication plugin for new users, see [Section 19.1.2.3, “Creating a User for Replication”](#).

### 19.1.5.2 Provisioning a Multi-Source Replica for GTID-Based Replication

If the sources in the multi-source replication topology have existing data, it can save time to provision the replica with the relevant data before starting replication. In a multi-source replication topology, cloning or copying of the data directory cannot be used to provision the replica with data from all of the sources, and you might also want to replicate only specific databases from each source. The best strategy for provisioning such a replica is therefore to use `mysqldump` to create an appropriate dump file on each source, then use the `mysql` client to import the dump file on the replica.

If you are using GTID-based replication, you need to pay attention to the `SET @@GLOBAL.gtid_purged` statement that `mysqldump` places in the dump output. This statement transfers the GTIDs for the

transactions executed on the source to the replica, and the replica requires this information. However, for any case more complex than provisioning one new, empty replica from one source, you need to check what effect the statement has in the version of MySQL used by the replica, and handle the statement accordingly. The following guidance summarizes suitable actions, but for more details, see the [mysqldump](#) documentation.

`SET @@GLOBAL.gtid_purged` adds the GTID set from the dump file to the existing `gtid_purged` set on the replica. The statement can therefore potentially be left in the dump output when you replay the dump files on the replica, and the dump files can be replayed at different times. However, it is important to note that the value that is included by `mysqldump` for the `SET @@GLOBAL.gtid_purged` statement includes the GTIDs of all transactions in the `gtid_executed` set on the source, even those that changed suppressed parts of the database, or other databases on the server that were not included in a partial dump. If you replay a second or subsequent dump file on the replica that contains any of the same GTIDs (for example, another partial dump from the same source, or a dump from another source that has overlapping transactions), any `SET @@GLOBAL.gtid_purged` statement in the second dump file fails, and must therefore be removed from the dump output.

As an alternative to removing the `SET @@GLOBAL.gtid_purged` statement, you can invoke `mysqldump` with `--set-gtid-purged=COMMENTED` to include the statement encased in SQL comments, so that it is not performed when you load the dump file. If you are provisioning the replica with two partial dumps from the same source, and the GTID set in the second dump is the same as the first (so no new transactions have been executed on the source in between the dumps), you can set `--set-gtid-purged=OFF` instead when you export the second dump file, to omit the statement.

In the following provisioning example, we assume that the `SET @@GLOBAL.gtid_purged` statement cannot be left in the dump output, and must be removed from the files and handled manually. We also assume that there are no wanted transactions with GTIDs on the replica before provisioning starts.

1. To create dump files for a database named `db1` on `source1` and a database named `db2` on `source2`, run `mysqldump` for `source1` as follows:

```
mysqldump -u<user> -p<password> --single-transaction --triggers --routines --set-gtid-purged=ON --databases
```

Then run `mysqldump` for `source2` as follows:

```
mysqldump -u<user> -p<password> --single-transaction --triggers --routines --set-gtid-purged=ON --databases
```

2. Record the `gtid_purged` value that `mysqldump` added to each of the dump files. You can extract the value like this:

```
cat dumpM1.sql | grep GTID_PURGED | perl -p0 -e 's#/*.*?*/##sg' | cut -f2 -d=' ' | cut -f2 -d$'\n'
cat dumpM2.sql | grep GTID_PURGED | perl -p0 -e 's#/*.*?*/##sg' | cut -f2 -d=' ' | cut -f2 -d$'\n'
```

The result in each case should be a GTID set, for example:

```
source1: 2174B383-5441-11E8-B90A-C80AA9429562:1-1029
source2: 224DA167-0C0C-11E8-8442-00059A3C7B00:1-2695
```

3. Remove the line from each dump file that contains the `SET @@GLOBAL.gtid_purged` statement. For example:

```
sed '/GTID_PURGED/d' dumpM1.sql > dumpM1_nopurge.sql
sed '/GTID_PURGED/d' dumpM2.sql > dumpM2_nopurge.sql
```

4. Use the `mysql` client to import each edited dump file into the replica. For example:

```
mysql -u<user> -p<password> < dumpM1_nopurge.sql
mysql -u<user> -p<password> < dumpM2_nopurge.sql
```

- On the replica, issue `RESET BINARY LOGS AND GTIDS` to clear the GTID execution history (assuming, as explained above, that all the dump files have been imported and that there are no wanted transactions with GTIDs on the replica). Then issue a `SET @@GLOBAL.gtid_purged` statement to set the `gtid_purged` value to the union of all the GTID sets from all the dump files, as you recorded in Step 2. For example:

```
mysql> RESET BINARY LOGS AND GTIDS;
mysql> SET @@GLOBAL.gtid_purged = "2174B383-5441-11E8-B90A-C80AA9429562:1-1029, 224DA167-0C0C-11E8-8442
```

If there are, or might be, overlapping transactions between the GTID sets in the dump files, you can use the stored functions described in [Section 19.1.3.8, “Stored Function Examples to Manipulate GTIDs”](#) to check this beforehand and to calculate the union of all the GTID sets.

### 19.1.5.3 Adding GTID-Based Sources to a Multi-Source Replica

These steps assume you have enabled GTIDs for transactions on the sources using `gtid_mode=ON`, created a replication user, ensured that the replica is using `TABLE` based replication applier metadata repositories, and provisioned the replica with data from the sources if appropriate.

Use `CHANGE REPLICATION SOURCE TO` to configure a replication channel for each source on the replica (see [Section 19.2.2, “Replication Channels”](#)). The `FOR CHANNEL` clause is used to specify the channel. For GTID-based replication, GTID auto-positioning is used to synchronize with the source (see [Section 19.1.3.3, “GTID Auto-Positioning”](#)). The `SOURCE_AUTO_POSITION` option is set to specify the use of auto-positioning.

For example, to add `source1` and `source2` as sources to the replica, use the `mysql` client to issue the statement twice on the replica, like this:

```
mysql> CHANGE REPLICATION SOURCE TO SOURCE_HOST="source1", SOURCE_USER="ted", \
SOURCE_PASSWORD="password", SOURCE_AUTO_POSITION=1 FOR CHANNEL "source_1";
mysql> CHANGE REPLICATION SOURCE TO SOURCE_HOST="source2", SOURCE_USER="ted", \
SOURCE_PASSWORD="password", SOURCE_AUTO_POSITION=1 FOR CHANNEL "source_2";
```

To make the replica replicate only database `db1` from `source1`, and only database `db2` from `source2`, use the `mysql` client to issue the `CHANGE REPLICATION FILTER` statement for each channel, like this:

```
mysql> CHANGE REPLICATION FILTER REPLICATE_WILD_DO_TABLE = ('db1.%') FOR CHANNEL "source_1";
mysql> CHANGE REPLICATION FILTER REPLICATE_WILD_DO_TABLE = ('db2.%') FOR CHANNEL "source_2";
```

For the full syntax of the `CHANGE REPLICATION FILTER` statement and other available options, see [Section 15.4.2.1, “CHANGE REPLICATION FILTER Statement”](#).

### 19.1.5.4 Adding Binary Log Based Replication Sources to a Multi-Source Replica

These steps assume that binary logging is enabled on the source (which is the default), the replica is using `TABLE` based replication applier metadata repositories (which is the default in MySQL 9.1), and that you have enabled a replication user and noted the current binary log file name and position.

Use a `CHANGE REPLICATION SOURCE TO` statement to configure a replication channel for each source on the replica (see [Section 19.2.2, “Replication Channels”](#)). The `FOR CHANNEL` clause is used to specify the channel. For example, to add `source1` and `source2` as sources to the replica, use the `mysql` client to issue the statement twice on the replica, like this:

```
mysql> CHANGE REPLICATION SOURCE TO SOURCE_HOST="source1", SOURCE_USER="ted", SOURCE_PASSWORD="password", \
SOURCE_LOG_FILE='source1-bin.000006', SOURCE_LOG_POS=628 FOR CHANNEL "source_1";
mysql> CHANGE REPLICATION SOURCE TO SOURCE_HOST="source2", SOURCE_USER="ted", SOURCE_PASSWORD="password", \
```

```
SOURCE_LOG_FILE='source2-bin.000018', SOURCE_LOG_POS=104 FOR CHANNEL "source_2";
```

To make the replica replicate only database `db1` from `source1`, and only database `db2` from `source2`, use the `mysql` client to issue the `CHANGE REPLICATION FILTER` statement for each channel, like this:

```
mysql> CHANGE REPLICATION FILTER REPLICATE_WILD_DO_TABLE = ('db1.%') FOR CHANNEL "source_1";
mysql> CHANGE REPLICATION FILTER REPLICATE_WILD_DO_TABLE = ('db2.%') FOR CHANNEL "source_2";
```

For the full syntax of the `CHANGE REPLICATION FILTER` statement and other available options, see [Section 15.4.2.1, “CHANGE REPLICATION FILTER Statement”](#).

### 19.1.5.5 Starting Multi-Source Replicas

Once you have added channels for all of the replication sources, issue a `START REPLICATION` statement to start replication. When you have enabled multiple channels on a replica, you can choose to either start all channels, or select a specific channel to start. For example, to start the two channels separately, use the `mysql` client to issue the following statements:

```
mysql> START REPLICATION FOR CHANNEL "source_1";
mysql> START REPLICATION FOR CHANNEL "source_2";
```

For the full syntax of the `START REPLICATION` statement and other available options, see [Section 15.4.2.4, “START REPLICATION Statement”](#).

To verify that both channels have started and are operating correctly, you can issue `SHOW REPLICATION STATUS` statements on the replica, for example:

```
mysql> SHOW REPLICATION STATUS FOR CHANNEL "source_1"\G
mysql> SHOW REPLICATION STATUS FOR CHANNEL "source_2"\G
```

### 19.1.5.6 Stopping Multi-Source Replicas

The `STOP REPLICATION` statement can be used to stop a multi-source replica. By default, if you use the `STOP REPLICATION` statement on a multi-source replica all channels are stopped. Optionally, use the `FOR CHANNEL channel` clause to stop only a specific channel.

- To stop all currently configured replication channels:

```
mysql> STOP REPLICATION;
```

- To stop only a named channel, use a `FOR CHANNEL channel` clause:

```
mysql> STOP REPLICATION FOR CHANNEL "source_1";
```

For the full syntax of the `STOP REPLICATION` statement and other available options, see [Section 15.4.2.5, “STOP REPLICATION Statement”](#).

### 19.1.5.7 Resetting Multi-Source Replicas

The `RESET REPLICATION` statement can be used to reset a multi-source replica. By default, if you use the `RESET REPLICATION` statement on a multi-source replica all channels are reset. Optionally, use the `FOR CHANNEL channel` clause to reset only a specific channel.

- To reset all currently configured replication channels:

```
mysql> RESET REPLICATION;
```

- To reset only a named channel, use a `FOR CHANNEL channel` clause:

```
mysql> RESET REPLICA FOR CHANNEL "source_1";
```

For GTID-based replication, note that `RESET REPLICA` has no effect on the replica's GTID execution history. If you want to clear this, issue `RESET BINARY LOGS AND GTIDS` on the replica.

`RESET REPLICA` makes the replica forget its replication position, and clears the relay log, but it does not change any replication connection parameters (such as the source host name) or replication filters. If you want to remove these for a channel, issue `RESET REPLICA ALL`.

### 19.1.5.8 Monitoring Multi-Source Replication

To monitor the status of replication channels the following options exist:

- Using the replication Performance Schema tables. The first column of these tables is `Channel_Name`. This enables you to write complex queries based on `Channel_Name` as a key. See [Section 29.12.11, “Performance Schema Replication Tables”](#).
- Using `SHOW REPLICA STATUS FOR CHANNEL channel`. By default, if the `FOR CHANNEL channel` clause is not used, this statement shows the replica status for all channels with one row per channel. The identifier `Channel_name` is added as a column in the result set. If a `FOR CHANNEL channel` clause is provided, the results show the status of only the named replication channel.

#### Note

The `SHOW VARIABLES` statement does not work with multiple replication channels. The information that was available through these variables has been migrated to the replication performance tables. Using a `SHOW VARIABLES` statement in a topology with multiple channels shows the status of only the default channel.

The error codes and messages that are issued when multi-source replication is enabled specify the channel that generated the error.

### Monitoring Channels Using Performance Schema Tables

This section explains how to use the replication Performance Schema tables to monitor channels. You can choose to monitor all channels, or a subset of the existing channels.

To monitor the connection status of all channels:

```
mysql> SELECT * FROM replication_connection_status\G;
***** 1. row *****
CHANNEL_NAME: source_1
GROUP_NAME:
SOURCE_UUID: 046e41f8-a223-11e4-a975-0811960cc264
THREAD_ID: 24
SERVICE_STATE: ON
COUNT_RECEIVED_HEARTBEATS: 0
LAST_HEARTBEAT_TIMESTAMP: 0000-00-00 00:00:00
RECEIVED_TRANSACTION_SET: 046e41f8-a223-11e4-a975-0811960cc264:4-37
LAST_ERROR_NUMBER: 0
LAST_ERROR_MESSAGE:
LAST_ERROR_TIMESTAMP: 0000-00-00 00:00:00
***** 2. row *****
CHANNEL_NAME: source_2
GROUP_NAME:
SOURCE_UUID: 7475e474-a223-11e4-a978-0811960cc264
THREAD_ID: 26
SERVICE_STATE: ON
```

```

COUNT_RECEIVED_HEARTBEATS: 0
LAST_HEARTBEAT_TIMESTAMP: 0000-00-00 00:00:00
RECEIVED_TRANSACTION_SET: 7475e474-a223-11e4-a978-0811960cc264:4-6
LAST_ERROR_NUMBER: 0
LAST_ERROR_MESSAGE:
LAST_ERROR_TIMESTAMP: 0000-00-00 00:00:00
2 rows in set (0.00 sec)

```

In the above output there are two channels enabled, and as shown by the `CHANNEL_NAME` field they are called `source_1` and `source_2`.

The addition of the `CHANNEL_NAME` field enables you to query the Performance Schema tables for a specific channel. To monitor the connection status of a named channel, use a `WHERE CHANNEL_NAME=channel` clause:

```

mysql> SELECT * FROM replication_connection_status WHERE CHANNEL_NAME='source_1'\G
***** 1. row *****
CHANNEL_NAME: source_1
GROUP_NAME:
SOURCE_UUID: 046e41f8-a223-11e4-a975-0811960cc264
THREAD_ID: 24
SERVICE_STATE: ON
COUNT_RECEIVED_HEARTBEATS: 0
LAST_HEARTBEAT_TIMESTAMP: 0000-00-00 00:00:00
RECEIVED_TRANSACTION_SET: 046e41f8-a223-11e4-a975-0811960cc264:4-37
LAST_ERROR_NUMBER: 0
LAST_ERROR_MESSAGE:
LAST_ERROR_TIMESTAMP: 0000-00-00 00:00:00
1 row in set (0.00 sec)

```

Similarly, the `WHERE CHANNEL_NAME=channel` clause can be used to monitor the other replication Performance Schema tables for a specific channel. For more information, see [Section 29.12.11, “Performance Schema Replication Tables”](#).

## 19.1.6 Replication and Binary Logging Options and Variables

The following sections contain information about `mysqld` options and server variables that are used in replication and for controlling the binary log. Options and variables for use on sources and replicas are covered separately, as are options and variables relating to binary logging and global transaction identifiers (GTIDs). A set of quick-reference tables providing basic information about these options and variables is also included.

Of particular importance is the `server_id` system variable.

Command-Line Format	<code>--server-id=#</code>
System Variable	<code>server_id</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	1
Minimum Value	0
Maximum Value	4294967295

This variable specifies the server ID. `server_id` is set to 1 by default. The server can be started with this default ID, but when binary logging is enabled, an informational message is issued if you did not set `server_id` explicitly to specify a server ID.

For servers that are used in a replication topology, you must specify a unique server ID for each replication server, in the range from 1 to  $2^{32} - 1$ . “Unique” means that each ID must be different from every other ID in use by any other source or replica in the replication topology. For additional information, see [Section 19.1.6.2, “Replication Source Options and Variables”](#), and [Section 19.1.6.3, “Replica Server Options and Variables”](#).

If the server ID is set to 0, binary logging takes place, but a source with a server ID of 0 refuses any connections from replicas, and a replica with a server ID of 0 refuses to connect to a source. Note that although you can change the server ID dynamically to a nonzero value, doing so does not enable replication to start immediately. You must change the server ID and then restart the server to initialize the replica.

For more information, see [Section 19.1.2.2, “Setting the Replica Configuration”](#).

#### `server_uuid`

The MySQL server generates a true UUID in addition to the default or user-supplied server ID set in the `server_id` system variable. This is available as the global, read-only variable `server_uuid`.

#### Note

The presence of the `server_uuid` system variable does not change the requirement for setting a unique `server_id` value for each MySQL server as part of preparing and running MySQL replication, as described earlier in this section.

System Variable	<code>server_uuid</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	String

When starting, the MySQL server automatically obtains a UUID as follows:

1. Attempt to read and use the UUID written in the file `data_dir/auto.cnf` (where `data_dir` is the server's data directory).
2. If `data_dir/auto.cnf` is not found, generate a new UUID and save it to this file, creating the file if necessary.

The `auto.cnf` file has a format similar to that used for `my.cnf` or `my.ini` files. `auto.cnf` has only a single `[auto]` section containing a single `server_uuid` setting and value; the file's contents appear similar to what is shown here:

```
[auto]
server_uuid=8a94f357-aab4-11df-86ab-c80aa9429562
```

#### Important

The `auto.cnf` file is automatically generated; do not attempt to write or modify this file.

When using MySQL replication, sources and replicas know each other's UUIDs. The value of a replica's UUID can be seen in the output of `SHOW REPLICAS`. Once `START REPLICA` has been executed, the value of the source's UUID is available on the replica in the output of `SHOW REPLICA STATUS`.

**Note**

Issuing a `STOP REPLICA` or `RESET REPLICA` statement does *not* reset the source's UUID as used on the replica.

A server's `server_uuid` is also used in GTIDs for transactions originating on that server. For more information, see [Section 19.1.3, “Replication with Global Transaction Identifiers”](#).

When starting, the replication I/O (receiver) thread generates an error and aborts if its source's UUID is equal to its own unless the `--replicate-same-server-id` option has been set. In addition, the replication receiver thread generates a warning if either of the following is true:

- No source having the expected `server_uuid` exists.
- The source's `server_uuid` has changed, although no `CHANGE REPLICATION SOURCE TO` statement has ever been executed.

### 19.1.6.1 Replication and Binary Logging Option and Variable Reference

The following two sections provide basic information about the MySQL command-line options and system variables applicable to replication and the binary log.

#### Replication Options and Variables

The command-line options and system variables in the following list relate to replication source servers and replicas. [Section 19.1.6.2, “Replication Source Options and Variables”](#) provides more detailed information about options and variables relating to replication source servers. For more information about options and variables relating to replicas, see [Section 19.1.6.3, “Replica Server Options and Variables”](#).

- `auto_increment_increment`: AUTO\_INCREMENT columns are incremented by this value.
- `auto_increment_offset`: Offset added to AUTO\_INCREMENT columns.
- `Com_change_replication_source`: Count of CHANGE REPLICATION SOURCE TO and CHANGE MASTER TO statements.
- `Com_replica_start`: Count of START REPLICA and START SLAVE statements.
- `Com_replica_stop`: Count of STOP REPLICA and STOP SLAVE statements.
- `Com_show_binary_log_status`: Count of SHOW BINARY LOG STATUS statements; use instead of `Com_show_master_status`.
- `Com_show_replica_status`: Count of SHOW REPLICA STATUS and SHOW SLAVE STATUS statements.
- `Com_show_replicas`: Count of SHOW REPLICAS and SHOW SLAVE HOSTS statements.
- `enforce_gtid_consistency`: Prevents execution of statements that cannot be logged in transactionally safe manner.
- `gtid_executed`: Global: All GTIDs in binary log (global) or current transaction (session). Read-only.
- `gtid_executed_compression_period`: Compress `gtid_executed` table each time this many transactions have occurred. 0 means never compress this table. Applies only when binary logging is disabled.

- `gtid_mode`: Controls whether GTID based logging is enabled and what type of transactions logs can contain.
- `gtid_next`: Specifies GTID for subsequent transaction or transactions; see documentation for details.
- `gtid_owned`: Set of GTIDs owned by this client (session), or by all clients, together with thread ID of owner (global). Read-only.
- `gtid_purged`: Set of all GTIDs that have been purged from binary log.
- `immediate_server_version`: MySQL Server release number of server which is immediate replication source.
- `init_replica`: Statements that are executed when replica connects to source.
- `init_slave`: Statements that are executed when replica connects to source.
- `log_bin_trust_function_creators`: If equal to 0 (default), then when `--log-bin` is used, stored function creation is allowed only to users having SUPER privilege and only if function created does not break binary logging.
- `log_statements_unsafe_for_binlog`: Disables error 1592 warnings being written to error log.
- `master-retry-count`: Number of tries replica makes to connect to source before giving up.
- `max_relay_log_size`: If nonzero, relay log is rotated automatically when its size exceeds this value. If zero, size at which rotation occurs is determined by value of `max_binlog_size`.
- `original_commit_timestamp`: Time when transaction was committed on original source.
- `original_server_version`: MySQL Server release number of server on which transaction was originally committed.
- `relay_log`: Location and base name to use for relay logs.
- `relay_log_basename`: Complete path to relay log, including file name.
- `relay_log_index`: Location and name to use for file that keeps list of last relay logs.
- `relay_log_purge`: Determines whether relay logs are purged.
- `relay_log_recovery`: Whether automatic recovery of relay log files from source at startup is enabled; must be enabled for crash-safe replica.
- `relay_log_space_limit`: Maximum space to use for all relay logs.
- `replica_checkpoint_group`: Maximum number of transactions processed by multithreaded replica before checkpoint operation is called to update progress status. Not supported by NDB Cluster.
- `replica_checkpoint_period`: Update progress status of multithreaded replica and flush relay log info to disk after this number of milliseconds. Not supported by NDB Cluster.
- `replica_compressed_protocol`: Use compression of source/replica protocol.
- `replica_exec_mode`: Allows for switching replication thread between IDEMPOTENT mode (key and some other errors suppressed) and STRICT mode; STRICT mode is default, except for NDB Cluster, where IDEMPOTENT is always used.
- `replica_load_tmpdir`: Location where replica should put its temporary files when replicating LOAD DATA statements.

- `replica_max_allowed_packet`: Maximum size, in bytes, of packet that can be sent from replication source server to replica; overrides `max_allowed_packet`.
- `replica_net_timeout`: Number of seconds to wait for more data from source/replica connection before aborting read.
- `Replica_open_temp_tables`: Number of temporary tables that replication SQL thread currently has open.
- `replica_parallel_type`: Tells replica to use timestamp information (`LOGICAL_CLOCK`) or database partitioning (`DATABASE`) to parallelize transactions.
- `replica_parallel_workers`: Number of applier threads for executing replication transactions. NDB Cluster: see documentation.
- `replica_pending_jobs_size_max`: Maximum size of replica worker queues holding events not yet applied.
- `replica_preserve_commit_order`: Ensures that all commits by replica workers happen in same order as on source to maintain consistency when using parallel applier threads.
- `replica_skip_errors`: Tells replication thread to continue replication when query returns error from provided list.
- `replica_transaction_retries`: Number of times replication SQL thread retries transaction in case it failed with deadlock or elapsed lock wait timeout, before giving up and stopping.
- `replica_type_conversions`: Controls type conversion mode on replica. Value is list of zero or more elements from this list: `ALL_LOSSY`, `ALL_NON_LOSSY`. Set to empty string to disallow type conversions between source and replica.
- `replicate-do-db`: Tells replication SQL thread to restrict replication to specified database.
- `replicate-do-table`: Tells replication SQL thread to restrict replication to specified table.
- `replicate-ignore-db`: Tells replication SQL thread not to replicate to specified database.
- `replicate-ignore-table`: Tells replication SQL thread not to replicate to specified table.
- `replicate-rewrite-db`: Updates to database with different name from original.
- `replicate-same-server-id`: In replication, if enabled, do not skip events having our server id.
- `replicate-wild-do-table`: Tells replication SQL thread to restrict replication to tables that match specified wildcard pattern.
- `replicate-wild-ignore-table`: Tells replication SQL thread not to replicate to tables that match given wildcard pattern.
- `replication_optimize_for_static_plugin_config`: Shared locks for semisynchronous replication.
- `replication_sender_observe_commit_only`: Limited callbacks for semisynchronous replication.
- `report_host`: Host name or IP of replica to be reported to source during replica registration.
- `report_password`: Arbitrary password which replica server should report to source; not same as password for replication user account.

- `report_port`: Port for connecting to replica reported to source during replica registration.
- `report_user`: Arbitrary user name which replica server should report to source; not same as name used for replication user account.
- `rpl_read_size`: Set minimum amount of data in bytes which is read from binary log files and relay log files.
- `Rpl_semi_sync_master_clients`: Number of semisynchronous replicas.
- `rpl_semi_sync_master_enabled`: Whether semisynchronous replication is enabled on source.
- `Rpl_semi_sync_master_net_avg_wait_time`: Average time source has waited for replies from replica.
- `Rpl_semi_sync_master_net_wait_time`: Total time source has waited for replies from replica.
- `Rpl_semi_sync_master_net_waits`: Total number of times source waited for replies from replica.
- `Rpl_semi_sync_master_no_times`: Number of times source turned off semisynchronous replication.
- `Rpl_semi_sync_master_no_tx`: Number of commits not acknowledged successfully.
- `Rpl_semi_sync_master_status`: Whether semisynchronous replication is operational on source.
- `Rpl_semi_sync_master_timefunc_failures`: Number of times source failed when calling time functions.
- `rpl_semi_sync_master_timeout`: Number of milliseconds to wait for replica acknowledgment.
- `rpl_semi_sync_master_trace_level`: Semisynchronous replication debug trace level on source.
- `Rpl_semi_sync_master_tx_avg_wait_time`: Average time source waited for each transaction.
- `Rpl_semi_sync_master_tx_wait_time`: Total time source waited for transactions.
- `Rpl_semi_sync_master_tx_waits`: Total number of times source waited for transactions.
- `rpl_semi_sync_master_wait_for_slave_count`: Number of replica acknowledgments source must receive per transaction before proceeding.
- `rpl_semi_sync_master_wait_no_slave`: Whether source waits for timeout even with no replicas.
- `rpl_semi_sync_master_wait_point`: Wait point for replica transaction receipt acknowledgment.
- `Rpl_semi_sync_master_wait_pos_backtraverse`: Total number of times source has waited for event with binary coordinates lower than events waited for previously.
- `Rpl_semi_sync_master_wait_sessions`: Number of sessions currently waiting for replica replies.
- `Rpl_semi_sync_master_yes_tx`: Number of commits acknowledged successfully.
- `rpl_semi_sync_replica_enabled`: Whether semisynchronous replication is enabled on replica.
- `Rpl_semi_sync_replica_status`: Whether semisynchronous replication is operational on replica.
- `rpl_semi_sync_replica_trace_level`: Semisynchronous replication debug trace level on replica.
- `rpl_semi_sync_slave_enabled`: Whether semisynchronous replication is enabled on replica.
- `Rpl_semi_sync_slave_status`: Whether semisynchronous replication is operational on replica.

- `rpl_semi_sync_slave_trace_level`: Semisynchronous replication debug trace level on replica.
- `Rpl_semi_sync_source_clients`: Number of semisynchronous replicas.
- `rpl_semi_sync_source_enabled`: Whether semisynchronous replication is enabled on source.
- `Rpl_semi_sync_source_net_avg_wait_time`: Average time source has waited for replies from replica.
- `Rpl_semi_sync_source_net_wait_time`: Total time source has waited for replies from replica.
- `Rpl_semi_sync_source_net_waits`: Total number of times source waited for replies from replica.
- `Rpl_semi_sync_source_no_times`: Number of times source turned off semisynchronous replication.
- `Rpl_semi_sync_source_no_tx`: Number of commits not acknowledged successfully.
- `Rpl_semi_sync_source_status`: Whether semisynchronous replication is operational on source.
- `Rpl_semi_sync_source_timefunc_failures`: Number of times source failed when calling time functions.
- `rpl_semi_sync_source_timeout`: Number of milliseconds to wait for replica acknowledgment.
- `rpl_semi_sync_source_trace_level`: Semisynchronous replication debug trace level on source.
- `Rpl_semi_sync_source_tx_avg_wait_time`: Average time source waited for each transaction.
- `Rpl_semi_sync_source_tx_wait_time`: Total time source waited for transactions.
- `Rpl_semi_sync_source_tx_waits`: Total number of times source waited for transactions.
- `rpl_semi_sync_source_wait_for_replica_count`: Number of replica acknowledgments source must receive per transaction before proceeding.
- `rpl_semi_sync_source_wait_no_replica`: Whether source waits for timeout even with no replicas.
- `rpl_semi_sync_source_wait_point`: Wait point for replica transaction receipt acknowledgment.
- `Rpl_semi_sync_source_wait_pos_backtraverse`: Total number of times source has waited for event with binary coordinates lower than events waited for previously.
- `Rpl_semi_sync_source_wait_sessions`: Number of sessions currently waiting for replica replies.
- `Rpl_semi_sync_source_yes_tx`: Number of commits acknowledged successfully.
- `rpl_stop_replica_timeout`: Number of seconds that STOP REPLICA waits before timing out.
- `rpl_stop_slave_timeout`: Number of seconds that STOP REPLICA or STOP SLAVE waits before timing out.
- `server_uuid`: Server's globally unique ID, automatically (re)generated at server start.
- `show-replica-auth-info`: Show user name and password in SHOW REPLICAS on this source.
- `show-slave-auth-info`: Show user name and password in SHOW REPLICAS and SHOW SLAVE HOSTS on this source.
- `skip-replica-start`: If set, replication is not autostarted when replica server starts.

- `skip_slave_start`: If set, replication is not autostarted when replica server starts.
- `slave_skip_errors`: Tells replication thread to continue replication when query returns error from provided list.
- `slave_checkpoint_group`: Maximum number of transactions processed by multithreaded replica before checkpoint operation is called to update progress status. Not supported by NDB Cluster.
- `slave_checkpoint_period`: Update progress status of multithreaded replica and flush relay log info to disk after this number of milliseconds. Not supported by NDB Cluster.
- `slave_compressed_protocol`: Use compression of source/replica protocol.
- `slave_exec_mode`: Allows for switching replication thread between IDEMPOTENT mode (key and some other errors suppressed) and STRICT mode; STRICT mode is default, except for NDB Cluster, where IDEMPOTENT is always used.
- `slave_load_tmpdir`: Location where replica should put its temporary files when replicating LOAD DATA statements.
- `slave_max_allowed_packet`: Maximum size, in bytes, of packet that can be sent from replication source server to replica; overrides `max_allowed_packet`.
- `slave_net_timeout`: Number of seconds to wait for more data from source/replica connection before aborting read.
- `Slave_open_temp_tables`: Number of temporary tables that replication SQL thread currently has open.
- `slave_parallel_type`: Tells replica to use timestamp information (LOGICAL\_CLOCK) or database partitioning (DATABASE) to parallelize transactions.
- `slave_parallel_workers`: Number of applier threads for executing replication transactions in parallel; 0 or 1 disables replica multithreading. NDB Cluster: see documentation.
- `slave_pending_jobs_size_max`: Maximum size of replica worker queues holding events not yet applied.
- `slave_preserve_commit_order`: Ensures that all commits by replica workers happen in same order as on source to maintain consistency when using parallel applier threads.
- `Slave_rows_last_search_algorithm_used`: Search algorithm most recently used by this replica to locate rows for row-based replication (index, table, or hash scan).
- `slave_transaction_retries`: Number of times replication SQL thread retries transaction in case it failed with deadlock or elapsed lock wait timeout, before giving up and stopping.
- `slave_type_conversions`: Controls type conversion mode on replica. Value is list of zero or more elements from this list: ALL\_LOSSY, ALL\_NON\_LOSSY. Set to empty string to disallow type conversions between source and replica.
- `sql_log_bin`: Controls binary logging for current session.
- `sql_replica_skip_counter`: Number of events from source that replica should skip. Not compatible with GTID replication.
- `sql_slave_skip_counter`: Number of events from source that replica should skip. Not compatible with GTID replication.

- `sync_master_info`: Synchronize source information after every #th event.
- `sync_relay_log`: Synchronize relay log to disk after every #th event.
- `sync_relay_log_info`: Synchronize relay.info file to disk after every #th event.
- `sync_source_info`: Synchronize source information after every #th event.
- `terminology_use_previous`: Use terminology from before specified version where changes are incompatible.

For a listing of all command-line options, system variables, and status variables used with `mysqld`, see [Section 7.1.4, “Server Option, System Variable, and Status Variable Reference”](#).

## Binary Logging Options and Variables

The command-line options and system variables in the following list relate to the binary log. [Section 19.1.6.4, “Binary Logging Options and Variables”](#), provides more detailed information about options and variables relating to binary logging. For additional general information about the binary log, see [Section 7.4.4, “The Binary Log”](#).

- `binlog-checksum`: Enable or disable binary log checksums.
- `binlog-do-db`: Limits binary logging to specific databases.
- `binlog-ignore-db`: Tells source that updates to given database should not be written to binary log.
- `binlog-row-event-max-size`: Binary log max event size.
- `Binlog_cache_disk_use`: Number of transactions which used temporary file instead of binary log cache.
- `binlog_cache_size`: Size of cache to hold SQL statements for binary log during transaction.
- `Binlog_cache_use`: Number of transactions that used temporary binary log cache.
- `binlog_checksum`: Enable or disable binary log checksums.
- `binlog_direct_non_transactional_updates`: Causes updates using statement format to nontransactional engines to be written directly to binary log. See documentation before using.
- `binlog_encryption`: Enable encryption for binary log files and relay log files on this server.
- `binlog_error_action`: Controls what happens when server cannot write to binary log.
- `binlog_expire_logs_auto_purge`: Controls automatic purging of binary log files; can be overridden when enabled, by setting both `binlog_expire_logs_seconds` and `expire_logs_days` to 0.
- `binlog_expire_logs_seconds`: Purge binary logs after this many seconds.
- `binlog_format`: Specifies format of binary log.
- `binlog_group_commit_sync_delay`: Sets number of microseconds to wait before synchronizing transactions to disk.
- `binlog_group_commit_sync_no_delay_count`: Sets maximum number of transactions to wait for before aborting current delay specified by `binlog_group_commit_sync_delay`.
- `binlog_max_flush_queue_time`: How long to read transactions before flushing to binary log.

- `binlog_order_commits`: Whether to commit in same order as writes to binary log.
- `binlog_rotate_encryption_master_key_at_startup`: Rotate binary log master key at server startup.
- `binlog_row_image`: Use full or minimal images when logging row changes.
- `binlog_row_metadata`: Whether to record all or only minimal table related metadata to binary log when using row-based logging.
- `binlog_row_value_options`: Enables binary logging of partial JSON updates for row-based replication.
- `binlog_rows_query_log_events`: When enabled, enables logging of rows query log events when using row-based logging. Disabled by default..
- `Binlog_stmt_cache_disk_use`: Number of nontransactional statements that used temporary file instead of binary log statement cache.
- `binlog_stmt_cache_size`: Size of cache to hold nontransactional statements for binary log during transaction.
- `Binlog_stmt_cache_use`: Number of statements that used temporary binary log statement cache.
- `binlog_transaction_compression`: Enable compression for transaction payloads in binary log files.
- `binlog_transaction_compression_level_zstd`: Compression level for transaction payloads in binary log files.
- `binlog_transaction_dependency_history_size`: Number of row hashes kept for looking up transaction that last updated some row.
- `Com_show_binlog_events`: Count of SHOW BINLOG EVENTS statements.
- `Com_show_binlogs`: Count of SHOW BINLOGS statements.
- `log-bin`: Base name for binary log files.
- `log-bin-index`: Name of binary log index file.
- `log_bin`: Whether binary log is enabled.
- `log_bin_basename`: Path and base name for binary log files.
- `log_replica_updates`: Whether replica should log updates performed by its replication SQL thread to its own binary log.
- `log_slave_updates`: Whether replica should log updates performed by its replication SQL thread to its own binary log.
- `master_verify_checksum`: Cause source to examine checksums when reading from binary log.
- `max-binlog-dump-events`: Option used by mysql-test for debugging and testing of replication.
- `max_binlog_cache_size`: Can be used to restrict total size in bytes used to cache multi-statement transactions.
- `max_binlog_size`: Binary log is rotated automatically when size exceeds this value.

- `max_binlog_stmt_cache_size`: Can be used to restrict total size used to cache all nontransactional statements during transaction.
- `replica_sql_verify_checksum`: Cause replica to examine checksums when reading from relay log.
- `slave-sql-verify-checksum`: Cause replica to examine checksums when reading from relay log.
- `slave_sql_verify_checksum`: Cause replica to examine checksums when reading from relay log.
- `source_verify_checksum`: Cause source to examine checksums when reading from binary log.
- `sporadic-binlog-dump-fail`: Option used by `mysql-test` for debugging and testing of replication.
- `sync_binlog`: Synchronously flush binary log to disk after every #th event.

For a listing of all command-line options, system and status variables used with `mysqld`, see [Section 7.1.4, “Server Option, System Variable, and Status Variable Reference”](#).

### 19.1.6.2 Replication Source Options and Variables

This section describes the server options and system variables that you can use on replication source servers. You can specify the options either on the [command line](#) or in an [option file](#). You can specify system variable values using [SET](#).

On the source and each replica, you must set the `server_id` system variable to establish a unique replication ID. For each server, you should pick a unique positive integer in the range from 1 to  $2^{32} - 1$ , and each ID must be different from every other ID in use by any other source or replica in the replication topology. Example: `server-id=3`.

For options used on the source for controlling binary logging, see [Section 19.1.6.4, “Binary Logging Options and Variables”](#).

### Startup Options for Replication Source Servers

The following list describes startup options for controlling replication source servers. Replication-related system variables are discussed later in this section.

- `--show-replica-auth-info`

Command-Line Format	<code>--show-replica-auth-info[={OFF ON} ]</code>
Type	Boolean
Default Value	OFF

Use `--show-replica-auth-info`, which displays replication user names and passwords in the output of `SHOW REPLICAS` on the source for replicas started with the `--report-user` and `--report-password` options.

- `--show-slave-auth-info`

Command-Line Format	<code>--show-slave-auth-info[={OFF ON} ]</code>
Deprecated	Yes
Type	Boolean
Default Value	OFF

Deprecated alias for `--show-replica-auth-info`.

## System Variables Used on Replication Source Servers

The following system variables are used for or by replication source servers:

- `auto_increment_increment`

Command-Line Format	<code>--auto-increment-increment=#</code>
System Variable	<code>auto_increment_increment</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Integer
Default Value	1
Minimum Value	1
Maximum Value	65535

`auto_increment_increment` and `auto_increment_offset` are intended for use with circular (source-to-source) replication, and can be used to control the operation of `AUTO_INCREMENT` columns. Both variables have global and session values, and each can assume an integer value between 1 and 65,535 inclusive. Setting the value of either of these two variables to 0 causes its value to be set to 1 instead. Attempting to set the value of either of these two variables to an integer greater than 65,535 or less than 0 causes its value to be set to 65,535 instead. Attempting to set the value of `auto_increment_increment` or `auto_increment_offset` to a noninteger value produces an error, and the actual value of the variable remains unchanged.

### Note

`auto_increment_increment` is also supported for use with `NDB` tables.

When Group Replication is started on a server, the value of `auto_increment_increment` is changed to the value of `group_replication_auto_increment_increment`, which defaults to 7, and the value of `auto_increment_offset` is changed to the server ID. The changes are reverted when Group Replication is stopped. These changes are only made and reverted if `auto_increment_increment` and `auto_increment_offset` each have their default value of 1. If their values have already been modified from the default, Group Replication does not alter them. These system variables are also not modified when Group Replication is in single-primary mode, where only one server writes.

`auto_increment_increment` and `auto_increment_offset` affect `AUTO_INCREMENT` column behavior as follows:

- `auto_increment_increment` controls the interval between successive column values. For example:

```
mysql> SHOW VARIABLES LIKE 'auto_inc%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| auto_increment_increment | 1 |
| auto_increment_offset | 1 |
+-----+-----+
2 rows in set (0.00 sec)

mysql> CREATE TABLE autoincl
-> (col INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
```

```

Query OK, 0 rows affected (0.04 sec)

mysql> SET @@auto_increment_increment=10;
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW VARIABLES LIKE 'auto_inc%';
+-----+
| Variable_name | Value |
+-----+
| auto_increment_increment | 10 |
| auto_increment_offset | 1 |
+-----+
2 rows in set (0.01 sec)

mysql> INSERT INTO autoinc1 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4 Duplicates: 0 Warnings: 0

mysql> SELECT col FROM autoinc1;
+-----+
| col |
+-----+
| 1 |
| 11 |
| 21 |
| 31 |
+-----+
4 rows in set (0.00 sec)

```

- `auto_increment_offset` determines the starting point for the `AUTO_INCREMENT` column value. Consider the following, assuming that these statements are executed during the same session as the example given in the description for `auto_increment_increment`:

```

mysql> SET @@auto_increment_offset=5;
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW VARIABLES LIKE 'auto_inc%';
+-----+
| Variable_name | Value |
+-----+
| auto_increment_increment | 10 |
| auto_increment_offset | 5 |
+-----+
2 rows in set (0.00 sec)

mysql> CREATE TABLE autoinc2
 -> (col INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
Query OK, 0 rows affected (0.06 sec)

mysql> INSERT INTO autoinc2 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4 Duplicates: 0 Warnings: 0

mysql> SELECT col FROM autoinc2;
+-----+
| col |
+-----+
| 5 |
| 15 |
| 25 |
| 35 |
+-----+

```

```
4 rows in set (0.02 sec)
```

When the value of `auto_increment_offset` is greater than that of `auto_increment_increment`, the value of `auto_increment_offset` is ignored.

If either of these variables is changed, and then new rows inserted into a table containing an `AUTO_INCREMENT` column, the results may seem counterintuitive because the series of `AUTO_INCREMENT` values is calculated without regard to any values already present in the column, and the next value inserted is the least value in the series that is greater than the maximum existing value in the `AUTO_INCREMENT` column. The series is calculated like this:

$$\text{auto\_increment\_offset} + N \times \text{auto\_increment\_increment}$$

where  $N$  is a positive integer value in the series [1, 2, 3, ...]. For example:

```
mysql> SHOW VARIABLES LIKE 'auto_inc%';
+-----+
| Variable_name | Value |
+-----+
| auto_increment_increment | 10 |
| auto_increment_offset | 5 |
+-----+
2 rows in set (0.00 sec)

mysql> SELECT col FROM autoinc1;
+-----+
| col |
+-----+
| 1 |
| 11 |
| 21 |
| 31 |
+-----+
4 rows in set (0.00 sec)

mysql> INSERT INTO autoinc1 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4 Duplicates: 0 Warnings: 0

mysql> SELECT col FROM autoinc1;
+-----+
| col |
+-----+
| 1 |
| 11 |
| 21 |
| 31 |
| 35 |
| 45 |
| 55 |
| 65 |
+-----+
8 rows in set (0.00 sec)
```

The values shown for `auto_increment_increment` and `auto_increment_offset` generate the series  $5 + N \times 10$ , that is, [5, 15, 25, 35, 45, ...]. The highest value present in the `col` column prior to the `INSERT` is 31, and the next available value in the `AUTO_INCREMENT` series is 35, so the inserted values for `col` begin at that point and the results are as shown for the `SELECT` query.

It is not possible to restrict the effects of these two variables to a single table; these variables control the behavior of all `AUTO_INCREMENT` columns in *all* tables on the MySQL server. If the global value of either variable is set, its effects persist until the global value is changed or overridden by setting the session

value, or until `mysqld` is restarted. If the local value is set, the new value affects `AUTO_INCREMENT` columns for all tables into which new rows are inserted by the current user for the duration of the session, unless the values are changed during that session.

The default value of `auto_increment_increment` is 1. See [Section 19.5.1.1, “Replication and AUTO\\_INCREMENT”](#).

- `auto_increment_offset`

Command-Line Format	<code>--auto-increment-offset=#</code>
System Variable	<code>auto_increment_offset</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Integer
Default Value	1
Minimum Value	1
Maximum Value	65535

This variable has a default value of 1. If it is left with its default value, and Group Replication is started on the server in multi-primary mode, it is changed to the server ID. For more information, see the description for `auto_increment_increment`.

#### Note

`auto_increment_offset` is also supported for use with `NDB` tables.

- `immediate_server_version`

System Variable	<code>immediate_server_version</code>
Scope	Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	999999
Minimum Value	0
Maximum Value	999999

For internal use by replication. This session system variable holds the MySQL Server release number of the server that is the immediate source in a replication topology (for example, `90100` for a MySQL 9.1.0 server instance). If this immediate server is at a release that does not support the session system variable, the value of the variable is set to 0 (`UNKNOWN_SERVER_VERSION`).

The value of the variable is replicated from a source to a replica. With this information the replica can correctly process data originating from a source at an older release, by recognizing where syntax changes or semantic changes have occurred between the releases involved and handling these appropriately. The information can also be used in a Group Replication environment where one or more members of the replication group is at a newer release than the others. The value of the variable can be viewed in the binary log for each transaction (as part of the `Gtid_log_event`,

or `Anonymous_gtid_log_event` if GTIDs are not in use on the server), and could be helpful in debugging cross-version replication issues.

Setting the session value of this system variable is a restricted operation. The session user must have either the `REPLICATION_APPLIER` privilege (see [Section 19.3.3, “Replication Privilege Checks”](#)), or privileges sufficient to set restricted session variables (see [Section 7.1.9.1, “System Variable Privileges”](#)). However, note that the variable is not intended for users to set; it is set automatically by the replication infrastructure.

- `original_server_version`

System Variable	<code>original_server_version</code>
Scope	Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	999999
Minimum Value	0
Maximum Value	999999

For internal use by replication. This session system variable holds the MySQL Server release number of the server where a transaction was originally committed (for example, `90100` for a MySQL 9.1.0 server instance). If this original server is at a release that does not support the session system variable, the value of the variable is set to 0 (`UNKNOWN_SERVER_VERSION`). Note that when a release number is set by the original server, the value of the variable is reset to 0 if the immediate server or any other intervening server in the replication topology does not support the session system variable, and so does not replicate its value.

The value of the variable is set and used in the same ways as for the `immediate_server_version` system variable. If the value of the variable is the same as that for the `immediate_server_version` system variable, only the latter is recorded in the binary log, with an indicator that the original server version is the same.

In a Group Replication environment, view change log events, which are special transactions queued by each group member when a new member joins the group, are tagged with the server version of the group member queuing the transaction. This ensures that the server version of the original donor is known to the joining member. Because the view change log events queued for a particular view change have the same GTID on all members, for this case only, instances of the same GTID might have a different original server version.

Setting the session value of this system variable is a restricted operation. The session user must have either the `REPLICATION_APPLIER` privilege (see [Section 19.3.3, “Replication Privilege Checks”](#)), or privileges sufficient to set restricted session variables (see [Section 7.1.9.1, “System Variable Privileges”](#)). However, note that the variable is not intended for users to set; it is set automatically by the replication infrastructure.

- `rpl_semi_sync_master_enabled`

Command-Line Format	<code>--rpl-semi-sync-master-enabled[={OFF ON}]</code>
System Variable	<code>rpl_semi_sync_master_enabled</code>

Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Boolean
Default Value	OFF

Deprecated synonym for [rpl\\_semi\\_sync\\_source\\_enabled](#).

- [rpl\\_semi\\_sync\\_master\\_timeout](#)

Command-Line Format	<code>--rpl-semi-sync-master-timeout=#</code>
System Variable	<a href="#">rpl_semi_sync_master_timeout</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	10000
Minimum Value	0
Maximum Value	4294967295
Unit	milliseconds

Deprecated synonym for [rpl\\_semi\\_sync\\_source\\_timeout](#).

- [rpl\\_semi\\_sync\\_master\\_trace\\_level](#)

Command-Line Format	<code>--rpl-semi-sync-master-trace-level=#</code>
System Variable	<a href="#">rpl_semi_sync_master_trace_level</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	32
Minimum Value	0
Maximum Value	4294967295

Deprecated synonym for [rpl\\_semi\\_sync\\_source\\_trace\\_level](#).

- [rpl\\_semi\\_sync\\_master\\_wait\\_for\\_slave\\_count](#)

Command-Line Format	<code>--rpl-semi-sync-master-wait-for-slave-count=#</code>
System Variable	<a href="#">rpl_semi_sync_master_wait_for_slave_count</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No

Type	Integer
Default Value	1
Minimum Value	1
Maximum Value	65535

Deprecated synonym for `rpl_semi_sync_source_wait_for_replica_count`.

- `rpl_semi_sync_master_wait_no_slave`

Command-Line Format	<code>--rpl-semi-sync-master-wait-no-slave[={OFF ON}]</code>
System Variable	<code>rpl_semi_sync_master_wait_no_slave</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	ON

Deprecated synonym for `rpl_semi_sync_source_wait_no_replica`.

- `rpl_semi_sync_master_wait_point`

Command-Line Format	<code>--rpl-semi-sync-master-wait-point=value</code>
System Variable	<code>rpl_semi_sync_master_wait_point</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Enumeration
Default Value	AFTER_SYNC
Valid Values	AFTER_SYNC AFTER_COMMIT

Deprecated synonym for `rpl_semi_sync_source_wait_point`.

- `rpl_semi_sync_source_enabled`

Command-Line Format	<code>--rpl-semi-sync-source-enabled[={OFF ON}]</code>
System Variable	<code>rpl_semi_sync_source_enabled</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	OFF

`rpl_semi_sync_source_enabled` is available when the `rpl_semi_sync_source` (`semisync_source.so` library) plugin was installed on the replica to set up semisynchronous replication.

`rpl_semi_sync_source_enabled` controls whether semisynchronous replication is enabled on the source server. To enable or disable the plugin, set this variable to `ON` or `OFF` (or 1 or 0), respectively. The default is `OFF`.

- `rpl_semi_sync_source_timeout`

Command-Line Format	<code>--rpl-semi-sync-source-timeout=#</code>
System Variable	<code>rpl_semi_sync_source_timeout</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	10000
Minimum Value	0
Maximum Value	4294967295
Unit	milliseconds

`rpl_semi_sync_source_timeout` is available when the `rpl_semi_sync_source` (`semisync_source.so` library) plugin is installed on the replica.

`rpl_semi_sync_source_timeout` controls how long the source waits on a commit for acknowledgment from a replica before timing out and reverting to asynchronous replication. The value is specified in milliseconds, and the default value is 10000 (10 seconds).

- `rpl_semi_sync_source_trace_level`

Command-Line Format	<code>--rpl-semi-sync-source-trace-level=#</code>
System Variable	<code>rpl_semi_sync_source_trace_level</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	32
Minimum Value	0
Maximum Value	4294967295

`rpl_semi_sync_source_trace_level` is available when the `rpl_semi_sync_source` (`semisync_source.so` library) plugin is installed on the replica.

`rpl_semi_sync_source_trace_level` specifies the semisynchronous replication debug trace level on the source server. Four levels are defined:

- 1 = general level (for example, time function failures)

- 16 = detail level (more verbose information)
- 32 = net wait level (more information about network waits)
- 64 = function level (information about function entry and exit)
- `rpl_semi_sync_source_wait_for_replica_count`

Command-Line Format	<code>--rpl-semi-sync-source-wait-for-replica-count=#</code>
System Variable	<code>rpl_semi_sync_source_wait_for_replica_count</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	1
Minimum Value	1
Maximum Value	65535

`rpl_semi_sync_source_wait_for_replica_count` is available when the `rpl_semi_sync_source` (`semisync_source.so` library) plugin is installed on the replica to set up semisynchronous replication.

`rpl_semi_sync_source_wait_for_replica_count` specifies the number of replica acknowledgments the source must receive per transaction before proceeding. By default `rpl_semi_sync_source_wait_for_replica_count` is 1, meaning that semisynchronous replication proceeds after receiving a single replica acknowledgment. Performance is best for small values of this variable.

For example, if `rpl_semi_sync_source_wait_for_replica_count` is 2, then 2 replicas must acknowledge receipt of the transaction before the timeout period configured by `rpl_semi_sync_source_timeout` for semisynchronous replication to proceed. If fewer replicas acknowledge receipt of the transaction during the timeout period, the source reverts to normal replication.

#### Note

This behavior also depends on `rpl_semi_sync_source_wait_no_replica`.

- `rpl_semi_sync_source_wait_no_replica`

Command-Line Format	<code>--rpl-semi-sync-source-wait-no-replica[={OFF ON}]</code>
System Variable	<code>rpl_semi_sync_source_wait_no_replica</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean

Default Value	ON
---------------	----

`rpl_semi_sync_source_wait_no_replica` is available when the `rpl_semi_sync_source` (`semisync_source.so` library) plugin is installed on the replica.

`rpl_semi_sync_source_wait_no_replica` controls whether the source waits for the timeout period configured by `rpl_semi_sync_source_timeout` to expire, even if the replica count drops to less than the number of replicas configured by `rpl_semi_sync_source_wait_for_replica_count` during the timeout period.

When the value of `rpl_semi_sync_source_wait_no_replica` is ON (the default), it is permissible for the replica count to drop to less than `rpl_semi_sync_source_wait_for_replica_count` during the timeout period. As long as enough replicas acknowledge the transaction before the timeout period expires, semisynchronous replication continues.

When the value of `rpl_semi_sync_source_wait_no_replica` is OFF, if the replica count drops to less than the number configured in `rpl_semi_sync_source_wait_for_replica_count` at any time during the timeout period configured by `rpl_semi_sync_source_timeout`, the source reverts to normal replication.

- `rpl_semi_sync_source_wait_point`

Command-Line Format	<code>--rpl-semi-sync-source-wait-point=value</code>
System Variable	<code>rpl_semi_sync_source_wait_point</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	AFTER_SYNC
Valid Values	AFTER_SYNC AFTER_COMMIT

`rpl_semi_sync_source_wait_point` is available when the `rpl_semi_sync_source` (`semisync_source.so` library) plugin is installed on the replica.

`rpl_semi_sync_source_wait_point` controls the point at which a semisynchronous replication source server waits for replica acknowledgment of transaction receipt before returning a status to the client that committed the transaction. These values are permitted:

- **AFTER\_SYNC** (the default): The source writes each transaction to its binary log and the replica, and syncs the binary log to disk. The source waits for replica acknowledgment of transaction receipt after the sync. Upon receiving acknowledgment, the source commits the transaction to the storage engine and returns a result to the client, which then can proceed.
- **AFTER\_COMMIT**: The source writes each transaction to its binary log and the replica, syncs the binary log, and commits the transaction to the storage engine. The source waits for replica acknowledgment

of transaction receipt after the commit. Upon receiving acknowledgment, the source returns a result to the client, which then can proceed.

The replication characteristics of these settings differ as follows:

- With `AFTER_SYNC`, all clients see the committed transaction at the same time: After it has been acknowledged by the replica and committed to the storage engine on the source. Thus, all clients see the same data on the source.

In the event of source failure, all transactions committed on the source have been replicated to the replica (saved to its relay log). An unexpected exit of the source server and failover to the replica is lossless because the replica is up to date. Note, however, that the source cannot be restarted in this scenario and must be discarded, because its binary log might contain uncommitted transactions that would cause a conflict with the replica when externalized after binary log recovery.

- With `AFTER_COMMIT`, the client issuing the transaction gets a return status only after the server commits to the storage engine and receives replica acknowledgment. After the commit and before replica acknowledgment, other clients can see the committed transaction before the committing client.

If something goes wrong such that the replica does not process the transaction, then in the event of an unexpected source server exit and failover to the replica, it is possible for such clients to see a loss of data relative to what they saw on the source.

### 19.1.6.3 Replica Server Options and Variables

This section explains the server options and system variables that apply to replica servers and contains the following:

- [Startup Options for Replica Servers](#)
- [System Variables Used on Replica Servers](#)

Specify the options either on the [command line](#) or in an [option file](#). Many of the options can be set while the server is running by using the `CHANGE REPLICATION SOURCE TO` statement. Specify system variable values using `SET`.

**Server ID.** On the source and each replica, you must set the `server_id` system variable to establish a unique replication ID in the range from 1 to  $2^{32} - 1$ . “Unique” means that each ID must be different from every other ID in use by any other source or replica in the replication topology. Example `my.cnf` file:

```
[mysqld]
server-id=3
```

### Startup Options for Replica Servers

This section explains startup options for controlling replica servers. Many of these options can be set while the server is running by using the `CHANGE REPLICATION SOURCE TO` statement. Others, such as the `--replicate-*` options, can be set only when the replica server starts. Replication-related system variables are discussed later in this section.

- `--master-retry-count=count`

Command-Line Format	<code>--master-retry-count=#</code>
Deprecated	Yes
Type	Integer
Default Value	10

Minimum Value	0
Maximum Value (64-bit platforms)	18446744073709551615
Maximum Value (32-bit platforms)	4294967295

This option is deprecated; expect it to be removed in a future MySQL release. Use the `SOURCE_RETRY_COUNT` option of the `CHANGE REPLICATION SOURCE TO` statement, instead.

- `--max-relay-log-size=size`

Command-Line Format	<code>--max-relay-log-size=#</code>
System Variable	<code>max_relay_log_size</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	1073741824
Unit	bytes
Block Size	4096

The size at which the server rotates relay log files automatically. If this value is nonzero, the relay log is rotated automatically when its size exceeds this value. If this value is zero (the default), the size at which relay log rotation occurs is determined by the value of `max_binlog_size`. For more information, see [Section 19.2.4.1, “The Relay Log”](#).

- `--relay-log-purge={0|1}`

Command-Line Format	<code>--relay-log-purge[={OFF ON}]</code>
System Variable	<code>relay_log_purge</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	ON

Disable or enable automatic purging of relay logs as soon as they are no longer needed. The default value is 1 (enabled). This is a global variable that can be changed dynamically with `SET GLOBAL relay_log_purge = N`. Disabling purging of relay logs when enabling the `--relay-log-recovery` option risks data consistency and is therefore not crash-safe.

- `--relay-log-space-limit=size`

Command-Line Format	<code>--relay-log-space-limit=#</code>
System Variable	<code>relay_log_space_limit</code>
Scope	Global

Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	18446744073709551615
Unit	bytes

This option places an upper limit on the total size in bytes of all relay logs on the replica. A value of 0 means “no limit”. This is useful for a replica server host that has limited disk space. When the limit is reached, the I/O (receiver) thread stops reading binary log events from the source server until the SQL thread has caught up and deleted some unused relay logs. Note that this limit is not absolute: There are cases where the SQL (applier) thread needs more events before it can delete relay logs. In that case, the receiver thread exceeds the limit until it becomes possible for the applier thread to delete some relay logs because not doing so would cause a deadlock. You should not set `--relay-log-space-limit` to less than twice the value of `--max-relay-log-size` (or `--max-binlog-size` if `--max-relay-log-size` is 0). In that case, there is a chance that the receiver thread waits for free space because `--relay-log-space-limit` is exceeded, but the applier thread has no relay log to purge and is unable to satisfy the receiver thread. This forces the receiver thread to ignore `--relay-log-space-limit` temporarily.

- `--replicate-do-db=db_name`

Command-Line Format	<code>--replicate-do-db=name</code>
Type	String

Creates a replication filter using the name of a database. Such filters can also be created using `CHANGE REPLICATION FILTER REPLICATE_DO_DB`.

This option supports channel specific replication filters, enabling multi-source replicas to use specific filters for different sources. To configure a channel specific replication filter on a channel named `channel_1` use `--replicate-do-db:channel_1:db_name`. In this case, the first colon is interpreted as a separator and subsequent colons are literal colons. See [Section 19.2.5.4, “Replication Channel Based Filters”](#) for more information.

#### Note

Global replication filters cannot be used on a MySQL server instance that is configured for Group Replication, because filtering transactions on some servers would make the group unable to reach agreement on a consistent state. Channel specific replication filters can be used on replication channels that are not directly involved with Group Replication, such as where a group member also acts as a replica to a source that is outside the group. They cannot be used on the `group_replication_applier` or `group_replication_recovery` channels.

The precise effect of this replication filter depends on whether statement-based or row-based replication is in use.

**Statement-based replication.** Tell the replication SQL thread to restrict replication to statements where the default database (that is, the one selected by `USE`) is `db_name`. To specify more than one database, use this option multiple times, once for each database; however, doing so does *not* replicate

cross-database statements such as `UPDATE some_db.some_table SET foo='bar'` while a different database (or no database) is selected.

### Warning

To specify multiple databases you *must* use multiple instances of this option. Because database names can contain commas, if you supply a comma separated list then the list is treated as the name of a single database.

An example of what does not work as you might expect when using statement-based replication: If the replica is started with `--replicate-do-db=sales` and you issue the following statements on the source, the `UPDATE` statement is *not* replicated:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The main reason for this “check just the default database” behavior is that it is difficult from the statement alone to know whether it should be replicated (for example, if you are using multiple-table `DELETE` statements or multiple-table `UPDATE` statements that act across multiple databases). It is also faster to check only the default database rather than all databases if there is no need.

**Row-based replication.** Tells the replication SQL thread to restrict replication to database `db_name`. Only tables belonging to `db_name` are changed; the current database has no effect on this. Suppose that the replica is started with `--replicate-do-db=sales` and row-based replication is in effect, and then the following statements are run on the source:

```
USE prices;
UPDATE sales.february SET amount=amount+100;
```

The `february` table in the `sales` database on the replica is changed in accordance with the `UPDATE` statement; this occurs whether or not the `USE` statement was issued. However, issuing the following statements on the source has no effect on the replica when using row-based replication and `--replicate-do-db=sales`:

```
USE prices;
UPDATE prices.march SET amount=amount-25;
```

Even if the statement `USE prices` were changed to `USE sales`, the `UPDATE` statement's effects would still not be replicated.

Another important difference in how `--replicate-do-db` is handled in statement-based replication as opposed to row-based replication occurs with regard to statements that refer to multiple databases. Suppose that the replica is started with `--replicate-do-db=db1`, and the following statements are executed on the source:

```
USE db1;
UPDATE db1.table1, db2.table2 SET db1.table1.col1 = 10, db2.table2.col2 = 20;
```

If you are using statement-based replication, then both tables are updated on the replica. However, when using row-based replication, only `table1` is affected on the replica; since `table2` is in a different database, `table2` on the replica is not changed by the `UPDATE`. Now suppose that, instead of the `USE db1` statement, a `USE db4` statement had been used:

```
USE db4;
UPDATE db1.table1, db2.table2 SET db1.table1.col1 = 10, db2.table2.col2 = 20;
```

In this case, the `UPDATE` statement would have no effect on the replica when using statement-based replication. However, if you are using row-based replication, the `UPDATE` would change `table1` on the

replica, but not `table2`—in other words, only tables in the database named by `--replicate-do-db` are changed, and the choice of default database has no effect on this behavior.

If you need cross-database updates to work, use `--replicate-wild-do-table=db_name.%` instead. See [Section 19.2.5, “How Servers Evaluate Replication Filtering Rules”](#).

#### Note

This option affects replication in the same manner that `--binlog-do-db` affects binary logging, and the effects of the replication format on how `--replicate-do-db` affects replication behavior are the same as those of the logging format on the behavior of `--binlog-do-db`.

This option has no effect on `BEGIN`, `COMMIT`, or `ROLLBACK` statements.

- `--replicate-ignore-db=db_name`

Command-Line Format	<code>--replicate-ignore-db=name</code>
Type	String

Creates a replication filter using the name of a database. Such filters can also be created using `CHANGE REPLICATION FILTER REPLICATE_IGNORE_DB`.

This option supports channel specific replication filters, enabling multi-source replicas to use specific filters for different sources. To configure a channel specific replication filter on a channel named `channel_1` use `--replicate-ignore-db:channel_1:db_name`. In this case, the first colon is interpreted as a separator and subsequent colons are literal colons. See [Section 19.2.5.4, “Replication Channel Based Filters”](#) for more information.

#### Note

Global replication filters cannot be used on a MySQL server instance that is configured for Group Replication, because filtering transactions on some servers would make the group unable to reach agreement on a consistent state. Channel specific replication filters can be used on replication channels that are not directly involved with Group Replication, such as where a group member also acts as a replica to a source that is outside the group. They cannot be used on

the `group_replication_applier` or `group_replication_recovery` channels.

To specify more than one database to ignore, use this option multiple times, once for each database. Because database names can contain commas, if you supply a comma-separated list, it is treated as the name of a single database.

As with `--replicate-do-db`, the precise effect of this filtering depends on whether statement-based or row-based replication is in use, and are described in the next several paragraphs.

**Statement-based replication.** Tells the replication SQL thread not to replicate any statement where the default database (that is, the one selected by `USE`) is `db_name`.

**Row-based replication.** Tells the replication SQL thread not to update any tables in the database `db_name`. The default database has no effect.

When using statement-based replication, the following example does not work as you might expect. Suppose that the replica is started with `--replicate-ignore-db=sales` and you issue the following statements on the source:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The `UPDATE` statement *is* replicated in such a case because `--replicate-ignore-db` applies only to the default database (determined by the `USE` statement). Because the `sales` database was specified explicitly in the statement, the statement has not been filtered. However, when using row-based replication, the `UPDATE` statement's effects are *not* propagated to the replica, and the replica's copy of the `sales.january` table is unchanged; in this instance, `--replicate-ignore-db=sales` causes *all* changes made to tables in the source's copy of the `sales` database to be ignored by the replica.

You should not use this option if you are using cross-database updates and you do not want these updates to be replicated. See [Section 19.2.5, “How Servers Evaluate Replication Filtering Rules”](#).

If you need cross-database updates to work, use `--replicate-wild-ignore-table=db_name.%` instead. See [Section 19.2.5, “How Servers Evaluate Replication Filtering Rules”](#).

#### Note

This option affects replication in the same manner that `--binlog-ignore-db` affects binary logging, and the effects of the replication format on how `--replicate-ignore-db` affects replication behavior are the same as those of the logging format on the behavior of `--binlog-ignore-db`.

This option has no effect on `BEGIN`, `COMMIT`, or `ROLLBACK` statements.

- `--replicate-do-table=db_name.tbl_name`

Command-Line Format	<code>--replicate-do-table=name</code>
Type	String

Creates a replication filter by telling the replication SQL thread to restrict replication to a given table. To specify more than one table, use this option multiple times, once for each table. This works for both cross-database updates and default database updates, in contrast to `--replicate-do-db`. See

[Section 19.2.5, “How Servers Evaluate Replication Filtering Rules”](#). You can also create such a filter by issuing a `CHANGE REPLICATION FILTER REPLICATE_DO_TABLE` statement.

This option supports channel specific replication filters, enabling multi-source replicas to use specific filters for different sources. To configure a channel specific replication filter on a channel named `channel_1` use `--replicate-do-table:channel_1:db_name.tbl_name`. In this case, the first colon is interpreted as a separator and subsequent colons are literal colons. See [Section 19.2.5.4, “Replication Channel Based Filters”](#) for more information.

#### Note

Global replication filters cannot be used on a MySQL server instance that is configured for Group Replication, because filtering transactions on some servers would make the group unable to reach agreement on a consistent state. Channel specific replication filters can be used on replication channels that are not directly involved with Group Replication, such as where a group member also acts as a replica to a source that is outside the group. They cannot be used on the `group_replication_applier` or `group_replication_recovery` channels.

This option affects only statements that apply to tables. It does not affect statements that apply only to other database objects, such as stored routines. To filter statements operating on stored routines, use one or more of the `--replicate-*-db` options.

- `--replicate-ignore-table=db_name.tbl_name`

Command-Line Format	<code>--replicate-ignore-table=name</code>
Type	String

Creates a replication filter by telling the replication SQL thread not to replicate any statement that updates the specified table, even if any other tables might be updated by the same statement. To specify more than one table to ignore, use this option multiple times, once for each table. This works for cross-database updates, in contrast to `--replicate-ignore-db`. See [Section 19.2.5, “How Servers Evaluate Replication Filtering Rules”](#). You can also create such a filter by issuing a `CHANGE REPLICATION FILTER REPLICATE_IGNORE_TABLE` statement.

This option supports channel specific replication filters, enabling multi-source replicas to use specific filters for different sources. To configure a channel specific replication filter on a channel named `channel_1` use `--replicate-ignore-table:channel_1:db_name.tbl_name`. In this case, the first colon is interpreted as a separator and subsequent colons are literal colons. See [Section 19.2.5.4, “Replication Channel Based Filters”](#) for more information.

#### Note

Global replication filters cannot be used on a MySQL server instance that is configured for Group Replication, because filtering transactions on some servers would make the group unable to reach agreement on a consistent state. Channel specific replication filters can be used on replication channels that are not directly involved with Group Replication, such as where a group member also acts as a replica to a source that is outside the group. They cannot be used on

the `group_replication_applier` or `group_replication_recovery` channels.

This option affects only statements that apply to tables. It does not affect statements that apply only to other database objects, such as stored routines. To filter statements operating on stored routines, use one or more of the `--replicate-*--db` options.

- `--replicate-rewrite-db=from_name->to_name`

Command-Line Format	<code>--replicate-rewrite-db=old_name-&gt;new_name</code>
Type	String

Tells the replica to create a replication filter that translates the specified database to `to_name` if it was `from_name` on the source. Only statements involving tables are affected, not statements such as `CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE`.

To specify multiple rewrites, use this option multiple times. The server uses the first one with a `from_name` value that matches. The database name translation is done *before* the `--replicate-*` rules are tested. You can also create such a filter by issuing a `CHANGE REPLICATION FILTER REPLICATE_REWRITE_DB` statement.

If you use the `--replicate-rewrite-db` option on the command line and the `>` character is special to your command interpreter, quote the option value. For example:

```
$> mysqld --replicate-rewrite-db="olddb->newdb"
```

The effect of the `--replicate-rewrite-db` option differs depending on whether statement-based or row-based binary logging format is used for the query. With statement-based format, DML statements are translated based on the current database, as specified by the `USE` statement. With row-based format, DML statements are translated based on the database where the modified table exists. DDL statements are always filtered based on the current database, as specified by the `USE` statement, regardless of the binary logging format.

To ensure that rewriting produces the expected results, particularly in combination with other replication filtering options, follow these recommendations when you use the `--replicate-rewrite-db` option:

- Create the `from_name` and `to_name` databases manually on the source and the replica with different names.
- If you use statement-based or mixed binary logging format, do not use cross-database queries, and do not specify database names in queries. For both DDL and DML statements, rely on the `USE` statement to specify the current database, and use only the table name in queries.
- If you use row-based binary logging format exclusively, for DDL statements, rely on the `USE` statement to specify the current database, and use only the table name in queries. For DML statements, you can use a fully qualified table name (`db.table`) if you want.

If these recommendations are followed, it is safe to use the `--replicate-rewrite-db` option in combination with table-level replication filtering options such as `--replicate-do-table`.

This option supports channel specific replication filters, enabling multi-source replicas to use specific filters for different sources. Specify the channel name followed by a colon, followed by the filter specification. The first colon is interpreted as a separator, and any subsequent colons are interpreted

as literal colons. For example, to configure a channel specific replication filter on a channel named `channel_1`, use:

```
$> mysqld --replicate-rewrite-db=channel_1:db_name1->db_name2
```

If you use a colon but do not specify a channel name, the option configures the replication filter for the default replication channel. See [Section 19.2.5.4, “Replication Channel Based Filters”](#) for more information.

#### Note

Global replication filters cannot be used on a MySQL server instance that is configured for Group Replication, because filtering transactions on some servers would make the group unable to reach agreement on a consistent state. Channel specific replication filters can be used on replication channels that are not directly involved with Group Replication, such as where a group member also acts as a replica to a source that is outside the group. They cannot be used on the `group_replication_applier` or `group_replication_recovery` channels.

- `--replicate-same-server-id`

Command-Line Format	<code>--replicate-same-server-id[={OFF ON}]</code>
Type	Boolean
Default Value	OFF

This option is for use on replicas. The default is 0 (`FALSE`). With this option set to 1 (`TRUE`), the replica does not skip events that have its own server ID. This setting is normally useful only in rare configurations.

When binary logging is enabled on a replica, the combination of the `--replicate-same-server-id` and `--log-replica-updates` options on the replica can cause infinite loops in replication if the server is part of a circular replication topology. (In MySQL 9.1, binary logging is enabled by default, and replica update logging is the default when binary logging is enabled.) However, the use of global transaction identifiers (GTIDs) prevents this situation by skipping the execution of transactions that have already been applied. If `gtid_mode=ON` is set on the replica, you can start the server with this combination of options, but you cannot change to any other GTID mode while the server is running. If any other GTID mode is set, the server does not start with this combination of options.

By default, the replication I/O (receiver) thread does not write binary log events to the relay log if they have the replica's server ID (this optimization helps save disk usage). If you want to use `--replicate-same-server-id`, be sure to start the replica with this option before you make the replica read its own events that you want the replication SQL (applier) thread to execute.

- `--replicate-wild-do-table=db_name.tbl_name`

Command-Line Format	<code>--replicate-wild-do-table=name</code>
Type	String

Creates a replication filter by telling the replication SQL (applier) thread to restrict replication to statements where any of the updated tables match the specified database and table name patterns. Patterns can contain the `%` and `_` wildcard characters, which have the same meaning as for the `LIKE` pattern-matching operator. To specify more than one table, use this option multiple times, once for each table. This works for cross-database updates. See [Section 19.2.5, “How Servers Evaluate Replication”](#)

**Filtering Rules**". You can also create such a filter by issuing a `CHANGE REPLICATION FILTER REPLICATE_WILD_DO_TABLE` statement.

This option supports channel specific replication filters, enabling multi-source replicas to use specific filters for different sources. To configure a channel specific replication filter on a channel named `channel_1` use `--replicate-wild-do-table:channel_1:db_name.tbl_name`. In this case, the first colon is interpreted as a separator and subsequent colons are literal colons. See [Section 19.2.5.4, "Replication Channel Based Filters"](#) for more information.

### Important

Global replication filters cannot be used on a MySQL server instance that is configured for Group Replication, because filtering transactions on some servers would make the group unable to reach agreement on a consistent state. Channel specific replication filters can be used on replication channels that are not directly involved with Group Replication, such as where a group member also acts as a replica to a source that is outside the group. They cannot be used on the `group_replication_applier` or `group_replication_recovery` channels.

The replication filter specified by the `--replicate-wild-do-table` option applies to tables, views, and triggers. It does not apply to stored procedures and functions, or events. To filter statements operating on the latter objects, use one or more of the `--replicate-*-db` options.

As an example, `--replicate-wild-do-table=foo%.bar%` replicates only updates that use a table where the database name starts with `foo` and the table name starts with `bar`.

If the table name pattern is `%`, it matches any table name and the option also applies to database-level statements (`CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE`). For example, if you use `--replicate-wild-do-table=foo%.`, database-level statements are replicated if the database name matches the pattern `foo%`.

### Important

Table-level replication filters are only applied to tables that are explicitly mentioned and operated on in the query. They do not apply to tables that are implicitly updated by the query. For example, a `GRANT` statement, which updates the `mysql.user` system table but does not mention that table, is not affected by a filter that specifies `mysql.%` as the wildcard pattern.

To include literal wildcard characters in the database or table name patterns, escape them with a backslash. For example, to replicate all tables of a database that is named `my_own%db`, but not replicate tables from the `my1ownAABCdb` database, you should escape the `_` and `%` characters like this: `--replicate-wild-do-table=my\_own\%db`. If you use the option on the command line, you might need to double the backslashes or quote the option value, depending on your command interpreter. For example, with the `bash` shell, you would need to type `--replicate-wild-do-table=my\\\_own\\%db`.

- `--replicate-wild-ignore-table=db_name.tbl_name`

Command-Line Format	<code>--replicate-wild-ignore-table=name</code>
Type	String

Creates a replication filter which keeps the replication SQL thread from replicating a statement in which any table matches the given wildcard pattern. To specify more than one table to ignore, use this option

multiple times, once for each table. This works for cross-database updates. See [Section 19.2.5, “How Servers Evaluate Replication Filtering Rules”](#). You can also create such a filter by issuing a `CHANGE REPLICATION FILTER REPLICATE_WILD_IGNORE_TABLE` statement.

This option supports channel specific replication filters, enabling multi-source replicas to use specific filters for different sources. To configure a channel specific replication filter on a channel named `channel_1` use `--replicate-wild-ignore:channel_1:db_name.tbl_name`. In this case, the first colon is interpreted as a separator and subsequent colons are literal colons. See [Section 19.2.5.4, “Replication Channel Based Filters”](#) for more information.

#### Important

Global replication filters cannot be used on a MySQL server instance that is configured for Group Replication, because filtering transactions on some servers would make the group unable to reach agreement on a consistent state. Channel specific replication filters can be used on replication channels that are not directly involved with Group Replication, such as where a group member also acts as a replica to a source that is outside the group. They cannot be used on the `group_replication_applier` or `group_replication_recovery` channels.

As an example, `--replicate-wild-ignore-table=foo%.bar%` does not replicate updates that use a table where the database name starts with `foo` and the table name starts with `bar`. For information about how matching works, see the description of the `--replicate-wild-do-table` option. The rules for including literal wildcard characters in the option value are the same as for `--replicate-wild-ignore-table` as well.

#### Important

Table-level replication filters are only applied to tables that are explicitly mentioned and operated on in the query. They do not apply to tables that are implicitly updated by the query. For example, a `GRANT` statement, which updates the `mysql.user` system table but does not mention that table, is not affected by a filter that specifies `mysql.%` as the wildcard pattern.

If you need to filter out `GRANT` statements or other administrative statements, a possible workaround is to use the `--replicate-ignore-db` filter. This filter operates on the default database that is currently in effect, as determined by the `USE` statement. You can therefore create a filter to ignore statements for a database that is not replicated, then issue the `USE` statement to switch the default database to that one immediately before issuing any administrative statements that you want to ignore. In the administrative statement, name the actual database where the statement is applied.

For example, if `--replicate-ignore-db=nonreplicated` is configured on the replica server, the following sequence of statements causes the `GRANT` statement to be ignored, because the default database `nonreplicated` is in effect:

```
USE nonreplicated;
GRANT SELECT, INSERT ON replicated.t1 TO 'someuser'@'somehost';
```

- `--skip-replica-start`

Command-Line Format	<code>--skip-replica-start[={OFF ON}]</code>
System Variable	<code>skip_replica_start</code>
Scope	Global

Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	OFF

`--skip-replica-start` tells the replica server not to start the replication I/O (receiver) and SQL (applier) threads when the server starts. To start the threads later, use a `START REPLICA` statement.

You can use the `skip_replica_start` system variable in place of the command line option to allow access to this feature using MySQL Server's privilege structure, so that database administrators do not need any privileged access to the operating system.

- `--skip-slave-start`

Command-Line Format	<code>--skip-slave-start[={OFF ON}]</code>
Deprecated	Yes
System Variable	<code>skip_slave_start</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	OFF

Deprecated alias for `--skip-replica-start`.

- `--slave-skip-errors=[err_code1,err_code2,...|all|ddl_exist_errors]`

Command-Line Format	<code>--slave-skip-errors=name</code>
Deprecated	Yes
System Variable	<code>slave_skip_errors</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value	OFF
Valid Values	OFF  [list of error codes]  all  ddl_exist_errors

Deprecated synonym for `--replica-skip-errors`.

- `--slave-sql-verify-checksum={0|1}`

Command-Line Format	<code>--slave-sql-verify-checksum[={OFF ON}]</code>
Type	Boolean
Default Value	ON

Deprecated synonym for `--replica-sql-verify-checksum`

## System Variables Used on Replica Servers

The following list describes system variables for controlling replica servers. They can be set at server startup and some of them can be changed at runtime using `SET`. Server options used with replicas are listed earlier in this section.

- `init_replica`

Command-Line Format	<code>--init-replica=name</code>
System Variable	<code>init_replica</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String

`init_replica` is similar to `init_connect`, but is a string to be executed by a replica server each time the replication SQL thread starts. The format of the string is the same as for the `init_connect` variable. The setting of this variable takes effect for subsequent `START REPLICATION` statements.

### Note

The replication SQL thread sends an acknowledgment to the client before it executes `init_replica`. Therefore, it is not guaranteed that `init_replica` has been executed when `START REPLICATION` returns. See [Section 15.4.2.4, “START REPLICATION Statement”](#) for more information.

- `init_slave`

Command-Line Format	<code>--init-slave=name</code>
Deprecated	Yes
System Variable	<code>init_slave</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String

Deprecated alias for `init_replica`.

- `log_slow_replica_statements`

Command-Line Format	<code>--log-slow-replica-statements[={OFF ON}]</code>
System Variable	<code>log_slow_replica_statements</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

When the slow query log is enabled, `log_slow_replica_statements` enables logging for queries that have taken more than `long_query_time` seconds to execute on the replica. Note that if row-based replication is in use (`binlog_format=ROW`), `log_slow_replica_statements` has no effect. Queries are only added to the replica's slow query log when they are logged in statement format in the binary log, that is, when `binlog_format=STATEMENT` is set, or when `binlog_format=MIXED` is set and the statement is logged in statement format. Slow queries that are logged in row format when `binlog_format=MIXED` is set, or that are logged when `binlog_format=ROW` is set, are not added to the replica's slow query log, even if `log_slow_replica_statements` is enabled.

Setting `log_slow_replica_statements` has no immediate effect. The state of the variable applies on all subsequent `START REPLICATION` statements. Also note that the global setting for `long_query_time` applies for the lifetime of the SQL thread. If you change that setting, you must stop and restart the replication SQL thread to implement the change there (for example, by issuing `STOP REPLICATION` and `START REPLICATION` statements with the `SQL_THREAD` option).

- `log_slow_slave_statements`

Command-Line Format	<code>--log-slow-slave-statements[={OFF ON}]</code>
Deprecated	Yes
System Variable	<code>log_slow_slave_statements</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Deprecated alias for `log_slow_replica_statements`.

- `max_relay_log_size`

Command-Line Format	<code>--max-relay-log-size=#</code>
System Variable	<code>max_relay_log_size</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer

Default Value	0
Minimum Value	0
Maximum Value	1073741824
Unit	bytes
Block Size	4096

If a write by a replica to its relay log causes the current log file size to exceed the value of this variable, the replica rotates the relay logs (closes the current file and opens the next one). If `max_relay_log_size` is 0, the server uses `max_binlog_size` for both the binary log and the relay log. If `max_relay_log_size` is greater than 0, it constrains the size of the relay log, which enables you to have different sizes for the two logs. You must set `max_relay_log_size` to between 4096 bytes and 1GB (inclusive), or to 0. The default value is 0. See [Section 19.2.3, “Replication Threads”](#).

- `relay_log`

Command-Line Format	<code>--relay-log=file_name</code>
System Variable	<code>relay_log</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	File name

The base name for relay log files. For the default replication channel, the default base name for relay logs is `host_name-relay-bin`. For non-default replication channels, the default base name for relay logs is `host_name-relay-bin-channel`, where `channel` is the name of the replication channel recorded in this relay log.

The server writes the file in the data directory unless the base name is given with a leading absolute path name to specify a different directory. The server creates relay log files in sequence by adding a numeric suffix to the base name.

The relay log and relay log index on a replication server cannot be given the same names as the binary log and binary log index, whose names are specified by the `--log-bin` and `--log-bin-index` options. The server issues an error message and does not start if the binary log and relay log file base names would be the same.

Due to the manner in which MySQL parses server options, if you specify this variable at server startup, you must supply a value; *the default base name is used only if the option is not actually specified*. If you specify the `relay_log` system variable at server startup without specifying a value, unexpected behavior is likely to result; this behavior depends on the other options used, the order in which they are specified, and whether they are specified on the command line or in an option file. For more information about how MySQL handles server options, see [Section 6.2.2, “Specifying Program Options”](#).

If you specify this variable, the value specified is also used as the base name for the relay log index file. You can override this behavior by specifying a different relay log index file base name using the `relay_log_index` system variable.

When the server reads an entry from the index file, it checks whether the entry contains a relative path. If it does, the relative part of the path is replaced with the absolute path set using the `relay_log` system

variable. An absolute path remains unchanged; in such a case, the index must be edited manually to enable the new path or paths to be used.

You may find the `relay_log` system variable useful in performing the following tasks:

- Creating relay logs whose names are independent of host names.
- If you need to put the relay logs in some area other than the data directory because your relay logs tend to be very large and you do not want to decrease `max_relay_log_size`.
- To increase speed by using load-balancing between disks.

You can obtain the relay log file name (and path) from the `relay_log_basename` system variable.

- `relay_log_basename`

System Variable	<code>relay_log_basename</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	File name
Default Value	<code>datadir + '/' + hostname + '-relay-bin'</code>

Holds the base name and complete path to the relay log file. The maximum variable length is 256. This variable is set by the server and is read only.

- `relay_log_index`

Command-Line Format	<code>--relay-log-index=file_name</code>
System Variable	<code>relay_log_index</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	File name
Default Value	<code>*host_name*-relay-bin.index</code>

The name for the relay log index file. The maximum variable length is 256. If you do not specify this variable, but the `relay_log` system variable is specified, its value is used as the default base name for the relay log index file. If `relay_log` is also not specified, then for the default replication channel, the default name is `host_name-relay-bin.index`, using the name of the host machine. For non-default replication channels, the default name is `host_name-relay-bin-channel.index`, where `channel` is the name of the replication channel recorded in this relay log index.

The default location for relay log files is the data directory, or any other location that was specified using the `relay_log` system variable. You can use the `relay_log_index` system variable to specify an alternative location, by adding a leading absolute path name to the base name to specify a different directory.

The relay log and relay log index on a replication server cannot be given the same names as the binary log and binary log index, whose names are specified by the `--log-bin` and `--log-bin-index`

options. The server issues an error message and does not start if the binary log and relay log file base names would be the same.

Due to the manner in which MySQL parses server options, if you specify this variable at server startup, you must supply a value; *the default base name is used only if the option is not actually specified*. If you specify the `relay_log_index` system variable at server startup without specifying a value, unexpected behavior is likely to result; this behavior depends on the other options used, the order in which they are specified, and whether they are specified on the command line or in an option file. For more information about how MySQL handles server options, see [Section 6.2.2, “Specifying Program Options”](#).

- `relay_log_purge`

Command-Line Format	<code>--relay-log-purge[={OFF ON}]</code>
System Variable	<code>relay_log_purge</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>ON</code>

Disables or enables automatic purging of relay log files as soon as they are not needed any more. The default value is 1 (`ON`).

- `relay_log_recovery`

Command-Line Format	<code>--relay-log-recovery[={OFF ON}]</code>
System Variable	<code>relay_log_recovery</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

If enabled, this variable enables automatic relay log recovery immediately following server startup. The recovery process creates a new relay log file, initializes the SQL (applier) thread position to this new relay log, and initializes the I/O (receiver) thread to the applier thread position. Reading of the relay log from the source then continues. If `SOURCE_AUTO_POSITION=1` was set for the replication channel using a `CHANGE REPLICATION SOURCE TO` statement, the source position used to start replication might be the one received in the connection and not the ones assigned in this process.

When `relay_log_recovery` is disabled, the server sanitizes the relay log on startup, by performing the following actions:

- Removing any transactions that remain uncompleted at the end of the log
- Removing any relay log file which contains only parts of unfinished transactions
- Removing any reference from the relay log index file to any relay log file that has been removed

- When a valid source position and source filename are obtained from the relay log, updating the position of the receiver thread to match this file and position; otherwise, updating the position of the receiver thread to match the the position of the applier

This global variable is read-only at runtime. Its value can be set with the `--relay-log-recovery` option at replica server startup, which should be used following an unexpected halt of a replica to ensure that no possibly corrupted relay logs are processed, and must be used in order to guarantee a crash-safe replica. The default value is 0 (disabled). For information on the combination of settings on a replica that is most resilient to unexpected halts, see [Section 19.4.2, “Handling an Unexpected Halt of a Replica”](#).

For a multithreaded replica (where `replica_parallel_workers` is greater than 0), setting `--relay-log-recovery` at startup automatically handles any inconsistencies and gaps in the sequence of transactions that have been executed from the relay log. These gaps can occur when file position based replication is in use. (For more details, see [Section 19.5.1.35, “Replication and Transaction Inconsistencies”](#).) The relay log recovery process deals with gaps using the same method as the `START REPLICA UNTIL SQL_AFTER_MTS_GAPS` statement would. When the replica reaches a consistent gap-free state, the relay log recovery process goes on to fetch further transactions from the source beginning at the SQL (applier) thread position. When GTID-based replication is in use, a multithreaded replica checks first whether `SOURCE_AUTO_POSITION` is set to `ON`, and if it is, omits the step of calculating the transactions that should be skipped or not skipped, so that the old relay logs are not required for the recovery process.

#### Note

This variable does not affect the following Group Replication channels:

- `group_replication_applier`
- `group_replication_recovery`

Any other channels running on a group are affected, such as a channel which is replicating from an outside source or another group.

- `relay_log_space_limit`

Command-Line Format	<code>--relay-log-space-limit=#</code>
System Variable	<code>relay_log_space_limit</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	18446744073709551615
Unit	bytes

The maximum amount of space to use for all relay logs.

- `replica_checkpoint_group`

Command-Line Format	<code>--replica-checkpoint-group=#</code>
System Variable	<code>replica_checkpoint_group</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	512
Minimum Value	32
Maximum Value	524280
Block Size	8

`replica_checkpoint_group` sets the maximum number of transactions that can be processed by a multithreaded replica before a checkpoint operation is called to update its status as shown by `SHOW REPLICA STATUS`. Setting this variable has no effect on replicas for which multithreading is not enabled. Setting this variable has no immediate effect. The state of the variable applies to all subsequent `START REPLICA` statements.

This variable works in combination with the `replica_checkpoint_period` system variable in such a way that, when either limit is exceeded, the checkpoint is executed and the counters tracking both the number of transactions and the time elapsed since the last checkpoint are reset.

The minimum allowed value for this variable is 32, unless the server was built using `-DWITH_DEBUG`, in which case the minimum value is 1. The effective value is always a multiple of 8; you can set it to a value that is not such a multiple, but the server rounds it down to the next lower multiple of 8 before storing the value. (*Exception:* No such rounding is performed by the debug server.) Regardless of how the server was built, the default value is 512, and the maximum allowed value is 524280.

- `replica_checkpoint_period`

Command-Line Format	<code>--replica-checkpoint-period=#</code>
System Variable	<code>replica_checkpoint_period</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	300
Minimum Value	1
Maximum Value	4294967295
Unit	milliseconds

`replica_checkpoint_period` sets the maximum time (in milliseconds) that is allowed to pass before a checkpoint operation is called to update the status of a multithreaded replica as shown by `SHOW REPLICA STATUS`. Setting this variable has no effect on replicas for which multithreading is not

enabled. Setting this variable takes effect for all replication channels immediately, including running channels.

This variable works in combination with the `replica_checkpoint_group` system variable in such a way that, when either limit is exceeded, the checkpoint is executed and the counters tracking both the number of transactions and the time elapsed since the last checkpoint are reset.

The minimum allowed value for this variable is 1, unless the server was built using `-DWITH_DEBUG`, in which case the minimum value is 0. Regardless of how the server was built, the default value is 300 milliseconds, and the maximum possible value is 4294967295 milliseconds (approximately 49.7 days).

- `replica_compressed_protocol`

Command-Line Format	<code>--replica-compressed-protocol[={OFF ON}]</code>
System Variable	<code>replica_compressed_protocol</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	OFF

`replica_compressed_protocol` specifies whether to use compression of the source/replica connection protocol if both source and replica support it. If this variable is disabled (the default), connections are uncompressed. Changes to this variable take effect on subsequent connection attempts; this includes after issuing a `START REPLICATION` statement, as well as reconnections made by a running replication I/O (receiver) thread.

Binary log transaction compression, enabled by the `binlog_transaction_compression` system variable, can also be used to save bandwidth. If you use binary log transaction compression in combination with protocol compression, protocol compression has less opportunity to act on the data, but can still compress headers and those events and transaction payloads that are uncompressed. For more information on binary log transaction compression, see [Section 7.4.4.5, “Binary Log Transaction Compression”](#).

If `replica_compressed_protocol` is enabled, it takes precedence over any `SOURCE_COMPRESSION_ALGORITHMS` option specified for the `CHANGE REPLICATION SOURCE TO` statement. In this case, connections to the source use `zlib` compression if both the source and replica support that algorithm. If `replica_compressed_protocol` is disabled, the value of `SOURCE_COMPRESSION_ALGORITHMS` applies. For more information, see [Section 6.2.8, “Connection Compression Control”](#).

- `replica_exec_mode`

Command-Line Format	<code>--replica-exec-mode=mode</code>
System Variable	<code>replica_exec_mode</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Enumeration

Default Value	<code>IDEMPOTENT</code> (NDB) <code>STRICT</code> (Other)
Valid Values	<code>STRICT</code> <code>IDEMPOTENT</code>

`replica_exec_mode` controls how a replication thread resolves conflicts and errors during replication. `IDEMPOTENT` mode causes suppression of duplicate-key and no-key-found errors; `STRICT` means no such suppression takes place.

`IDEMPOTENT` mode is intended for use in multi-source replication, circular replication, and some other special replication scenarios for NDB Cluster Replication. (See [Section 25.7.10, “NDB Cluster Replication: Bidirectional and Circular Replication”](#), and [Section 25.7.12, “NDB Cluster Replication Conflict Resolution”](#), for more information.) NDB Cluster ignores any value explicitly set for `replica_exec_mode`, and always treats it as `IDEMPOTENT`.

In MySQL Server 9.1, `STRICT` mode is the default value.

Setting this variable takes immediate effect for all replication channels, including running channels.

For storage engines other than `NDB`, `IDEMPOTENT` mode *should be used only when you are absolutely sure that duplicate-key errors and key-not-found errors can safely be ignored*. It is meant to be used in fail-over scenarios for NDB Cluster where multi-source replication or circular replication is employed, and is not recommended for use in other cases.

- `replica_load_tmpdir`

Command-Line Format	<code>--replica-load-tmpdir=dir_name</code>
System Variable	<code>replica_load_tmpdir</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Directory name
Default Value	Value of <code>--tmpdir</code>

`replica_load_tmpdir` specifies the name of the directory where the replica creates temporary files. Setting this variable takes effect for all replication channels immediately, including running channels. The variable value is by default equal to the value of the `tmpdir` system variable, or the default that applies when that system variable is not specified.

When the replication SQL thread replicates a `LOAD DATA` statement, it extracts the file to be loaded from the relay log into temporary files, and then loads these into the table. If the file loaded on the source is huge, the temporary files on the replica are huge, too. Therefore, it might be advisable to use this option to tell the replica to put temporary files in a directory located in some file system that has a lot of available space. In that case, the relay logs are huge as well, so you might also want to set the `relay_log` system variable to place the relay logs in that file system.

The directory specified by this option should be located in a disk-based file system (not a memory-based file system) so that the temporary files used to replicate `LOAD DATA` statements can survive machine restarts. The directory also should not be one that is cleared by the operating system during the system

startup process. However, replication can now continue after a restart if the temporary files have been removed.

- `replica_max_allowed_packet`

Command-Line Format	<code>--replica-max-allowed-packet=#</code>
System Variable	<code>replica_max_allowed_packet</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	1073741824
Minimum Value	1024
Maximum Value	1073741824
Unit	bytes
Block Size	1024

`replica_max_allowed_packet` sets the maximum packet size in bytes that the replication SQL (applier) and I/O (receiver) threads can handle. Setting this variable takes effect for all replication channels immediately, including running channels. It is possible for a source to write binary log events longer than its `max_allowed_packet` setting once the event header is added. The setting for `replica_max_allowed_packet` must be larger than the `max_allowed_packet` setting on the source, so that large updates using row-based replication do not cause replication to fail.

This global variable always has a value that is a positive integer multiple of 1024; if you set it to some value that is not, the value is rounded down to the next highest multiple of 1024 for it is stored or used; setting `replica_max_allowed_packet` to 0 causes 1024 to be used. (A truncation warning is issued in all such cases.) The default and maximum value is 1073741824 (1 GB); the minimum is 1024.

- `replica_net_timeout`

Command-Line Format	<code>--replica-net-timeout=#</code>
System Variable	<code>replica_net_timeout</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	60
Minimum Value	1
Maximum Value	31536000
Unit	seconds

`replica_net_timeout` specifies the number of seconds to wait for more data or a heartbeat signal from the source before the replica considers the connection broken, aborts the read, and tries

to reconnect. Setting this variable has no immediate effect. The state of the variable applies on all subsequent `START REPLICATION` commands.

The default value is 60 seconds (one minute). The first retry occurs immediately after the timeout. The interval between retries is controlled by the `SOURCE_CONNECT_RETRY` option for the `CHANGE REPLICATION SOURCE TO` statement, and the number of reconnection attempts is limited by the `SOURCE_RETRY_COUNT` option.

The heartbeat interval, which stops the connection timeout occurring in the absence of data if the connection is still good, is controlled by the `SOURCE_HEARTBEAT_PERIOD` option for the `CHANGE REPLICATION SOURCE TO` statement. The heartbeat interval defaults to half the value of `replica_net_timeout`, and it is recorded in the replica's connection metadata repository and shown in the `replication_connection_configuration` Performance Schema table. Note that a change to the value or default setting of `replica_net_timeout` does not automatically change the heartbeat interval, whether that has been set explicitly or is using a previously calculated default. If the connection timeout is changed, you must also issue `CHANGE REPLICATION SOURCE TO` to adjust the heartbeat interval to an appropriate value so that it occurs before the connection timeout.

- `replica_parallel_type`

Command-Line Format	<code>--replica-parallel-type=value</code>
Deprecated	Yes
System Variable	<code>replica_parallel_type</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Enumeration
Default Value	<code>LOGICAL_CLOCK</code>
Valid Values	<code>DATABASE</code>  <code>LOGICAL_CLOCK</code>

For multithreaded replicas (replicas on which `replica_parallel_workers` is set to a value greater than 0), `replica_parallel_type` specifies the policy used to decide which transactions are allowed to execute in parallel on the replica. The variable has no effect on replicas for which multithreading is not enabled. The possible values are:

- `LOGICAL_CLOCK`: Transactions are applied in parallel on the replica, based on timestamps which the replication source writes to the binary log. Dependencies between transactions are tracked based on their timestamps to provide additional parallelization where possible.
- `DATABASE`: Transactions that update different databases are applied in parallel. This value is only appropriate if data is partitioned into multiple databases which are being updated independently and

concurrently on the source. There must be no cross-database constraints, as such constraints may be violated on the replica.

When `replica_preserve_commit_order` is enabled, you must use `LOGICAL_CLOCK`. Multithreading is enabled by default for replica servers (`replica_parallel_workers=4` by default), and `LOGICAL_CLOCK` is the default. (`replica_preserve_commit_order` is also enabled by default.)

When the replication topology uses multiple levels of replicas, `LOGICAL_CLOCK` may achieve less parallelization for each level the replica is away from the source.

When binary log transaction compression is enabled using the `binlog_transaction_compression` system variable, if `replica_parallel_type` is set to `DATABASE`, all the databases affected by the transaction are mapped before the transaction is scheduled. The use of binary log transaction compression with the `DATABASE` policy can reduce parallelism compared to uncompressed transactions, which are mapped and scheduled for each event.

`replica_parallel_type` is deprecated, as is support for parallelization of transactions using database partitioning. Expect support for these to be removed in a future release, and for `LOGICAL_CLOCK` to be used exclusively thereafter.

- `replica_parallel_workers`

Command-Line Format	<code>--replica-parallel-workers=#</code>
System Variable	<code>replica_parallel_workers</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	4
Minimum Value	0
Maximum Value	1024

`replica_parallel_workers` enables multithreading on the replica and sets the number of applier threads for executing replication transactions in parallel. When the value is greater than or equal to 1, the replica uses the specified number of worker threads to execute transactions, plus a coordinator thread that reads transactions from the relay log and schedules them to workers. When the value is 0, there is only one thread that reads and applies transactions sequentially. If you are using multiple replication channels, the value of this variable applies to the threads used by each channel.

The default value is 4, which means that replicas are multithreaded by default.

Setting this variable to 0 is deprecated, raises a warning, and is subject to removal in a future MySQL release. For a single worker, set `replica_parallel_workers` to 1 instead.

When `replica_preserve_commit_order` is `ON` (the default), transactions on a replica are externalized on the replica in the same order as they appear in the replica's relay log. The way in which transactions are distributed among applier threads is determined by `replica_parallel_type`. These system variables also have appropriate defaults for multithreading.

To disable parallel execution, set `replica_parallel_workers` to 1, in which case the replica uses one coordinator thread which reads transactions, and one worker thread which applies them, which means that transactions are applied sequentially. When `replica_parallel_workers` is equal

to 1, the `replica_parallel_type` and `replica_preserve_commit_order` system variables have no effect and are ignored. If `replica_parallel_workers` is equal to 0 while the `CHANGE REPLICATION SOURCE TO` option `GTID_ONLY` is enabled, the replica has one coordinator thread and one worker thread, exactly as if `replica_parallel_workers` had been set to 1. With one parallel worker, the `replica_preserve_commit_order` system variable also has no effect.

Setting `replica_parallel_workers` has no immediate effect but rather applies to all subsequent `START REPLICATION` statements.

Multithreaded replicas are also supported by NDB Cluster 9.1. See [Section 25.7.11, “NDB Cluster Replication Using the Multithreaded Applier”](#), for more information.

Increasing the number of workers improves the potential for parallelism. Typically, this improves performance up to a certain point, beyond which increasing the number of workers reduces performance due to concurrency effects such as lock contention. The ideal number depends on both hardware and workload; it can be difficult to predict and typically has to be found by testing. Tables without primary keys, which always harm performance, may have even greater negative performance impact on replicas having `replica_parallel_workers` > 1; so make sure that all tables have primary keys before enabling this option.

- `replica_pending_jobs_size_max`

Command-Line Format	<code>--replica-pending-jobs-size-max=#</code>
System Variable	<code>replica_pending_jobs_size_max</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	128M
Minimum Value	1024
Maximum Value	16EiB
Unit	bytes
Block Size	1024

For multithreaded replicas, this variable sets the maximum amount of memory (in bytes) available to applier queues holding events not yet applied. Setting this variable has no effect on replicas for which multithreading is not enabled. Setting this variable has no immediate effect. The state of the variable applies on all subsequent `START REPLICATION` commands.

The minimum possible value for this variable is 1024 bytes; the default is 128MB. The maximum possible value is 18446744073709551615 (16 exbibytes). Values that are not exact multiples of 1024 bytes are rounded down to the next lower multiple of 1024 bytes prior to being stored.

The value of this variable is a soft limit and can be set to match the normal workload. If an unusually large event exceeds this size, the transaction is held until all the worker threads have empty queues, and then processed. All subsequent transactions are held until the large transaction has been completed.

- `replica_preserve_commit_order`

Command-Line Format	<code>--replica-preserve-commit-order[={OFF ON}]</code>
---------------------	---------------------------------------------------------

System Variable	<code>replica_preserve_commit_order</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>ON</code>

For multithreaded replicas (replicas on which `replica_parallel_workers` is set to a value greater than 0), setting `replica_preserve_commit_order=ON` ensures that transactions are executed and committed on the replica in the same order as they appear in the replica's relay log. This prevents gaps in the sequence of transactions that have been executed from the replica's relay log, and preserves the same transaction history on the replica as on the source (with the limitations listed below). This variable has no effect on replicas for which multithreading is not enabled.

Multithreading is enabled by default in MySQL 9.1 for replica servers (`replica_parallel_workers=4` by default), so `replica_preserve_commit_order=ON` is the default, and the setting `replica_parallel_type=LOGICAL_CLOCK` is also the default. In addition, the setting for `replica_preserve_commit_order` is ignored if `replica_parallel_workers` is set to 1, because in that situation the order of transactions is preserved anyway.

Binary logging and replica update logging are not required on the replica to set `replica_preserve_commit_order=ON`, and can be disabled if wanted. Setting `replica_preserve_commit_order=ON` requires that `replica_parallel_type` is set to `LOGICAL_CLOCK`, the default in MySQL 9.1. Before changing the value of `replica_preserve_commit_order` and `replica_parallel_type`, the replication SQL thread (for all replication channels if you are using multiple replication channels) must be stopped.

When `replica_preserve_commit_order=OFF` is set, the transactions that a multithreaded replica applies in parallel may commit out of order. Therefore, checking for the most recently executed transaction does not guarantee that all previous transactions from the source have been executed on the replica. There is a chance of gaps in the sequence of transactions that have been executed from the replica's relay log. This has implications for logging and recovery when using a multithreaded replica. See [Section 19.5.1.35, “Replication and Transaction Inconsistencies”](#) for more information.

When `replica_preserve_commit_order=ON` is set, the executing worker thread waits until all previous transactions are committed before committing. While a given thread is waiting for other worker threads to commit their transactions, it reports its status as `Waiting for preceding transaction to commit`. With this mode, a multithreaded replica never enters a state that the source was not in. This supports the use of replication for read scale-out. See [Section 19.4.5, “Using Replication for Scale-Out”](#).

#### Note

- `replica_preserve_commit_order=ON` does not prevent source binary log position lag, where `Exec_master_log_pos` is behind the position up to which transactions have been executed. See [Section 19.5.1.35, “Replication and Transaction Inconsistencies”](#).
- `replica_preserve_commit_order=ON` does not preserve the commit order and transaction history if the replica uses filters on its binary log, such as `--binlog-do-db`.

- `replica_preserve_commit_order=ON` does not preserve the order of non-transactional DML updates. These might commit before transactions that precede them in the relay log, which might result in gaps in the sequence of transactions that have been executed from the replica's relay log.
- A limitation to preserving the commit order on the replica can occur if statement-based replication is in use, and both transactional and non-transactional storage engines participate in a non-XA transaction that is rolled back on the source. Normally, non-XA transactions that are rolled back on the source are not replicated to the replica, but in this particular situation, the transaction might be replicated to the replica. If this does happen, a multithreaded replica without binary logging does not handle the transaction rollback, so the commit order on the replica diverges from the relay log order of the transactions in that case.

- `replica_sql_verify_checksum`

Command-Line Format	<code>--replica-sql-verify-checksum[={OFF ON}]</code>
System Variable	<code>replica_sql_verify_checksum</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>ON</code>

`replica_sql_verify_checksum` causes the replication SQL (applier) thread to verify data using the checksums read from the relay log. In the event of a mismatch, the replica stops with an error. Setting this variable takes effect for all replication channels immediately, including running channels.

**Note**

The replication I/O (receiver) thread always reads checksums if possible when accepting events from over the network.

- `replica_transaction_retries`

Command-Line Format	<code>--replica-transaction-retries=#</code>
System Variable	<code>replica_transaction_retries</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	<code>10</code>
Minimum Value	<code>0</code>
Maximum Value	<code>18446744073709551615</code>

`replica_transaction_retries` sets the maximum number of times for replication SQL threads on a single-threaded or multithreaded replica to automatically retry failed transactions before stopping.

Setting this variable takes effect for all replication channels immediately, including running channels. The default value is 10. Setting the variable to 0 disables automatic retrying of transactions.

If a replication SQL thread fails to execute a transaction because of an [InnoDB](#) deadlock or because the transaction's execution time exceeded [InnoDB's innodb\\_lock\\_wait\\_timeout](#) or [NDB's TransactionDeadlockDetectionTimeout](#) or [TransactionInactiveTimeout](#), it automatically retries [replica\\_transaction\\_retries](#) times before stopping with an error. Transactions with a non-temporary error are not retried.

The Performance Schema table [replication\\_applier\\_status](#) shows the number of retries that took place on each replication channel, in the [COUNT\\_TRANSACTIONS\\_RETRIES](#) column. The Performance Schema table [replication\\_applier\\_status\\_by\\_worker](#) shows detailed information on transaction retries by individual applier threads on a single-threaded or multithreaded replica, and identifies the errors that caused the last transaction and the transaction currently in progress to be reattempted.

- [replica\\_type\\_conversions](#)

Command-Line Format	<a href="#">--replica-type-conversions=set</a>
System Variable	<a href="#">replica_type_conversions</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Set
Default Value	
Valid Values	<a href="#">ALL_LOSSY</a> <a href="#">ALL_NON_LOSSY</a> <a href="#">ALL_SIGNED</a> <a href="#">ALL_UNSIGNED</a>

[replica\\_type\\_conversions](#) controls the type conversion mode in effect on the replica when using row-based replication. Its value is a comma-delimited set of zero or more elements from the list: [ALL\\_LOSSY](#), [ALL\\_NON\\_LOSSY](#), [ALL\\_SIGNED](#), [ALL\\_UNSIGNED](#). Set this variable to an empty string to disallow type conversions between the source and the replica. Setting this variable takes effect for all replication channels immediately, including running channels.

For additional information on type conversion modes applicable to attribute promotion and demotion in row-based replication, see [Row-based replication: attribute promotion and demotion](#).

- [replication\\_optimize\\_for\\_static\\_plugin\\_config](#)

Command-Line Format	<a href="#">--replication-optimize-for-static-plugin-config[={OFF ON}]</a>
System Variable	<a href="#">replication_optimize_for_static_plugin_config</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No

Type	Boolean
Default Value	OFF

Use shared locks, and avoid unnecessary lock acquisitions, to improve performance for semisynchronous replication. This setting and [replication\\_sender\\_observe\\_commit\\_only](#) help as the number of replicas increases, because contention for locks can slow down performance. While this system variable is enabled, the semisynchronous replication plugin cannot be uninstalled, so you must disable the system variable before the uninstall can complete.

This system variable can be enabled before or after installing the semisynchronous replication plugin, and can be enabled while replication is running. Semisynchronous replication source servers can also get performance benefits from enabling this system variable, because they use the same locking mechanisms as the replicas.

[replication\\_optimize\\_for\\_static\\_plugin\\_config](#) can be enabled when Group Replication is in use on a server. In that scenario, it might benefit performance when there is contention for locks due to high workloads.

- [replication\\_sender\\_observe\\_commit\\_only](#)

Command-Line Format	<code>--replication-sender-observe-commit-only[={OFF ON}]</code>
System Variable	<a href="#">replication_sender_observe_commit_only</a>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Limit callbacks to improve performance for semisynchronous replication. This setting and [replication\\_optimize\\_for\\_static\\_plugin\\_config](#) help as the number of replicas increases, because contention for locks can slow down performance.

This system variable can be enabled before or after installing the semisynchronous replication plugin, and can be enabled while replication is running. Semisynchronous replication source servers can also get performance benefits from enabling this system variable, because they use the same locking mechanisms as the replicas.

- [report\\_host](#)

Command-Line Format	<code>--report-host=host_name</code>
System Variable	<a href="#">report_host</a>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No

Type	String
------	--------

The host name or IP address of the replica to be reported to the source during replica registration. This value appears in the output of `SHOW REPLICAS` on the source server. Leave the value unset if you do not want the replica to register itself with the source.

#### Note

It is not sufficient for the source to simply read the IP address of the replica server from the TCP/IP socket after the replica connects. Due to NAT and other routing issues, that IP may not be valid for connecting to the replica from the source or other hosts.

- `report_password`

Command-Line Format	<code>--report-password=name</code>
System Variable	<code>report_password</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	String

The account password of the replica to be reported to the source during replica registration. This value appears in the output of `SHOW REPLICAS` on the source server if the source was started with `--show-replica-auth-info`.

Although the name of this variable might imply otherwise, `report_password` is not connected to the MySQL user privilege system and so is not necessarily (or even likely to be) the same as the password for the MySQL replication user account.

- `report_port`

Command-Line Format	<code>--report-port=port_num</code>
System Variable	<code>report_port</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	<code>[slave_port]</code>
Minimum Value	0
Maximum Value	65535

The TCP/IP port number for connecting to the replica, to be reported to the source during replica registration. Set this only if the replica is listening on a nondefault port or if you have a special tunnel from the source or other clients to the replica. If you are not sure, do not use this option.

The default value for this option is the port number actually used by the replica. This is also the default value displayed by `SHOW REPLICAS`.

- `report_user`

Command-Line Format	<code>--report-user=name</code>
System Variable	<code>report_user</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	String

The account user name of the replica to be reported to the source during replica registration. This value appears in the output of `SHOW REPLICAS` on the source server if the source was started with `--show-replica-auth-info`.

Although the name of this variable might imply otherwise, `report_user` is not connected to the MySQL user privilege system and so is not necessarily (or even likely to be) the same as the name of the MySQL replication user account.

- `rpl_read_size`

Command-Line Format	<code>--rpl-read-size=#</code>
System Variable	<code>rpl_read_size</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	8192
Minimum Value	8192
Maximum Value	4294959104
Unit	bytes
Block Size	8192

The `rpl_read_size` system variable controls the minimum amount of data in bytes that is read from the binary log files and relay log files. If heavy disk I/O activity for these files is impeding performance for the database, increasing the read size might reduce file reads and I/O stalls when the file data is not currently cached by the operating system.

The minimum and default value for `rpl_read_size` is 8192 bytes. The value must be a multiple of 4KB. Note that a buffer the size of this value is allocated for each thread that reads from the binary log and relay log files, including dump threads on sources and coordinator threads on replicas. Setting a large value might therefore have an impact on memory consumption for servers.

- `rpl_semi_sync_replica_enabled`

Command-Line Format	<code>--rpl-semi-sync-replica-enabled[={OFF ON}]</code>
System Variable	<code>rpl_semi_sync_replica_enabled</code>
Scope	Global
Dynamic	Yes

<a href="#">SET_VAR</a> Hint Applies	No
Type	Boolean
Default Value	<a href="#">OFF</a>

[rpl\\_semi\\_sync\\_replica\\_enabled](#) controls whether semisynchronous replication is enabled on the replica server. To enable or disable the plugin, set this variable to [ON](#) or [OFF](#) (or 1 or 0), respectively. The default is [OFF](#).

This variable is available only if the replica-side semisynchronous replication plugin is installed.

- [rpl\\_semi\\_sync\\_replica\\_trace\\_level](#)

Command-Line Format	<code>--rpl-semi-sync-replica-trace-level=#</code>
System Variable	<a href="#">rpl_semi_sync_replica_trace_level</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	<a href="#">32</a>
Minimum Value	<a href="#">0</a>
Maximum Value	<a href="#">4294967295</a>

[rpl\\_semi\\_sync\\_replica\\_trace\\_level](#) controls the semisynchronous replication debug trace level on the replica server. See [rpl\\_semi\\_sync\\_master\\_trace\\_level](#) for the permissible values.

This variable is available only if the replica-side semisynchronous replication plugin is installed.

- [rpl\\_semi\\_sync\\_slave\\_enabled](#)

Command-Line Format	<code>--rpl-semi-sync-slave-enabled[={OFF ON}]</code>
System Variable	<a href="#">rpl_semi_sync_slave_enabled</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Boolean
Default Value	<a href="#">OFF</a>

Deprecated synonym for [rpl\\_semi\\_sync\\_replica\\_enabled](#).

- [rpl\\_semi\\_sync\\_slave\\_trace\\_level](#)

Command-Line Format	<code>--rpl-semi-sync-slave-trace-level=#</code>
System Variable	<a href="#">rpl_semi_sync_slave_trace_level</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No

Type	Integer
Default Value	32
Minimum Value	0
Maximum Value	4294967295

Deprecated synonym for `rpl_semi_sync_replica_trace_level`.

- `rpl_stop_replica_timeout`

Command-Line Format	<code>--rpl-stop-replica-timeout=#</code>
System Variable	<code>rpl_stop_replica_timeout</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	31536000
Minimum Value	2
Maximum Value	31536000
Unit	seconds

You can control the length of time (in seconds) that `STOP REPLICA` waits before timing out by setting this variable. This can be used to avoid deadlocks between `STOP REPLICA` and other SQL statements using different client connections to the replica.

The maximum and default value of `rpl_stop_replica_timeout` is 31536000 seconds (1 year). The minimum is 2 seconds. Changes to this variable take effect for subsequent `STOP REPLICA` statements.

This variable affects only the client that issues a `STOP REPLICA` statement. When the timeout is reached, the issuing client returns an error message stating that the command execution is incomplete. The client then stops waiting for the replication I/O (receiver) and SQL (applier) threads to stop, but the replication threads continue to try to stop, and the `STOP REPLICA` statement remains in effect. Once the replication threads are no longer busy, the `STOP REPLICA` statement is executed and the replica stops.

- `rpl_stop_slave_timeout`

Command-Line Format	<code>--rpl-stop-slave-timeout=#</code>
Deprecated	Yes
System Variable	<code>rpl_stop_slave_timeout</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	31536000
Minimum Value	2
Maximum Value	31536000
Unit	seconds

Deprecated synonym for `rpl_stop_replica_timeout`.

- `skip_replica_start`

Command-Line Format	<code>--skip-replica-start[={OFF ON}]</code>
System Variable	<code>skip_replica_start</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

`skip_replica_start` tells the replica server not to start the replication I/O (receiver) and SQL (applier) threads when the server starts. To start the threads later, use a `START REPLICA` statement.

This system variable is read-only and can be set by using the `PERSIST_ONLY` keyword or the `@@persist_only` qualifier with the `SET` statement. The `--skip-replica-start` command line option also sets this system variable. You can use the system variable in place of the command line option to allow access to this feature using MySQL Server's privilege structure, so that database administrators do not need any privileged access to the operating system.

- `skip_slave_start`

Command-Line Format	<code>--skip-slave-start[={OFF ON}]</code>
Deprecated	Yes
System Variable	<code>skip_slave_start</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Deprecated synonym for `--skip-replica-start`.

- `slave_checkpoint_group`

Command-Line Format	<code>--slave-checkpoint-group=#</code>
Deprecated	Yes
System Variable	<code>slave_checkpoint_group</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	<code>512</code>
Minimum Value	<code>32</code>

Maximum Value	524280
Block Size	8

Deprecated synonym for `replica_checkpoint_group`.

- `slave_checkpoint_period`

Command-Line Format	<code>--slave-checkpoint-period=#</code>
Deprecated	Yes
System Variable	<code>slave_checkpoint_period</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	300
Minimum Value	1
Maximum Value	4294967295
Unit	milliseconds

Deprecated synonym for `replica_checkpoint_period`.

- `slave_compressed_protocol`

Command-Line Format	<code>--slave-compressed-protocol[={OFF ON}]</code>
Deprecated	Yes
System Variable	<code>slave_compressed_protocol</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Deprecated alias for `replica_compressed_protocol`.

- `slave_exec_mode`

Command-Line Format	<code>--slave-exec-mode=mode</code>
System Variable	<code>slave_exec_mode</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	IDEMPOTENT (NDB)

	STRICT (Other)
Valid Values	STRICT IDEMPOTENT

Deprecated alias for `replica_exec_mode`.

- `slave_load_tmpdir`

Command-Line Format	<code>--slave-load-tmpdir=dir_name</code>
Deprecated	Yes
System Variable	<code>slave_load_tmpdir</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Directory name
Default Value	Value of <code>--tmpdir</code>

Deprecated alias for `replica_load_tmpdir`.

- `slave_max_allowed_packet`

Command-Line Format	<code>--slave-max-allowed-packet=#</code>
Deprecated	Yes
System Variable	<code>slave_max_allowed_packet</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	1073741824
Minimum Value	1024
Maximum Value	1073741824
Unit	bytes
Block Size	1024

Deprecated alias for `replica_max_allowed_packet`.

- `slave_net_timeout`

Command-Line Format	<code>--slave-net-timeout=#</code>
Deprecated	Yes
System Variable	<code>slave_net_timeout</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No

Type	Integer
Default Value	60
Minimum Value	1
Maximum Value	31536000
Unit	seconds

Deprecated alias for `replica_net_timeout`.

- `slave_parallel_type`

Command-Line Format	<code>--slave-parallel-type=value</code>
Deprecated	Yes
System Variable	<code>slave_parallel_type</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Enumeration
Default Value	<code>LOGICAL_CLOCK</code>
Valid Values	<code>DATABASE</code> <code>LOGICAL_CLOCK</code>

Deprecated alias for `replica_parallel_type`.

- `slave_parallel_workers`

Command-Line Format	<code>--slave-parallel-workers=#</code>
Deprecated	Yes
System Variable	<code>slave_parallel_workers</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	4
Minimum Value	0
Maximum Value	1024

Deprecated alias for `replica_parallel_workers`.

- `slave_pending_jobs_size_max`

Command-Line Format	<code>--slave-pending-jobs-size-max=#</code>
Deprecated	Yes
System Variable	<code>slave_pending_jobs_size_max</code>
Scope	Global

Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	128M
Minimum Value	1024
Maximum Value	16EiB
Unit	bytes
<a href="#">Block Size</a>	1024

Deprecated alias for [replica\\_pending\\_jobs\\_size\\_max](#).

- [slave\\_preserve\\_commit\\_order](#)

Command-Line Format	<code>--slave-preserve-commit-order[={OFF ON}]</code>
Deprecated	Yes
System Variable	<a href="#">slave_preserve_commit_order</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Boolean
Default Value	ON

Deprecated alias for [replica\\_preserve\\_commit\\_order](#).

- [slave\\_skip\\_errors](#)

Command-Line Format	<code>--slave-skip-errors=name</code>
Deprecated	Yes
System Variable	<a href="#">slave_skip_errors</a>
Scope	Global
Dynamic	No
<a href="#">SET_VAR</a> Hint Applies	No
Type	String
Default Value	OFF
Valid Values	OFF  [ <a href="#">list of error codes</a> ] all  <a href="#">ddl_exist_errors</a>

Deprecated alias for [replica\\_skip\\_errors](#).

- `replica_skip_errors`

Command-Line Format	<code>--replica-skip-errors=name</code>
System Variable	<code>replica_skip_errors</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value	<code>OFF</code>
Valid Values	<code>OFF</code>  <code>[list of error codes]</code>  <code>all</code>  <code>ddl_exist_errors</code>

Normally, replication stops when an error occurs on the replica, which gives you the opportunity to resolve the inconsistency in the data manually. This variable causes the replication SQL thread to continue replication when a statement returns any of the errors listed in the variable value.

- `slave_sql_verify_checksum`

Command-Line Format	<code>--slave-sql-verify-checksum[={OFF ON}]</code>
Deprecated	Yes
System Variable	<code>slave_sql_verify_checksum</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>ON</code>

Deprecated alias for `replica_sql_verify_checksum`.

- `slave_transaction_retries`

Command-Line Format	<code>--slave-transaction-retries=#</code>
Deprecated	Yes
System Variable	<code>slave_transaction_retries</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	<code>10</code>
Minimum Value	<code>0</code>

Maximum Value (64-bit platforms)	18446744073709551615
Maximum Value (32-bit platforms)	4294967295

Deprecated alias for `replica_transaction_retries`.

- `slave_type_conversions`

Command-Line Format	<code>--slave-type-conversions=set</code>
Deprecated	Yes
System Variable	<code>slave_type_conversions</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Set
Default Value	
Valid Values	<code>ALL_LOSSY</code> <code>ALL_NON_LOSSY</code> <code>ALL_SIGNED</code> <code>ALL_UNSIGNED</code>

Deprecated alias for `replica_type_conversions`.

- `sql_replica_skip_counter`

System Variable	<code>sql_replica_skip_counter</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	4294967295

`sql_replica_skip_counter` specifies the number of events from the source that a replica should skip. Setting the option has no immediate effect. The variable applies to the next `START REPLICA` statement; the next `START REPLICA` statement also changes the value back to 0. When this variable is set to a nonzero value and there are multiple replication channels configured, the `START REPLICA` statement can only be used with the `FOR CHANNEL channel` clause.

This option is incompatible with GTID-based replication, and must not be set to a nonzero value when `gtid_mode=ON` is set. If you need to skip transactions when employing GTIDs, use `gtid_executed` from the source instead. If you have enabled GTID assignment on a replication channel using the

`ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS` option of the `CHANGE REPLICATION SOURCE TO` statement, `sql_replica_skip_counter` is available. See [Section 19.1.7.3, “Skipping Transactions”](#).

### Important

If skipping the number of events specified by setting this variable would cause the replica to begin in the middle of an event group, the replica continues to skip until it finds the beginning of the next event group and begins from that point. For more information, see [Section 19.1.7.3, “Skipping Transactions”](#).

- `sql_slave_skip_counter`

Deprecated	Yes
System Variable	<code>sql_slave_skip_counter</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	4294967295

Deprecated alias for `sql_replica_skip_counter`.

- `sync_master_info`

Command-Line Format	<code>--sync-master-info=#</code>
Deprecated	Yes
System Variable	<code>sync_master_info</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	10000
Minimum Value	0
Maximum Value	4294967295

Deprecated alias for `sync_source_info`.

- `sync_relay_log`

Command-Line Format	<code>--sync-relay-log=#</code>
System Variable	<code>sync_relay_log</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No

Type	Integer
Default Value	10000
Minimum Value	0
Maximum Value	4294967295

If the value of this variable is greater than 0, the MySQL server synchronizes its relay log to disk (using `fdatsync()`) after every `sync_relay_log` events are written to the relay log. Setting this variable takes effect for all replication channels immediately, including running channels.

Setting `sync_relay_log` to 0 causes no synchronization to be done to disk; in this case, the server relies on the operating system to flush the relay log's contents from time to time as for any other file.

A value of 1 is the safest choice because in the event of an unexpected halt you lose at most one event from the relay log. However, it is also the slowest choice (unless the disk has a battery-backed cache, which makes synchronization very fast). For information on the combination of settings on a replica that is most resilient to unexpected halts, see [Section 19.4.2, “Handling an Unexpected Halt of a Replica”](#).

- `sync_relay_log_info`

Command-Line Format	<code>--sync-relay-log-info=#</code>
Deprecated	Yes
System Variable	<code>sync_relay_log_info</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	10000
Minimum Value	0
Maximum Value	4294967295

The number of transactions after which the replica updates the applier metadata repository. When the applier metadata repository is stored as an `InnoDB` table, which is the default, it is updated after every transaction and this system variable is ignored. If the applier metadata repository is stored as a file (deprecated), the replica synchronizes its `relay-log.info` file to disk (using `fdatsync()`) after this many transactions. 0 (zero) means that the file contents are flushed by the operating system only. Setting this variable takes effect for all replication channels immediately, including running channels.

Since storing applier metadata as a file is deprecated, this variable is also deprecated, and the server raises a warning whenever you set it or read its value. You should expect `sync_relay_log_info` to be removed in a future version of MySQL, and migrate applications now that may depend on it.

- `sync_source_info`

Command-Line Format	<code>--sync-source-info=#</code>
System Variable	<code>sync_source_info</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No

Type	Integer
Default Value	10000
Minimum Value	0
Maximum Value	4294967295

`sync_source_info` specifies the number of events after which the replica updates the connection metadata repository. When the connection metadata repository is stored as an `InnoDB` table (the default, it is updated after this number of events. If the connection metadata repository is stored as a file (deprecated), the replica synchronizes its `master.info` file to disk (using `fdatasync()`) after this number of events. The default value is 10000, and a zero value means that the repository is never updated. Setting this variable takes effect for all replication channels immediately, including running channels.

- `terminology_use_previous`

Command-Line Format	<code>--terminology-use-previous=#</code>
System Variable	<code>terminology_use_previous</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Enumeration
Default Value	<code>NONE</code>
Valid Values	<code>NONE</code>  <code>BEFORE_8_0_26</code>  <code>BEFORE_8_2_0</code>

Incompatible changes were made in MySQL 8.0 to instrumentation names containing the terms `master`, `slave`, and `mts` (for “Multi-Threaded Slave”), which were changed respectively to `source`, `replica`, and `mta` (for “Multi-Threaded Applier”). If these incompatible changes impact your applications, set `terminology_use_previous` to `BEFORE_8_0_26` to make the MySQL server use the old versions of the names for the objects specified in the previous list. This enables monitoring tools that rely on the old names to continue working until they can be updated to use the new names.

MySQL 9.1 normally displays `REPLICA_SIDE_DISABLED` rather than `SLAVESIDE_DISABLED` in the output of `SHOW CREATE EVENT`, `SHOW EVENTS`, and queries against the Information Schema `EVENTS` table. You can cause `SLAVESIDE_DISABLED` to be shown instead by setting `terminology_use_previous` to `BEFORE_8_0_26` or `BEFORE_8_2_0`.

Set the `terminology_use_previous` system variable with session scope to support individual users, or with global scope to be the default for all new sessions. When global scope is used, the slow query log contains the old versions of the names.

The affected instrumentation names are given in the following list. The `terminology_use_previous` system variable only affects these items. It does not affect the new aliases for system variables, status variables, and command-line options that were also introduced in MySQL 8.0, and these can still be used when it is enabled.

- Instrumented locks (mutexes), visible in the `mutex_instances` and `events_waits_*` Performance Schema tables with the prefix `wait/synch/mutex/`

- Read/write locks, visible in the `rwlock_instances` and `events_waits_*` Performance Schema tables with the prefix `wait/synch/rwlock/`
- Instrumented condition variables, visible in the `cond_instances` and `events_waits_*` Performance Schema tables with the prefix `wait/synch/cond/`
- Instrumented memory allocations, visible in the `memory_summary_*` Performance Schema tables with the prefix `memory/sql/`
- Thread names, visible in the `threads` Performance Schema table with the prefix `thread/sql/`
- Thread stages, visible in the `events_stages_*` Performance Schema tables with the prefix `stage/sql/`, and without the prefix in the `threads` and `processlist` Performance Schema tables, the output from the `SHOW PROCESSLIST` statement, the Information Schema `processlist` table, and the slow query log
- Thread commands, visible in the `events_statements_history*` and `events_statements_summary*_by_event_name` Performance Schema tables with the prefix `statement/com/`, and without the prefix in the `threads` and `processlist` Performance Schema tables, the output from the `SHOW PROCESSLIST` statement, the Information Schema `processlist` table, and the output from the `SHOW REPLICA STATUS` statement

#### 19.1.6.4 Binary Logging Options and Variables

- [Startup Options Used with Binary Logging](#)
- [System Variables Used with Binary Logging](#)

You can use the `mysqld` options and system variables that are described in this section to affect the operation of the binary log as well as to control which statements are written to the binary log. For additional information about the binary log, see [Section 7.4.4, “The Binary Log”](#). For additional information about using MySQL server options and system variables, see [Section 7.1.7, “Server Command Options”](#), and [Section 7.1.8, “Server System Variables”](#).

#### Startup Options Used with Binary Logging

The following list describes startup options for enabling and configuring the binary log. System variables used with binary logging are discussed later in this section.

- `--binlog-row-event-max-size=N`

Command-Line Format	<code>--binlog-row-event-max-size=#</code>
System Variable	<code>binlog_row_event_max_size</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	8192
Minimum Value	256
Maximum Value (64-bit platforms)	18446744073709551615
Maximum Value (32-bit platforms)	4294967295
Unit	bytes

When row-based binary logging is used, this setting is a soft limit on the maximum size of a row-based binary log event, in bytes. Where possible, rows stored in the binary log are grouped into events with a size not exceeding the value of this setting. If an event cannot be split, the maximum size can be exceeded. The value must be (or else gets rounded down to) a multiple of 256. The default is 8192 bytes.

- `--log-bin[=base_name]`

Command-Line Format	<code>--log-bin=<i>file_name</i></code>
Type	File name

Specifies the base name to use for binary log files. With binary logging enabled, the server logs all statements that change data to the binary log, which is used for backup and replication. The binary log is a sequence of files with a base name and numeric extension. The `--log-bin` option value is the base name for the log sequence. The server creates binary log files in sequence by adding a numeric suffix to the base name.

If you do not supply the `--log-bin` option, MySQL uses `binlog` as the default base name for the binary log files. For compatibility with earlier releases, if you supply the `--log-bin` option with no string or with an empty string, the base name defaults to `host_name-bin`, using the name of the host machine.

The default location for binary log files is the data directory. You can use the `--log-bin` option to specify an alternative location, by adding a leading absolute path name to the base name to specify a different directory. When the server reads an entry from the binary log index file, which tracks the binary log files that have been used, it checks whether the entry contains a relative path. If it does, the relative part of the path is replaced with the absolute path set using the `--log-bin` option. An absolute path recorded in the binary log index file remains unchanged; in such a case, the index file must be edited manually to enable a new path or paths to be used. The binary log file base name and any specified path are available as the `log_bin_basename` system variable.

In MySQL 9.1, binary logging is enabled by default, whether or not you specify the `--log-bin` option. The exception is if you use `mysqld` to initialize the data directory manually by invoking it with the `--initialize` or `--initialize-insecure` option, when binary logging is disabled by default. It is possible to enable binary logging in this case by specifying the `--log-bin` option. When binary logging is enabled, the `log_bin` system variable, which shows the status of binary logging on the server, is set to ON.

To disable binary logging, you can specify the `--skip-log-bin` or `--disable-log-bin` option at startup. If either of these options is specified and `--log-bin` is also specified, the option specified later takes precedence. When binary logging is disabled, the `log_bin` system variable is set to OFF.

When GTIDs are in use on the server, if you disable binary logging when restarting the server after an abnormal shutdown, some GTIDs are likely to be lost, causing replication to fail. In a normal shutdown, the set of GTIDs from the current binary log file is saved in the `mysql.gtid_executed` table. Following an abnormal shutdown where this did not happen, during recovery the GTIDs are added to the table from the binary log file, provided that binary logging is still enabled. If binary logging is disabled for the server restart, the server cannot access the binary log file to recover the GTIDs, so replication cannot be started. Binary logging can be disabled safely after a normal shutdown.

The `--log-replica-updates` and `--replica-preserve-commit-order` options require binary logging. If you disable binary logging, either omit these options, or specify `--log-replica-updates=OFF` and `--skip-replica-preserve-commit-order`. MySQL disables these options by default when `--skip-log-bin` or `--disable-log-bin` is specified. If you specify `--log-replica-`

`updates` or `--replica-preserve-commit-order` together with `--skip-log-bin` or `--disable-log-bin`, a warning or error message is issued.

The server can be started with the default server ID when binary logging is enabled, but an informational message is issued if you do not specify a server ID explicitly by setting the `server_id` system variable. For servers that are used in a replication topology, you must specify a unique nonzero server ID for each server.

For information on the format and management of the binary log, see [Section 7.4.4, “The Binary Log”](#).

- `--log-bin-index[=file_name]`

Command-Line Format	<code>--log-bin-index=file_name</code>
System Variable	<code>log_bin_index</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	File name

The name for the binary log index file, which contains the names of the binary log files. By default, it has the same location and base name as the value specified for the binary log files using the `--log-bin` option, plus the extension `.index`. If you do not specify `--log-bin`, the default binary log index file name is `binlog.index`. If you specify `--log-bin` option with no string or an empty string, the default binary log index file name is `host_name-bin.index`, using the name of the host machine.

For information on the format and management of the binary log, see [Section 7.4.4, “The Binary Log”](#).

**Statement selection options.** The options in the following list affect which statements are written to the binary log, and thus sent by a replication source server to its replicas. There are also options for replicas that control which statements received from the source should be executed or ignored. For details, see [Section 19.1.6.3, “Replica Server Options and Variables”](#).

- `--binlog-do-db=db_name`

Command-Line Format	<code>--binlog-do-db=name</code>
Type	String

This option affects binary logging in a manner similar to the way that `--replicate-do-db` affects replication.

The effects of this option depend on whether the statement-based or row-based logging format is in use, in the same way that the effects of `--replicate-do-db` depend on whether statement-based or row-based replication is in use. You should keep in mind that the format used to log a given statement may not necessarily be the same as that indicated by the value of `binlog_format`. For example, DDL statements such as `CREATE TABLE` and `ALTER TABLE` are always logged as statements, without regard to the logging format in effect, so the following statement-based rules for `--binlog-do-db` always apply in determining whether or not the statement is logged.

**Statement-based logging.** Only those statements are written to the binary log where the default database (that is, the one selected by `USE`) is `db_name`. To specify more than one database, use this option multiple times, once for each database; however, doing so does *not* cause cross-database statements such as `UPDATE some_db.some_table SET foo='bar'` to be logged while a different database (or no database) is selected.

### Warning

To specify multiple databases you *must* use multiple instances of this option. Because database names can contain commas, the list is treated as the name of a single database if you supply a comma-separated list.

An example of what does not work as you might expect when using statement-based logging: If the server is started with `--binlog-do-db=sales` and you issue the following statements, the `UPDATE` statement is *not* logged:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The main reason for this “just check the default database” behavior is that it is difficult from the statement alone to know whether it should be replicated (for example, if you are using multiple-table `DELETE` statements or multiple-table `UPDATE` statements that act across multiple databases). It is also faster to check only the default database rather than all databases if there is no need.

Another case which may not be self-evident occurs when a given database is replicated even though it was not specified when setting the option. If the server is started with `--binlog-do-db=sales`, the following `UPDATE` statement is logged even though `prices` was not included when setting `--binlog-do-db`:

```
USE sales;
UPDATE prices.discounts SET percentage = percentage + 10;
```

Because `sales` is the default database when the `UPDATE` statement is issued, the `UPDATE` is logged.

**Row-based logging.** Logging is restricted to database `db_name`. Only changes to tables belonging to `db_name` are logged; the default database has no effect on this. Suppose that the server is started with `--binlog-do-db=sales` and row-based logging is in effect, and then the following statements are executed:

```
USE prices;
UPDATE sales.february SET amount=amount+100;
```

The changes to the `february` table in the `sales` database are logged in accordance with the `UPDATE` statement; this occurs whether or not the `USE` statement was issued. However, when using the row-based logging format and `--binlog-do-db=sales`, changes made by the following `UPDATE` are not logged:

```
USE prices;
UPDATE prices.march SET amount=amount-25;
```

Even if the `USE prices` statement were changed to `USE sales`, the `UPDATE` statement's effects would still not be written to the binary log.

Another important difference in `--binlog-do-db` handling for statement-based logging as opposed to the row-based logging occurs with regard to statements that refer to multiple databases. Suppose that the server is started with `--binlog-do-db=db1`, and the following statements are executed:

```
USE db1;
UPDATE db1.table1, db2.table2 SET db1.table1.col1 = 10, db2.table2.col2 = 20;
```

If you are using statement-based logging, the updates to both tables are written to the binary log. However, when using the row-based format, only the changes to `table1` are logged; `table2` is in a

different database, so it is not changed by the `UPDATE`. Now suppose that, instead of the `USE db1` statement, a `USE db4` statement had been used:

```
USE db4;
UPDATE db1.table1, db2.table2 SET db1.table1.col1 = 10, db2.table2.col2 = 20;
```

In this case, the `UPDATE` statement is not written to the binary log when using statement-based logging. However, when using row-based logging, the change to `table1` is logged, but not that to `table2`—in other words, only changes to tables in the database named by `--binlog-ignore-db` are logged, and the choice of default database has no effect on this behavior.

- `--binlog-ignore-db=db_name`

Command-Line Format	<code>--binlog-ignore-db=name</code>
Type	String

This option affects binary logging in a manner similar to the way that `--replicate-ignore-db` affects replication.

The effects of this option depend on whether the statement-based or row-based logging format is in use, in the same way that the effects of `--replicate-ignore-db` depend on whether statement-based or row-based replication is in use. You should keep in mind that the format used to log a given statement may not necessarily be the same as that indicated by the value of `binlog_format`. For example, DDL statements such as `CREATE TABLE` and `ALTER TABLE` are always logged as statements, without regard to the logging format in effect, so the following statement-based rules for `--binlog-ignore-db` always apply in determining whether or not the statement is logged.

**Statement-based logging.** Tells the server to not log any statement where the default database (that is, the one selected by `USE`) is `db_name`.

When there is no default database, no `--binlog-ignore-db` options are applied, and such statements are always logged. (Bug #11829838, Bug #60188)

**Row-based format.** Tells the server not to log updates to any tables in the database `db_name`. The current database has no effect.

When using statement-based logging, the following example does not work as you might expect. Suppose that the server is started with `--binlog-ignore-db=sales` and you issue the following statements:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The `UPDATE` statement *is* logged in such a case because `--binlog-ignore-db` applies only to the default database (determined by the `USE` statement). Because the `sales` database was specified explicitly in the statement, the statement has not been filtered. However, when using row-based logging, the `UPDATE` statement's effects are *not* written to the binary log, which means that no changes to the `sales.january` table are logged; in this instance, `--binlog-ignore-db=sales` causes *all* changes made to tables in the source's copy of the `sales` database to be ignored for purposes of binary logging.

To specify more than one database to ignore, use this option multiple times, once for each database. Because database names can contain commas, the list is treated as the name of a single database if you supply a comma-separated list.

You should not use this option if you are using cross-database updates and you do not want these updates to be logged.

**Checksum options.** MySQL supports reading and writing of binary log checksums. These are enabled using the two options listed here:

- `--binlog-checksum={NONE|CRC32}`

Command-Line Format	<code>--binlog-checksum=type</code>
Type	String
Default Value	<code>CRC32</code>
Valid Values	<code>NONE</code> <code>CRC32</code>

Enabling this option causes the source to write checksums for events written to the binary log. Set to `NONE` to disable, or the name of the algorithm to be used for generating checksums; currently, only `CRC32` checksums are supported, and `CRC32` is the default. You cannot change the setting for this option within a transaction.

To control reading of checksums by the replica (from the relay log), use the `--replica-sql-verify-checksum` option.

**Testing and debugging options.** The following binary log options are used in replication testing and debugging. They are not intended for use in normal operations.

- `--max-binlog-dump-events=N`

Command-Line Format	<code>--max-binlog-dump-events=#</code>
Type	Integer
Default Value	<code>0</code>

This option is used internally by the MySQL test suite for replication testing and debugging.

- `--sporadic-binlog-dump-fail`

Command-Line Format	<code>--sporadic-binlog-dump-fail[={OFF ON}]</code>
Type	Boolean
Default Value	<code>OFF</code>

This option is used internally by the MySQL test suite for replication testing and debugging.

## System Variables Used with Binary Logging

The following list describes system variables for controlling binary logging. They can be set at server startup and some of them can be changed at runtime using `SET`. Server options used to control binary logging are listed earlier in this section.

- `binlog_cache_size`

Command-Line Format	<code>--binlog-cache-size=#</code>
System Variable	<code>binlog_cache_size</code>
Scope	Global
Dynamic	Yes

<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	32768
Minimum Value	4096
Maximum Value (64-bit platforms)	18446744073709547520
Maximum Value (32-bit platforms)	4294963200
Unit	bytes
<a href="#">Block Size</a>	4096

The size of the memory buffer to hold changes to the binary log during a transaction.

When binary logging is enabled on the server (with the [log\\_bin](#) system variable set to ON), a binary log cache is allocated for each client if the server supports any transactional storage engines. If the data for the transaction exceeds the space in the memory buffer, the excess data is stored in a temporary file. When binary log encryption is active on the server, the memory buffer is not encrypted, but any temporary file used to hold the binary log cache is encrypted. After each transaction is committed, the binary log cache is reset by clearing the memory buffer and truncating the temporary file if used.

If you often use large transactions, you can increase this cache size to get better performance by reducing or eliminating the need to write to temporary files. The [Binlog\\_cache\\_use](#) and [Binlog\\_cache\\_disk\\_use](#) status variables can be useful for tuning the size of this variable. See [Section 7.4.4, “The Binary Log”](#).

[binlog\\_cache\\_size](#) sets the size for the transaction cache only; the size of the statement cache is governed by the [binlog\\_stmt\\_cache\\_size](#) system variable.

- [binlog\\_checksum](#)

Command-Line Format	<code>--binlog-checksum=type</code>
System Variable	<a href="#">binlog_checksum</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	String
Default Value	CRC32
Valid Values	NONE CRC32

When enabled, this variable causes the source to write a checksum for each event in the binary log. [binlog\\_checksum](#) supports the values [NONE](#) (which disables checksums) and [CRC32](#). The default is [CRC32](#). When [binlog\\_checksum](#) is disabled (value [NONE](#)), the server verifies that it is writing only

complete events to the binary log by writing and checking the event length (rather than a checksum) for each event.

Setting this variable on the source to a value unrecognized by the replica causes the replica to set its own `binlog_checksum` value to `NONE`, and to stop replication with an error. If backward compatibility with older replicas is a concern, you may want to set the value explicitly to `NONE`.

Group Replication in MySQL 9.1 supports checksums, so group members may use the default setting.

Changing the value of `binlog_checksum` causes the binary log to be rotated, because checksums must be written for an entire binary log file, and never for only part of one. You cannot change the value of `binlog_checksum` within a transaction.

When binary log transaction compression is enabled using the `binlog_transaction_compression` system variable, checksums are not written for individual events in a compressed transaction payload. Instead a checksum is written for the GTID event, and a checksum for the compressed `Transaction_payload_event`.

- `binlog_direct_non_transactional_updates`

Command-Line Format	<code>--binlog-direct-non-transactional-updates[={OFF ON}]</code>
System Variable	<code>binlog_direct_non_transactional_updates</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Due to concurrency issues, a replica can become inconsistent when a transaction contains updates to both transactional and nontransactional tables. MySQL tries to preserve causality among these statements by writing nontransactional statements to the transaction cache, which is flushed upon commit. However, problems arise when modifications done to nontransactional tables on behalf of a transaction become immediately visible to other connections because these changes may not be written immediately into the binary log.

The `binlog_direct_non_transactional_updates` variable offers one possible workaround to this issue. By default, this variable is disabled. Enabling `binlog_direct_non_transactional_updates` causes updates to nontransactional tables to be written directly to the binary log, rather than to the transaction cache.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 7.1.9.1, “System Variable Privileges”](#).

`binlog_direct_non_transactional_updates` works only for statements that are replicated using the statement-based binary logging format; that is, it works only when the value of `binlog_format` is `STATEMENT`, or when `binlog_format` is `MIXED` and a given statement is being replicated using

the statement-based format. This variable has no effect when the binary log format is [ROW](#), or when `binlog_format` is set to [MIXED](#) and a given statement is replicated using the row-based format.

### Important

Before enabling this variable, you must make certain that there are no dependencies between transactional and nontransactional tables; an example of such a dependency would be the statement `INSERT INTO myisam_table SELECT * FROM innodb_table`. Otherwise, such statements are likely to cause the replica to diverge from the source.

This variable has no effect when the binary log format is [ROW](#) or [MIXED](#).

- [binlog\\_encryption](#)

Command-Line Format	<code>--binlog-encryption[={OFF ON}]</code>
System Variable	<a href="#">binlog_encryption</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Boolean
Default Value	<a href="#">OFF</a>

Enables encryption for binary log files and relay log files on this server. [OFF](#) is the default. [ON](#) sets encryption on for binary log files and relay log files. Binary logging does not need to be enabled on the server to enable encryption, so you can encrypt the relay log files on a replica that has no binary log. To use encryption, a keyring plugin must be installed and configured to supply MySQL Server's keyring service. For instructions to do this, see [Section 8.4.4, “The MySQL Keyring”](#). Any supported keyring plugin can be used to store binary log encryption keys.

When you first start the server with binary log encryption enabled, a new binary log encryption key is generated before the binary log and relay logs are initialized. This key is used to encrypt a file password for each binary log file (if the server has binary logging enabled) and relay log file (if the server has replication channels), and further keys generated from the file passwords are used to encrypt the data in the files. Relay log files are encrypted for all channels, including Group Replication applier channels and new channels that are created after encryption is activated. The binary log index file and relay log index file are never encrypted.

If you activate encryption while the server is running, a new binary log encryption key is generated at that time. The exception is if encryption was active previously on the server and was then disabled, in which case the binary log encryption key that was in use before is used again. The binary log file and relay log files are rotated immediately, and file passwords for the new files and all subsequent binary log files and relay log files are encrypted using this binary log encryption key. Existing binary log files and relay log files still present on the server are not automatically encrypted, but you can purge them if they are no longer needed.

If you deactivate encryption by changing the [binlog\\_encryption](#) system variable to [OFF](#), the binary log file and relay log files are rotated immediately and all subsequent logging is unencrypted. Previously encrypted files are not automatically decrypted, but the server is still able to read them. The [BINLOG\\_ENCRYPTION\\_ADMIN](#) privilege (or the deprecated [SUPER](#) privilege) is required to activate or deactivate encryption while the server is running. Group Replication applier channels are not included in the relay log rotation request, so unencrypted logging for these channels does not start until their logs are rotated in normal use.

For more information on binary log file and relay log file encryption, see [Section 19.3.2, “Encrypting Binary Log Files and Relay Log Files”](#).

- `binlog_error_action`

Command-Line Format	<code>--binlog-error-action[=value]</code>
System Variable	<code>binlog_error_action</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Enumeration
Default Value	<code>ABORT_SERVER</code>
Valid Values	<code>IGNORE_ERROR</code> <code>ABORT_SERVER</code>

Controls what happens when the server encounters an error such as not being able to write to, flush or synchronize the binary log, which can cause the source's binary log to become inconsistent and replicas to lose synchronization.

This variable defaults to `ABORT_SERVER`, which makes the server halt logging and shut down whenever it encounters such an error with the binary log. On restart, recovery proceeds as in the case of an unexpected server halt (see [Section 19.4.2, “Handling an Unexpected Halt of a Replica”](#)).

When `binlog_error_action` is set to `IGNORE_ERROR`, if the server encounters such an error it continues the ongoing transaction, logs the error then halts logging, and continues performing updates. To resume binary logging `log_bin` must be enabled again, which requires a server restart. This setting provides backward compatibility with older versions of MySQL.

- `binlog_expire_logs_seconds`

Command-Line Format	<code>--binlog-expire-logs-seconds=#</code>
System Variable	<code>binlog_expire_logs_seconds</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	2592000
Minimum Value	0
Maximum Value	4294967295

Unit	seconds
------	---------

Sets the binary log expiration period in seconds. After their expiration period ends, binary log files can be automatically removed. Possible removals happen at startup and when the binary log is flushed. Log flushing occurs as indicated in [Section 7.4, “MySQL Server Logs”](#).

The default binary log expiration period is 2592000 seconds, which equals 30 days (30\*24\*60\*60 seconds).

Automatic purging of the binary log can be disabled by setting the `binlog_expire_logs_auto_purge` system variable to `OFF`. This takes precedence over any setting for `binlog_expire_logs_seconds`.

To remove binary log files manually, use the `PURGE BINARY LOGS` statement. See [Section 15.4.1.1, “PURGE BINARY LOGS Statement”](#).

- `binlog_expire_logs_auto_purge`

Command-Line Format	<code>--binlog-expire-logs-auto-purge={ON OFF}</code>
System Variable	<code>binlog_expire_logs_auto_purge</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>ON</code>

Enables or disables automatic purging of binary log files. Setting this variable to `ON` (the default) enables automatic purging; setting it to `OFF` disables automatic purging. The interval to wait before purging is controlled by `binlog_expire_logs_seconds`.

#### Note

Even if `binlog_expire_logs_auto_purge` is `ON`, setting `binlog_expire_logs_seconds` to 0 stops automatic purging from taking place.

This variable has no effect on `PURGE BINARY LOGS`.

- `binlog_format`

Command-Line Format	<code>--binlog-format=format</code>
Deprecated	Yes
System Variable	<code>binlog_format</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Enumeration
Default Value	<code>ROW</code>
Valid Values	<code>MIXED</code>

	STATEMENT
	ROW

This system variable sets the binary logging format, and can be any one of [STATEMENT](#), [ROW](#), or [MIXED](#). (See [Section 19.2.1, “Replication Formats”](#).) The setting takes effect when binary logging is enabled on the server, which is the case when the `log_bin` system variable is set to `ON`. In MySQL 9.1, binary logging is enabled by default, and by default uses the row-based format.

#### Note

`binlog_format` is deprecated, and subject to removal in a future version of MySQL. This implies that support for logging formats other than row-based is also subject to removal in a future release. Thus, only row-based logging should be employed for any new MySQL Replication setups.

`binlog_format` can be set at startup or at runtime, except that under some conditions, changing this variable at runtime is not possible or causes replication to fail, as described later.

The default is `ROW`. *Exception:* In NDB Cluster, the default is `MIXED`; statement-based replication is not supported for NDB Cluster.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 7.1.9.1, “System Variable Privileges”](#).

The rules governing when changes to this variable take effect and how long the effect lasts are the same as for other MySQL server system variables. For more information, see [Section 15.7.6.1, “SET Syntax for Variable Assignment”](#).

When `MIXED` is specified, statement-based replication is used, except for cases where only row-based replication is guaranteed to lead to proper results. For example, this happens when statements contain loadable functions or the `UUID()` function.

For details of how stored programs (stored procedures and functions, triggers, and events) are handled when each binary logging format is set, see [Section 27.8, “Stored Program Binary Logging”](#).

There are exceptions when you cannot switch the replication format at runtime:

- The replication format cannot be changed from within a stored function or a trigger.
- If a session has open temporary tables, the replication format cannot be changed for the session (`SET @@SESSION.binlog_format`).
- If any replication channel has open temporary tables, the replication format cannot be changed globally (`SET @@GLOBAL.binlog_format` or `SET @@PERSIST.binlog_format`).
- If any replication channel applier thread is currently running, the replication format cannot be changed globally (`SET @@GLOBAL.binlog_format` or `SET @@PERSIST.binlog_format`).

Trying to switch the replication format in any of these cases (or attempting to set the current replication format) results in an error. You can, however, use `PERSIST_ONLY` (`SET`

`@@PERSIST_ONLY.binlog_format`) to change the replication format at any time, because this action does not modify the runtime global system variable value, and takes effect only after a server restart.

Switching the replication format at runtime is not recommended when any temporary tables exist, because temporary tables are logged only when using statement-based replication, whereas with row-based replication and mixed replication, they are not logged.

Changing the logging format on a replication source server does not cause a replica to change its logging format to match. Switching the replication format while replication is ongoing can cause issues if a replica has binary logging enabled, and the change results in the replica using `STATEMENT` format logging while the source is using `ROW` or `MIXED` format logging. A replica is not able to convert binary log entries received in `ROW` logging format to `STATEMENT` format for use in its own binary log, so this situation can cause replication to fail. For more information, see [Section 7.4.4.2, “Setting The Binary Log Format”](#).

The binary log format affects the behavior of the following server options:

- `--replicate-do-db`
- `--replicate-ignore-db`
- `--binlog-do-db`
- `--binlog-ignore-db`

These effects are discussed in detail in the descriptions of the individual options.

- `binlog_group_commit_sync_delay`

Command-Line Format	<code>--binlog-group-commit-sync-delay=#</code>
System Variable	<code>binlog_group_commit_sync_delay</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	1000000
Unit	microseconds

Controls how many microseconds the binary log commit waits before synchronizing the binary log file to disk. By default `binlog_group_commit_sync_delay` is set to 0, meaning that there is no delay. Setting `binlog_group_commit_sync_delay` to a microsecond delay enables more transactions to be synchronized together to disk at once, reducing the overall time to commit a group of transactions because the larger groups require fewer time units per group.

When `sync_binlog=0` or `sync_binlog=1` is set, the delay specified by `binlog_group_commit_sync_delay` is applied for every binary log commit group before

synchronization (or in the case of `sync_binlog=0`, before proceeding). When `sync_binlog` is set to a value *n* greater than 1, the delay is applied after every *n* binary log commit groups.

Setting `binlog_group_commit_sync_delay` can increase the number of parallel committing transactions on any server that has (or might have after a failover) a replica, and therefore can increase parallel execution on the replicas. To benefit from this effect, the replica servers must have `replica_parallel_type=LOGICAL_CLOCK` set. It is important to take into account both source and replica throughput when you are setting `binlog_group_commit_sync_delay`.

Setting `binlog_group_commit_sync_delay` can also reduce the number of `fsync()` calls to the binary log on any server (source or replica) that has a binary log.

Note that setting `binlog_group_commit_sync_delay` increases the latency of transactions on the server, which might affect client applications. Also, on highly concurrent workloads, it is possible for the delay to increase contention and therefore reduce throughput. Typically, the benefits of setting a delay outweigh the drawbacks, but tuning should always be carried out to determine the optimal setting.

- `binlog_group_commit_sync_no_delay_count`

Command-Line Format	<code>--binlog-group-commit-sync-no-delay-count=#</code>
System Variable	<code>binlog_group_commit_sync_no_delay_count</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	100000

The maximum number of transactions to wait for before aborting the current delay as specified by `binlog_group_commit_sync_delay`. If `binlog_group_commit_sync_delay` is set to 0, then this option has no effect.

- `binlog_max_flush_queue_time`

Command-Line Format	<code>--binlog-max-flush-queue-time=#</code>
Deprecated	Yes
System Variable	<code>binlog_max_flush_queue_time</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	100000

Unit	microseconds
------	--------------

`binlog_max_flush_queue_time` is deprecated, and is marked for eventual removal in a future MySQL release. Formerly, this system variable controlled the time in microseconds to continue reading transactions from the flush queue before proceeding with group commit. It no longer has any effect.

- `binlog_order_commits`

Command-Line Format	<code>--binlog-order-commits[={OFF ON}]</code>
System Variable	<code>binlog_order_commits</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>ON</code>

When this variable is enabled on a replication source server (which is the default), transaction commit instructions issued to storage engines are serialized on a single thread, so that transactions are always committed in the same order as they are written to the binary log. Disabling this variable permits transaction commit instructions to be issued using multiple threads. Used in combination with binary log group commit, this prevents the commit rate of a single transaction being a bottleneck to throughput, and might therefore produce a performance improvement.

Transactions are written to the binary log at the point when all the storage engines involved have confirmed that the transaction is prepared to commit. The binary log group commit logic then commits a group of transactions after their binary log write has taken place. When `binlog_order_commits` is disabled, because multiple threads are used for this process, transactions in a commit group might be committed in a different order from their order in the binary log. (Transactions from a single client always commit in chronological order.) In many cases this does not matter, as operations carried out in separate transactions should produce consistent results, and if that is not the case, a single transaction ought to be used instead.

If you want to ensure that the transaction history on the source and on a multithreaded replica remains identical, set `replica_preserve_commit_order=1` on the replica.

- `binlog_rotate_encryption_master_key_at_startup`

Command-Line Format	<code>--binlog-rotate-encryption-master-key-at-startup[={OFF ON}]</code>
System Variable	<code>binlog_rotate_encryption_master_key_at_startup</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Specifies whether or not the binary log master key is rotated at server startup. The binary log master key is the binary log encryption key that is used to encrypt file passwords for the binary log files and relay log files on the server. When a server is started for the first time with binary log encryption enabled (`binlog_encryption=ON`), a new binary log encryption key is generated and used as the binary

log master key. If the `binlog_rotate_encryption_master_key_at_startup` system variable is also set to `ON`, whenever the server is restarted, a further binary log encryption key is generated and used as the binary log master key for all subsequent binary log files and relay log files. If the `binlog_rotate_encryption_master_key_at_startup` system variable is set to `OFF`, which is the default, the existing binary log master key is used again after the server restarts. For more information on binary log encryption keys and the binary log master key, see [Section 19.3.2, “Encrypting Binary Log Files and Relay Log Files”](#).

- `binlog_row_event_max_size`

Command-Line Format	<code>--binlog-row-event-max-size=#</code>
System Variable	<code>binlog_row_event_max_size</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	8192
Minimum Value	256
Maximum Value (64-bit platforms)	18446744073709551615
Maximum Value (32-bit platforms)	4294967295
Unit	bytes

When row-based binary logging is used, this setting is a soft limit on the maximum size of a row-based binary log event, in bytes. Where possible, rows stored in the binary log are grouped into events with a size not exceeding the value of this setting. If an event cannot be split, the maximum size can be exceeded. The default is 8192 bytes.

This global system variable is read-only and can be set only at server startup. Its value can therefore only be modified by using the `PERSIST_ONLY` keyword or the `@@persist_only` qualifier with the `SET` statement.

- `binlog_row_image`

Command-Line Format	<code>--binlog-row-image=image_type</code>
System Variable	<code>binlog_row_image</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Enumeration
Default Value	<code>full</code>
Valid Values	<code>full</code> (Log all columns)  <code>minimal</code> (Log only changed columns, and columns needed to identify rows)

<code>noblob</code> (Log all columns, except for unneeded BLOB and TEXT columns)
----------------------------------------------------------------------------------

For MySQL row-based replication, this variable determines how row images are written to the binary log.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 7.1.9.1, “System Variable Privileges”](#).

In MySQL row-based replication, each row change event contains two images, a “before” image whose columns are matched against when searching for the row to be updated, and an “after” image containing the changes. Normally, MySQL logs full rows (that is, all columns) for both the before and after images. However, it is not strictly necessary to include every column in both images, and we can often save disk, memory, and network usage by logging only those columns which are actually required.

#### Note

When deleting a row, only the before image is logged, since there are no changed values to propagate following the deletion. When inserting a row, only the after image is logged, since there is no existing row to be matched. Only when updating a row are both the before and after images required, and both written to the binary log.

For the before image, it is necessary only that the minimum set of columns required to uniquely identify rows is logged. If the table containing the row has a primary key, then only the primary key column or columns are written to the binary log. Otherwise, if the table has a unique key all of whose columns are `NOT NULL`, then only the columns in the unique key need be logged. (If the table has neither a primary key nor a unique key without any `NULL` columns, then all columns must be used in the before image, and logged.) In the after image, it is necessary to log only the columns which have actually changed.

You can cause the server to log full or minimal rows using the `binlog_row_image` system variable. This variable actually takes one of three possible values, as shown in the following list:

- `full`: Log all columns in both the before image and the after image.
- `minimal`: Log only those columns in the before image that are required to identify the row to be changed; log only those columns in the after image where a value was specified by the SQL statement, or generated by auto-increment.
- `noblob`: Log all columns (same as `full`), except for `BLOB` and `TEXT` columns that are not required to identify rows, or that have not changed.

#### Note

This variable is not supported by NDB Cluster; setting it has no effect on the logging of `NDB` tables.

The default value is `full`.

When using `minimal` or `noblob`, deletes and updates are guaranteed to work correctly for a given table if and only if the following conditions are true for both the source and destination tables:

- All columns must be present and in the same order; each column must use the same data type as its counterpart in the other table.

- The tables must have identical primary key definitions.

(In other words, the tables must be identical with the possible exception of indexes that are not part of the tables' primary keys.)

If these conditions are not met, it is possible that the primary key column values in the destination table may prove insufficient to provide a unique match for a delete or update. In this event, no warning or error is issued; the source and replica silently diverge, thus breaking consistency.

Setting this variable has no effect when the binary logging format is `STATEMENT`. When `binlog_format` is `MIXED`, the setting for `binlog_row_image` is applied to changes that are logged using row-based format, but this setting has no effect on changes logged as statements.

Setting `binlog_row_image` on either the global or session level does not cause an implicit commit; this means that this variable can be changed while a transaction is in progress without affecting the transaction.

- `binlog_row_metadata`

Command-Line Format	<code>--binlog-row-metadata=metadata_type</code>
System Variable	<code>binlog_row_metadata</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Enumeration
Default Value	<code>MINIMAL</code>
Valid Values	<code>FULL</code> (All metadata is included) <code>MINIMAL</code> (Limit included metadata)

Configures the amount of table metadata added to the binary log when using row-based logging. When set to `MINIMAL`, the default, only metadata related to `SIGNED` flags, column character set and geometry types are logged. When set to `FULL` complete metadata for tables is logged, such as column name, `ENUM` or `SET` string values, `PRIMARY KEY` information, and so on.

The extended metadata serves the following purposes:

- Replicas use the metadata to transfer data when its table structure is different from the source's.
- External software can use the metadata to decode row events and store the data into external databases, such as a data warehouse.

- `binlog_row_value_options`

Command-Line Format	<code>--binlog-row-value-options=#</code>
System Variable	<code>binlog_row_value_options</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Set

Default Value	
Valid Values	<a href="#">PARTIAL_JSON</a>

When set to [PARTIAL\\_JSON](#), this enables use of a space-efficient binary log format for updates that modify only a small portion of a JSON document, which causes row-based replication to write only the modified parts of the JSON document to the after-image for the update in the binary log, rather than writing the full document (see [Partial Updates of JSON Values](#)). This works for an [UPDATE](#) statement which modifies a JSON column using any sequence of [JSON\\_SET\(\)](#), [JSON\\_REPLACE\(\)](#), and [JSON\\_REMOVE\(\)](#). If the server is unable to generate a partial update, the full document is used instead.

The default value is an empty string, which disables use of the format. To unset [binlog\\_row\\_value\\_options](#) and revert to writing the full JSON document, set its value to the empty string.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 7.1.9.1, “System Variable Privileges”](#).

[binlog\\_row\\_value\\_options=PARTIAL\\_JSON](#) takes effect only when binary logging is enabled and [binlog\\_format](#) is set to [ROW](#) or [MIXED](#). Statement-based replication *always* logs only the modified parts of the JSON document, regardless of any value set for [binlog\\_row\\_value\\_options](#). To maximize the amount of space saved, use [binlog\\_row\\_image=NOBLOB](#) or [binlog\\_row\\_image=MINIMAL](#) together with this option. [binlog\\_row\\_image=FULL](#) saves less space than either of these, since the full JSON document is stored in the before-image, and the partial update is stored only in the after-image.

[mysqlbinlog](#) output includes partial JSON updates in the form of events encoded as base-64 strings using [BINLOG](#) statements. If the [--verbose](#) option is specified, [mysqlbinlog](#) displays the partial JSON updates as readable JSON using pseudo-SQL statements.

MySQL Replication generates an error if a modification cannot be applied to the JSON document on the replica. This includes a failure to find the path. Be aware that, even with this and other safety checks, if a JSON document on a replica has diverged from that on the source and a partial update is applied, it remains theoretically possible to produce a valid but unexpected JSON document on the replica.

- [binlog\\_rows\\_query\\_log\\_events](#)

Command-Line Format	<a href="#">--binlog-rows-query-log-events[={OFF ON}]</a>
System Variable	<a href="#">binlog_rows_query_log_events</a>
Scope	Global, Session
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Boolean
Default Value	<a href="#">OFF</a>

This system variable affects row-based logging only. When enabled, it causes the server to write informational log events such as row query log events into its binary log. This information can be used

for debugging and related purposes, such as obtaining the original query issued on the source when it cannot be reconstructed from the row updates.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 7.1.9.1, “System Variable Privileges”](#).

These informational events are normally ignored by MySQL programs reading the binary log and so cause no issues when replicating or restoring from backup. To view them, increase the verbosity level by using mysqlbinlog's `--verbose` option twice, either as `-vv` or `--verbose --verbose`.

- `binlog_stmt_cache_size`

Command-Line Format	<code>--binlog-stmt-cache-size=#</code>
System Variable	<code>binlog_stmt_cache_size</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	32768
Minimum Value	4096
Maximum Value (64-bit platforms)	18446744073709547520
Maximum Value (32-bit platforms)	4294963200
Unit	bytes
Block Size	4096

The size of the memory buffer for the binary log to hold nontransactional statements issued during a transaction.

When binary logging is enabled on the server (with the `log_bin` system variable set to ON), separate binary log transaction and statement caches are allocated for each client if the server supports any transactional storage engines. If the data for the nontransactional statements used in the transaction exceeds the space in the memory buffer, the excess data is stored in a temporary file. When binary log encryption is active on the server, the memory buffer is not encrypted, but any temporary file used to hold the binary log cache is encrypted. After each transaction is committed, the binary log statement cache is reset by clearing the memory buffer and truncating the temporary file if used.

If you often use large nontransactional statements during transactions, you can increase this cache size to get better performance by reducing or eliminating the need to write to temporary files. The `Binlog_stmt_cache_use` and `Binlog_stmt_cache_disk_use` status variables can be useful for tuning the size of this variable. See [Section 7.4.4, “The Binary Log”](#).

The `binlog_cache_size` system variable sets the size for the transaction cache.

- `binlog_transaction_compression`

Command-Line Format	<code>--binlog-transaction-compression[={OFF ON}]</code>
System Variable	<code>binlog_transaction_compression</code>
Scope	Global, Session
Dynamic	Yes

<a href="#">SET_VAR</a> Hint Applies	No
Type	Boolean
Default Value	<a href="#">OFF</a>

Enables compression for transactions that are written to binary log files on this server. [OFF](#) is the default. Use the [binlog\\_transaction\\_compression\\_level\\_zstd](#) system variable to set the level for the [zstd](#) algorithm that is used for compression.

Setting [binlog\\_transaction\\_compression](#) has no immediate effect but rather applies to all subsequent [START REPLICA](#) statements.

When binary log transaction compression is enabled, transaction payloads are compressed and then written to the binary log file as a single event ([Transaction\\_payload\\_event](#)). Compressed transaction payloads remain in a compressed state while they are sent in the replication stream to replicas, other Group Replication group members, or clients such as [mysqlbinlog](#), and are written to the relay log still in their compressed state. Binary log transaction compression therefore saves storage space both on the originator of the transaction and on the recipient (and for their backups), and saves network bandwidth when the transactions are sent between server instances.

For [binlog\\_transaction\\_compression=ON](#) to have a direct effect, binary logging must be enabled on the server. When a MySQL 9.1 server instance has no binary log, it can receive, handle, and display compressed transaction payloads regardless of its value for [binlog\\_transaction\\_compression](#). Compressed transaction payloads received by such server instances are written in their compressed state to the relay log, so they benefit indirectly from compression carried out by other servers in the replication topology.

This system variable cannot be changed within the context of a transaction. Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 7.1.9.1, “System Variable Privileges”](#).

For more information on binary log transaction compression, including details of what events are and are not compressed, and changes in behavior when transaction compression is in use, see [Section 7.4.4.5, “Binary Log Transaction Compression”](#).

You can use the [ndb\\_log\\_transaction\\_compression](#) system variable to enable this feature for [NDB](#). In addition, setting [--binlog-transaction-compression=ON](#) on the command line or in a [my.cnf](#) file causes [ndb\\_log\\_transaction\\_compression](#) to be enabled on server startup. See the description of the variable for further information.

- [binlog\\_transaction\\_compression\\_level\\_zstd](#)

Command-Line Format	<a href="#">--binlog-transaction-compression-level-zstd=#</a>
System Variable	<a href="#">binlog_transaction_compression_level_zstd</a>
Scope	Global, Session
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	3
Minimum Value	1
Maximum Value	22

Sets the compression level for binary log transaction compression on this server, which is enabled by the `binlog_transaction_compression` system variable. The value is an integer that determines the compression effort, from 1 (the lowest effort) to 22 (the highest effort). If you do not specify this system variable, the compression level is set to 3.

Setting `binlog_transaction_compression_level_zstd` has no immediate effect but rather applies to all subsequent `START REPLICA` statements.

As the compression level increases, the data compression ratio increases, which reduces the storage space and network bandwidth required for the transaction payload. However, the effort required for data compression also increases, taking time and CPU and memory resources on the originating server. Increases in the compression effort do not have a linear relationship to increases in the data compression ratio.

This system variable cannot be changed within the context of a transaction. Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 7.1.9.1, “System Variable Privileges”](#).

This variable has no effect on logging of transactions on `NDB` tables; use `ndb_log_transaction_compression_level_zstd` instead.

- `binlog_transaction_dependency_history_size`

Command-Line Format	<code>--binlog-transaction-dependency-history-size=#</code>
System Variable	<code>binlog_transaction_dependency_history_size</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	25000
Minimum Value	1
Maximum Value	1000000

Sets an upper limit on the number of row hashes which are kept in memory and used for looking up the transaction that last modified a given row. Once this number of hashes has been reached, the history is purged.

- `log_bin`

System Variable	<code>log_bin</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Boolean

Shows the status of binary logging on the server, either enabled (`ON`) or disabled (`OFF`). With binary logging enabled, the server logs all statements that change data to the binary log, which is used for

backup and replication. `ON` means that the binary log is available, `OFF` means that it is not in use. The `--log-bin` option can be used to specify a base name and location for the binary log.

In earlier MySQL versions, binary logging was disabled by default, and was enabled if you specified the `--log-bin` option. Binary logging is enabled by default, with the `log_bin` system variable set to `ON`, whether or not you specify the `--log-bin` option. The exception is if you use `mysqld` to initialize the data directory manually by invoking it with the `--initialize` or `--initialize-insecure` option, when binary logging is disabled by default. It is possible to enable binary logging in this case by specifying the `--log-bin` option.

If the `--skip-log-bin` or `--disable-log-bin` option is specified at startup, binary logging is disabled, with the `log_bin` system variable set to `OFF`. If either of these options is specified and `--log-bin` is also specified, the option specified later takes precedence.

For information on the format and management of the binary log, see [Section 7.4.4, “The Binary Log”](#).

- `log_bin_basename`

System Variable	<code>log_bin_basename</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	File name

Holds the base name and path for the binary log files, which can be set with the `--log-bin` server option. The maximum variable length is 256. In MySQL 9.1, if the `--log-bin` option is not supplied, the default base name is `binlog`. For compatibility with MySQL 5.7, if the `--log-bin` option is supplied with no string or with an empty string, the default base name is `host_name-bin`, using the name of the host machine. The default location is the data directory.

- `log_bin_index`

Command-Line Format	<code>--log-bin-index=file_name</code>
System Variable	<code>log_bin_index</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	File name

Holds the base name and path for the binary log index file, which can be set with the `--log-bin-index` server option. The maximum variable length is 256.

- `log_bin_trust_function_creators`

Command-Line Format	<code>--log-bin-trust-function-creators[={OFF ON}]</code>
Deprecated	Yes
System Variable	<code>log_bin_trust_function_creators</code>
Scope	Global
Dynamic	Yes

<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

This variable applies when binary logging is enabled. It controls whether stored function creators can be trusted not to create stored functions that may cause unsafe events to be written to the binary log. If set to 0 (the default), users are not permitted to create or alter stored functions unless they have the `SUPER` privilege in addition to the `CREATE ROUTINE` or `ALTER ROUTINE` privilege. A setting of 0 also enforces the restriction that a function must be declared with the `DETERMINISTIC` characteristic, or with the `READS SQL DATA` or `NO SQL` characteristic. If the variable is set to 1, MySQL does not enforce these restrictions on stored function creation. This variable also applies to trigger creation. See [Section 27.8, “Stored Program Binary Logging”](#).

- `log_replica_updates`

Command-Line Format	<code>--log-replica-updates[={OFF ON}]</code>
System Variable	<code>log_replica_updates</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>ON</code>

`log_replica_updates` specifies whether updates received by a replica server from a replication source server should be logged to the replica's own binary log.

Enabling this variable causes the replica to write the updates that are received from a source and performed by the replication SQL thread to the replica's own binary log. Binary logging, which is controlled by the `--log-bin` option and is enabled by default, must also be enabled on the replica for updates to be logged. See [Section 19.1.6, “Replication and Binary Logging Options and Variables”](#). `log_replica_updates` is enabled by default, unless you specify `--skip-log-bin` to disable binary logging, in which case MySQL also disables replica update logging by default. If you need to disable replica update logging when binary logging is enabled, specify `--log-replica-updates=OFF` at replica server startup.

Enabling `log_replica_updates` enables replication servers to be chained. For example, you might want to set up replication servers using this arrangement:

```
A -> B -> C
```

Here, `A` serves as the source for the replica `B`, and `B` serves as the source for the replica `C`. For this to work, `B` must be both a source *and* a replica. With binary logging enabled and `log_replica_updates` enabled, which are the default settings, updates received from `A` are logged by `B` to its binary log, and can therefore be passed on to `C`.

- `log_slave_updates`

Command-Line Format	<code>--log-slave-updates[={OFF ON}]</code>
Deprecated	Yes
System Variable	<code>log_slave_updates</code>

Scope	Global
Dynamic	No
<a href="#">SET_VAR</a> Hint Applies	No
Type	Boolean
Default Value	<a href="#">ON</a>

Deprecated alias for [log\\_replica\\_updates](#).

- [log\\_statements\\_unsafe\\_for\\_binlog](#)

Command-Line Format	<a href="#">--log-statements-unsafe-for-binlog[={OFF ON}]</a>
Deprecated	Yes
System Variable	<a href="#">log_statements_unsafe_for_binlog</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Boolean
Default Value	<a href="#">ON</a>

If error 1592 is encountered, controls whether the generated warnings are added to the error log or not.

- [master\\_verify\\_checksum](#)

Command-Line Format	<a href="#">--master-verify-checksum[={OFF ON}]</a>
Deprecated	Yes
System Variable	<a href="#">master_verify_checksum</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Boolean
Default Value	<a href="#">OFF</a>

Deprecated alias for [source\\_verify\\_checksum](#).

- [max\\_binlog\\_cache\\_size](#)

Command-Line Format	<a href="#">--max-binlog-cache-size=#</a>
System Variable	<a href="#">max_binlog_cache_size</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value (64-bit platforms)	<a href="#">18446744073709547520</a>
Default Value (32-bit platforms)	<a href="#">4294967295</a>

Minimum Value	4096
Maximum Value (64-bit platforms)	18446744073709547520
Maximum Value (32-bit platforms)	4294967295
Unit	bytes
Block Size	4096

If a transaction requires more than this many bytes, the server generates a `Multi-statement transaction required more than 'max_binlog_cache_size' bytes of storage error`. When `gtid_mode` is not `ON`, the maximum recommended value is 4GB, due to the fact that, in this case, MySQL cannot work with binary log positions greater than 4GB; when `gtid_mode` is `ON`, this limitation does not apply, and the server can work with binary log positions of arbitrary size.

If, because `gtid_mode` is not `ON`, or for some other reason, you need to guarantee that the binary log does not exceed a given size `maxsize`, you should set this variable according to the formula shown here:

```
max_binlog_cache_size <
 (((maxsize - max_binlog_size) / max_connections) - 1000) / 1.2
```

This calculation takes into account the following conditions:

- The server writes to the binary log as long as the size before it begins to write is less than `max_binlog_size`.
- The server does not write single transactions, but rather groups of transactions. The maximum possible number of transactions in a group is equal to `max_connections`.
- The server writes data that is not included in the cache. This includes a 4-byte checksum for each event; while this adds less than 20% to the transaction size, this amount is non-negligible. In addition, the server writes a `Gtid_log_event` for each transaction; each of these events can add another 1 KB to what is written to the binary log.

`max_binlog_cache_size` sets the size for the transaction cache only; the upper limit for the statement cache is governed by the `max_binlog_stmt_cache_size` system variable.

The visibility to sessions of `max_binlog_cache_size` matches that of the `binlog_cache_size` system variable; in other words, changing its value affects only new sessions that are started after the value is changed.

- `max_binlog_size`

Command-Line Format	<code>--max-binlog-size=#</code>
System Variable	<code>max_binlog_size</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	1073741824
Minimum Value	4096
Maximum Value	1073741824

Unit	bytes
Block Size	4096

If a write to the binary log causes the current log file size to exceed the value of this variable, the server rotates the binary logs (closes the current file and opens the next one). The minimum value is 4096 bytes. The maximum and default value is 1GB. Encrypted binary log files have an additional 512-byte header, which is included in `max_binlog_size`.

A transaction is written in one chunk to the binary log, so it is never split between several binary logs. Therefore, if you have big transactions, you might see binary log files larger than `max_binlog_size`.

If `max_relay_log_size` is 0, the value of `max_binlog_size` applies to relay logs as well.

With GTIDs in use on the server, when `max_binlog_size` is reached, if the system table `mysql.gtid_executed` cannot be accessed to write the GTIDs from the current binary log file, the binary log cannot be rotated. In this situation, the server responds according to its `binlog_error_action` setting. If `IGNORE_ERROR` is set, an error is logged on the server and binary logging is halted, or if `ABORT_SERVER` is set, the server shuts down.

- `max_binlog_stmt_cache_size`

Command-Line Format	<code>--max-binlog-stmt-cache-size=#</code>
System Variable	<code>max_binlog_stmt_cache_size</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	18446744073709547520
Minimum Value	4096
Maximum Value	18446744073709547520
Unit	bytes
Block Size	4096

If nontransactional statements within a transaction require more than this many bytes of memory, the server generates an error. The minimum value is 4096. The maximum and default values are 4GB on 32-bit platforms and 16EB (exabytes) on 64-bit platforms.

`max_binlog_stmt_cache_size` sets the size for the statement cache only; the upper limit for the transaction cache is governed exclusively by the `max_binlog_cache_size` system variable.

- `original_commit_timestamp`

System Variable	<code>original_commit_timestamp</code>
Scope	Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No

Type	Numeric
------	---------

For internal use by replication. When re-executing a transaction on a replica, this is set to the time when the transaction was committed on the original source, measured in microseconds since the epoch. This allows the original commit timestamp to be propagated throughout a replication topology.

Setting the session value of this system variable is a restricted operation. The session user must have either the `REPLICATION_APPLIER` privilege (see [Section 19.3.3, “Replication Privilege Checks”](#)), or privileges sufficient to set restricted session variables (see [Section 7.1.9.1, “System Variable Privileges”](#)). However, note that the variable is not intended for users to set; it is set automatically by the replication infrastructure.

- `source_verify_checksum`

Command-Line Format	<code>--source-verify-checksum[={OFF ON}]</code>
System Variable	<code>source_verify_checksum</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Enabling `source_verify_checksum` causes the source to verify events read from the binary log by examining checksums, and to stop with an error in the event of a mismatch. `source_verify_checksum` is disabled by default; in this case, the source uses the event length from the binary log to verify events, so that only complete events are read from the binary log.

- `sql_log_bin`

System Variable	<code>sql_log_bin</code>
Scope	Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>ON</code>

This variable controls whether logging to the binary log is enabled for the current session (assuming that the binary log itself is enabled). The default value is `ON`. To disable or enable binary logging for the current session, set the session `sql_log_bin` variable to `OFF` or `ON`.

Set this variable to `OFF` for a session to temporarily disable binary logging while making changes to the source you do not want replicated to the replica.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 7.1.9.1, “System Variable Privileges”](#).

It is not possible to set the session value of `sql_log_bin` within a transaction or subquery.

Setting this variable to `OFF` prevents GTIDs from being assigned to transactions in the binary log. If you are using GTIDs for replication, this means that even when binary logging is later enabled again,

the GTIDs written into the log from this point do not account for any transactions that occurred in the meantime, so in effect those transactions are lost.

- `sync_binlog`

Command-Line Format	<code>--sync-binlog=#</code>
System Variable	<code>sync_binlog</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	1
Minimum Value	0
Maximum Value	4294967295

Controls how often the MySQL server synchronizes the binary log to disk.

- `sync_binlog=0`: Disables synchronization of the binary log to disk by the MySQL server. Instead, the MySQL server relies on the operating system to flush the binary log to disk from time to time as it does for any other file. This setting provides the best performance, but in the event of a power failure or operating system crash, it is possible that the server has committed transactions that have not been synchronized to the binary log.
- `sync_binlog=1`: Enables synchronization of the binary log to disk before transactions are committed. This is the safest setting but can have a negative impact on performance due to the increased number of disk writes. In the event of a power failure or operating system crash, transactions that are missing from the binary log are only in a prepared state. This permits the automatic recovery routine to roll back the transactions, which guarantees that no transaction is lost from the binary log.
- `sync_binlog=N`, where *N* is a value other than 0 or 1: The binary log is synchronized to disk after *N* binary log commit groups have been collected. In the event of a power failure or operating system crash, it is possible that the server has committed transactions that have not been flushed to the binary log. This setting can have a negative impact on performance due to the increased number of disk writes. A higher value improves performance, but with an increased risk of data loss.

For the greatest possible durability and consistency in a replication setup that uses `InnoDB` with transactions, use these settings:

- `sync_binlog=1`.
- `innodb_flush_log_at_trx_commit=1`.

#### Caution

Many operating systems and some disk hardware fool the flush-to-disk operation. They may tell `mysqld` that the flush has taken place, even though it has not. In this case, the durability of transactions is not guaranteed even with the recommended settings, and in the worst case, a power outage can corrupt `InnoDB` data. Using a battery-backed disk cache in the SCSI disk controller or in the disk itself speeds up file flushes, and makes the operation safer. You can also try to disable the caching of disk writes in hardware caches.

### 19.1.6.5 Global Transaction ID System Variables

The MySQL Server system variables described in this section are used to monitor and control Global Transaction Identifiers (GTIDs). For additional information, see [Section 19.1.3, “Replication with Global Transaction Identifiers”](#).

- `binlog_gtid_simple_recovery`

Command-Line Format	<code>--binlog-gtid-simple-recovery[={OFF ON}]</code>
System Variable	<code>binlog_gtid_simple_recovery</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	ON

This variable controls how binary log files are iterated during the search for GTIDs when MySQL starts or restarts.

When `binlog_gtid_simple_recovery=TRUE` (the default), the values of `gtid_executed` and `gtid_purged` are computed at startup based on the values of `Previous_gtids_log_event` in the most recent and oldest binary log files. For a description of the computation, see [The `gtid\_purged` System Variable](#). This setting accesses only two binary log files during server restart. If all binary logs on the server were generated using MySQL 5.7.8 or later, `binlog_gtid_simple_recovery=TRUE` can always safely be used.

If any binary logs from MySQL 5.7.7 or older are present on the server (for example, following an upgrade of an older server to MySQL 9.1), with `binlog_gtid_simple_recovery=TRUE`, `gtid_executed` and `gtid_purged` might be initialized incorrectly in the following two situations:

- The newest binary log was generated by MySQL 5.7.5 or earlier, and `gtid_mode` was `ON` for some binary logs but `OFF` for the newest binary log.
- A `SET @@GLOBAL.gtid_purged` statement was issued on MySQL 5.7.7 or earlier, and the binary log that was active at the time of the `SET @@GLOBAL.gtid_purged` statement has not yet been purged.

If an incorrect GTID set is computed in either situation, it remains incorrect even if the server is later restarted with `binlog_gtid_simple_recovery=FALSE`. If either of these situations apply or might apply on the server, set `binlog_gtid_simple_recovery=FALSE` before starting or restarting the server.

When `binlog_gtid_simple_recovery=FALSE` is set, the method of computing `gtid_executed` and `gtid_purged` as described in [The `gtid\_purged` System Variable](#) is changed to iterate the binary log files as follows:

- Instead of using the value of `Previous_gtids_log_event` and GTID log events from the newest binary log file, the computation for `gtid_executed` iterates from the newest binary log file, and uses the value of `Previous_gtids_log_event` and any GTID log events from the first binary log file where it finds a `Previous_gtids_log_event` value. If the server's most recent binary log files do not have GTID log events, for example if `gtid_mode=ON` was used but the server was later changed to `gtid_mode=OFF`, this process can take a long time.

- Instead of using the value of `Previous_gtid_log_event` from the oldest binary log file, the computation for `gtid_purged` iterates from the oldest binary log file, and uses the value of `Previous_gtid_log_event` from the first binary log file where it finds either a nonempty `Previous_gtid_log_event` value, or at least one GTID log event (indicating that the use of GTIDs starts at that point). If the server's older binary log files do not have GTID log events, for example if `gtid_mode=ON` was only set recently on the server, this process can take a long time.
- `enforce_gtid_consistency`

Command-Line Format	<code>--enforce-gtid-consistency[=value]</code>
System Variable	<code>enforce_gtid_consistency</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Enumeration
Default Value	<code>OFF</code>
Valid Values	<code>OFF</code> <code>ON</code> <code>WARN</code>

Depending on the value of this variable, the server enforces GTID consistency by allowing execution of only statements that can be safely logged using a GTID. You *must* set this variable to `ON` before enabling GTID based replication.

The values that `enforce_gtid_consistency` can be configured to are:

- `OFF`: all transactions are allowed to violate GTID consistency.
- `ON`: no transaction is allowed to violate GTID consistency.
- `WARN`: all transactions are allowed to violate GTID consistency, but a warning is generated in this case.

`--enforce-gtid-consistency` only takes effect if binary logging takes place for a statement. If binary logging is disabled on the server, or if statements are not written to the binary log because they are removed by a filter, GTID consistency is not checked or enforced for the statements that are not logged.

Only statements that can be logged using GTID safe statements can be logged when `enforce_gtid_consistency` is set to `ON`, so the operations listed here cannot be used with this option:

- `CREATE TEMPORARY TABLE` or `DROP TEMPORARY TABLE` statements inside transactions.
- Transactions or statements that update both transactional and nontransactional tables. There is an exception that nontransactional DML is allowed in the same transaction or in the same statement as transactional DML, if all *nontransactional* tables are temporary.

- `CREATE TABLE ... SELECT` statements are supported for storage engines that support atomic DDL.

For more information, see [Section 19.1.3.7, “Restrictions on Replication with GTIDs”](#).

Prior to MySQL 5.7 and in early releases in that release series, the boolean `enforce_gtid_consistency` defaulted to `OFF`. To maintain compatibility with these earlier releases, the enumeration defaults to `OFF`, and setting `--enforce-gtid-consistency` without a value is interpreted as setting the value to `ON`. The variable also has multiple textual aliases for the values: `0=OFF=FALSE`, `1=ON=TRUE`, `2=WARN`. This differs from other enumeration types but maintains compatibility with the boolean type used in previous releases. These changes impact on what is returned by the variable. Using `SELECT @@ENFORCE_GTID_CONSISTENCY`, `SHOW VARIABLES LIKE 'ENFORCE_GTID_CONSISTENCY'`, and `SELECT * FROM INFORMATION_SCHEMA.VARIABLES WHERE 'VARIABLE_NAME' = 'ENFORCE_GTID_CONSISTENCY'`, all return the textual form, not the numeric form. This is an incompatible change, since `@@ENFORCE_GTID_CONSISTENCY` returns the numeric form for booleans but returns the textual form for `SHOW` and the Information Schema.

- `gtid_executed`

System Variable	<code>gtid_executed</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	String
Unit	set of GTIDs

When used with global scope, this variable contains a representation of the set of all transactions executed on the server and GTIDs that have been set by a `SET gtid_purged` statement. This is the same as the value of the `Executed_Gtid_Set` column in the output of `SHOW BINARY LOG STATUS` and `SHOW REPLICA STATUS`. The value of this variable is a GTID set, see [GTID Sets](#) for more information.

When the server starts, `@@GLOBAL.gtid_executed` is initialized. See [binlog\\_gtid\\_simple\\_recovery](#) for more information on how binary logs are iterated to populate `gtid_executed`. GTIDs are then added to the set as transactions are executed, or if any `SET gtid_purged` statement is executed.

The set of transactions that can be found in the binary logs at any given time is equal to `GTID_SUBTRACT(@@GLOBAL.gtid_executed, @@GLOBAL.gtid_purged)`; that is, to all transactions in the binary log that have not yet been purged.

Issuing `RESET BINARY LOGS AND GTIDS` causes this variable to be reset to an empty string. GTIDs are not otherwise removed from this set other than when the set is cleared due to `RESET BINARY LOGS AND GTIDS`.

- `gtid_executed_compression_period`

Command-Line Format	<code>--gtid-executed-compression-period=#</code>
System Variable	<code>gtid_executed_compression_period</code>
Scope	Global
Dynamic	Yes

<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	4294967295

Compress the `mysql.gtid_executed` table each time this many transactions have been processed. When binary logging is enabled on the server, this compression method is not used, and instead the `mysql.gtid_executed` table is compressed on each binary log rotation. When binary logging is disabled on the server, the compression thread sleeps until the specified number of transactions have been executed, then wakes up to perform compression of the `mysql.gtid_executed` table. Setting the value of this system variable to 0 means that the thread never wakes up, so this explicit compression method is not used. Instead, compression occurs implicitly as required.

`InnoDB` transactions are written to the `mysql.gtid_executed` table by a separate process to non-`InnoDB` transactions. If the server has a mix of `InnoDB` transactions and non-`InnoDB` transactions, the compression controlled by this system variable interferes with the work of this process and can slow it significantly. For this reason, from that release it is recommended that you set `gtid_executed_compression_period` to 0.

All transactions (regardless of storage engine) are written to the `mysql.gtid_executed` table by the same process, and the `gtid_executed_compression_period` default value is 0.

See [mysql.gtid\\_executed Table Compression](#) for more information.

- `gtid_mode`

Command-Line Format	<code>--gtid-mode=MODE</code>
System Variable	<code>gtid_mode</code>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Enumeration
Default Value	OFF
Valid Values	OFF OFF_PERMISSIVE ON_PERMISSIVE ON

Controls whether GTID based logging is enabled and what type of transactions the logs can contain. You must have privileges sufficient to set global system variables. See [Section 7.1.9.1, “System Variable](#)

**Privileges**. `enforce_gtid_consistency` must be set to `ON` before you can set `gtid_mode=ON`. Before modifying this variable, see [Section 19.1.4, “Changing GTID Mode on Online Servers”](#).

Logged transactions can be either anonymous or use GTIDs. Anonymous transactions rely on binary log file and position to identify specific transactions. GTID transactions have a unique identifier that is used to refer to transactions. The different modes are:

- `OFF`: Both new and replicated transactions must be anonymous.
- `OFF_PERMISSIVE`: New transactions are anonymous. Replicated transactions can be either anonymous or GTID transactions.
- `ON_PERMISSIVE`: New transactions are GTID transactions. Replicated transactions can be either anonymous or GTID transactions.
- `ON`: Both new and replicated transactions must be GTID transactions.

Changes from one value to another can only be one step at a time. For example, if `gtid_mode` is currently set to `OFF_PERMISSIVE`, it is possible to change to `OFF` or `ON_PERMISSIVE` but not to `ON`.

The values of `gtid_purged` and `gtid_executed` are persistent regardless of the value of `gtid_mode`. Therefore even after changing the value of `gtid_mode`, these variables contain the correct values.

- `gtid_next`

System Variable	<code>gtid_next</code>
Scope	Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Enumeration
Default Value	<code>AUTOMATIC</code>
Valid Values	<code>AUTOMATIC</code> <code>AUTOMATIC : &lt;TAG&gt;</code> <code>ANONYMOUS</code> <code>&lt;UUID&gt; : &lt;NUMBER&gt;</code> <code>&lt;UUID&gt; : &lt;TAG&gt; : &lt;NUMBER&gt;</code>

This variable is used to specify whether and how to obtain the next GTID (see [Section 19.1.3, “Replication with Global Transaction Identifiers”](#)).

Setting the session value of this system variable is a restricted operation. The session user must have either the `REPLICATION_APPLIER` privilege (see [Section 19.3.3, “Replication Privilege Checks”](#)), or privileges sufficient to set restricted session variables (see [Section 7.1.9.1, “System Variable Privileges”](#)).

`gtid_next` can take any of the following values:

- `AUTOMATIC`: Use the next automatically-generated global transaction ID.

- **AUTOMATIC:TAG**: Use the next automatically-generated global transaction ID, with the addition of a user-specified tag, in **UUID:TAG:NUMBER** format.

The tag must match the regular expression `[a-z_][a-z0-9_]{0,7}`; in other words, it must conform to the following rules:

- The tag must consist of 1-8 characters (inclusive).
- The first character can be any letter `a` through `z`, or an underscore (`_`).
- Each of the remaining characters can be any of the letters `a` through `z`, the digits `0` through `9`, or an underscore (`_`).

Setting `gtid_next` on the replication source to **AUTOMATIC:TAG** or **UUID:TAG:NUMBER** requires the **TRANSACTION\_GTID\_TAG** privilege plus at least one of the privileges **SYSTEM\_VARIABLES\_ADMIN**, **SESSION\_VARIABLES\_ADMIN**, or **REPLICATION\_APPLIER**. For the **REPLICATION\_CHECKS\_APPLIER** this privilege is also required to set `gtid_next` to either of these values, in addition to the **REPLICATION\_APPLIER** privilege; these privileges are checked when starting the replication applier thread.

- **ANONYMOUS**: Transactions do not have global identifiers, and are identified by file and position only.
- A global transaction ID in either of the formats **UUID:NUMBER** or **UUID:TAG:NUMBER**.

Exactly which of the options just listed are valid depends on the setting of `gtid_mode`; see [Section 19.1.4.1, “Replication Mode Concepts”](#) for more information. Setting this variable has no effect if `gtid_mode` is **OFF**.

After this variable has been set to **UUID:NUMBER** or **UUID:TAG:NUMBER**, and a transaction has been committed or rolled back, an explicit `SET gtid_next` statement must again be issued before any other statement.

**DROP TABLE** or **DROP TEMPORARY TABLE** fails with an explicit error when used on a combination of nontemporary tables with temporary tables, or of temporary tables using transactional storage engines with temporary tables using nontransactional storage engines.

For more information, see [The gtid\\_next System Variable](#), as well as [Section 19.1.4, “Changing GTID Mode on Online Servers”](#).

- `gtid_owned`

System Variable	<code>gtid_owned</code>
Scope	Global, Session
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	String
Unit	set of GTIDs

This read-only variable is primarily for internal use. Its contents depend on its scope.

- When used with global scope, `gtid_owned` holds a list of all the GTIDs that are currently in use on the server, with the IDs of the threads that own them. This variable is mainly useful for a multi-threaded replica to check whether a transaction is already being applied on another thread. An

applier thread takes ownership of a transaction's GTID all the time it is processing the transaction, so `@@global.gtid_owned` shows the GTID and owner for the duration of processing. When a transaction has been committed (or rolled back), the applier thread releases ownership of the GTID.

- When used with session scope, `gtid_owned` holds a single GTID that is currently in use by and owned by this session. This variable is mainly useful for testing and debugging the use of GTIDs when the client has explicitly assigned a GTID for the transaction by setting `gtid_next`. In this case, `@@session.gtid_owned` displays the GTID all the time the client is processing the transaction, until the transaction has been committed (or rolled back). When the client has finished processing the transaction, the variable is cleared. If `gtid_next=AUTOMATIC` is used for the session, `gtid_owned` is populated only briefly during the execution of the commit statement for the transaction, so it cannot be observed from the session concerned, although it is listed if `@@global.gtid_owned` is read at the right point. If you have a requirement to track the GTIDs that are handled by a client in a session, you can enable the session state tracker controlled by the `session_track_gtids` system variable.
- `gtid_purged`

System Variable	<code>gtid_purged</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String
Unit	set of GTIDs

The global value of the `gtid_purged` system variable (`@@GLOBAL.gtid_purged`) is a GTID set consisting of the GTIDs of all the transactions that have been committed on the server, but do not exist in any binary log file on the server. `gtid_purged` is a subset of `gtid_executed`. The following categories of GTIDs are in `gtid_purged`:

- GTIDs of replicated transactions that were committed with binary logging disabled on the replica.
- GTIDs of transactions that were written to a binary log file that has now been purged.
- GTIDs that were added explicitly to the set by the statement `SET @@GLOBAL.gtid_purged`.

When the server starts, the global value of `gtid_purged` is initialized to a set of GTIDs. For information on how this GTID set is computed, see [The `gtid\_purged` System Variable](#). If binary logs from MySQL 5.7.7 or older are present on the server, you might need to set `binlog_gtid_simple_recovery=FALSE` in the server's configuration file to produce the correct computation. See the description for `binlog_gtid_simple_recovery` for details of the situations in which this setting is needed.

You must have the `TRANSACTION_GTID_TAG` to set `gtid_purged`.

Issuing `RESET BINARY LOGS AND GTIDS` causes the value of `gtid_purged` to be reset to an empty string.

You can set the value of `gtid_purged` in order to record on the server that the transactions in a certain GTID set have been applied, although they do not exist in any binary log on the server. An example use

case for this action is when you are restoring a backup of one or more databases on a server, but you do not have the relevant binary logs containing the transactions on the server.

### Important

GTIDs are only available on a server instance up to the number of non-negative values for a signed 64-bit integer ( $2^{63} - 1$ ). If you set the value of `gtid_purged` to a number that approaches this limit, subsequent commits can cause the server to run out of GTIDs and take the action specified by `binlog_error_action`. A warning message is issued when the server instance is approaching the limit.

There are two ways to set the value of `gtid_purged`. You can either replace the value of `gtid_purged` with your specified GTID set, or you can append your specified GTID set to the GTID set that is already held by `gtid_purged`. If the server has no existing GTIDs, for example an empty server that you are provisioning with a backup of an existing database, both methods have the same result. If you are restoring a backup that overlaps the transactions that are already on the server, for example replacing a corrupted table with a partial dump from the source made using `mysqldump` (which includes the GTIDs of all the transactions on the server, even though the dump is partial), use the first method of replacing the value of `gtid_purged`. If you are restoring a backup that is disjoint from the transactions that are already on the server, for example provisioning a multi-source replica using dumps from two different servers, use the second method of adding to the value of `gtid_purged`.

- To replace the value of `gtid_purged` with your specified GTID set, use the following statement:

```
SET @@GLOBAL.gtid_purged = 'gtid_set'
```

`gtid_set` must be a superset of the current value of `gtid_purged`, and must not intersect with `gtid_subtract(gtid_executed, gtid_purged)`. In other words, the new GTID set **must** include any GTIDs that were already in `gtid_purged`, and **must not** include any GTIDs in `gtid_executed` that have not yet been purged. `gtid_set` also cannot include any GTIDs that are in `@@global.gtid_owned`, that is, the GTIDs for transactions that are currently being processed on the server.

The result is that the global value of `gtid_purged` is set equal to `gtid_set`, and the value of `gtid_executed` becomes the union of `gtid_set` and the previous value of `gtid_executed`.

- To append your specified GTID set to `gtid_purged`, use the following statement with a plus sign (+) before the GTID set:

```
SET @@GLOBAL.gtid_purged = '+gtid_set'
```

`gtid_set` **must not** intersect with the current value of `gtid_executed`. In other words, the new GTID set must not include any GTIDs in `gtid_executed`, including transactions that are already also in `gtid_purged`. `gtid_set` also cannot include any GTIDs that are in `@@global.gtid_owned`, that is, the GTIDs for transactions that are currently being processed on the server.

The result is that `gtid_set` is added to both `gtid_executed` and `gtid_purged`.

### Note

If any binary logs from MySQL 5.7.7 or older are present on the server (for example, following an upgrade of an older server to MySQL 9.1), after issuing a `SET @@GLOBAL.gtid_purged` statement, you might need to set `binlog_gtid_simple_recovery=FALSE` in the server's configuration file before restarting the server, otherwise `gtid_purged` can be computed incorrectly. See

the description for [binlog\\_gtid\\_simple\\_recovery](#) for details of the situations in which this setting is needed.

## 19.1.7 Common Replication Administration Tasks

Once replication has been started it executes without requiring much regular administration. This section describes how to check the status of replication, how to pause a replica, and how to skip a failed transaction on a replica.

### Tip

To deploy multiple instances of MySQL, you can use [InnoDB Cluster](#) which enables you to easily administer a group of MySQL server instances in [MySQL Shell](#). InnoDB Cluster wraps MySQL Group Replication in a programmatic environment that enables you easily deploy a cluster of MySQL instances to achieve high availability. In addition, InnoDB Cluster interfaces seamlessly with [MySQL Router](#), which enables your applications to connect to the cluster without writing your own failover process. For similar use cases that do not require high availability, however, you can use [InnoDB ReplicaSet](#). Installation instructions for MySQL Shell can be found [here](#).

### 19.1.7.1 Checking Replication Status

The most common task when managing a replication process is to ensure that replication is taking place and that there have been no errors between the replica and the source.

The `SHOW REPLICATION STATUS` statement, which you must execute on each replica, provides information about the configuration and status of the connection between the replica server and the source server. The MySQL Performance Schema contains replication tables that provide this information in a more accessible form. See [Section 29.12.11, “Performance Schema Replication Tables”](#).

The replication heartbeat information shown in the Performance Schema replication tables lets you check that the replication connection is active even if the source has not sent events to the replica recently. The source sends a heartbeat signal to a replica if there are no updates to, and no unsent events in, the binary log for a longer period than the heartbeat interval. The `SOURCE_HEARTBEAT_PERIOD` setting on the source (set by `CHANGE REPLICATION SOURCE TO`) specifies the frequency of the heartbeat, which defaults to half of the connection timeout interval for the replica (specified by the system variable `replica_net_timeout`). The `replication_connection_status` Performance Schema table shows when the most recent heartbeat signal was received by a replica, and how many heartbeat signals it has received.

You can use `SHOW REPLICATION STATUS` to check on the status of an individual replica; this statement provides the information shown here:

```
mysql> SHOW REPLICATION STATUS\G
***** 1. row *****
 Replica_IO_State: Waiting for source to send event

```

The key fields from the status report to examine are:

- **Replica\_IO\_State:** The current status of the replica. See [Section 10.14.5, “Replication I/O \(Receiver\) Thread States”](#), and [Section 10.14.6, “Replication SQL Thread States”](#), for more information.
- **Replica\_IO\_Running:** Whether the I/O (receiver) thread for reading the source's binary log is running. Normally, you want this to be **Yes** unless you have not yet started replication or have explicitly stopped it with **STOP REPLICATION**.
- **Replica\_SQL\_Running:** Whether the SQL thread for executing events in the relay log is running. As with the I/O thread, this should normally be **Yes**.
- **Last\_IO\_Error, Last\_SQL\_Error:** The last errors registered by the I/O (receiver) and SQL (applier) threads when processing the relay log. Ideally these should be blank, indicating no errors.

- `Seconds_Behind_Source`: The number of seconds that the replication SQL (applier) thread is behind processing the source binary log. A high number (or an increasing one) can indicate that the replica is unable to handle events from the source in a timely fashion.

A value of 0 for `Seconds_Behind_Source` can usually be interpreted as meaning that the replica has caught up with the source, but there are some cases where this is not strictly true. For example, this can occur if the network connection between source and replica is broken but the replication I/O (receiver) thread has not yet noticed this; that is, the time period set by `replica_net_timeout` has not yet elapsed.

It is also possible that transient values for `Seconds_Behind_Source` may not reflect the situation accurately. When the replication SQL (applier) thread has caught up on I/O, `Seconds_Behind_Source` displays 0; but when the replication I/O (receiver) thread is still queuing up a new event, `Seconds_Behind_Source` may show a large value until the replication applier thread finishes executing the new event. This is especially likely when the events have old timestamps; in such cases, if you execute `SHOW REPLICA STATUS` several times in a relatively short period, you may see this value change back and forth repeatedly between 0 and a relatively large value.

Several pairs of fields provide information about the progress of the replica in reading events from the source binary log and processing them in the relay log:

- (`Master_Log_File`, `Read_Master_Log_Pos`): Coordinates in the source binary log indicating how far the replication I/O (receiver) thread has read events from that log.
- (`Relay_Master_Log_File`, `Exec_Master_Log_Pos`): Coordinates in the source binary log indicating how far the replication SQL (applier) thread has executed events received from that log.
- (`Relay_Log_File`, `Relay_Log_Pos`): Coordinates in the replica relay log indicating how far the replication SQL (applier) thread has executed the relay log. These correspond to the preceding coordinates, but are expressed in replica relay log coordinates rather than source binary log coordinates.

On the source, you can check the status of connected replicas using `SHOW PROCESSLIST` to examine the list of running processes. Replica connections have `Binlog Dump` in the `Command` field:

```
mysql> SHOW PROCESSLIST \G;
***** 4. row *****
 Id: 10
 User: root
 Host: replical:58371
 db: NULL
Command: Binlog Dump
 Time: 777
 State: Has sent all binlog to slave; waiting for binlog to be updated
 Info: NULL
```

Because it is the replica that drives the replication process, very little information is available in this report.

For replicas that were started with the `--report-host` option and are connected to the source, the `SHOW REPLICAS` statement on the source shows basic information about the replicas. The output includes the ID of the replica server, the value of the `--report-host` option, the connecting port, and source ID:

```
mysql> SHOW REPLICAS;
+-----+-----+-----+-----+-----+
| Server_id | Host | Port | Rpl_recovery_rank | Source_id |
+-----+-----+-----+-----+-----+
| 10 | replical | 3306 | 0 | 1 |
+-----+-----+-----+-----+-----+
1 row in set (0.00 sec)
```

### 19.1.7.2 Pausing Replication on the Replica

You can stop and start replication on the replica using the `STOP REPLICATION` and `START REPLICATION` statements.

To stop processing of the binary log from the source, use `STOP REPLICATION`:

```
mysql> STOP REPLICATION;
```

When replication is stopped, the replication I/O (receiver) thread stops reading events from the source binary log and writing them to the relay log, and the SQL thread stops reading events from the relay log and executing them. You can pause the I/O (receiver) or SQL (applier) thread individually by specifying the thread type:

```
mysql> STOP REPLICATION IO_THREAD;
mysql> STOP REPLICATION SQL_THREAD;
```

To start execution again, use the `START REPLICATION` statement:

```
mysql> START REPLICATION;
```

To start a particular thread, specify the thread type:

```
mysql> START REPLICATION IO_THREAD;
mysql> START REPLICATION SQL_THREAD;
```

For a replica that performs updates only by processing events from the source, stopping only the SQL thread can be useful if you want to perform a backup or other task. The I/O (receiver) thread continues to read events from the source but they are not executed. This makes it easier for the replica to catch up when you restart the SQL (applier) thread.

Stopping only the receiver thread enables the events in the relay log to be executed by the applier thread up to the point where the relay log ends. This can be useful when you want to pause execution to catch up with events already received from the source, when you want to perform administration on the replica but also ensure that it has processed all updates to a specific point. This method can also be used to pause event receipt on the replica while you conduct administration on the source. Stopping the receiver thread but permitting the applier thread to run helps ensure that there is not a massive backlog of events to be executed when replication is started again.

### 19.1.7.3 Skipping Transactions

If replication stops due to an issue with an event in a replicated transaction, you can resume replication by skipping the failed transaction on the replica. Before skipping a transaction, ensure that the replication I/O (receiver) thread is stopped as well as the SQL (applier) thread.

First you need to identify the replicated event that caused the error. Details of the error and the last successfully applied transaction are recorded in the Performance Schema table `replication_applier_status_by_worker`. You can use `mysqlbinlog` to retrieve and display the events that were logged around the time of the error. For instructions to do this, see [Section 9.5, “Point-in-Time \(Incremental\) Recovery”](#). Alternatively, you can issue `SHOW RELAYLOG EVENTS` on the replica or `SHOW BINLOG EVENTS` on the source.

Before skipping the transaction and restarting the replica, check these points:

- Is the transaction that stopped replication from an unknown or untrusted source? If so, investigate the cause in case there are any security considerations that indicate the replica should not be restarted.
- Does the transaction that stopped replication need to be applied on the replica? If so, either make the appropriate corrections and reapply the transaction, or manually reconcile the data on the replica.

- Did the transaction that stopped replication need to be applied on the source? If not, undo the transaction manually on the server where it originally took place.

To skip the transaction, choose one of the following methods as appropriate:

- When GTIDs are in use (`gtid_mode` is `ON`), see [Skipping Transactions With GTIDs](#).
- When GTIDs are not in use or are being phased in (`gtid_mode` is `OFF`, `OFF_PERMISSIVE`, or `ON_PERMISSIVE`), see [Skipping Transactions Without GTIDs](#).
- If you have enabled GTID assignment on a replication channel using the `ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS` option of the `CHANGE REPLICATION SOURCE TO` statement, see [Skipping Transactions Without GTIDs](#). Using `ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS` on a replication channel is not the same as introducing GTID-based replication for the channel, and you cannot use the transaction skipping method for GTID-based replication with those channels.

To restart replication after skipping the transaction, issue `START REPLICATION`, with the `FOR CHANNEL` clause if the replica is a multi-source replica.

## Skipping Transactions With GTIDs

When GTIDs are in use (`gtid_mode` is `ON`), the GTID for a committed transaction is persisted on the replica even if the content of the transaction is filtered out. This feature prevents a replica from retrieving previously filtered transactions when it reconnects to the source using GTID auto-positioning. It can also be used to skip a transaction on the replica, by committing an empty transaction in place of the failing transaction.

This method of skipping transactions is not suitable when you have enabled GTID assignment on a replication channel using the `ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS` option of the `CHANGE REPLICATION SOURCE TO` statement.

If the failing transaction generated an error in a worker thread, you can obtain its GTID directly from the `APPLYING_TRANSACTION` field in the Performance Schema table `replication_applier_status_by_worker`. To see what the transaction is, issue `SHOW RELAYLOG EVENTS` on the replica or `SHOW BINLOG EVENTS` on the source, and search the output for a transaction preceded by that GTID.

When you have assessed the failing transaction for any other appropriate actions as described previously (such as security considerations), to skip it, commit an empty transaction on the replica that has the same GTID as the failing transaction. For example:

```
SET GTID_NEXT= 'aaa-bbb-ccc-ddd:N' ;
BEGIN;
COMMIT;
SET GTID_NEXT= 'AUTOMATIC' ;
```

The presence of this empty transaction on the replica means that when you issue a `START REPLICATION` statement to restart replication, the replica uses the auto-skip function to ignore the failing transaction, because it sees a transaction with that GTID has already been applied. If the replica is a multi-source replica, you do not need to specify the channel name when you commit the empty transaction, but you do need to specify the channel name when you issue `START REPLICATION`.

Note that if binary logging is in use on this replica, the empty transaction enters the replication stream if the replica becomes a source or primary in the future. If you need to avoid this possibility, consider flushing and purging the replica's binary logs, as in this example:

```
FLUSH LOGS;
PURGE BINARY LOGS TO 'binlog.000146';
```

The GTID of the empty transaction is persisted, but the transaction itself is removed by purging the binary log files.

## Skipping Transactions Without GTIDs

To skip failing transactions when GTIDs are not in use or are being phased in (`gtid_mode` is `OFF`, `OFF_PERMISSIVE`, or `ON_PERMISSIVE`), you can skip a specified number of events by issuing `SET GLOBAL sql_replica_skip_counter`. Alternatively, you can skip past an event or events by issuing a `CHANGE REPLICATION SOURCE TO` statement to move the source binary log position forward.

These methods are also suitable when you have enabled GTID assignment on a replication channel using the `ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS` option of the `CHANGE REPLICATION SOURCE TO` statement.

When you use these methods, it is important to understand that you are not necessarily skipping a complete transaction, as is always the case with the GTID-based method described previously. These non-GTID-based methods are not aware of transactions as such, but instead operate on events. The binary log is organized as a sequence of groups known as event groups, and each event group consists of a sequence of events.

- For transactional tables, an event group corresponds to a transaction.
- For nontransactional tables, an event group corresponds to a single SQL statement.

While it is possible for a single transaction to contain changes to both transactional and nontransactional tables, support for such transactions is deprecated and you should expect it to be removed in a future version of MySQL. See [Section 19.5.1.36, “Replication and Transactions”](#). For some of the reasons for this deprecation, see [Section 19.1.3.7, “Restrictions on Replication with GTIDs”](#).

When you use a `SET GLOBAL sql_replica_skip_counter` statement to skip events and the resulting position is in the middle of an event group, the replica continues to skip events until it reaches the end of the group. Execution then starts with the next event group. The `CHANGE REPLICATION SOURCE TO` statement does not have this function, so you must be careful to identify the correct location to restart replication at the beginning of an event group. However, using `CHANGE REPLICATION SOURCE TO` means you do not have to count the events that need to be skipped, as you do with `SET GLOBAL sql_replica_skip_counter`, and instead you can just specify the location to restart.

## Skipping Transactions With `SET GLOBAL sql_replica_skip_counter`

When you have assessed the failing transaction for any other appropriate actions as described previously (such as security considerations), count the number of events that you need to skip. One event normally corresponds to one SQL statement in the binary log, but note that statements that use `AUTO_INCREMENT` or `LAST_INSERT_ID()` count as two events in the binary log. When binary log transaction compression is in use, a compressed transaction payload (`Transaction_payload_event`) is counted as a single counter value, so all the events inside it are skipped as a unit.

If you want to skip the complete transaction, you can count the events to the end of the transaction, or you can just skip the relevant event group. Remember that with `SET GLOBAL sql_replica_skip_counter`, the replica continues to skip to the end of an event group. Make sure you do not skip too far forward and go into the next event group or transaction so that it is not also skipped.

Issue the `SET` statement as follows, where `N` is the number of events from the source to skip:

```
SET GLOBAL sql_replica_skip_counter = N
```

This statement cannot be issued if `gtid_mode=ON` is set, or if the replication I/O (receiver) and SQL (applier) threads are running.

The `SET GLOBAL sql_replica_skip_counter` statement has no immediate effect. When you issue the `START REPLICATION` statement for the next time following this `SET` statement, the new value for the system variable `sql_replica_skip_counter` is applied, and the events are skipped. That `START REPLICATION` statement also automatically sets the value of the system variable back to 0. If the replica is a multi-source replica, when you issue that `START REPLICATION` statement, the `FOR CHANNEL` clause is required. Make sure that you name the correct channel, otherwise events are skipped on the wrong channel.

### **Skipping Transactions With `CHANGE REPLICATION SOURCE TO`**

When you have assessed the failing transaction for any other appropriate actions as described previously (such as security considerations), identify the coordinates (file and position) in the source's binary log that represent a suitable position to restart replication. This can be the start of the event group following the event that caused the issue, or the start of the next transaction. The replication I/O (receiver) thread begins reading from the source at these coordinates the next time the thread starts, skipping the failing event. Make sure that you have identified the position accurately, because this statement does not take event groups into account.

Issue the `CHANGE REPLICATION SOURCE TO` statement as follows, where `source_log_name` is the binary log file that contains the restart position, and `source_log_pos` is the number representing the restart position as stated in the binary log file:

```
CHANGE REPLICATION SOURCE TO SOURCE_LOG_FILE='source_log_name', SOURCE_LOG_POS=source_log_pos;
```

If the replica is a multi-source replica, you must use the `FOR CHANNEL` clause to name the appropriate channel on the `CHANGE REPLICATION SOURCE TO` statement.

This statement cannot be issued if `SOURCE_AUTO_POSITION` is 1, or if the replication I/O (receiver) and SQL (applier) threads are running. If you need to use this method of skipping a transaction when `SOURCE_AUTO_POSITION=1`, you can change the setting to `SOURCE_AUTO_POSITION=0` while issuing the statement, then change it back again afterwards. For example:

```
CHANGE REPLICATION SOURCE TO SOURCE_AUTO_POSITION=0, SOURCE_LOG_FILE='binlog.000145', SOURCE_LOG_POS=235;
CHANGE REPLICATION SOURCE TO SOURCE_AUTO_POSITION=1;
```

## **19.2 Replication Implementation**

Replication is based on the source server keeping track of all changes to its databases (updates, deletes, and so on) in its binary log. The binary log serves as a written record of all events that modify database structure or content (data) from the moment the server was started. Typically, `SELECT` statements are not recorded because they modify neither database structure nor content.

Each replica that connects to the source requests a copy of the binary log. That is, it pulls the data from the source, rather than the source pushing the data to the replica. The replica also executes the events from the binary log that it receives. This has the effect of repeating the original changes just as they were made on the source. Tables are created or their structure modified, and data is inserted, deleted, and updated according to the changes that were originally made on the source.

Because each replica is independent, the replaying of the changes from the source's binary log occurs independently on each replica that is connected to the source. In addition, because each replica receives a copy of the binary log only by requesting it from the source, the replica is able to read and update the copy of the database at its own pace and can start and stop the replication process at will without affecting the ability to update to the latest database status on either the source or replica side.

For more information on the specifics of the replication implementation, see [Section 19.2.3, “Replication Threads”](#).

Source servers and replicas report their status in respect of the replication process regularly so that you can monitor them. See [Section 10.14, “Examining Server Thread \(Process\) Information”](#), for descriptions of all replicated-related states.

The source's binary log is written to a local relay log on the replica before it is processed. The replica also records information about the current position with the source's binary log and the local relay log. See [Section 19.2.4, “Relay Log and Replication Metadata Repositories”](#).

Database changes are filtered on the replica according to a set of rules that are applied according to the various configuration options and variables that control event evaluation. For details on how these rules are applied, see [Section 19.2.5, “How Servers Evaluate Replication Filtering Rules”](#).

## 19.2.1 Replication Formats

Replication works because events written to the binary log are read from the source and then processed on the replica. The events are recorded within the binary log in different formats according to the type of event. The different replication formats used correspond to the binary logging format used when the events were recorded in the source's binary log. The correlation between binary logging formats and the terms used during replication are:

- When using statement-based binary logging, the source writes SQL statements to the binary log. Replication of the source to the replica works by executing the SQL statements on the replica. This is called *statement-based replication* (which can be abbreviated as *SBR*), which corresponds to the MySQL statement-based binary logging format.
- When using row-based logging, the source writes *events* to the binary log that indicate how individual table rows are changed. Replication of the source to the replica works by copying the events representing the changes to the table rows to the replica. This is called *row-based replication* (which can be abbreviated as *RBR*).

Row-based logging is the default method.

- You can also configure MySQL to use a mix of both statement-based and row-based logging, depending on which is most appropriate for the change to be logged. This is called *mixed-format logging*. When using mixed-format logging, a statement-based log is used by default. Depending on certain statements, and also the storage engine being used, the log is automatically switched to row-based in particular cases. Replication using the mixed format is referred to as *mixed-based replication* or *mixed-format replication*. For more information, see [Section 7.4.4.3, “Mixed Binary Logging Format”](#).

**NDB Cluster.** The default binary logging format in MySQL NDB Cluster 9.1 is `ROW`. NDB Cluster Replication uses row-based replication; that the `NDB` storage engine is incompatible with statement-based replication. See [Section 25.7.2, “General Requirements for NDB Cluster Replication”](#), for more information.

When using `MIXED` format, the binary logging format is determined in part by the storage engine being used and the statement being executed. For more information on mixed-format logging and the rules governing the support of different logging formats, see [Section 7.4.4.3, “Mixed Binary Logging Format”](#).

The logging format in a running MySQL server is controlled by setting the `binlog_format` server system variable. This variable can be set with session or global scope. The rules governing when and how the new setting takes effect are the same as for other MySQL server system variables. Setting the variable for the current session lasts only until the end of that session, and the change is not visible to other sessions. Setting the variable globally takes effect for clients that connect after the change, but not for any current client sessions, including the session where the variable setting was changed. To make the global system variable setting permanent so that it applies across server restarts, you must set it in an option file. For more information, see [Section 15.7.6.1, “SET Syntax for Variable Assignment”](#).

There are conditions under which you cannot change the binary logging format at runtime or doing so causes replication to fail. See [Section 7.4.4.2, “Setting The Binary Log Format”](#).

Changing the global `binlog_format` value requires privileges sufficient to set global system variables. Changing the session `binlog_format` value requires privileges sufficient to set restricted session system variables. See [Section 7.1.9.1, “System Variable Privileges”](#).

**Note**

Changing the binary logging format (`binlog_format` system variable) was deprecated in MySQL 8.0; in a future version of MySQL, you can expect `binlog_format` to be removed altogether, and the row-based format to become the only logging format used by MySQL.

The statement-based and row-based replication formats have different issues and limitations. For a comparison of their relative advantages and disadvantages, see [Section 19.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”](#).

With statement-based replication, you may encounter issues with replicating stored routines or triggers. You can avoid these issues by using row-based replication instead. For more information, see [Section 27.8, “Stored Program Binary Logging”](#).

### 19.2.1.1 Advantages and Disadvantages of Statement-Based and Row-Based Replication

Each binary logging format has advantages and disadvantages. For most users, the mixed replication format should provide the best combination of data integrity and performance. If, however, you want to take advantage of the features specific to the statement-based or row-based replication format when performing certain tasks, you can use the information in this section, which provides a summary of their relative advantages and disadvantages, to determine which is best for your needs.

- [Advantages of statement-based replication](#)
- [Disadvantages of statement-based replication](#)
- [Advantages of row-based replication](#)
- [Disadvantages of row-based replication](#)

#### Advantages of statement-based replication

- Proven technology.
- Less data written to log files. When updates or deletes affect many rows, this results in *much* less storage space required for log files. This also means that taking and restoring from backups can be accomplished more quickly.
- Log files contain all statements that made any changes, so they can be used to audit the database.

#### Disadvantages of statement-based replication

- **Statements that are unsafe for SBR.**  
Not all statements which modify data (such as `INSERT DELETE`, `UPDATE`, and `REPLACE` statements) can be replicated using statement-based replication. Any nondeterministic behavior is difficult to replicate when using statement-based replication. Examples of such Data Modification Language (DML) statements include the following:
  - A statement that depends on a loadable function or stored program that is nondeterministic, since the value returned by such a function or stored program or depends on factors other than the parameters supplied to it. (Row-based replication, however, simply replicates the value returned by the function or

stored program, so its effect on table rows and data is the same on both the source and replica.) See [Section 19.5.1.16, “Replication of Invoked Features”](#), for more information.

- `DELETE` and `UPDATE` statements that use a `LIMIT` clause without an `ORDER BY` are nondeterministic. See [Section 19.5.1.19, “Replication and LIMIT”](#).
- Locking read statements (`SELECT ... FOR UPDATE` and `SELECT ... FOR SHARE`) that use `NOWAIT` or `SKIP LOCKED` options. See [Locking Read Concurrency with NOWAIT and SKIP LOCKED](#).
- Deterministic loadable functions must be applied on the replicas.
- Statements using any of the following functions cannot be replicated properly using statement-based replication:
  - `LOAD_FILE()`
  - `UUID()`, `UUID_SHORT()`
  - `USER()`
  - `FOUND_ROWS()`
  - `SYSDATE()` (unless both the source and the replica are started with the `--sysdate-is-now` option)
  - `GET_LOCK()`
  - `IS_FREE_LOCK()`
  - `IS_USED_LOCK()`
  - `RAND()`
  - `RELEASE_LOCK()`
  - `SOURCE_POS_WAIT()`
  - `SLEEP()`
  - `VERSION()`

However, all other functions are replicated correctly using statement-based replication, including `NOW()` and so forth.

For more information, see [Section 19.5.1.14, “Replication and System Functions”](#).

Statements that cannot be replicated correctly using statement-based replication are logged with a warning like the one shown here:

```
[Warning] Statement is not safe to log in statement format.
```

A similar warning is also issued to the client in such cases. The client can display it using `SHOW WARNINGS`.

- `INSERT ... SELECT` requires a greater number of row-level locks than with row-based replication.
- `UPDATE` statements that require a table scan (because no index is used in the `WHERE` clause) must lock a greater number of rows than with row-based replication.

- For **InnoDB**: An **INSERT** statement that uses **AUTO\_INCREMENT** blocks other nonconflicting **INSERT** statements.
- For complex statements, the statement must be evaluated and executed on the replica before the rows are updated or inserted. With row-based replication, the replica only has to modify the affected rows, not execute the full statement.
- If there is an error in evaluation on the replica, particularly when executing complex statements, statement-based replication may slowly increase the margin of error across the affected rows over time. See [Section 19.5.1.30, “Replica Errors During Replication”](#).
- Stored functions execute with the same **NOW()** value as the calling statement. However, this is not true of stored procedures.
- Deterministic loadable functions must be applied on the replicas.
- Table definitions must be (nearly) identical on source and replica. See [Section 19.5.1.9, “Replication with Differing Table Definitions on Source and Replica”](#), for more information.
- DML operations that read data from MySQL grant tables (through a join list or subquery) but do not modify them are performed as non-locking reads on the MySQL grant tables and are therefore not safe for statement-based replication. For more information, see [Grant Table Concurrency](#).

### Advantages of row-based replication

- All changes can be replicated. This is the safest form of replication.

#### Note

Statements that update the information in the **mysql** system schema, such as **GRANT**, **REVOKE** and the manipulation of triggers, stored routines (including stored procedures), and views, are all replicated to replicas using statement-based replication.

For statements such as **CREATE TABLE ... SELECT**, a **CREATE** statement is generated from the table definition and replicated using statement-based format, while the row insertions are replicated using row-based format.

- Fewer row locks are required on the source, which thus achieves higher concurrency, for the following types of statements:
  - **INSERT ... SELECT**
  - **INSERT** statements with **AUTO\_INCREMENT**
  - **UPDATE** or **DELETE** statements with **WHERE** clauses that do not use keys or do not change most of the examined rows.
- Fewer row locks are required on the replica for any **INSERT**, **UPDATE**, or **DELETE** statement.

### Disadvantages of row-based replication

- RBR can generate more data that must be logged. To replicate a DML statement (such as an **UPDATE** or **DELETE** statement), statement-based replication writes only the statement to the binary log. By contrast, row-based replication writes each changed row to the binary log. If the statement changes many rows, row-based replication may write significantly more data to the binary log; this is true even for statements that are rolled back. This also means that making and restoring a backup can require more time. In

addition, the binary log is locked for a longer time to write the data, which may cause concurrency problems. Use `binlog_row_image=minimal` to reduce the disadvantage considerably.

- Deterministic loadable functions that generate large `BLOB` values take longer to replicate with row-based replication than with statement-based replication. This is because the `BLOB` column value is logged, rather than the statement generating the data.
- You cannot see on the replica what statements were received from the source and executed. However, you can see what data was changed using `mysqlbinlog` with the options `--base64-output=DECODE-ROWS` and `--verbose`.

Alternatively, use the `binlog_rows_query_log_events` variable, which if enabled adds a `Rows_query` event with the statement to `mysqlbinlog` output when the `-vv` option is used.

- For tables using the `MyISAM` storage engine, a stronger lock is required on the replica for `INSERT` statements when applying them as row-based events to the binary log than when applying them as statements. This means that concurrent inserts on `MyISAM` tables are not supported when using row-based replication.

### 19.2.1.2 Usage of Row-Based Logging and Replication

MySQL uses statement-based logging (SBL), row-based logging (RBL) or mixed-format logging. The type of binary log used impacts the size and efficiency of logging. Therefore the choice between row-based replication (RBR) or statement-based replication (SBR) depends on your application and environment. This section describes known issues when using a row-based format log, and describes some best practices using it in replication.

For additional information, see [Section 19.2.1, “Replication Formats”](#), and [Section 19.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”](#).

For information about issues specific to NDB Cluster Replication (which depends on row-based replication), see [Section 25.7.3, “Known Issues in NDB Cluster Replication”](#).

- **Row-based logging of temporary tables.** As noted in [Section 19.5.1.32, “Replication and Temporary Tables”](#), temporary tables are not replicated when using row-based or mixed format. For more information, see [Section 19.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”](#).

Temporary tables are not replicated when using row-based or mixed format because there is no need. In addition, because temporary tables can be read only from the thread which created them, there is seldom if ever any benefit obtained from replicating them, even when using statement-based format.

You can switch from statement-based to row-based binary logging format at runtime even when temporary tables have been created, but you cannot switch from row-based or mixed format for binary logging to statement-based format at runtime, due to any `CREATE TEMPORARY TABLE` statements having been omitted from the binary log in the previous mode.

The MySQL server tracks the logging mode that was in effect when each temporary table was created. When a given client session ends, the server logs a `DROP TEMPORARY TABLE IF EXISTS` statement for each temporary table that still exists and was created when statement-based binary logging was in use. If row-based or mixed format binary logging was in use when the table was created, the `DROP TEMPORARY TABLE IF EXISTS` statement is not logged.

Nontransactional DML statements involving temporary tables are allowed when using `binlog_format=ROW`, as long as any nontransactional tables affected by the statements are temporary tables.

- **RBL and synchronization of nontransactional tables.** When many rows are affected, the set of changes is split into several events; when the statement commits, all of these events are written to the binary log. When executing on the replica, a table lock is taken on all tables involved, and then the rows are applied in batch mode. Depending on the engine used for the replica's copy of the table, this may or may not be effective.
- **Latency and binary log size.** RBL writes changes for each row to the binary log and so its size can increase quite rapidly. This can significantly increase the time required to make changes on the replica that match those on the source. You should be aware of the potential for this delay in your applications.
- **Reading the binary log.** `mysqlbinlog` displays row-based events in the binary log using the `BINLOG` statement. This statement displays an event as a base 64-encoded string, the meaning of which is not evident. When invoked with the `--base64-output=DECODE-ROWS` and `--verbose` options, `mysqlbinlog` formats the contents of the binary log to be human readable. When binary log events were written in row-based format and you want to read or recover from a replication or database failure you can use this command to read contents of the binary log. For more information, see [Section 6.6.9.2, “mysqlbinlog Row Event Display”](#).
- **Binary log execution errors and replica execution mode.** Using `replica_exec_mode=IDEMPOTENT` is generally only useful with MySQL NDB Cluster replication, for which `IDEMPOTENT` is the default value. (See [Section 25.7.10, “NDB Cluster Replication: Bidirectional and Circular Replication”](#)). When `replica_exec_mode` is `IDEMPOTENT`, a failure to apply changes from RBL because the original row cannot be found does not trigger an error or cause replication to fail. This means that it is possible that updates are not applied on the replica, so that the source and replica are no longer synchronized. Latency issues and use of nontransactional tables with RBL when `replica_exec_mode` is `IDEMPOTENT` can cause the source and replica to diverge even further. For more information about `replica_exec_mode`, see [Section 7.1.8, “Server System Variables”](#).

For other scenarios, setting `replica_exec_mode` to `STRICT` is normally sufficient; this is the default value for storage engines other than `NDB`.

- **Filtering based on server ID not supported.** You can filter based on server ID using the `IGNORE_SERVER_IDS` option for `CHANGE REPLICATION SOURCE TO`. This option works with both the statement-based and row-based logging formats, but cannot be used when `gtid_mode=ON`. Another method to filter out changes on some replicas is to use a `WHERE` clause that includes the relation `@@server_id <> id_value` clause with `UPDATE` and `DELETE` statements. For example, `WHERE @@server_id <> 1`. However, this does not work correctly with row-based logging. To use the `server_id` system variable for statement filtering, use statement-based logging.
- **RBL, nontransactional tables, and stopped replicas.** When using row-based logging, if the replica server is stopped while a replica thread is updating a nontransactional table, the replica database can reach an inconsistent state. For this reason, it is recommended that you use a transactional storage engine such as `InnoDB` for all tables replicated using the row-based format. Use of `STOP REPLICATION` or `STOP REPLICATION SQL_THREAD` prior to shutting down the replica MySQL server helps prevent issues from occurring, and is always recommended regardless of the logging format or storage engine you use.

### 19.2.1.3 Determination of Safe and Unsafe Statements in Binary Logging

The “safeness” of a statement in MySQL replication refers to whether the statement and its effects can be replicated correctly using statement-based format. If this is true of the statement, we refer to the statement as *safe*; otherwise, we refer to it as *unsafe*.

In general, a statement is safe if it deterministic, and unsafe if it is not. However, certain nondeterministic functions are *not* considered unsafe (see [Nondeterministic functions not considered unsafe](#), later in this section). In addition, statements using results from floating-point math functions—which are hardware-

dependent—are always considered unsafe (see [Section 19.5.1.12, “Replication and Floating-Point Values”](#)).

**Handling of safe and unsafe statements.** A statement is treated differently depending on whether the statement is considered safe, and with respect to the binary logging format (that is, the current value of `binlog_format`).

- When using row-based logging, no distinction is made in the treatment of safe and unsafe statements.
- When using mixed-format logging, statements flagged as unsafe are logged using the row-based format; statements regarded as safe are logged using the statement-based format.
- When using statement-based logging, statements flagged as being unsafe generate a warning to this effect. Safe statements are logged normally.

Each statement flagged as unsafe generates a warning. If a large number of such statements were executed on the source, this could lead to excessively large error log files. To prevent this, MySQL has a warning suppression mechanism. Whenever the 50 most recent `ER_BINLOG_UNSAFE_STATEMENT` warnings have been generated more than 50 times in any 50-second period, warning suppression is enabled. When activated, this causes such warnings not to be written to the error log; instead, for each 50 warnings of this type, a note `The last warning was repeated N times in last S seconds` is written to the error log. This continues as long as the 50 most recent such warnings were issued in 50 seconds or less; once the rate has decreased below this threshold, the warnings are once again logged normally. Warning suppression has no effect on how the safety of statements for statement-based logging is determined, nor on how warnings are sent to the client. MySQL clients still receive one warning for each such statement.

For more information, see [Section 19.2.1, “Replication Formats”](#).

#### Statements considered unsafe.

Statements with the following characteristics are considered unsafe:

- **Statements containing system functions that may return a different value on the replica.** These functions include `FOUND_ROWS()`, `GET_LOCK()`, `IS_FREE_LOCK()`, `IS_USED_LOCK()`, `LOAD_FILE()`, `RAND()`, `RELEASE_LOCK()`, `ROW_COUNT()`, `SESSION_USER()`, `SLEEP()`, `SOURCE_POS_WAIT()`, `SYSDATE()`, `SYSTEM_USER()`, `USER()`, `UUID()`, and `UUID_SHORT()`.

**Nondeterministic functions not considered unsafe.** Although these functions are not deterministic, they are treated as safe for purposes of logging and replication: `CONNECTION_ID()`, `CURDATE()`, `CURRENT_DATE()`, `CURRENT_TIME()`, `CURRENT_TIMESTAMP()`, `CURTIME()`, `LAST_INSERT_ID()`, `LOCALTIME()`, `LOCALTIMESTAMP()`, `NOW()`, `UNIX_TIMESTAMP()`, `UTC_DATE()`, `UTC_TIME()`, and `UTC_TIMESTAMP()`.

For more information, see [Section 19.5.1.14, “Replication and System Functions”](#).

- **References to system variables.** Most system variables are not replicated correctly using the statement-based format. See [Section 19.5.1.40, “Replication and Variables”](#). For exceptions, see [Section 7.4.4.3, “Mixed Binary Logging Format”](#).
- **Loadable Functions.** Since we have no control over what a loadable function does, we must assume that it is executing unsafe statements.
- **Fulltext plugin.** This plugin may behave differently on different MySQL servers; therefore, statements depending on it could have different results. For this reason, all statements relying on the fulltext plugin are treated as unsafe in MySQL.
- **Trigger or stored program updates a table having an `AUTO_INCREMENT` column.** This is unsafe because the order in which the rows are updated may differ on the source and the replica.

In addition, an `INSERT` into a table that has a composite primary key containing an `AUTO_INCREMENT` column that is not the first column of this composite key is unsafe.

For more information, see [Section 19.5.1.1, “Replication and AUTO\\_INCREMENT”](#).

- **INSERT ... ON DUPLICATE KEY UPDATE statements on tables with multiple primary or unique keys.** When executed against a table that contains more than one primary or unique key, this statement is considered unsafe, being sensitive to the order in which the storage engine checks the keys, which is not deterministic, and on which the choice of rows updated by the MySQL Server depends.

An `INSERT ... ON DUPLICATE KEY UPDATE` statement against a table having more than one unique or primary key is marked as unsafe for statement-based replication. (Bug #11765650, Bug #58637)

- **Updates using LIMIT.** The order in which rows are retrieved is not specified, and is therefore considered unsafe. See [Section 19.5.1.19, “Replication and LIMIT”](#).
- **Accesses or references log tables.** The contents of the system log table may differ between source and replica.
- **Nontransactional operations after transactional operations.** Within a transaction, allowing any nontransactional reads or writes to execute after any transactional reads or writes is considered unsafe.

For more information, see [Section 19.5.1.36, “Replication and Transactions”](#).

- **Accesses or references self-logging tables.** All reads and writes to self-logging tables are considered unsafe. Within a transaction, any statement following a read or write to self-logging tables is also considered unsafe.
- **LOAD DATA statements.** `LOAD DATA` is treated as unsafe and when `binlog_format=MIXED` the statement is logged in row-based format. When `binlog_format=STATEMENT` `LOAD DATA` does not generate a warning, unlike other unsafe statements.
- **XA transactions.** If two XA transactions committed in parallel on the source are being prepared on the replica in the inverse order, locking dependencies can occur with statement-based replication that cannot be safely resolved, and it is possible for replication to fail with deadlock on the replica. When `binlog_format=STATEMENT` is set, DML statements inside XA transactions are flagged as being unsafe and generate a warning. When `binlog_format=MIXED` or `binlog_format=ROW` is set, DML statements inside XA transactions are logged using row-based replication, and the potential issue is not present.
- **DEFAULT clause that refers to a nondeterministic function.** If an expression default value refers to a nondeterministic function, any statement that causes the expression to be evaluated is unsafe for statement-based replication. This includes statements such as `INSERT`, `UPDATE`, and `ALTER TABLE`. Unlike most other unsafe statements, this category of statement cannot be replicated safely in row-based format. When `binlog_format` is set to `STATEMENT`, the statement is logged and executed but a warning message is written to the error log. When `binlog_format` is set to `MIXED` or `ROW`, the statement is not executed and an error message is written to the error log. For more information on the handling of explicit defaults, see [Explicit Default Handling](#).

For additional information, see [Section 19.5.1, “Replication Features and Issues”](#).

## 19.2.2 Replication Channels

In MySQL multi-source replication, a replica opens multiple replication channels, one for each source server. The replication channels represent the path of transactions flowing from a source to the replica. Each replication channel has its own receiver (I/O) thread, one or more applier (SQL) threads, and relay log. When transactions from a source are received by a channel's receiver thread, they are added to the channel's relay log file and passed through to the channel's applier threads. This enables each channel to function independently.

This section describes how channels can be used in a replication topology, and the impact they have on single-source replication. For instructions to configure sources and replicas for multi-source replication, to start, stop and reset multi-source replicas, and to monitor multi-source replication, see [Section 19.1.5, “MySQL Multi-Source Replication”](#).

The maximum number of channels that can be created on one replica server in a multi-source replication topology is 256. Each replication channel must have a unique (nonempty) name, as explained in [Section 19.2.2.4, “Replication Channel Naming Conventions”](#). The error codes and messages that are issued when multi-source replication is enabled specify the channel that generated the error.

**Note**

Each channel on a multi-source replica must replicate from a different source. You cannot set up multiple replication channels from a single replica to a single source. This is because the server IDs of replicas must be unique in a replication topology. The source distinguishes replicas only by their server IDs, not by the names of the replication channels, so it cannot recognize different replication channels from the same replica.

A multi-source replica can also be set up as a multi-threaded replica, by setting the system variable `replica_parallel_workers` to a value greater than 0. When you do this on a multi-source replica, each channel on the replica has the specified number of applier threads, plus a coordinator thread to manage them. You cannot configure the number of applier threads for individual channels.

Multi-source replicas can be configured with replication filters on specific replication channels. Channel specific replication filters can be used when the same database or table is present on multiple sources, and you only need the replica to replicate it from one source. For GTID-based replication, if the same transaction might arrive from multiple sources (such as in a diamond topology), you must ensure the filtering setup is the same on all channels. For more information, see [Section 19.2.5.4, “Replication Channel Based Filters”](#).

To provide compatibility with previous versions, the MySQL server automatically creates on startup a default channel whose name is the empty string ( `" "` ). This channel is always present; it cannot be created or destroyed by the user. If no other channels (having nonempty names) have been created, replication statements act on the default channel only, so that all replication statements from older replicas function as expected (see [Section 19.2.2.2, “Compatibility with Previous Replication Statements”](#)). Statements applying to replication channels as described in this section can be used only when there is at least one named channel.

### 19.2.2.1 Commands for Operations on a Single Channel

To enable MySQL replication operations to act on individual replication channels, use the `FOR CHANNEL channel` clause with the following replication statements:

- `CHANGE REPLICATION SOURCE TO`
- `START REPLICATION`
- `STOP REPLICATION`

- `SHOW RELAYLOG EVENTS`
- `FLUSH RELAY LOGS`
- `SHOW REPLICA STATUS`
- `RESET REPLICA`

The `SOURCE_POS_WAIT()` function has a `channel` parameter.

`START REPLICA` and `STOP REPLICA` are disallowed for the `group_replication_recovery` and `group_replication_applier` channels. `SHOW REPLICA STATUS` is also not allowed with the `group_replication_applier` channel.

`FLUSH RELAY LOGS` is allowed for the `group_replication_applier` channel, but if the request is received while a transaction is being applied, the request is not performed until after the transaction ends. The requester must wait while the transaction is completed and the rotation takes place. This prevents transactions from being split, which is not allowed for Group Replication.

### 19.2.2.2 Compatibility with Previous Replication Statements

When a replica has multiple channels and a `FOR CHANNEL channel` option is not specified, a valid statement generally acts on all available channels, with some specific exceptions.

For example, the following statements behave as expected for all except certain Group Replication channels:

- `START REPLICA` starts replication threads for all channels, except the `group_replication_recovery` and `group_replication_applier` channels.
- `STOP REPLICA` stops replication threads for all channels, except the `group_replication_recovery` and `group_replication_applier` channels.
- `SHOW REPLICA STATUS` reports the status for all channels, except the `group_replication_applier` channel.
- `RESET REPLICA` resets all channels.

#### Warning

Use `RESET REPLICA` with caution as this statement deletes all existing channels, purges their relay log files, and recreates only the default channel.

Some replication statements cannot operate on all channels. In this case, error 1964 `Multiple channels exist on the replica. Please provide channel name as an argument.` is generated. The following statements and functions generate this error when used in a multi-source replication topology and a `FOR CHANNEL channel` option is not used to specify which channel to act on:

- `SHOW RELAYLOG EVENTS`
- `CHANGE REPLICATION SOURCE TO`
- `SOURCE_POS_WAIT()`

Note that a default channel always exists in a single source replication topology, where statements and functions behave as in previous versions of MySQL.

### 19.2.2.3 Startup Options and Replication Channels

This section describes startup options which are impacted by the addition of replication channels.

The following startup options now affect *all* channels in a replication topology.

- `--log-replica-updates`

All transactions received by the replica (even from multiple sources) are written in the binary log.

- `--relay-log-purge`

When set, each channel purges its own relay log automatically.

- `--replica-transaction-retries`

The specified number of transaction retries can take place on all applier threads of all channels.

- `--skip-replica-start`

No replication threads start on any channels.

- `--replica-skip-errors`

Execution continues and errors are skipped for all channels.

The values set for the following startup options apply on each channel; since these are `mysqld` startup options, they are applied on every channel.

- `--max-relay-log-size=size`

Maximum size of the individual relay log file for each channel; after reaching this limit, the file is rotated.

- `--relay-log-space-limit=size`

Upper limit for the total size of all relay logs combined, for each individual channel. For *N* channels, the combined size of these logs is limited to `relay_log_space_limit * N`.

- `--replica-parallel-workers=value`

Number of replication applier threads per channel.

- `replica_checkpoint_group`

Waiting time by an receiver thread for each source.

- `--relay-log-index=filename`

Base name for each channel's relay log index file. See [Section 19.2.2.4, “Replication Channel Naming Conventions”](#).

- `--relay-log=filename`

Denotes the base name of each channel's relay log file. See [Section 19.2.2.4, “Replication Channel Naming Conventions”](#).

- `--replica-net-timeout=N`

This value is set per channel, so that each channel waits for *N* seconds to check for a broken connection.

- `--replica-skip-counter=N`

This value is set per channel, so that each channel skips *N* events from its source.

#### 19.2.2.4 Replication Channel Naming Conventions

This section describes how naming conventions are impacted by replication channels.

Each replication channel has a unique name which is a string with a maximum length of 64 characters and is case-insensitive. Because channel names are used in the replica's applier metadata repository table, the character set used for these is always UTF-8. Although you are generally free to use any name for channels, the following names are reserved:

- `group_replication_applier`
- `group_replication_recovery`

The name you choose for a replication channel also influences the file names used by a multi-source replica. The relay log files and index files for each channel are named `relay_log_basename-channel.xxxxxx`, where `relay_log_basename` is a base name specified using the `relay_log` system variable, and `channel` is the name of the channel logged to this file. If you do not specify the `relay_log` system variable, a default file name is used that also includes the name of the channel.

### 19.2.3 Replication Threads

MySQL replication capabilities are implemented using the following types of threads:

- **Binary log dump thread.** The source creates a thread to send the binary log contents to a replica when the replica connects. This thread can be identified in the output of `SHOW PROCESSLIST` on the source as the `Binlog Dump` thread.
- **Replication I/O receiver thread.** When a `START REPLICA` statement is issued on a replica server, the replica creates an I/O (receiver) thread, which connects to the source and asks it to send the updates recorded in its binary logs.

The replication receiver thread reads the updates that the source's `Binlog Dump` thread sends (see previous item) and copies them to local files that comprise the replica's relay log.

The state of this thread is shown as `Slave_IO_running` in the output of `SHOW REPLICA STATUS`.

- **Replication SQL applier thread.** When `replica_parallel_workers` is equal to 0, the replica creates an SQL (applier) thread to read the relay log that is written by the replication receiver thread and execute the transactions contained in it. When `replica_parallel_workers` is  $N \geq 1$ , there are *N* applier threads and one coordinator thread, which reads transactions sequentially from the relay log, and schedules them to be applied by worker threads. Each worker applies the transactions that the coordinator has assigned to it.

You can enable further parallelization for tasks on a replica by setting the system variable `replica_parallel_workers` to a value greater than 0. When this is done, the replica creates the specified number of worker threads to apply transactions, plus a coordinator thread which reads transactions from the relay log and assigns them to workers. A replica with `replica_parallel_workers` (`slave_parallel_workers`) set to a value greater than 0 is called a multithreaded replica. If you are using multiple replication channels, each channel has the number of threads specified using this variable.

Multithreaded replicas are also supported by NDB Cluster. See [Section 25.7.11, “NDB Cluster Replication Using the Multithreaded Applier”](#), for more information.

### 19.2.3.1 Monitoring Replication Main Threads

The `SHOW PROCESSLIST` statement provides information that tells you what is happening on the source and on the replica regarding replication. For information on source states, see [Section 10.14.4, “Replication Source Thread States”](#). For replica states, see [Section 10.14.5, “Replication I/O \(Receiver\) Thread States”](#), and [Section 10.14.6, “Replication SQL Thread States”](#).

The following example illustrates how the three main replication threads, the binary log dump thread, replication I/O (receiver) thread, and replication SQL (applier) thread, show up in the output from `SHOW PROCESSLIST`.

On the source server, the output from `SHOW PROCESSLIST` looks like this:

```
mysql> SHOW PROCESSLIST\G
***** 1. row *****
 Id: 2
 User: root
 Host: localhost:32931
 db: NULL
Command: Binlog Dump
 Time: 94
 State: Has sent all binlog to slave; waiting for binlog to
 be updated
 Info: NULL
```

Here, thread 2 is a [Binlog Dump](#) thread that services a connected replica. The [State](#) information indicates that all outstanding updates have been sent to the replica and that the source is waiting for more updates to occur. If you see no [Binlog Dump](#) threads on a source server, this means that replication is not running; that is, no replicas are currently connected.

On a replica server, the output from `SHOW PROCESSLIST` looks like this:

```
mysql> SHOW PROCESSLIST\G
***** 1. row *****
 Id: 10
 User: system user
 Host:
 db: NULL
Command: Connect
 Time: 11
 State: Waiting for master to send event
 Info: NULL
***** 2. row *****
 Id: 11
 User: system user
 Host:
 db: NULL
Command: Connect
 Time: 11
 State: Has read all relay log; waiting for the slave I/O
 thread to update it
 Info: NULL
```

The [State](#) information indicates that thread 10 is the replication I/O (receiver) thread that is communicating with the source server, and thread 11 is the replication SQL (applier) thread that is processing the updates stored in the relay logs. At the time that `SHOW PROCESSLIST` was run, both threads were idle, waiting for further updates.

The value in the [Time](#) column can show how late the replica is compared to the source. See [Section A.14, “MySQL 9.1 FAQ: Replication”](#). If sufficient time elapses on the source side without activity on the [Binlog Dump](#) thread, the source determines that the replica is no longer connected. As for any other client

connection, the timeouts for this depend on the values of `net_write_timeout` and `net_retry_count`; for more information about these, see [Section 7.1.8, “Server System Variables”](#).

The `SHOW REPLICA STATUS` statement provides additional information about replication processing on a replica server. See [Section 19.1.7.1, “Checking Replication Status”](#).

You can also retrieve information on the source's `Binlog Dump` threads with the following:

```
SELECT * FROM performance_schema.threads WHERE PROCESSLIST_COMMAND LIKE "Binlog Dump%"
```

`Binlog Dump%` is used to retrieve either `Binlog Dump` or `Binlog Dump GTID`, depending on which mode binlog dumping is in.

### 19.2.3.2 Monitoring Replication Applier Worker Threads

On a multithreaded replica, the Performance Schema tables `replication_applier_status_by_coordinator` and `replication_applier_status_by_worker` show status information for the replica's coordinator thread and applier worker threads respectively. For a replica with multiple channels, the threads for each channel are identified.

A multithreaded replica's coordinator thread also prints statistics to the replica's error log on a regular basis if the verbosity setting is set to display informational messages. The statistics are printed depending on the volume of events that the coordinator thread has assigned to applier worker threads, with a maximum frequency of once every 120 seconds. The message lists the following statistics for the relevant replication channel, or the default replication channel (which is not named):

Seconds elapsed	The difference in seconds between the current time and the last time this information was printed to the error log.
Events assigned	The total number of events that the coordinator thread has queued to all applier worker threads since the coordinator thread was started.
Worker queues filled over overrun level	The current number of events that are queued to any of the applier worker threads in excess of the overrun level, which is set at 90% of the maximum queue length of 16384 events. If this value is zero, no applier worker threads are operating at the upper limit of their capacity.
Waited due to worker queue full	The number of times that the coordinator thread had to wait to schedule an event because an applier worker thread's queue was full. If this value is zero, no applier worker threads exhausted their capacity.
Waited due to the total size	The number of times that the coordinator thread had to wait to schedule an event because the <code>replica_pending_jobs_size_max</code> limit had been reached. This system variable sets the maximum amount of memory (in bytes) available to applier worker thread queues holding events not yet applied. If an unusually large event exceeds this size, the transaction is held until all the applier worker threads have empty queues, and then processed. All subsequent transactions are held until the large transaction has been completed.
Waited at clock conflicts	The number of nanoseconds that the coordinator thread had to wait to schedule an event because a transaction that the event depended on had not yet been committed. If <code>replica_parallel_type</code> is set to <code>DATABASE</code> (rather than <code>LOGICAL_CLOCK</code> ), this value is always zero.

Waited (count) when workers occupied	The number of times that the coordinator thread slept for a short period, which it might do in two situations. The first situation is where the coordinator thread assigns an event and finds the applier worker thread's queue is filled beyond the underrun level of 10% of the maximum queue length, in which case it sleeps for a maximum of 1 millisecond. The second situation is where <code>replica_parallel_type</code> is set to <code>LOGICAL_CLOCK</code> and the coordinator thread needs to assign the first event of a transaction to an applier worker thread's queue, it only does this to a worker with an empty queue, so if no queues are empty, the coordinator thread sleeps until one becomes empty.
Waited when workers occupied	The number of nanoseconds that the coordinator thread slept while waiting for an empty applier worker thread queue (that is, in the second situation described above, where <code>replica_parallel_type</code> is set to <code>LOGICAL_CLOCK</code> and the first event of a transaction needs to be assigned).

## 19.2.4 Relay Log and Replication Metadata Repositories

A replica server creates several repositories of information to use for the replication process:

- The replica's *relay log*, which is written by the replication I/O (receiver) thread, contains the transactions read from the replication source server's binary log. The transactions in the relay log are applied on the replica by the replication SQL (applier) thread. For information about the relay log, see [Section 19.2.4.1, “The Relay Log”](#).
- The replica's *connection metadata repository* contains information that the replication receiver thread needs to connect to the replication source server and retrieve transactions from the source's binary log. The connection metadata repository is written to the `mysql.slave_master_info` table.
- The replica's *applier metadata repository* contains information that the replication applier thread needs to read and apply transactions from the replica's relay log. The applier metadata repository is written to the `mysql.slave_relay_log_info` table.

The replica's connection metadata repository and applier metadata repository are collectively known as the replication metadata repositories. For information about these, see [Section 19.2.4.2, “Replication Metadata Repositories”](#).

**Making replication resilient to unexpected halts.** The `mysql.slave_master_info` and `mysql.slave_relay_log_info` tables are created using the transactional storage engine `InnoDB`. Updates to the replica's applier metadata repository table are committed together with the transactions, meaning that the replica's progress information recorded in that repository is always consistent with what has been applied to the database, even in the event of an unexpected server halt. For information on the combination of settings on the replica that is most resilient to unexpected halts, see [Section 19.4.2, “Handling an Unexpected Halt of a Replica”](#).

### 19.2.4.1 The Relay Log

The relay log, like the binary log, consists of a set of numbered files containing events that describe database changes, and an index file that contains the names of all used relay log files. The default location for relay log files is the data directory.

The term “relay log file” generally denotes an individual numbered file containing database events. The term “relay log” collectively denotes the set of numbered relay log files plus the index file.

Relay log files have the same format as binary log files and can be read using `mysqlbinlog` (see [Section 6.6.9, “mysqlbinlog — Utility for Processing Binary Log Files”](#)). If binary log transaction

compression is in use, transaction payloads written to the relay log are compressed in the same way as for the binary log. For more information on binary log transaction compression, see [Section 7.4.4.5, “Binary Log Transaction Compression”](#).

For the default replication channel, relay log file names have the default form `host_name-relay-bin.nnnnnn`, where `host_name` is the name of the replica server host and `nnnnnn` is a sequence number. Successive relay log files are created using successive sequence numbers, beginning with `000001`. For non-default replication channels, the default base name is `host_name-relay-bin-channel`, where `channel` is the name of the replication channel recorded in the relay log.

The replica uses an index file to track the relay log files currently in use. The default relay log index file name is `host_name-relay-bin.index` for the default channel, and `host_name-relay-bin-channel.index` for non-default replication channels.

The default relay log file and relay log index file names and locations can be overridden with, respectively, the `relay_log` and `relay_log_index` system variables (see [Section 19.1.6, “Replication and Binary Logging Options and Variables”](#)).

If a replica uses the default host-based relay log file names, changing a replica's host name after replication has been set up can cause replication to fail with the errors `Failed to open the relay log` and `Could not find target log during relay log initialization`. This is a known issue (see Bug #2122). If you anticipate that a replica's host name might change in the future (for example, if networking is set up on the replica such that its host name can be modified using DHCP), you can avoid this issue entirely by using the `relay_log` and `relay_log_index` system variables to specify relay log file names explicitly when you initially set up the replica. This causes the names to be independent of server host name changes.

If you encounter the issue after replication has already begun, one way to work around it is to stop the replica server, prepend the contents of the old relay log index file to the new one, and then restart the replica. On a Unix system, this can be done as shown here:

```
$> cat new_relay_log_name.index >> old_relay_log_name.index
$> mv old_relay_log_name.index new_relay_log_name.index
```

A replica server creates a new relay log file under the following conditions:

- Each time the replication I/O (receiver) thread starts.
- When the logs are flushed (for example, with `FLUSH LOGS` or `mysqladmin flush-logs`).
- When the size of the current relay log file becomes too large, which is determined as follows:
  - If the value of `max_relay_log_size` is greater than 0, that is the maximum relay log file size.
  - If the value of `max_relay_log_size` is 0, `max_binlog_size` determines the maximum relay log file size.

The replication SQL (applier) thread automatically deletes each relay log file after it has executed all events in the file and no longer needs it. There is no explicit mechanism for deleting relay logs because the replication SQL thread takes care of doing so. However, `FLUSH LOGS` rotates relay logs, which influences when the replication SQL thread deletes them.

### 19.2.4.2 Replication Metadata Repositories

A replica server creates two replication metadata repositories, the connection metadata repository and the applier metadata repository. The replication metadata repositories survive a replica server's shutdown. If binary log file position based replication is in use, when the replica restarts, it reads the two repositories to determine how far it previously proceeded in reading the binary log from the source and in processing

its own relay log. If GTID-based replication is in use, the replica does not use the replication metadata repositories for that purpose, but does need them for the other metadata that they contain.

- The replica's *connection metadata repository* contains information that the replication I/O (receiver) thread needs to connect to the replication source server and retrieve transactions from the source's binary log. The metadata in this repository includes the connection configuration, the replication user account details, the SSL settings for the connection, and the file name and position where the replication receiver thread is currently reading from the source's binary log.
- The replica's *applier metadata repository* contains information that the replication SQL (applier) thread needs to read and apply transactions from the replica's relay log. The metadata in this repository includes the file name and position up to which the replication applier thread has executed the transactions in the relay log, and the equivalent position in the source's binary log. It also includes metadata for the process of applying transactions, such as the number of worker threads and the `PRIVILEGE_CHECKS_USER` account for the channel.

The connection metadata repository is written to the `slave_master_info` table in the `mysql` system schema, and the applier metadata repository is written to the `slave_relay_log_info` table in the `mysql` system schema. A warning message is issued if `mysqld` is unable to initialize the tables for the replication metadata repositories, but the replica is allowed to continue starting. This situation is most likely to occur when upgrading from a version of MySQL that does not support the use of tables for the repositories to one in which they are supported.

#### Important

1. Do not attempt to update or insert rows in the `mysql.slave_master_info` or `mysql.slave_relay_log_info` tables manually. Doing so can cause undefined behavior, and is not supported. Execution of any statement requiring a write lock on either or both of the `slave_master_info` and `slave_relay_log_info` tables is disallowed while replication is ongoing (although statements that perform only reads are permitted at any time).
2. Access privileges for the connection metadata repository table `mysql.slave_master_info` should be restricted to the database administrator, because it contains the replication user account name and password for connecting to the source. Use a restricted access mode to protect database backups that include this table. You can clear the replication user account credentials from the connection metadata repository, and instead always provide them using a `START REPLICATION` statement to start the replication channel. This approach means that the replication channel always needs operator intervention to restart, but the account name and password are not recorded in the replication metadata repositories.

`RESET REPLICATION` clears the data in the replication metadata repositories, with the exception of the replication connection parameters (depending on the MySQL Server release). For details, see the description for `RESET REPLICATION`.

You can set the `GTID_ONLY` option of the `CHANGE REPLICATION SOURCE TO` statement to stop a replication channel from persisting file names and file positions in the replication metadata repositories. This avoids writes and reads to the tables in situations where GTID-based replication does not actually require them. With the `GTID_ONLY` setting, the connection metadata repository and the applier metadata repository are not updated when the replica queues and applies events in a transaction, or when the replication threads are stopped and started. File positions are tracked in memory, and can be viewed using `SHOW REPLICATION STATUS` if they are needed. The replication metadata repositories are only synchronized in the following situations:

- When a `CHANGE REPLICATION SOURCE TO` statement is issued.
- When a `RESET REPLICA` statement is issued. `RESET REPLICA ALL` deletes rather than updates the repositories, so they are synchronized implicitly.
- When a replication channel is initialized.
- If the replication metadata repositories are moved from files to tables.

Creating the replication metadata repositories as tables is the default; the use of files is deprecated.

The `mysql.slave_master_info` and `mysql.slave_relay_log_info` tables are created using the `InnoDB` transactional storage engine. Updates to the applier metadata repository table are committed together with the transactions, meaning that the replica's progress information recorded in that repository is always consistent with what has been applied to the database, even in the event of an unexpected server halt. For information on the combination of settings on a replica that is most resilient to unexpected halts, see [Section 19.4.2, “Handling an Unexpected Halt of a Replica”](#).

When you back up the replica's data or transfer a snapshot of its data to create a new replica, ensure that you include the `mysql.slave_master_info` and `mysql.slave_relay_log_info` tables containing the replication metadata repositories. For cloning operations, note that when the replication metadata repositories are created as tables, they are copied to the recipient during a cloning operation, but when they are created as files, they are not copied. When binary log file position based replication is in use, the replication metadata repositories are needed to resume replication after restarting the restored, copied, or cloned replica. If you do not have the relay log files, but still have the applier metadata repository, you can check it to determine how far the replication SQL thread has executed in the source's binary log. Then you can use a `CHANGE REPLICATION SOURCE TO` statement with the `SOURCE_LOG_FILE` and `SOURCE_LOG_POS` options to tell the replica to re-read the binary logs from the source from that point (provided that the required binary logs still exist on the source).

One additional repository, the applier worker metadata repository, is created primarily for internal use, and holds status information about worker threads on a multithreaded replica. The applier worker metadata repository includes the names and positions for the relay log file and the source's binary log file for each worker thread. If the applier metadata repository is created as a table, which is the default, the applier worker metadata repository is written to the `mysql.slave_worker_info` table. If the applier metadata repository is written to a file, the applier worker metadata repository is written to the `worker-relay-log.info` file. For external use, status information for worker threads is presented in the Performance Schema `replication_applier_status_by_worker` table.

The replication metadata repositories originally contained information similar to that shown in the output of the `SHOW REPLICA STATUS` statement, which is discussed in [Section 15.4.2, “SQL Statements for Controlling Replica Servers”](#). Further information has since been added to the replication metadata repositories which is not displayed by the `SHOW REPLICA STATUS` statement.

For the connection metadata repository, the following table shows the correspondence between the columns in the `mysql.slave_master_info` table, the columns displayed by `SHOW REPLICA STATUS`, and the lines in the deprecated `master.info` file.

<code>slave_master_info</code> Table Column	<code>SHOW REPLICA STATUS</code> Column	<code>master.info</code> File Line	Description
<code>Number_of_lines</code>	[None]	1	Number of columns in the table (or lines in the file)
<code>Master_log_name</code>	<code>Source_Log_File</code>	2	The name of the binary log currently being read from the source

<code>slave_master_info</code> Table Column	<code>SHOW REPLICA STATUS</code> Column	<code>master.info</code> File Line	Description
<code>Master_log_pos</code>	<code>Read_Source_Log_Pos</code>	3	The current position within the binary log that has been read from the source
<code>Host</code>	<code>Source_Host</code>	4	The host name of the replication source server
<code>User_name</code>	<code>Source_User</code>	5	The replication user account name used to connect to the source
<code>User_password</code>	Password (not shown by <code>SHOW REPLICA STATUS</code> )	6	The replication user account password used to connect to the source
<code>Port</code>	<code>Source_Port</code>	7	The network port used to connect to the replication source server
<code>Connect_retry</code>	<code>Connect_Retry</code>	8	The period (in seconds) that the replica waits before trying to reconnect to the source
<code>Enabled_ssl</code>	<code>Source_SSL_Allowed</code>	9	Whether the replica supports SSL connections
<code>Ssl_ca</code>	<code>Source_SSL_CA_File</code>	10	The file used for the Certificate Authority (CA) certificate
<code>Ssl_capath</code>	<code>Source_SSL_CA_Path</code>	11	The path to the Certificate Authority (CA) certificate
<code>Ssl_cert</code>	<code>Source_SSL_Cert</code>	12	The name of the SSL certificate file
<code>Ssl_cipher</code>	<code>Source_SSL_Cipher</code>	13	The list of possible ciphers used in the handshake for the SSL connection
<code>Ssl_key</code>	<code>Source_SSL_Key</code>	14	The name of the SSL key file
<code>Ssl_verify_server_cert</code>	<code>Source_SSL_Verify_Server_Cert</code>	15	Whether to verify the server certificate
<code>Heartbeat</code>	[None]	16	Interval between replication heartbeats, in seconds
<code>Bind</code>	<code>Source_Bind</code>	17	Which of the replica's network interfaces should be used for connecting to the source

<code>slave_master_info</code> Table Column	<code>SHOW REPLICA STATUS</code> Column	<code>master.info</code> File Line	Description
<code>Ignored_server_ids</code>	<code>Replicate_Ignore_Server_Ids</code>	18	The list of server IDs to be ignored. Note that for <code>Ignored_server_ids</code> the list of server IDs is preceded by the total number of server IDs to ignore.
<code>Uuid</code>	<code>Source_UUID</code>	19	The source's unique ID
<code>Retry_count</code>	<code>Source_Retry_Count</code>	20	Maximum number of reconnection attempts permitted
<code>Ssl_crl</code>	[None]	21	Path to an SSL certificate revocation-list file
<code>Ssl_crlpath</code>	[None]	22	Path to a directory containing SSL certificate revocation-list files
<code>Enabled_auto_positioning</code>	<code>Auto_position</code>	23	Whether GTID auto-positioning is in use or not
<code>Channel_name</code>	<code>Channel_name</code>	24	The name of the replication channel
<code>Tls_version</code>	<code>Source_TLS_Version</code>	25	TLS version on the source
<code>Public_key_path</code>	<code>Source_public_key_path</code>	26	Name of the RSA public key file
<code>Get_public_key</code>	<code>Get_source_public_key</code>	27	Whether to request RSA public key from source
<code>Network_namespace</code>	<code>Network_namespace</code>	28	Network namespace
<code>Master_compression_algorithm</code>	[None]	29	Permitted compression algorithms for the connection to the source
<code>Master_zstd_compression_level</code>	[None]	30	<code>zstd</code> compression level
<code>Tls_ciphersuites</code>	[None]	31	Permitted ciphersuites for TLSv1.3
<code>Source_connection_authentication_failover</code>	[None]	32	Whether the asynchronous connection failover mechanism is activated
<code>Gtid_only</code>	[None]	33	Whether the channel uses only GTIDs and does not persist positions

For the applier metadata repository, the following table shows the correspondence between the columns in the `mysql.slave_relay_log_info` table, the columns displayed by `SHOW REPLICA STATUS`, and the lines in the deprecated `relay-log.info` file.

<code>slave_relay_log_info</code> Table Column	<code>SHOW REPLICA STATUS</code> Column	Line in <code>relay-log.info</code> File	Description
<code>Number_of_lines</code>	[None]	1	Number of columns in the table or lines in the file
<code>Relay_log_name</code>	<code>Relay_Log_File</code>	2	The name of the current relay log file
<code>Relay_log_pos</code>	<code>Relay_Log_Pos</code>	3	The current position within the relay log file; events up to this position have been executed on the replica database
<code>Master_log_name</code>	<code>Relay_Source_Log_File</code>	4	The name of the source's binary log file from which the events in the relay log file were read
<code>Master_log_pos</code>	<code>Exec_Source_Log_Pos</code>	5	The equivalent position within the source's binary log file of the events that have been executed on the replica
<code>Sql_delay</code>	<code>SQL_Delay</code>	6	The number of seconds that the replica must lag the source
<code>Number_of_workers</code>	[None]	7	The number of worker threads for applying replication transactions in parallel
<code>Id</code>	[None]	8	ID used for internal purposes; currently this is always 1
<code>Channel_name</code>	<code>Channel_name</code>	9	The name of the replication channel
<code>Privilege_checks_user</code>	[None]	10	The user name for the <code>PRIVILEGE_CHECKS_USER</code> account for the channel
<code>Privilege_checks_host</code>	[None]	11	The host name for the <code>PRIVILEGE_CHECKS_USER</code> account for the channel
<code>Require_row_format</code>	[None]	12	Whether the channel accepts only row-based events
<code>Require_table_primary_key</code>	[None]	13	The channel's policy on whether tables must have primary keys for <code>CREATE TABLE</code> and <code>ALTER TABLE</code> operations
<code>Assign_gtid_to_anonymous_transactions</code>	[None]	14	If the channel assigns a GTID to replicated

<code>slave_relay_log_info</code> Table Column	<code>SHOW REPLICA STATUS</code> Column	Line in <code>relay-log.info</code> File	Description
			transactions that do not already have one, using the replica's local UUID, this value is <code>LOCAL</code> ; if the channel does so using instead a UUID which has been set manually, the value is <code>UUID</code> . If the channel does not assign a GTID in such cases, the value is <code>OFF</code> .
<code>Assign_gtid_to_anon[None]_transactions_value</code>	<code>[None]</code>	15	The UUID used in the GTIDs assigned to anonymous transactions

## 19.2.5 How Servers Evaluate Replication Filtering Rules

If a replication source server does not write a statement to its binary log, the statement is not replicated. If the server does log the statement, the statement is sent to all replicas and each replica determines whether to execute it or ignore it.

On the source, you can control which databases to log changes for by using the `--binlog-do-db` and `--binlog-ignore-db` options to control binary logging. For a description of the rules that servers use in evaluating these options, see [Section 19.2.5.1, “Evaluation of Database-Level Replication and Binary Logging Options”](#). You should not use these options to control which databases and tables are replicated. Instead, use filtering on the replica to control the events that are executed on the replica.

On the replica side, decisions about whether to execute or ignore statements received from the source are made according to the `--replicate-*` options that the replica was started with. (See [Section 19.1.6, “Replication and Binary Logging Options and Variables”](#).) The filters governed by these options can also be set dynamically using the `CHANGE REPLICATION FILTER` statement. The rules governing such filters are the same whether they are created on startup using `--replicate-*` options or while the replica server is running by `CHANGE REPLICATION FILTER`. Note that replication filters cannot be used on Group Replication-specific channels on a MySQL server instance that is configured for Group Replication, because filtering transactions on some servers would make the group unable to reach agreement on a consistent state.

In the simplest case, when there are no `--replicate-*` options, the replica executes all statements that it receives from the source. Otherwise, the result depends on the particular options given.

Database-level options (`--replicate-do-db`, `--replicate-ignore-db`) are checked first; see [Section 19.2.5.1, “Evaluation of Database-Level Replication and Binary Logging Options”](#), for a description of this process. If no database-level options are used, option checking proceeds to any table-level options that may be in use (see [Section 19.2.5.2, “Evaluation of Table-Level Replication Options”](#), for a discussion of these). If one or more database-level options are used but none are matched, the statement is not replicated.

For statements affecting databases only (that is, `CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE`), database-level options always take precedence over any `--replicate-wild-do-table` options. In other words, for such statements, `--replicate-wild-do-table` options are checked if and only if there are no database-level options that apply.

To make it easier to determine what effect a given set of options has, it is recommended that you avoid mixing `do-*` and `ignore-*` options, or options containing wildcards with options which do not.

If any `--replicate-rewrite-db` options were specified, they are applied before the `--replicate-*` filtering rules are tested.

#### Note

All replication filtering options follow the same rules for case sensitivity that apply to names of databases and tables elsewhere in the MySQL server, including the effects of the `lower_case_table_names` system variable.

Filtering rules are applied before performing any privilege checks; if a transaction is filtered out, no privilege check is performed for that transaction, and thus no error can be raised by it. See [Section 19.5.1.30, “Replica Errors During Replication”](#), for more information.

### 19.2.5.1 Evaluation of Database-Level Replication and Binary Logging Options

When evaluating replication options, the replica begins by checking to see whether there are any `--replicate-do-db` or `--replicate-ignore-db` options that apply. When using `--binlog-do-db` or `--binlog-ignore-db`, the process is similar, but the options are checked on the source.

The database that is checked for a match depends on the binary log format of the statement that is being handled. If the statement has been logged using the row format, the database where data is to be changed is the database that is checked. If the statement has been logged using the statement format, the default database (specified with a `USE` statement) is the database that is checked.

#### Note

Only DML statements can be logged using the row format. DDL statements are always logged as statements, even when `binlog_format=ROW`. All DDL statements are therefore always filtered according to the rules for statement-based replication. This means that you must select the default database explicitly with a `USE` statement in order for a DDL statement to be applied.

For replication, the steps involved are listed here:

1. Which logging format is used?
  - **STATEMENT.** Test the default database.
  - **ROW.** Test the database affected by the changes.
2. Are there any `--replicate-do-db` options?
  - **Yes.** Does the database match any of them?
    - **Yes.** Continue to Step 4.
    - **No.** Ignore the update and exit.
  - **No.** Continue to step 3.
3. Are there any `--replicate-ignore-db` options?
  - **Yes.** Does the database match any of them?
    - **Yes.** Ignore the update and exit.

- **No.** Continue to step 4.
  - **No.** Continue to step 4.
4. Proceed to checking the table-level replication options, if there are any. For a description of how these options are checked, see [Section 19.2.5.2, “Evaluation of Table-Level Replication Options”](#).

#### Important

A statement that is still permitted at this stage is not yet actually executed. The statement is not executed until all table-level options (if any) have also been checked, and the outcome of that process permits execution of the statement.

For binary logging, the steps involved are listed here:

1. Are there any `--binlog-do-db` or `--binlog-ignore-db` options?
  - **Yes.** Continue to step 2.
  - **No.** Log the statement and exit.
2. Is there a default database (has any database been selected by `USE`)?
  - **Yes.** Continue to step 3.
  - **No.** Ignore the statement and exit.
3. There is a default database. Are there any `--binlog-do-db` options?
  - **Yes.** Do any of them match the database?
    - **Yes.** Log the statement and exit.
    - **No.** Ignore the statement and exit.
  - **No.** Continue to step 4.
4. Do any of the `--binlog-ignore-db` options match the database?
  - **Yes.** Ignore the statement and exit.
  - **No.** Log the statement and exit.

#### Important

For statement-based logging, an exception is made in the rules just given for the `CREATE DATABASE`, `ALTER DATABASE`, and `DROP DATABASE` statements. In those cases, the database being *created*, *altered*, or *dropped* replaces the default database when determining whether to log or ignore updates.

`--binlog-do-db` can sometimes mean “ignore other databases”. For example, when using statement-based logging, a server running with only `--binlog-do-db=sales` does not write to the binary log statements for which the default database differs from `sales`. When using row-based logging with the same option, the server logs only those updates that change data in `sales`.

### 19.2.5.2 Evaluation of Table-Level Replication Options

The replica checks for and evaluates table options only if either of the following two conditions is true:

- No matching database options were found.
- One or more database options were found, and were evaluated to arrive at an “execute” condition according to the rules described in the previous section (see [Section 19.2.5.1, “Evaluation of Database-Level Replication and Binary Logging Options”](#)).

First, as a preliminary condition, the replica checks whether statement-based replication is enabled. If so, and the statement occurs within a stored function, the replica executes the statement and exits. If row-based replication is enabled, the replica does not know whether a statement occurred within a stored function on the source, so this condition does not apply.

### Note

For statement-based replication, replication events represent statements (all changes making up a given event are associated with a single SQL statement); for row-based replication, each event represents a change in a single table row (thus a single statement such as `UPDATE mytable SET mycol = 1` may yield many row-based events). When viewed in terms of events, the process of checking table options is the same for both row-based and statement-based replication.

Having reached this point, if there are no table options, the replica simply executes all events. If there are any `--replicate-do-table` or `--replicate-wild-do-table` options, the event must match one of these if it is to be executed; otherwise, it is ignored. If there are any `--replicate-ignore-table` or `--replicate-wild-ignore-table` options, all events are executed except those that match any of these options.

### Important

Table-level replication filters are only applied to tables that are explicitly mentioned and operated on in the query. They do not apply to tables that are implicitly updated by the query. For example, a `GRANT` statement, which updates the `mysql.user` system table but does not mention that table, is not affected by a filter that specifies `mysql.%` as the wildcard pattern.

The following steps describe this evaluation in more detail. The starting point is the end of the evaluation of the database-level options, as described in [Section 19.2.5.1, “Evaluation of Database-Level Replication and Binary Logging Options”](#).

1. Are there any table replication options?
  - **Yes.** Continue to step 2.
  - **No.** Execute the update and exit.
2. Which logging format is used?
  - **STATEMENT.** Carry out the remaining steps for each statement that performs an update.
  - **ROW.** Carry out the remaining steps for each update of a table row.
3. Are there any `--replicate-do-table` options?
  - **Yes.** Does the table match any of them?
    - **Yes.** Execute the update and exit.
    - **No.** Continue to step 4.

- **No.** Continue to step 4.
4. Are there any `--replicate-ignore-table` options?
    - **Yes.** Does the table match any of them?
      - **Yes.** Ignore the update and exit.
      - **No.** Continue to step 5.
    - **No.** Continue to step 5.
  5. Are there any `--replicate-wild-do-table` options?
    - **Yes.** Does the table match any of them?
      - **Yes.** Execute the update and exit.
      - **No.** Continue to step 6.
    - **No.** Continue to step 6.
  6. Are there any `--replicate-wild-ignore-table` options?
    - **Yes.** Does the table match any of them?
      - **Yes.** Ignore the update and exit.
      - **No.** Continue to step 7.
    - **No.** Continue to step 7.
  7. Is there another table to be tested?
    - **Yes.** Go back to step 3.
    - **No.** Continue to step 8.
  8. Are there any `--replicate-do-table` or `--replicate-wild-do-table` options?
    - **Yes.** Ignore the update and exit.
    - **No.** Execute the update and exit.

**Note**

Statement-based replication stops if a single SQL statement operates on both a table that is included by a `--replicate-do-table` or `--replicate-wild-do-table` option, and another table that is ignored by a `--replicate-ignore-table` or `--replicate-wild-ignore-table` option. The replica must either execute or ignore the complete statement (which forms a replication event), and it cannot logically do this. This also applies to row-based replication for DDL statements, because DDL statements are always logged as statements, without regard to the logging format in effect. The only type of statement that can update both an included and an ignored table and still be replicated successfully is a DML statement that has been logged with `binlog_format=ROW`.

### 19.2.5.3 Interactions Between Replication Filtering Options

If you use a combination of database-level and table-level replication filtering options, the replica first accepts or ignores events using the database options, then it evaluates all events permitted by those options according to the table options. This can sometimes lead to results that seem counterintuitive. It is also important to note that the results vary depending on whether the operation is logged using statement-based or row-based binary logging format. If you want to be sure that your replication filters always operate in the same way independently of the binary logging format, which is particularly important if you are using mixed binary logging format, follow the guidance in this topic.

The effect of the replication filtering options differs between binary logging formats because of the way the database name is identified. With statement-based format, DML statements are handled based on the current database, as specified by the `USE` statement. With row-based format, DML statements are handled based on the database where the modified table exists. DDL statements are always filtered based on the current database, as specified by the `USE` statement, regardless of the binary logging format.

An operation that involves multiple tables can also be affected differently by replication filtering options depending on the binary logging format. Operations to watch out for include transactions involving multi-table `UPDATE` statements, triggers, cascading foreign keys, stored functions that update multiple tables, and DML statements that invoke stored functions that update one or more tables. If these operations update both filtered-in and filtered-out tables, the results can vary with the binary logging format.

If you need to guarantee that your replication filters operate consistently regardless of the binary logging format, particularly if you are using mixed binary logging format (`binlog_format=MIXED`), use only table-level replication filtering options, and do not use database-level replication filtering options. Also, do not use multi-table DML statements that update both filtered-in and filtered-out tables.

If you need to use a combination of database-level and table-level replication filters, and want these to operate as consistently as possible, choose one of the following strategies:

1. If you use row-based binary logging format (`binlog_format=ROW`), for DDL statements, rely on the `USE` statement to set the database and do not specify the database name. You can consider changing to row-based binary logging format for improved consistency with replication filtering. See [Section 7.4.4.2, “Setting The Binary Log Format”](#) for the conditions that apply to changing the binary logging format.
2. If you use statement-based or mixed binary logging format (`binlog_format=STATEMENT` or `MIXED`), for both DML and DDL statements, rely on the `USE` statement and do not use the database name. Also, do not use multi-table DML statements that update both filtered-in and filtered-out tables.

#### Example 19.7 A `--replicate-ignore-db` option and a `--replicate-do-table` option

On the replication source server, the following statements are issued:

```
USE db1;
CREATE TABLE t2 LIKE t1;
INSERT INTO db2.t3 VALUES (1);
```

The replica has the following replication filtering options set:

```
replicate-ignore-db = db1
replicate-do-table = db2.t3
```

The DDL statement `CREATE TABLE` creates the table in `db1`, as specified by the preceding `USE` statement. The replica filters out this statement according to its `--replicate-ignore-db = db1` option, because `db1` is the current database. This result is the same whatever the binary logging format is on the replication source server. However, the result of the DML `INSERT` statement is different depending on the binary logging format:

- If row-based binary logging format is in use on the source (`binlog_format=ROW`), the replica evaluates the `INSERT` operation using the database where the table exists, which is named as `db2`. The database-level option `--replicate-ignore-db = db1`, which is evaluated first, therefore does not apply. The table-level option `--replicate-do-table = db2.t3` does apply, so the replica applies the change to table `t3`.
- If statement-based binary logging format is in use on the source (`binlog_format=STATEMENT`), the replica evaluates the `INSERT` operation using the default database, which was set by the `USE` statement to `db1` and has not been changed. According to its database-level `--replicate-ignore-db = db1` option, it therefore ignores the operation and does not apply the change to table `t3`. The table-level option `--replicate-do-table = db2.t3` is not checked, because the statement already matched a database-level option and was ignored.

If the `--replicate-ignore-db = db1` option on the replica is necessary, and the use of statement-based (or mixed) binary logging format on the source is also necessary, the results can be made consistent by omitting the database name from the `INSERT` statement and relying on a `USE` statement instead, as follows:

```
USE db1;
CREATE TABLE t2 LIKE t1;
USE db2;
INSERT INTO t3 VALUES (1);
```

In this case, the replica always evaluates the `INSERT` statement based on the database `db2`. Whether the operation is logged in statement-based or row-based binary format, the results remain the same.

#### 19.2.5.4 Replication Channel Based Filters

This section explains how to work with replication filters when multiple replication channels exist, for example in a multi-source replication topology. Replication filters can be global or specific to a channel, enabling you to configure multi-source replicas with replication filters on specific replication channels. Channel specific replication filters are particularly useful in a multi-source replication topology when the same database or table is present on multiple sources, and the replica is only required to replicate it from one source.

For instructions to set up replication channels, see [Section 19.1.5, “MySQL Multi-Source Replication”](#), and for more information on how they work, see [Section 19.2.2, “Replication Channels”](#).

##### Important

Each channel on a multi-source replica must replicate from a different source. You cannot set up multiple replication channels from a single replica to a single source, even if you use replication filters to select different data to replicate on each channel. This is because the server IDs of replicas must be unique in a replication topology. The source distinguishes replicas only by their server IDs, not by the names of the replication channels, so it cannot recognize different replication channels from the same replica.

##### Important

On a MySQL server instance that is configured for Group Replication, channel specific replication filters can be used on replication channels that are not directly involved with Group Replication, such as where a group member also acts as a replica to a source that is outside the group. They cannot be used on the `group_replication_applier` or `group_replication_recovery` channels. Filtering on these channels would make the group unable to reach agreement on a consistent state.

### Important

For a multi-source replica in a diamond topology (where the replica replicates from two or more sources, which in turn replicate from a common source), when GTID-based replication is in use, ensure that any replication filters or other channel configuration are identical on all channels on the multi-source replica. With GTID-based replication, filters are applied only to the transaction data, and GTIDs are not filtered out. This happens so that a replica's GTID set stays consistent with the source's, meaning GTID auto-positioning can be used without re-acquiring filtered out transactions each time. In the case where the downstream replica is multi-source and receives the same transaction from multiple sources in a diamond topology, the downstream replica now has multiple versions of the transaction, and the result depends on which channel applies the transaction first. The second channel to attempt it skips the transaction using GTID auto-skip, because the transaction's GTID was added to the `gtid_executed` set by the first channel. With identical filtering on the channels, there is no problem because all versions of the transaction contain the same data, so the results are the same. However, with different filtering on the channels, the database can become inconsistent and replication can hang.

## Overview of Replication Filters and Channels

When multiple replication channels exist, for example in a multi-source replication topology, replication filters are applied as follows:

- Any global replication filter specified is added to the global replication filters of the filter type (`do_db`, `do_ignore_table`, and so on).
- Any channel specific replication filter adds the filter to the specified channel's replication filters for the specified filter type.
- Each replication channel copies global replication filters to its channel specific replication filters if no channel specific replication filter of this type is configured.
- Each channel uses its channel specific replication filters to filter the replication stream.

The syntax to create channel specific replication filters extends the existing SQL statements and command options. When a replication channel is not specified the global replication filter is configured to ensure backwards compatibility. The `CHANGE REPLICATION FILTER` statement supports the `FOR CHANNEL` clause to configure channel specific filters online. The `--replicate-*` command options to configure filters can specify a replication channel using the form `--replicate-filter-type=channel_name:filter_details`. Suppose channels `channel_1` and `channel_2` exist before the server starts; in this case, starting the replica with the command line options `--replicate-do-db=db1 --replicate-do-db=channel_1:db2 --replicate-do-db=db3 --replicate-ignore-db=db4 --replicate-ignore-db=channel_2:db5 --replicate-wild-do-table=channel_1:db6.t1%` would result in:

- *Global replication filters:* `do_db=db1,db3; ignore_db=db4`
- *Channel specific filters on channel\_1:* `do_db=db2; ignore_db=db4; wild-do-table=db6.t1%`
- *Channel specific filters on channel\_2:* `do_db=db1,db3; ignore_db=db5`

These same rules could be applied at startup when included in the replica's `my.cnf` file, like this:

```
replicate-do-db=db1
replicate-do-db=channel_1:db2
replicate-ignore-db=db4
```

```
replicate-ignore-db=channel_2:db5
replicate-wild-do-table=db6.channel_1.t1%
```

To monitor the replication filters in such a setup use the `replication_applier_global_filters` and `replication_applier_filters` tables.

## Configuring Channel Specific Replication Filters at Startup

The replication filter related command options can take an optional `channel` followed by a colon, followed by the filter specification. The first colon is interpreted as a separator, subsequent colons are interpreted as literal colons. The following command options support channel specific replication filters using this format:

- `--replicate-do-db=channel:database_id`
- `--replicate-ignore-db=channel:database_id`
- `--replicate-do-table=channel:table_id`
- `--replicate-ignore-table=channel:table_id`
- `--replicate-rewrite-db=channel:db1-db2`
- `--replicate-wild-do-table=channel:table pattern`
- `--replicate-wild-ignore-table=channel:table pattern`

All of the options just listed can be used in the replica's `my.cnf` file, as with most other MySQL server startup options, by omitting the two leading dashes. See [Overview of Replication Filters and Channels](#), for a brief example, as well as [Section 6.2.2.2, “Using Option Files”](#).

If you use a colon but do not specify a `channel` for the filter option, for example `--replicate-do-db=:database_id`, the option configures the replication filter for the default replication channel. The default replication channel is the replication channel which always exists once replication has been started, and differs from multi-source replication channels which you create manually. When neither the colon nor a `channel` is specified the option configures the global replication filters, for example `--replicate-do-db=database_id` configures the global `--replicate-do-db` filter.

If you configure multiple `rewrite-db=from_name->to_name` options with the same `from_name` database, all filters are added together (put into the `rewrite_do` list) and the first one takes effect.

The `pattern` used for the `--replicate-wild-*-table` options can include any characters allowed in identifiers as well as the wildcards `%` and `_`. These work the same way as when used with the `LIKE` operator; for example, `tbl%` matches any table name beginning with `tbl`, and `tbl_` matches any table name matching `tbl` plus one additional character.

## Changing Channel Specific Replication Filters Online

In addition to the `--replicate-*` options, replication filters can be configured using the `CHANGE REPLICATION FILTER` statement. This removes the need to restart the server, but the replication SQL thread must be stopped while making the change. To make this statement apply the filter to a specific channel, use the `FOR CHANNEL channel` clause. For example:

```
CHANGE REPLICATION FILTER REPLICATE_DO_DB=(db1) FOR CHANNEL channel_1;
```

When a `FOR CHANNEL` clause is provided, the statement acts on the specified channel's replication filters. If multiple types of filters (`do_db`, `do_ignore_table`, `wild_do_table`, and so on) are specified, only the specified filter types are replaced by the statement. In a replication topology with multiple channels, for example on a multi-source replica, when no `FOR CHANNEL` clause is provided, the statement acts on the global replication filters and all channels' replication filters, using a similar logic as the `FOR CHANNEL` case. For more information see [Section 15.4.2.1, “CHANGE REPLICATION FILTER Statement”](#).

## Removing Channel Specific Replication Filters

When channel specific replication filters have been configured, you can remove the filter by issuing an empty filter type statement. For example to remove all `REPLICATE_REWRITE_DB` filters from a replication channel named `channel_1` issue:

```
CHANGE REPLICATION FILTER REPLICATE_REWRITE_DB=() FOR CHANNEL channel_1;
```

Any `REPLICATE_REWRITE_DB` filters previously configured, using either command options or `CHANGE REPLICATION FILTER`, are removed.

The `RESET REPLICA ALL` statement removes channel specific replication filters that were set on channels deleted by the statement. When the deleted channel or channels are recreated, any global replication filters specified for the replica are copied to them, and no channel specific replication filters are applied.

## 19.3 Replication Security

To protect against unauthorized access to data that is stored on and transferred between replication source servers and replicas, set up all the servers involved using the security measures that you would choose for any MySQL instance in your installation, as described in [Chapter 8, Security](#). In addition, for servers in a replication topology, consider implementing the following security measures:

- Set up sources and replicas to use encrypted connections to transfer the binary log, which protects this data in motion. Encryption for these connections must be activated using a `CHANGE REPLICATION SOURCE TO` statement, in addition to setting up the servers to support encrypted network connections. See [Section 19.3.1, “Setting Up Replication to Use Encrypted Connections”](#).
- Encrypt the binary log files and relay log files on sources and replicas, which protects this data at rest, and also any data in use in the binary log cache. Binary log encryption is activated using the `binlog_encryption` system variable. See [Section 19.3.2, “Encrypting Binary Log Files and Relay Log Files”](#).
- Apply privilege checks to replication appliers, which help to secure replication channels against the unauthorized or accidental use of privileged or unwanted operations. Privilege checks are implemented by setting up a `PRIVILEGE_CHECKS_USER` account, which MySQL uses to verify that you have authorized each specific transaction for that channel. See [Section 19.3.3, “Replication Privilege Checks”](#).

For Group Replication, binary log encryption and privilege checks can be used as a security measure on replication group members. You should also consider encrypting the connections between group members, comprising group communication connections and distributed recovery connections, and applying IP address allowlisting to exclude untrusted hosts. For information on these security measures specific to Group Replication, see [Section 20.6, “Group Replication Security”](#).

### 19.3.1 Setting Up Replication to Use Encrypted Connections

To use an encrypted connection for the transfer of the binary log required during replication, both the source and the replica servers must support encrypted network connections. If either server does not support encrypted connections (because it has not been compiled or configured for them), replication through an encrypted connection is not possible.

Setting up encrypted connections for replication is similar to doing so for client/server connections. You must obtain (or create) a suitable security certificate that you can use on the source, and a similar certificate (from the same certificate authority) on each replica. You must also obtain suitable key files.

For more information on setting up a server and client for encrypted connections, see [Section 8.3.1, “Configuring MySQL to Use Encrypted Connections”](#).

To enable encrypted connections on the source, you must create or obtain suitable certificate and key files, and then add the following configuration parameters to the `[mysqld]` section of the source `my.cnf` file, changing the file names as necessary:

```
[mysqld]
ssl_ca=cacert.pem
ssl_cert=server-cert.pem
ssl_key=server-key.pem
```

The paths to the files may be relative or absolute; we recommend that you always use complete paths for this purpose.

The configuration parameters are as follows:

- `ssl_ca`: The path name of the Certificate Authority (CA) certificate file. (`ssl_capath` is similar but specifies the path name of a directory of CA certificate files.)
- `ssl_cert`: The path name of the server public key certificate file. This certificate can be sent to the client and authenticated against the CA certificate that it has.
- `ssl_key`: The path name of the server private key file.

To enable encrypted connections on the replica, use the `CHANGE REPLICATION SOURCE TO` statement.

- To name the replica's certificate and SSL private key files using `CHANGE REPLICATION SOURCE TO`, add the appropriate `SOURCE_SSL_XXX` options, like this:

```
-> SOURCE_SSL_CA = 'ca_file_name',
-> SOURCE_SSL_CAPATH = 'ca_directory_name',
-> SOURCE_SSL_CERT = 'cert_file_name',
-> SOURCE_SSL_KEY = 'key_file_name',
```

These options correspond to the `--ssl-xxx` options with the same names, as described in [Command Options for Encrypted Connections](#). For these options to take effect, `SOURCE_SSL=1` must also be set. For a replication connection, specifying a value for either of `SOURCE_SSL_CA` or `SOURCE_SSL_CAPATH` corresponds to setting `--ssl-mode=VERIFY_CA`. The connection attempt succeeds only if a valid matching Certificate Authority (CA) certificate is found using the specified information.

- To activate host name identity verification, add the `SOURCE_SSL_VERIFY_SERVER_CERT` option, like this:

```
-> SOURCE_SSL_VERIFY_SERVER_CERT=1,
```

For a replication connection, specifying `SOURCE_SSL_VERIFY_SERVER_CERT=1` corresponds to setting `--ssl-mode=VERIFY_IDENTITY`, as described in [Command Options for Encrypted Connections](#). For this option to take effect, `SOURCE_SSL=1` must also be set. Host name identity verification does not work with self-signed certificates.

- To activate certificate revocation list (CRL) checks, add the `SOURCE_SSL_CRL` or `SOURCE_SSL_CRLPATH` option, as shown here:

```
-> SOURCE_SSL_CRL = 'crl_file_name',
-> SOURCE_SSL_CRLPATH = 'crl_directory_name',
```

These options correspond to the `--ssl-xxx` options with the same names, as described in [Command Options for Encrypted Connections](#). If they are not specified, no CRL checking takes place.

- To specify lists of ciphers, ciphersuites, and encryption protocols permitted by the replica for the replication connection, use the `SOURCE_SSL_CIPHER`, `SOURCE_TLS_VERSION`, and `SOURCE_TLS_CIPHERSUITES` options, like this:

```
-> SOURCE_SSL_CIPHER = 'cipher_list',
-> SOURCE_TLS_VERSION = 'protocol_list',
-> SOURCE_TLS_CIPHERSUITES = 'ciphersuite_list',
```

- The `SOURCE_SSL_CIPHER` option specifies a colon-separated list of one or more ciphers permitted by the replica for the replication connection.
- The `SOURCE_TLS_VERSION` option specifies a comma-separated list of the TLS encryption protocols permitted by the replica for the replication connection, in a format like that for the `tls_version` server system variable. The connection procedure negotiates the use of the highest TLS version that both the source and the replica permit. To be able to connect, the replica must have at least one TLS version in common with the source.
- The `SOURCE_TLS_CIPHERSUITES` option specifies a colon-separated list of one or more ciphersuites that are permitted by the replica for the replication connection if TLSv1.3 is used for the connection. If this option is set to `NULL` when TLSv1.3 is used (which is the default if you do not set the option), the ciphersuites that are enabled by default are allowed. If you set the option to an empty string, no cipher suites are allowed, and TLSv1.3 is therefore not used.

The protocols, ciphers, and ciphersuites that you can specify in these lists depend on the SSL library used to compile MySQL. For information about the formats, the permitted values, and the defaults if you do not specify the options, see [Section 8.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#).

## Note

You can use the `SOURCE_TLS_CIPHERSUITES` option to specify any selection of ciphersuites, including only non-default ciphersuites if you want.

- After the source information has been updated, start the replication process on the replica, like this:

```
mysql> START REPLICA;
```

You can use the `SHOW REPLICA STATUS` statement to confirm that an encrypted connection was established successfully.

- Requiring encrypted connections on the replica does not ensure that the source requires encrypted connections from replicas. If you want to ensure that the source only accepts replicas that connect using encrypted connections, create a replication user account on the source using the `REQUIRE SSL` option, then grant that user the `REPLICATION SLAVE` privilege. For example:

```
mysql> CREATE USER 'repl'@'%.example.com' IDENTIFIED BY 'password'
-> REQUIRE SSL;
mysql> GRANT REPLICATION SLAVE ON *.*
-> TO 'repl'@'%.example.com';
```

If you have an existing replication user account on the source, you can add `REQUIRE SSL` to it with this statement:

```
mysql> ALTER USER 'repl'@'%.example.com' REQUIRE SSL;
```

## 19.3.2 Encrypting Binary Log Files and Relay Log Files

MySQL binary log files and relay log files can be encrypted, helping to protect these files and the potentially sensitive data contained in them from being misused by outside attackers, and also from unauthorized viewing by users of the operating system where they are stored. The encryption algorithm used for the files, the AES (Advanced Encryption Standard) cipher algorithm, is built in to MySQL Server and cannot be configured.

You enable this encryption on a MySQL server by setting the `binlog_encryption` system variable to `ON`. `OFF` is the default. The system variable sets encryption on for binary log files and relay log files. Binary logging does not need to be enabled on the server to enable encryption, so you can encrypt the relay log files on a replica that has no binary log. To use encryption, a keyring component or plugin must be installed and configured to supply MySQL Server's keyring service. For instructions to do this, see [Section 8.4.4, “The MySQL Keyring”](#). Any supported keyring component or plugin can be used to store binary log encryption keys.

When you first start the server with encryption enabled, a new binary log encryption key is generated before the binary log and relay logs are initialized. This key is used to encrypt a file password for each binary log file (if the server has binary logging enabled) and relay log file (if the server has replication channels), and further keys generated from the file passwords are used to encrypt the data in the files. The binary log encryption key that is currently in use on the server is called the binary log master key. The two tier encryption key architecture means that the binary log master key can be rotated (replaced by a new master key) as required, and only the file password for each file needs to be re-encrypted with the new master key, not the whole file. Relay log files are encrypted for all channels, including new channels that are created after encryption is activated. The binary log index file and relay log index file are never encrypted.

If you activate encryption while the server is running, a new binary log encryption key is generated at that time. The exception is if encryption was active previously on the server and was then disabled, in which case the binary log encryption key that was in use before is used again. The binary log file and relay log files are rotated immediately, and file passwords for the new files and all subsequent binary log files and relay log files are encrypted using this binary log encryption key. Existing binary log files and relay log files still present on the server are not encrypted, but you can purge them if they are no longer needed.

If you deactivate encryption by changing the `binlog_encryption` system variable to `OFF`, the binary log file and relay log files are rotated immediately and all subsequent logging is unencrypted. Previously encrypted files are not automatically decrypted, but the server is still able to read them. The `BINLOG_ENCRYPTION_ADMIN` privilege is required to activate or deactivate encryption while the server is running.

Encrypted and unencrypted binary log files can be distinguished using the magic number at the start of the file header for encrypted log files (`0xFD62696E`), which differs from that used for unencrypted log files (`0xFE62696E`). The `SHOW BINARY LOGS` statement shows whether each binary log file is encrypted or unencrypted.

When binary log files have been encrypted, `mysqlbinlog` cannot read them directly, but can read them from the server using the `--read-from-remote-server` option. If you back up encrypted binary log files using `mysqlbinlog`, note that the copies of the files that are generated using `mysqlbinlog` are stored in an unencrypted format.

Binary log encryption can be combined with binary log transaction compression. For more information on binary log transaction compression, see [Section 7.4.4.5, “Binary Log Transaction Compression”](#).

### 19.3.2.1 Scope of Binary Log Encryption

When binary log encryption is active for a MySQL server instance, the encryption coverage is as follows:

- Data at rest that is written to the binary log files and relay log files is encrypted from the point in time where encryption is started, using the two tier encryption architecture described above. Existing binary log files and relay log files that were present on the server when you started encryption are not encrypted. You can purge these files when they are no longer needed.
- Data in motion in the replication event stream, which is sent to MySQL clients including `mysqlbinlog`, is decrypted for transmission, and should therefore be protected in transit by the use of connection

encryption (see [Section 8.3, “Using Encrypted Connections”](#) and [Section 19.3.1, “Setting Up Replication to Use Encrypted Connections”](#)).

- Data in use that is held in the binary log transaction and statement caches during a transaction is in unencrypted format in the memory buffer that stores the cache. The data is written to a temporary file on disk if it exceeds the space available in the memory buffer. When binary log encryption is active on the server, temporary files used to hold the binary log cache are encrypted using AES-CTR (AES Counter mode) for stream encryption. Because the temporary files are volatile and tied to a single process, they are encrypted using single-tier encryption, using a randomly generated file password and initialization vector that exist only in memory and are never stored on disk or in the keyring. After each transaction is committed, the binary log cache is reset: the memory buffer is cleared, any temporary file used to hold the binary log cache is truncated, and a new file password and initialization vector are randomly generated for use with the next transaction. This reset also takes place when the server is restarted after a normal shutdown or an unexpected halt.

#### Note

If you use `LOAD DATA` when `binlog_format=STATEMENT` is set, which is not recommended as the statement is considered unsafe for statement-based replication, a temporary file containing the data is created on the replica where the changes are applied. These temporary files are not encrypted when binary log encryption is active on the server. Use row-based or mixed binary logging format instead, which do not create the temporary files.

### 19.3.2.2 Binary Log Encryption Keys

The binary log encryption keys used to encrypt the file passwords for the log files are 256-bit keys that are generated specifically for each MySQL server instance using MySQL Server's keyring service (see [Section 8.4.4, “The MySQL Keyring”](#)). The keyring service handles the creation, retrieval, and deletion of the binary log encryption keys. A server instance only creates and removes keys generated for itself, but it can read keys generated for other instances if they are stored in the keyring, as in the case of a server instance that has been cloned by file copying.

#### Important

The binary log encryption keys for a MySQL server instance must be included in your backup and recovery procedures, because if the keys required to decrypt the file passwords for current and retained binary log files or relay log files are lost, it might not be possible to start the server.

The format of binary log encryption keys in the keyring is as follows:

```
MySQLReplicationKey_{UUID}_{SEQ_NO}
```

For example:

```
MySQLReplicationKey_00508583-b5ce-11e8-a6a5-0010e0734796_1
```

`{UUID}` is the true UUID generated by the MySQL server (the value of the `server_uuid` system variable). `{SEQ_NO}` is the sequence number for the binary log encryption key, which is incremented by 1 for each new key that is generated on the server.

The binary log encryption key that is currently in use on the server is called the binary log master key. The sequence number for the current binary log master key is stored in the keyring. The binary log master key is used to encrypt each new log file's file password, which is a randomly generated 32-byte file password specific to the log file that is used to encrypt the file data. The file password is encrypted using AES-CBC (AES Cipher Block Chaining mode) with the 256-bit binary log encryption key and a random initialization vector (IV), and is stored in the log file's file header. The file data is encrypted using AES-CTR (AES

Counter mode) with a 256-bit key generated from the file password and a nonce also generated from the file password. It is technically possible to decrypt an encrypted file offline, if the binary log encryption key used to encrypt the file password is known, by using tools available in the OpenSSL cryptography toolkit.

If you use file copying to clone a MySQL server instance that has encryption active so its binary log files and relay log files are encrypted, ensure that the keyring is also copied, so that the clone server can read the binary log encryption keys from the source server. When encryption is activated on the clone server (either at startup or subsequently), the clone server recognizes that the binary log encryption keys used with the copied files include the generated UUID of the source server. It automatically generates a new binary log encryption key using its own generated UUID, and uses this to encrypt the file passwords for subsequent binary log files and relay log files. The copied files continue to be read using the source server's keys.

### 19.3.2.3 Binary Log Master Key Rotation

When binary log encryption is enabled, you can rotate the binary log master key at any time while the server is running by issuing `ALTER INSTANCE ROTATE BINLOG MASTER KEY`. When the binary log master key is rotated manually using this statement, the passwords for the new and subsequent files are encrypted using the new binary log master key, and also the file passwords for existing encrypted binary log files and relay log files are re-encrypted using the new binary log master key, so the encryption is renewed completely. You can rotate the binary log master key on a regular basis to comply with your organization's security policy, and also if you suspect that the current or any of the previous binary log master keys might have been compromised.

When you rotate the binary log master key manually, MySQL Server takes the following actions in sequence:

1. A new binary log encryption key is generated with the next available sequence number, stored on the keyring, and used as the new binary log master key.
2. The binary log and relay log files are rotated on all channels.
3. The new binary log master key is used to encrypt the file passwords for the new binary log and relay log files, and subsequent files until the key is changed again.
4. The file passwords for existing encrypted binary log files and relay log files on the server are re-encrypted in turn using the new binary log master key, starting with the most recent files. Any unencrypted files are skipped.
5. Binary log encryption keys that are no longer in use for any files after the re-encryption process are removed from the keyring.

The `BINLOG_ENCRYPTION_ADMIN` privilege is required to issue `ALTER INSTANCE ROTATE BINLOG MASTER KEY`, and the statement cannot be used if the `binlog_encryption` system variable is set to `OFF`.

As the final step of the binary log master key rotation process, all binary log encryption keys that no longer apply to any retained binary log files or relay log files are cleaned up from the keyring. If a retained binary log file or relay log file cannot be initialized for re-encryption, the relevant binary log encryption keys are not deleted in case the files can be recovered in the future. For example, this might be the case if a file listed in a binary log index file is currently unreadable, or if a channel fails to initialize. If the server UUID changes, for example because a backup created using MySQL Enterprise Backup is used to set up a new replica, issuing `ALTER INSTANCE ROTATE BINLOG MASTER KEY` on the new server does not delete any earlier binary log encryption keys that include the original server UUID.

If any of the first four steps of the binary log master key rotation process cannot be completed correctly, an error message is issued explaining the situation and the consequences for the encryption status of

the binary log files and relay log files. Files that were previously encrypted are always left in an encrypted state, but their file passwords might still be encrypted using an old binary log master key. If you see these errors, first retry the process by issuing `ALTER INSTANCE ROTATE BINLOG MASTER KEY` again. Then investigate the status of individual files to see what is blocking the process, especially if you suspect that the current or any of the previous binary log master keys might have been compromised.

If the final step of the binary log master key rotation process cannot be completed correctly, a warning message is issued explaining the situation. The warning message identifies whether the process could not clean up the auxiliary keys in the keyring for rotating the binary log master key, or could not clean up unused binary log encryption keys. You can choose to ignore the message as the keys are auxiliary keys or no longer in use, or you can issue `ALTER INSTANCE ROTATE BINLOG MASTER KEY` again to retry the process.

If the server stops and is restarted with binary log encryption still set to `ON` during the binary log master key rotation process, new binary log files and relay log files after the restart are encrypted using the new binary log master key. However, the re-encryption of existing files is not continued, so files that did not get re-encrypted before the server stopped are left encrypted using the previous binary log master key. To complete re-encryption and clean up unused binary log encryption keys, issue `ALTER INSTANCE ROTATE BINLOG MASTER KEY` again after the restart.

`ALTER INSTANCE ROTATE BINLOG MASTER KEY` actions are not written to the binary log and are not executed on replicas. Binary log master key rotation can therefore be carried out in replication environments including a mix of MySQL versions. To schedule regular rotation of the binary log master key on all applicable source and replica servers, you can enable the MySQL Event Scheduler on each server and issue the `ALTER INSTANCE ROTATE BINLOG MASTER KEY` statement using a `CREATE EVENT` statement. If you rotate the binary log master key because you suspect that the current or any of the previous binary log master keys might have been compromised, issue the statement on every applicable source and replica server. Issuing the statement on individual servers ensures that you can verify immediate compliance, even in the case of replicas that are lagging, belong to multiple replication topologies, or are not currently active in the replication topology but have binary log and relay log files.

The `binlog_rotate_encryption_master_key_at_startup` system variable controls whether the binary log master key is automatically rotated when the server is restarted. If this system variable is set to `ON`, a new binary log encryption key is generated and used as the new binary log master key whenever the server is restarted. If it is set to `OFF`, which is the default, the existing binary log master key is used again after the restart. When the binary log master key is rotated at startup, the file passwords for the new binary log and relay log files are encrypted using the new key. The file passwords for the existing encrypted binary log files and relay log files are not re-encrypted, so they remain encrypted using the old key, which remains available on the keyring.

### 19.3.3 Replication Privilege Checks

By default, MySQL replication (including Group Replication) does not carry out privilege checks when transactions that were already accepted by another server are applied on a replica or group member. You can create a user account with the appropriate privileges to apply the transactions that are normally replicated on a channel, and specify this as the `PRIVILEGE_CHECKS_USER` account for the replication applier, using a `CHANGE REPLICATION SOURCE TO` statement. MySQL then checks each transaction against the user account's privileges to verify that you have authorized the operation for that channel. The account can also be safely used by an administrator to apply or reapply transactions from `mysqlbinlog` output, for example to recover from a replication error on the channel.

The use of a `PRIVILEGE_CHECKS_USER` account helps secure a replication channel against the unauthorized or accidental use of privileged or unwanted operations. The `PRIVILEGE_CHECKS_USER` account provides an additional layer of security in situations such as these:

- You are replicating between a server instance on your organization's network, and a server instance on another network, such as an instance supplied by a cloud service provider.
- You want to have multiple on-premise or off-site deployments administered as separate units, without giving one administrator account privileges on all the deployments.
- You want to have an administrator account that enables an administrator to perform only operations that are directly relevant to the replication channel and the databases it replicates, rather than having wide privileges on the server instance.

You can increase the security of a replication channel where privilege checks are applied by adding one or both of these options to the `CHANGE REPLICATION SOURCE TO` statement when you specify the `PRIVILEGE_CHECKS_USER` account for the channel:

- The `REQUIRE_ROW_FORMAT` option makes the replication channel accept only row-based replication events. When `REQUIRE_ROW_FORMAT` is set, you must use row-based binary logging (`binlog_format=ROW`) on the source server. With statement-based binary logging, some administrator-level privileges might be required for the `PRIVILEGE_CHECKS_USER` account to execute transactions successfully.
- The `REQUIRE_TABLE_PRIMARY_KEY_CHECK` option makes the replication channel use its own policy for primary key checks. Setting `ON` means that primary keys are always required, and setting `OFF` means that primary keys are never required. The default setting, `STREAM`, sets the session value of the `sql_require_primary_key` system variable using the value that is replicated from the source for each transaction. When `PRIVILEGE_CHECKS_USER` is set, setting `REQUIRE_TABLE_PRIMARY_KEY_CHECK` to either `ON` or `OFF` means that the user account does not need session administration level privileges to set restricted session variables, which are required to change the value of `sql_require_primary_key`. It also normalizes the behavior across replication channels for different sources.

You grant the `REPLICATION_APPLIER` privilege to enable a user account to appear as the `PRIVILEGE_CHECKS_USER` for a replication applier thread, and to execute the internal-use `BINLOG` statements used by `mysqlbinlog`. The user name and host name for the `PRIVILEGE_CHECKS_USER` account must follow the syntax described in [Section 8.2.4, “Specifying Account Names”](#), and the user must not be an anonymous user (with a blank user name) or the `CURRENT_USER`. To create a new account, use `CREATE USER`. To grant this account the `REPLICATION_APPLIER` privilege, use the `GRANT` statement. For example, to create a user account `priv_repl`, which can be used manually by an administrator from any host in the `example.com` domain, and requires an encrypted connection, issue the following statements:

```
mysql> SET sql_log_bin = 0;
mysql> CREATE USER 'priv_repl'@'%.example.com' IDENTIFIED BY 'password' REQUIRE SSL;
mysql> GRANT REPLICATION_APPLIER ON *.* TO 'priv_repl'@'%.example.com';
mysql> SET sql_log_bin = 1;
```

The `SET sql_log_bin` statements are used so that the account management statements are not added to the binary log and sent to the replication channels (see [Section 15.4.1.3, “SET sql\\_log\\_bin Statement”](#)).

### Important

The `caching_sha2_password` authentication plugin is the default for new users (for details, see [Section 8.4.1.1, “Caching SHA-2 Pluggable Authentication”](#)). To connect to a server using a user account that authenticates with this plugin, you must either set up an encrypted connection as described in [Section 19.3.1, “Setting Up Replication to Use Encrypted Connections”](#), or enable the unencrypted connection to support password exchange using an RSA key pair.

After setting up the user account, use the `GRANT` statement to grant additional privileges to enable the user account to make the database changes that you expect the applier thread to carry out, such as updating specific tables held on the server. These same privileges enable an administrator to use the account if they need to execute any of those transactions manually on the replication channel. If an unexpected operation is attempted for which you did not grant the appropriate privileges, the operation is disallowed and the replication applier thread stops with an error. [Section 19.3.3.1, “Privileges For The Replication PRIVILEGE\\_CHECKS\\_USER Account”](#) explains what additional privileges the account needs. For example, to grant the `priv_repl` user account the `INSERT` privilege to add rows to the `cust` table in `db1`, issue the following statement:

```
mysql> GRANT INSERT ON db1.cust TO 'priv_repl'@'%.example.com';
```

You assign the `PRIVILEGE_CHECKS_USER` account for a replication channel using a `CHANGE REPLICATION SOURCE TO` statement. If replication is running, issue `STOP REPLICA` before the `CHANGE REPLICATION SOURCE TO` statement, and `START REPLICA` after it. The use of row-based binary logging is strongly recommended when `PRIVILEGE_CHECKS_USER` is set; you can use the statement to set `REQUIRE_ROW_FORMAT` to enforce this.

When you restart the replication channel, checks on dynamic privileges are applied from that point on. However, static global privileges are not active in the applier's context until you reload the grant tables, because these privileges are not changed for a connected client. To activate static privileges, perform a flush-privileges operation. This can be done by issuing a `FLUSH PRIVILEGES` statement or by executing a `mysqladmin flush-privileges` or `mysqladmin reload` command.

For example, to start privilege checks on the channel `channel_1` on a running replica, issue the following statements:

```
mysql> STOP REPLICA FOR CHANNEL 'channel_1';
mysql> CHANGE REPLICATION SOURCE TO
> PRIVILEGE_CHECKS_USER = 'priv_repl'@'%.example.com',
> REQUIRE_ROW_FORMAT = 1 FOR CHANNEL 'channel_1';
mysql> FLUSH PRIVILEGES;
mysql> START REPLICA FOR CHANNEL 'channel_1';
```

If you do not specify a channel and no other channels exist, the statement is applied to the default channel. The user name and host name for the `PRIVILEGE_CHECKS_USER` account for a channel are shown in the Performance Schema `replication_applier_configuration` table, where they are properly escaped so they can be copied directly into SQL statements to execute individual transactions.

If you are using the `Rewriter` plugin, you should grant the `PRIVILEGE_CHECKS_USER` user account the `SKIP_QUERY_REWRITE` privilege. This prevents statements issued by this user from being rewritten. See [Section 7.6.4, “The Rewriter Query Rewrite Plugin”](#), for more information.

When `REQUIRE_ROW_FORMAT` is set for a replication channel, the replication applier does not create or drop temporary tables, and so does not set the `pseudo_thread_id` session system variable. It does not execute `LOAD DATA INFILE` instructions, and so does not attempt file operations to access or delete the temporary files associated with data loads (logged as a `Format_description_log_event`). It does not execute `INTVAR`, `RAND`, and `USER_VAR` events, which are used to reproduce the client's connection state for statement-based replication. (An exception is `USER_VAR` events that are associated with DDL queries, which are executed.) It does not execute any statements that are logged within DML transactions. If the replication applier detects any of these types of event while attempting to queue or apply a transaction, the event is not applied, and replication stops with an error.

You can set `REQUIRE_ROW_FORMAT` for a replication channel whether or not you set a `PRIVILEGE_CHECKS_USER` account. The restrictions implemented when you set this option increase the security of the replication channel even without privilege checks. You can also specify the `--require-row-format` option when you use `mysqlbinlog`, to enforce row-based replication events in `mysqlbinlog` output.

**Security Context.** By default, when a replication applier thread is started with a user account specified as the `PRIVILEGE_CHECKS_USER`, the security context is created using default roles, or with all roles if `activate_all_roles_on_login` is set to `ON`.

You can use roles to supply a general privilege set to accounts that are used as `PRIVILEGE_CHECKS_USER` accounts, as in the following example. Here, instead of granting the `INSERT` privilege for the `db1.cust` table directly to a user account as in the earlier example, this privilege is granted to the role `priv_repl_role` along with the `REPLICATION_APPLIER` privilege. The role is then used to grant the privilege set to two user accounts, both of which can now be used as `PRIVILEGE_CHECKS_USER` accounts:

```
mysql> SET sql_log_bin = 0;
mysql> CREATE USER 'priv_repa'@'%.example.com'
 IDENTIFIED BY 'password'
 REQUIRE SSL;
mysql> CREATE USER 'priv_repb'@'%.example.com'
 IDENTIFIED BY 'password'
 REQUIRE SSL;
mysql> CREATE ROLE 'priv_repl_role';
mysql> GRANT REPLICATION_APPLIER TO 'priv_repl_role';
mysql> GRANT INSERT ON db1.cust TO 'priv_repl_role';
mysql> GRANT 'priv_repl_role' TO
 'priv_repa'@'%.example.com',
 'priv_repb'@'%.example.com';
mysql> SET DEFAULT ROLE 'priv_repl_role' TO
 'priv_repa'@'%.example.com',
 'priv_repb'@'%.example.com';
mysql> SET sql_log_bin = 1;
```

Be aware that when the replication applier thread creates the security context, it checks the privileges for the `PRIVILEGE_CHECKS_USER` account, but does not carry out password validation, and does not carry out checks relating to account management, such as checking whether the account is locked. The security context that is created remains unchanged for the lifetime of the replication applier thread.

### 19.3.3.1 Privileges For The Replication `PRIVILEGE_CHECKS_USER` Account

The user account that is specified using the `CHANGE REPLICATION SOURCE TO` statement as the `PRIVILEGE_CHECKS_USER` account for a replication channel must have the `REPLICATION_APPLIER` privilege, otherwise the replication applier thread does not start. As explained in [Section 19.3.3, “Replication Privilege Checks”](#), the account requires further privileges that are sufficient to apply all the expected transactions expected on the replication channel. These privileges are checked only when relevant transactions are executed.

The use of row-based binary logging (`binlog_format=ROW`) is strongly recommended for replication channels that are secured using a `PRIVILEGE_CHECKS_USER` account. With statement-based binary logging, some administrator-level privileges might be required for the `PRIVILEGE_CHECKS_USER` account to execute transactions successfully. The `REQUIRE_ROW_FORMAT` setting can be applied to secured channels, which restricts the channel from executing events that would require these privileges.

The `REPLICATION_APPLIER` privilege explicitly or implicitly allows the `PRIVILEGE_CHECKS_USER` account to carry out the following operations that a replication thread needs to perform:

- Setting the value of the system variables `gtid_next`, `original_commit_timestamp`, `original_server_version`, `immediate_server_version`, and `pseudo_replica_mode`, to apply appropriate metadata and behaviors when executing transactions.
- Executing internal-use `BINLOG` statements to apply `mysqlbinlog` output, provided that the account also has permission for the tables and operations in those statements.

- Updating the system tables `mysql.gtid_executed`, `mysql.slave_relay_log_info`, `mysql.slave_worker_info`, and `mysql.slave_master_info`, to update replication metadata. (If events access these tables explicitly for other purposes, you must grant the appropriate privileges on the tables.)
- Applying a binary log `Table_map_log_event`, which provides table metadata but does not make any database changes.

If the `REQUIRE_TABLE_PRIMARY_KEY_CHECK` option of the `CHANGE REPLICATION SOURCE TO` statement is set to the default value `STREAM`, the `PRIVILEGE_CHECKS_USER` account needs privileges sufficient to set restricted session variables, so that it can change the value of the `sql_require_primary_key` system variable for the duration of a session to match the setting replicated from the source. The `SESSION_VARIABLES_ADMIN` privilege gives the account this capability. This privilege also allows the account to apply `mysqlbinlog` output that was created using the `--disable-log-bin` option. If you set `REQUIRE_TABLE_PRIMARY_KEY_CHECK` to either `ON` or `OFF`, the replica always uses that value for the `sql_require_primary_key` system variable in replication operations, and so does not need these session administration level privileges.

If table encryption is in use, the `table_encryption_privilege_check` system variable is set to `ON`, and the encryption setting for the tablespace involved in any event differs from the applying server's default encryption setting (specified by the `default_table_encryption` system variable), the `PRIVILEGE_CHECKS_USER` account needs the `TABLE_ENCRYPTION_ADMIN` privilege in order to override the default encryption setting. It is strongly recommended that you do not grant this privilege. Instead, ensure that the default encryption setting on a replica matches the encryption status of the tablespaces that it replicates, and that replication group members have the same default encryption setting, so that the privilege is not needed.

In order to execute specific replicated transactions from the relay log, or transactions from `mysqlbinlog` output as required, the `PRIVILEGE_CHECKS_USER` account must have the following privileges:

- For a row insertion logged in row format (which are logged as a `Write_rows_log_event`), the `INSERT` privilege on the relevant table.
- For a row update logged in row format (which are logged as an `Update_rows_log_event`), the `UPDATE` privilege on the relevant table.
- For a row deletion logged in row format (which are logged as a `Delete_rows_log_event`), the `DELETE` privilege on the relevant table.

If statement-based binary logging is in use (which is not recommended with a `PRIVILEGE_CHECKS_USER` account), for a transaction control statement such as `BEGIN` or `COMMIT` or DML logged in statement format (which are logged as a `Query_log_event`), the `PRIVILEGE_CHECKS_USER` account needs privileges to execute the statement contained in the event.

If `LOAD DATA` operations need to be carried out on the replication channel, use row-based binary logging (`binlog_format=ROW`). With this logging format, the `FILE` privilege is not needed to execute the event, so do not give the `PRIVILEGE_CHECKS_USER` account this privilege. The use of row-based binary logging is strongly recommended with replication channels that are secured using a `PRIVILEGE_CHECKS_USER` account. If `REQUIRE_ROW_FORMAT` is set for the channel, row-based binary logging is required. The `Format_description_log_event`, which deletes any temporary files created by `LOAD DATA` events, is processed without privilege checks. For more information, see [Section 19.5.1.20, “Replication and LOAD DATA”](#).

If the `init_replica` system variable is set to specify one or more SQL statements to be executed when the replication SQL thread starts, the `PRIVILEGE_CHECKS_USER` account must have the privileges needed to execute these statements.

It is recommended that you never give any ACL privileges to the `PRIVILEGE_CHECKS_USER` account, including `CREATE USER`, `CREATE ROLE`, `DROP ROLE`, and `GRANT OPTION`, and do not permit the account to update the `mysql.user` table. With these privileges, the account could be used to create or modify user accounts on the server. To avoid ACL statements issued on the source server being replicated to the secured channel for execution (where they fail in the absence of these privileges), you can issue `SET sql_log_bin = 0` before all ACL statements and `SET sql_log_bin = 1` after them, to omit the statements from the source's binary log. Alternatively, you can set a dedicated current database before executing all ACL statements, and use a replication filter (`--binlog-ignore-db`) to filter out this database on the replica.

### 19.3.3.2 Privilege Checks For Group Replication Channels

You can also use a `PRIVILEGE_CHECKS_USER` account to secure the two replication applier threads used by Group Replication. The `group_replication_applier` thread on each group member is used for applying group transactions, and the `group_replication_recovery` thread on each group member is used for state transfer from the binary log as part of distributed recovery when the member joins or rejoins the group.

To secure one of these threads, stop Group Replication, then issue the `CHANGE REPLICATION SOURCE TO` statement with the `PRIVILEGE_CHECKS_USER` option, specifying `group_replication_applier` or `group_replication_recovery` as the channel name. For example:

```
mysql> STOP GROUP_REPLICATION;
mysql> CHANGE REPLICATION SOURCE TO PRIVILEGE_CHECKS_USER = 'gr_repl'@'%.example.com'
 FOR CHANNEL 'group_replication_recovery';
mysql> FLUSH PRIVILEGES;
mysql> START GROUP_REPLICATION;
```

For Group Replication channels, the `REQUIRE_ROW_FORMAT` setting is automatically enabled when the channel is created, and cannot be disabled, so you do not need to specify this.

Group Replication requires every table that is to be replicated by the group to have a defined primary key, or primary key equivalent where the equivalent is a non-null unique key. Rather than using the checks carried out by the `sql_require_primary_key` system variable, Group Replication has its own built-in set of checks for primary keys or primary key equivalents. You may set the `REQUIRE_TABLE_PRIMARY_KEY_CHECK` option of the `CHANGE REPLICATION SOURCE TO` statement to `ON` for a Group Replication channel. However, be aware that you might find some transactions that are permitted under Group Replication's built-in checks are not permitted under the checks carried out when you set `sql_require_primary_key = ON` or `REQUIRE_TABLE_PRIMARY_KEY_CHECK = ON`. For this reason, new and upgraded Group Replication channels have `REQUIRE_TABLE_PRIMARY_KEY_CHECK` set to the default value `STREAM`, rather than `ON`.

If a remote cloning operation is used for distributed recovery in Group Replication (see [Section 20.5.4.2, “Cloning for Distributed Recovery”](#)), the `PRIVILEGE_CHECKS_USER` account and related settings from the donor are cloned to the joining member. If the joining member is set to start Group Replication on boot, it automatically uses the account for privilege checks on the appropriate replication channels.

### 19.3.3.3 Recovering From Failed Replication Privilege Checks

If a privilege check against the `PRIVILEGE_CHECKS_USER` account fails, the transaction is not executed and replication stops for the channel. Details of the error and the last applied transaction are recorded in the Performance Schema `replication_applier_status_by_worker` table. Follow this procedure to recover from the error:

1. Identify the replicated event that caused the error and verify whether or not the event is expected and from a trusted source. You can use `mysqlbinlog` to retrieve and display the events that were logged

around the time of the error. For instructions to do this, see [Section 9.5, “Point-in-Time \(Incremental\) Recovery”](#).

2. If the replicated event is not expected or is not from a known and trusted source, investigate the cause. If you can identify why the event took place and there are no security considerations, proceed to fix the error as described below.
3. If the `PRIVILEGE_CHECKS_USER` account should have been permitted to execute the transaction, but has been misconfigured, grant the missing privileges to the account, use a `FLUSH PRIVILEGES` statement or execute a `mysqladmin flush-privileges` or `mysqladmin reload` command to reload the grant tables, then restart replication for the channel.
4. If the transaction needs to be executed and you have verified that it is trusted, but the `PRIVILEGE_CHECKS_USER` account should not have this privilege normally, you can grant the required privilege to the `PRIVILEGE_CHECKS_USER` account temporarily. After the replicated event has been applied, remove the privilege from the account, and take any necessary steps to ensure the event does not recur if it is avoidable.
5. If the transaction is an administrative action that should only have taken place on the source and not on the replica, or should only have taken place on a single replication group member, skip the transaction on the server or servers where it stopped replication, then issue `START REPLICA` to restart replication on the channel. To avoid the situation in future, you could issue such administrative statements with `SET sql_log_bin = 0` before them and `SET sql_log_bin = 1` after them, so that they are not logged on the source.
6. If the transaction is a DDL or DML statement that should not have taken place on either the source or the replica, skip the transaction on the server or servers where it stopped replication, undo the transaction manually on the server where it originally took place, then issue `START REPLICA` to restart replication.

To skip a transaction, if GTIDs are in use, commit an empty transaction that has the GTID of the failing transaction, for example:

```
SET GTID_NEXT= 'aaa-bbb-ccc-ddd:N' ;
BEGIN;
COMMIT;
SET GTID_NEXT= 'AUTOMATIC' ;
```

If GTIDs are not in use, issue a `SET GLOBAL sql_replica_skip_counter` statement to skip the event. For instructions to use this alternative method and more details about skipping transactions, see [Section 19.1.7.3, “Skipping Transactions”](#).

## 19.4 Replication Solutions

Replication can be used in many different environments for a range of purposes. This section provides general notes and advice on using replication for specific solution types.

For information on using replication in a backup environment, including notes on the setup, backup procedure, and files to back up, see [Section 19.4.1, “Using Replication for Backups”](#).

For advice and tips on using different storage engines on the source and replica, see [Section 19.4.4, “Using Replication with Different Source and Replica Storage Engines”](#).

Using replication as a scale-out solution requires some changes in the logic and operation of applications that use the solution. See [Section 19.4.5, “Using Replication for Scale-Out”](#).

For performance or data distribution reasons, you may want to replicate different databases to different replicas. See [Section 19.4.6, “Replicating Different Databases to Different Replicas”](#)

As the number of replicas increases, the load on the source can increase and lead to reduced performance (because of the need to replicate the binary log to each replica). For tips on improving your replication performance, including using a single secondary server as the source, see [Section 19.4.7, “Improving Replication Performance”](#).

For guidance on switching sources, or converting replicas into sources as part of an emergency failover solution, see [Section 19.4.8, “Switching Sources During Failover”](#).

For information on security measures specific to servers in a replication topology, see [Section 19.3, “Replication Security”](#).

## 19.4.1 Using Replication for Backups

To use replication as a backup solution, replicate data from the source to a replica, and then back up the replica. The replica can be paused and shut down without affecting the running operation of the source, so you can produce an effective snapshot of “live” data that would otherwise require the source to be shut down.

How you back up a database depends on its size and whether you are backing up only the data, or the data and the replica state so that you can rebuild the replica in the event of failure. There are therefore two choices:

- If you are using replication as a solution to enable you to back up the data on the source, and the size of your database is not too large, the `mysqldump` tool may be suitable. See [Section 19.4.1.1, “Backing Up a Replica Using mysqldump”](#).
- For larger databases, where `mysqldump` would be impractical or inefficient, you can back up the raw data files instead. Using the raw data files option also means that you can back up the binary and relay logs that make it possible to re-create the replica in the event of a replica failure. For more information, see [Section 19.4.1.2, “Backing Up Raw Data from a Replica”](#).

Another backup strategy, which can be used for either source or replica servers, is to put the server in a read-only state. The backup is performed against the read-only server, which then is changed back to its usual read/write operational status. See [Section 19.4.1.3, “Backing Up a Source or Replica by Making It Read Only”](#).

### 19.4.1.1 Backing Up a Replica Using mysqldump

Using `mysqldump` to create a copy of a database enables you to capture all of the data in the database in a format that enables the information to be imported into another instance of MySQL Server (see [Section 6.5.4, “mysqldump — A Database Backup Program”](#)). Because the format of the information is SQL statements, the file can easily be distributed and applied to running servers in the event that you need access to the data in an emergency. However, if the size of your data set is very large, `mysqldump` may be impractical.

#### Tip

Consider using the [MySQL Shell dump utilities](#), which provide parallel dumping with multiple threads, file compression, and progress information display, as well as cloud features such as Oracle Cloud Infrastructure Object Storage streaming, and MySQL HeatWave Service compatibility checks and modifications. Dumps can be easily imported into a MySQL Server instance or a MySQL HeatWave Service DB System using the [MySQL Shell load dump utilities](#). Installation instructions for MySQL Shell can be found [here](#).

When using `mysqldump`, you should stop replication on the replica before starting the dump process to ensure that the dump contains a consistent set of data:

1. Stop the replica from processing requests. You can stop replication completely on the replica using `mysqladmin`:

```
$> mysqladmin stop-replica
```

Alternatively, you can stop only the replication SQL thread to pause event execution:

```
$> mysql -e 'STOP REPLICATION SQL_THREAD;'
```

This enables the replica to continue to receive data change events from the source's binary log and store them in the relay logs using the replication receiver thread, but prevents the replica from executing these events and changing its data. Within busy replication environments, permitting the replication receiver thread to run during backup may speed up the catch-up process when you restart the replication applier thread.

2. Run `mysqldump` to dump your databases. You may either dump all databases or select databases to be dumped. For example, to dump all databases:

```
$> mysqldump --all-databases > fulldb.dump
```

3. Once the dump has completed, start replication again:

```
$> mysqladmin start-replica
```

In the preceding example, you may want to add login credentials (user name, password) to the commands, and bundle the process up into a script that you can run automatically each day.

If you use this approach, make sure you monitor the replication process to ensure that the time taken to run the backup does not affect the replica's ability to keep up with events from the source. See [Section 19.1.7.1, “Checking Replication Status”](#). If the replica is unable to keep up, you may want to add another replica and distribute the backup process. For an example of how to configure this scenario, see [Section 19.4.6, “Replicating Different Databases to Different Replicas”](#).

### 19.4.1.2 Backing Up Raw Data from a Replica

To guarantee the integrity of the files that are copied, backing up the raw data files on your MySQL replica should take place while your replica server is shut down. If the MySQL server is still running, background tasks may still be updating the database files, particularly those involving storage engines with background processes such as `InnoDB`. With `InnoDB`, these problems should be resolved during crash recovery, but since the replica server can be shut down during the backup process without affecting the execution of the source it makes sense to take advantage of this capability.

To shut down the server and back up the files:

1. Shut down the replica MySQL server:

```
$> mysqladmin shutdown
```

2. Copy the data files. You can use any suitable copying or archive utility, including `cp`, `tar` or `WinZip`. For example, assuming that the data directory is located under the current directory, you can archive the entire directory as follows:

```
$> tar cf /tmp/dbbackup.tar ./data
```

3. Start the MySQL server again. Under Unix:

```
$> mysqld_safe &
```

Under Windows:

```
C:\> "C:\Program Files\MySQL\MySQL Server 9.1\bin\mysqld"
```

Normally you should back up the entire data directory for the replica MySQL server. If you want to be able to restore the data and operate as a replica (for example, in the event of failure of the replica), in addition to the data, you need to have the replica's connection metadata repository and applier metadata repository, and the relay log files. These items are needed to resume replication after you restore the replica's data. Assuming tables have been used for the replica's connection metadata repository and applier metadata repository (see [Section 19.2.4, “Relay Log and Replication Metadata Repositories”](#)), which is the default in MySQL 9.1, these tables are backed up along with the data directory. If files have been used for the repositories, which is deprecated, you must back these up separately. The relay log files must be backed up separately if they have been placed in a different location to the data directory.

If you lose the relay logs but still have the `relay-log.info` file, you can check it to determine how far the replication SQL thread has executed in the source's binary logs. Then you can use `CHANGE REPLICATION SOURCE TO` with the `SOURCE_LOG_FILE` and `SOURCE_LOG_POS` options to tell the replica to re-read the binary logs from that point. This requires that the binary logs still exist on the source server.

If your replica is replicating `LOAD DATA` statements, you should also back up any `SQL_LOAD-*` files that exist in the directory that the replica uses for this purpose. The replica needs these files to resume replication of any interrupted `LOAD DATA` operations. The location of this directory is the value of the system variable `replica_load_tmpdir`. If the server was not started with that variable set, the directory location is the value of the `tmpdir` system variable.

### 19.4.1.3 Backing Up a Source or Replica by Making It Read Only

It is possible to back up either source or replica servers in a replication setup by acquiring a global read lock and manipulating the `read_only` system variable to change the read-only state of the server to be backed up:

1. Make the server read-only, so that it processes only retrievals and blocks updates.
2. Perform the backup.
3. Change the server back to its normal read/write state.

#### Note

The instructions in this section place the server to be backed up in a state that is safe for backup methods that get the data from the server, such as `mysqldump` (see [Section 6.5.4, “mysqldump — A Database Backup Program”](#)). You should not attempt to use these instructions to make a binary backup by copying files directly because the server may still have modified data cached in memory and not flushed to disk.

The following instructions describe how to do this for a source and for a replica. For both scenarios discussed here, suppose that you have the following replication setup:

- A source server S1
- A replica server R1 that has S1 as its source
- A client C1 connected to S1
- A client C2 connected to R1

In either scenario, the statements to acquire the global read lock and manipulate the `read_only` variable are performed on the server to be backed up and do not propagate to any replicas of that server.

### Scenario 1: Backup with a Read-Only Source

Put the source S1 in a read-only state by executing these statements on it:

```
mysql> FLUSH TABLES WITH READ LOCK;
mysql> SET GLOBAL read_only = ON;
```

While S1 is in a read-only state, the following properties are true:

- Requests for updates sent by C1 to S1 block because the server is in read-only mode.
- Requests for query results sent by C1 to S1 succeed.
- Making a backup on S1 is safe.
- Making a backup on R1 is not safe. This server is still running, and might be processing the binary log or update requests coming from client C2.

While S1 is read only, perform the backup. For example, you can use `mysqldump`.

After the backup operation on S1 completes, restore S1 to its normal operational state by executing these statements:

```
mysql> SET GLOBAL read_only = OFF;
mysql> UNLOCK TABLES;
```

Although performing the backup on S1 is safe (as far as the backup is concerned), it is not optimal for performance because clients of S1 are blocked from executing updates.

This strategy applies to backing up a source in a replication setup, but can also be used for a single server in a nonreplication setting.

### Scenario 2: Backup with a Read-Only Replica

Put the replica R1 in a read-only state by executing these statements on it:

```
mysql> FLUSH TABLES WITH READ LOCK;
mysql> SET GLOBAL read_only = ON;
```

While R1 is in a read-only state, the following properties are true:

- The source S1 continues to operate, so making a backup on the source is not safe.
- The replica R1 is stopped, so making a backup on the replica R1 is safe.

These properties provide the basis for a popular backup scenario: Having one replica busy performing a backup for a while is not a problem because it does not affect the entire network, and the system is still running during the backup. In particular, clients can still perform updates on the source server, which remains unaffected by backup activity on the replica.

While R1 is read only, perform the backup. For example, you can use `mysqldump`.

After the backup operation on R1 completes, restore R1 to its normal operational state by executing these statements:

```
mysql> SET GLOBAL read_only = OFF;
mysql> UNLOCK TABLES;
```

After the replica is restored to normal operation, it again synchronizes to the source by catching up with any outstanding updates from the source's binary log.

## 19.4.2 Handling an Unexpected Halt of a Replica

In order for replication to be resilient to unexpected halts of the server (sometimes described as crash-safe) it must be possible for the replica to recover its state before halting. This section describes the impact of an unexpected halt of a replica during replication, and how to configure a replica for the best chance of recovery to continue replication.

After an unexpected halt of a replica, upon restart the replication SQL thread must recover information about which transactions have been executed already. The information required for recovery is stored in the replica's applier metadata repository. This repository is created by default as an [InnoDB](#) table named `mysql.slave_relay_log_info`. By using this transactional storage engine the information is always recoverable upon restart. Updates to the applier metadata repository are committed together with the transactions, meaning that the replica's progress information recorded in that repository is always consistent with what has been applied to the database, even in the event of an unexpected server halt. For more information on the applier metadata repository, see [Section 19.2.4, "Relay Log and Replication Metadata Repositories"](#).

DML transactions and also atomic DDL update the replication positions in the replica's applier metadata repository in the `mysql.slave_relay_log_info` table together with applying the changes to the database, as an atomic operation. In all other cases, including DDL statements that are not fully atomic, and exempted storage engines that do not support atomic DDL, the `mysql.slave_relay_log_info` table might be missing updates associated with replicated data if the server halts unexpectedly. Restoring updates in this case is a manual process. For details on atomic DDL support in MySQL 9.1, and the resulting behavior for the replication of certain statements, see [Section 15.1.1, "Atomic Data Definition Statement Support"](#).

The recovery process by which a replica recovers from an unexpected halt varies depending on the configuration of the replica. The details of the recovery process are influenced by the chosen method of replication, whether the replica is single-threaded or multithreaded, and the setting of relevant system variables. The overall aim of the recovery process is to identify what transactions had already been applied on the replica's database before the unexpected halt occurred, and retrieve and apply the transactions that the replica missed following the unexpected halt.

- For GTID-based replication, the recovery process needs the GTIDs of the transactions that were already received or committed by the replica. The missing transactions can be retrieved from the source using GTID auto-positioning, which automatically compares the source's transactions to the replica's transactions and identifies the missing transactions.
- For file position based replication, the recovery process needs an accurate replication SQL thread (applier) position showing the last transaction that was applied on the replica. Based on that position, the replication I/O thread (receiver) retrieves from the source's binary log all of the transactions that should be applied on the replica from that point on.

Using GTID-based replication makes it easiest to configure replication to be resilient to unexpected halts. GTID auto-positioning means the replica can reliably identify and retrieve missing transactions, even if there are gaps in the sequence of applied transactions.

The following information provides combinations of settings that are appropriate for different types of replica to guarantee recovery as far as this is under the control of replication.

### Important

Some factors outside the control of replication can have an impact on the replication recovery process and the overall state of replication after the recovery process. In particular, the settings that influence the recovery process for individual storage

engines might result in transactions being lost in the event of an unexpected halt of a replica, and therefore unavailable to the replication recovery process. The `innodb_flush_log_at_trx_commit=1` setting mentioned in the list below is a key setting for a replication setup that uses InnoDB with transactions. However, other settings specific to InnoDB or to other storage engines, especially those relating to flushing or synchronization, can also have an impact. Always check for and apply recommendations made by your chosen storage engines about crash-safe settings.

The following combination of settings on a replica is the most resilient to unexpected halts:

- When GTID-based replication is in use (`gtid_mode=ON`), set `SOURCE_AUTO_POSITION=1`, which activates GTID auto-positioning for the connection to the source to automatically identify and retrieve missing transactions. This option is set using a `CHANGE REPLICATION SOURCE TO` statement. If the replica has multiple replication channels, you need to set this option for each channel individually. For details of how GTID auto-positioning works, see [Section 19.1.3.3, “GTID Auto-Positioning”](#). When file position based replication is in use, `SOURCE_AUTO_POSITION=1` is not used, and instead the binary log position or relay log position is used to control where replication starts.
- When GTID-based replication is in use (`gtid_mode=ON`), set `GTID_ONLY=1`, which makes the replica use only GTIDs in the recovery process, and stop persisting binary log and relay log file names and file positions in the replication metadata repositories. This option is set using a `CHANGE REPLICATION SOURCE TO` statement. If the replica has multiple replication channels, you need to set this option for each channel individually. With `GTID_ONLY=1`, during recovery, the file position information is ignored and GTID auto-skip is used to skip transactions that have already been supplied, rather than identifying the correct file position. This strategy is more efficient provided that you purge relay logs using the default setting for `relay_log_purge`, which means only one relay log file needs to be inspected.
- Set `sync_relay_log=1`, which instructs the replication receiver thread to synchronize the relay log to disk after each received transaction is written to it. This means the replica's record of the current position read from the source's binary log (in the applier metadata repository) is never ahead of the record of transactions saved in the relay log. Note that although this setting is the safest, it is also the slowest due to the number of disk writes involved. With `sync_relay_log > 1`, or `sync_relay_log=0` (where synchronization is handled by the operating system), in the event of an unexpected halt of a replica there might be committed transactions that have not been synchronized to disk. Such transactions can cause the recovery process to fail if the recovering replica, based on the information it has in the relay log as last synchronized to disk, tries to retrieve and apply the transactions again instead of skipping them. Setting `sync_relay_log=1` is particularly important for a multi-threaded replica, where the recovery process fails if gaps in the sequence of transactions cannot be filled using the information in the relay log. For a single-threaded replica, the recovery process only needs to use the relay log if the relevant information is not available in the applier metadata repository.
- Set `innodb_flush_log_at_trx_commit=1`, which synchronizes the InnoDB logs to disk before each transaction is committed. This setting, which is the default, ensures that InnoDB tables and the InnoDB logs are saved on disk so that there is no longer a requirement for the information in the relay log regarding the transaction. Combined with the setting `sync_relay_log=1`, this setting further ensures that the content of the InnoDB tables and the InnoDB logs is consistent with the content of the relay log at all times, so that purging the relay log files cannot cause unfillable gaps in the replica's history of transactions in the event of an unexpected halt.
- Set `relay_log_info_repository = TABLE`, which stores the replication SQL thread position in the InnoDB table `mysql.slave_relay_log_info`, and updates it together with the transaction commit to ensure a record that is always accurate. This setting is the default; `FILE` is deprecated. The system variable itself is also deprecated, so omit it and allow it to assume the default. If `FILE` is used, the information is stored in a file in the data directory that is updated after the transaction

has been applied. This creates a risk of losing synchrony with the source depending at which stage of processing a transaction the replica halts at, or even corruption of the file itself. With `relay_log_info_repository = FILE`, recovery is not guaranteed.

- Set `relay_log_recovery = ON`, which enables automatic relay log recovery immediately following server startup. This global variable defaults to `OFF` and is read-only at runtime, but you can set it to `ON` with the `--relay-log-recovery` option at replica startup following an unexpected halt of a replica. Note that this setting ignores the existing relay log files, in case they are corrupted or inconsistent. The relay log recovery process starts a new relay log file and fetches transactions from the source beginning at the replication SQL thread position recorded in the applier metadata repository. The previous relay log files are removed over time by the replica's normal purge mechanism.

For a multithreaded replica, setting `relay_log_recovery = ON` automatically handles any inconsistencies and gaps in the sequence of transactions that have been executed from the relay log. These gaps can occur when file position based replication is in use. (For more details, see [Section 19.5.1.35, “Replication and Transaction Inconsistencies”](#).) The relay log recovery process deals with gaps using the same method as the `START REPLICA UNTIL SQL_AFTER_MTS_GAPS` statement would. When the replica reaches a consistent gap-free state, the relay log recovery process goes on to fetch further transactions from the source beginning at the replication SQL thread position. When GTID-based replication is in use, a multithreaded replica checks first whether `SOURCE_AUTO_POSITION` is set to `ON`, and if it is, omits the step of calculating the transactions that should be skipped or not skipped, so that the old relay logs are not required for the recovery process.

### 19.4.3 Monitoring Row-based Replication

The current progress of the replication applier (SQL) thread when using row-based replication is monitored through Performance Schema instrument stages, enabling you to track the processing of operations and check the amount of work completed and work estimated. When these Performance Schema instrument stages are enabled the `events_stages_current` table shows stages for applier threads and their progress. For background information, see [Section 29.12.5, “Performance Schema Stage Event Tables”](#).

To track progress of all three row-based replication event types (write, update, delete):

- Enable the three Performance Schema stages by issuing:

```
mysql> UPDATE performance_schema.setup_instruments SET ENABLED = 'YES'
-> WHERE NAME LIKE 'stage/sql/Applying batch of row changes%';
```

- Wait for some events to be processed by the replication applier thread and then check progress by looking into the `events_stages_current` table. For example to get progress for `update` events issue:

```
mysql> SELECT WORK_COMPLETED, WORK_ESTIMATED FROM performance_schema.events_stages_current
-> WHERE EVENT_NAME LIKE 'stage/sql/Applying batch of row changes (update)';
```

- If `binlog_rows_query_log_events` is enabled, information about queries is stored in the binary log and is exposed in the `processlist_info` field. To see the original query that triggered this event:

```
mysql> SELECT db, processlist_state, processlist_info FROM performance_schema.threads
-> WHERE processlist_state LIKE 'stage/sql/Applying batch of row changes%' AND thread_id = N;
```

### 19.4.4 Using Replication with Different Source and Replica Storage Engines

It does not matter for the replication process whether the original table on the source and the replicated table on the replica use different storage engine types. In fact, the `default_storage_engine` system variable is not replicated.

This provides a number of benefits in the replication process in that you can take advantage of different engine types for different replication scenarios. For example, in a typical scale-out scenario (see [Section 19.4.5, “Using Replication for Scale-Out”](#)), you want to use [InnoDB](#) tables on the source to take advantage of the transactional functionality, but use [MyISAM](#) on the replicas where transaction support is not required because the data is only read. When using replication in a data-logging environment you may want to use the [Archive](#) storage engine on the replica.

Configuring different engines on the source and replica depends on how you set up the initial replication process:

- If you used [mysqldump](#) to create the database snapshot on your source, you could edit the dump file text to change the engine type used on each table.

Another alternative for [mysqldump](#) is to disable engine types that you do not want to use on the replica before using the dump to build the data on the replica. For example, you can add the [--skip-federated](#) option on your replica to disable the [FEDERATED](#) engine. If a specific engine does not exist for a table to be created, MySQL uses the default engine type, usually [InnoDB](#). (This requires that the [NO\\_ENGINE\\_SUBSTITUTION](#) SQL mode is not enabled.) If you want to disable additional engines in this way, you may want to consider building a special binary to be used on the replica that supports only the engines you want.

- If you use raw data files (a binary backup) to set up the replica, it is not possible to change the initial table format. Instead, use [ALTER TABLE](#) to change the table types after the replica has been started.
- For new source/replica replication setups where there are currently no tables on the source, avoid specifying the engine type when creating new tables.

If you are already running a replication solution and want to convert your existing tables to another engine type, follow these steps:

1. Stop the replica from running replication updates:

```
mysql> STOP REPLICA;
```

This makes it possible to change engine types without interruption.

2. Execute an [ALTER TABLE ... ENGINE='engine\\_type'](#) for each table to be changed.
3. Start the replication process again:

```
mysql> START REPLICA;
```

Although the [default\\_storage\\_engine](#) variable is not replicated, be aware that [CREATE TABLE](#) and [ALTER TABLE](#) statements that include the engine specification are replicated to the replica correctly. If, in the case of a [CSV](#) table, you execute this statement:

```
mysql> ALTER TABLE csvtable ENGINE='MyISAM';
```

This statement is replicated; the table's engine type on the replica is converted to [InnoDB](#), even if you have previously changed the table type on the replica to an engine other than [CSV](#). If you want to retain engine differences on the source and replica, you should be careful to use the [default\\_storage\\_engine](#) variable on the source when creating a new table. For example, instead of:

```
mysql> CREATE TABLE tablea (columna int) Engine=MyISAM;
```

Use this format:

```
mysql> SET default_storage_engine=MyISAM;
mysql> CREATE TABLE tablea (columna int);
```

When replicated, the `default_storage_engine` variable is ignored, and the `CREATE TABLE` statement executes on the replica using the replica's default engine.

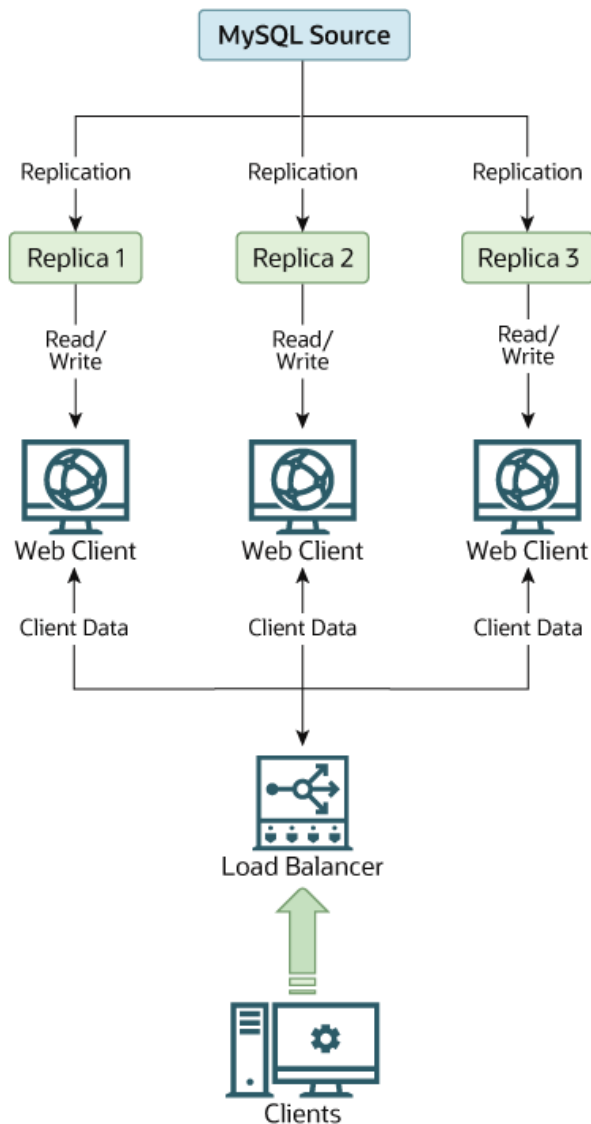

### 19.4.5 Using Replication for Scale-Out

You can use replication as a scale-out solution; that is, where you want to split up the load of database queries across multiple database servers, within some reasonable limitations.

Because replication works from the distribution of one source to one or more replicas, using replication for scale-out works best in an environment where you have a high number of reads and low number of writes/updates. Most websites fit into this category, where users are browsing the website, reading articles, posts, or viewing products. Updates only occur during session management, or when making a purchase or adding a comment/message to a forum.

Replication in this situation enables you to distribute the reads over the replicas, while still enabling your web servers to communicate with the source when a write is required. You can see a sample replication layout for this scenario in [Figure 19.1, “Using Replication to Improve Performance During Scale-Out”](#).

**Figure 19.1 Using Replication to Improve Performance During Scale-Out**

If the part of your code that is responsible for database access has been properly abstracted/modularized, converting it to run with a replicated setup should be very smooth and easy. Change the implementation of your database access to send all writes to the source, and to send reads to either the source or a replica. If your code does not have this level of abstraction, setting up a replicated system gives you the opportunity and motivation to clean it up. Start by creating a wrapper library or module that implements the following functions:

- `safe_writer_connect()`
- `safe_reader_connect()`
- `safe_reader_statement()`
- `safe_writer_statement()`

`safe_` in each function name means that the function takes care of handling all error conditions. You can use different names for the functions. The important thing is to have a unified interface for connecting for reads, connecting for writes, doing a read, and doing a write.

Then convert your client code to use the wrapper library. This may be a painful and scary process at first, but it pays off in the long run. All applications that use the approach just described are able to take advantage of a source/replica configuration, even one involving multiple replicas. The code is much easier to maintain, and adding troubleshooting options is trivial. You need modify only one or two functions (for example, to log how long each statement took, or which statement among those issued gave you an error).

If you have written a lot of code, you may want to automate the conversion task by writing a conversion script. Ideally, your code uses consistent programming style conventions. If not, then you are probably better off rewriting it anyway, or at least going through and manually regularizing it to use a consistent style.

## 19.4.6 Replicating Different Databases to Different Replicas

There may be situations where you have a single source server and want to replicate different databases to different replicas. For example, you may want to distribute different sales data to different departments to help spread the load during data analysis. A sample of this layout is shown in [Figure 19.2, “Replicating Databases to Separate Replicas”](#).

**Figure 19.2 Replicating Databases to Separate Replicas**

You can achieve this separation by configuring the source and replicas as normal, and then limiting the binary log statements that each replica processes by using the `--replicate-wild-do-table` configuration option on each replica.

### Important

You should *not* use `--replicate-do-db` for this purpose when using statement-based replication, since statement-based replication causes this option's effects to vary according to the database that is currently selected. This applies to mixed-format replication as well, since this enables some updates to be replicated using the statement-based format.

However, it should be safe to use `--replicate-do-db` for this purpose if you are using row-based replication only, since in this case the currently selected database has no effect on the option's operation.

For example, to support the separation as shown in [Figure 19.2, “Replicating Databases to Separate Replicas”](#), you should configure each replica as follows, before executing `START REPLICA`:

- Replica 1 should use `--replicate-wild-do-table=databaseA.%`.
- Replica 2 should use `--replicate-wild-do-table=databaseB.%`.
- Replica 3 should use `--replicate-wild-do-table=databaseC.%`.

Each replica in this configuration receives the entire binary log from the source, but executes only those events from the binary log that apply to the databases and tables included by the `--replicate-wild-do-table` option in effect on that replica.

If you have data that must be synchronized to the replicas before replication starts, you have a number of choices:

- Synchronize all the data to each replica, and delete the databases, tables, or both that you do not want to keep.
- Use `mysqldump` to create a separate dump file for each database and load the appropriate dump file on each replica.
- Use a raw data file dump and include only the specific files and databases that you need for each replica.

### Note

This does not work with `InnoDB` databases unless you use `innodb_file_per_table`.

## 19.4.7 Improving Replication Performance

As the number of replicas connecting to a source increases, the load, although minimal, also increases, as each replica uses a client connection to the source. Also, as each replica must receive a full copy of the source's binary log, the network load on the source may also increase and create a bottleneck.

If you are using a large number of replicas connected to one source, and that source is also busy processing requests (for example, as part of a scale-out solution), then you may want to improve the performance of the replication process.

One way to improve the performance of the replication process is to create a deeper replication structure that enables the source to replicate to only one replica, and for the remaining replicas to connect to this primary replica for their individual replication requirements. A sample of this structure is shown in [Figure 19.3, “Using an Additional Replication Source to Improve Performance”](#).

**Figure 19.3 Using an Additional Replication Source to Improve Performance**

For this to work, you must configure the MySQL instances as follows:

- Source 1 is the primary source where all changes and updates are written to the database. Binary logging is enabled on both source servers, which is the default.
- Source 2 is the replica to the server Source 1 that provides the replication functionality to the remainder of the replicas in the replication structure. Source 2 is the only machine permitted to connect to Source 1. Source 2 has the `--log-replica-updates` option enabled (the default). With this option, replication instructions from Source 1 are also written to Source 2's binary log so that they can then be replicated to the true replicas.
- Replica 1, Replica 2, and Replica 3 act as replicas to Source 2, and replicate the information from Source 2, which actually consists of the upgrades logged on Source 1.

The above solution reduces the client load and the network interface load on the primary source, which should improve the overall performance of the primary source when used as a direct database solution.

If your replicas are having trouble keeping up with the replication process on the source, there are a number of options available:

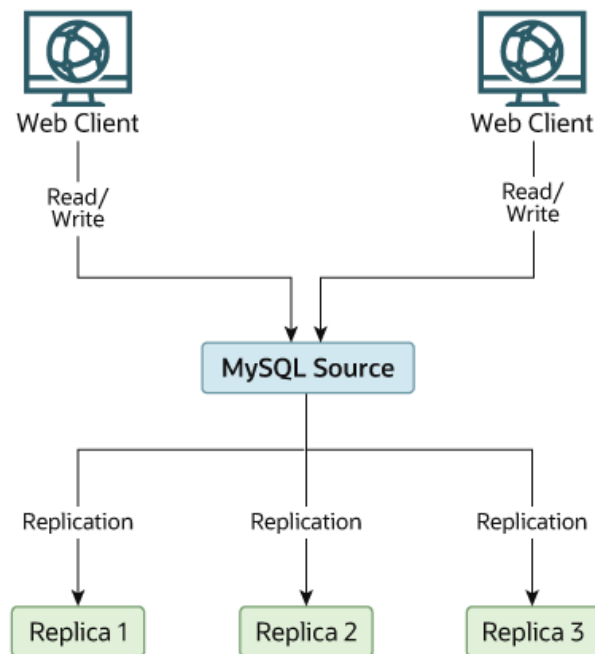

- If possible, put the relay logs and the data files on different physical drives. To do this, set the `relay_log` system variable to specify the location of the relay log.
- If heavy disk I/O activity for reads of the binary log file and relay log files is an issue, consider increasing the value of the `rpl_read_size` system variable. This system variable controls the minimum amount of data read from the log files, and increasing it might reduce file reads and I/O stalls when the file data is not currently cached by the operating system. Note that a buffer the size of this value is allocated for each thread that reads from the binary log and relay log files, including dump threads on sources and coordinator threads on replicas. Setting a large value might therefore have an impact on memory consumption for servers.
- If the replicas are significantly slower than the source, you may want to divide up the responsibility for replicating different databases to different replicas. See [Section 19.4.6, “Replicating Different Databases to Different Replicas”](#).
- If your source makes use of transactions and you are not concerned about transaction support on your replicas, use `MyISAM` or another nontransactional engine on the replicas. See [Section 19.4.4, “Using Replication with Different Source and Replica Storage Engines”](#).
- If your replicas are not acting as sources, and you have a potential solution in place to ensure that you can bring up a source in the event of failure, then you can disable `log_replica_updates`. This prevents “dumb” replicas from also logging events they have executed into their own binary log.

## 19.4.8 Switching Sources During Failover

You can tell a replica to change to a new source using the `CHANGE REPLICATION SOURCE TO` statement. The replica does not check whether the databases on the source are compatible with those on the replica; it simply begins reading and executing events from the specified coordinates in the new source's binary log. In a failover situation, all the servers in the group are typically executing the same events from the same binary log file, so changing the source of the events should not affect the structure or integrity of the database, provided that you exercise care in making the change.

Replicas should be run with binary logging enabled (the `--log-bin` option), which is the default. If you are not using GTIDs for replication, then the replicas should also be run with `--log-replica-updates=OFF` (logging replica updates is the default). In this way, the replica is ready to become a source without restarting the replica `mysqld`. Assume that you have the structure shown in [Figure 19.4, “Redundancy Using Replication, Initial Structure”](#).

**Figure 19.4 Redundancy Using Replication, Initial Structure**

In this diagram, the `Source` holds the source database, the `Replica*` hosts are replicas, and the `Web Client` machines are issuing database reads and writes. Web clients that issue only reads (and would normally be connected to the replicas) are not shown, as they do not need to switch to a new server in the event of failure. For a more detailed example of a read/write scale-out replication structure, see [Section 19.4.5, “Using Replication for Scale-Out”](#).

Each MySQL replica (`Replica 1`, `Replica 2`, and `Replica 3`) is a replica running with binary logging enabled, and with `--log-replica-updates=OFF`. Because updates received by a replica from the source are not written to the binary log when `--log-replica-updates=OFF` is specified, the binary log on each replica is initially empty. If for some reason `Source` becomes unavailable, you can pick one of the replicas to become the new source. For example, if you pick `Replica 1`, all `Web Clients` should be redirected to `Replica 1`, which writes the updates to its binary log. `Replica 2` and `Replica 3` should then replicate from `Replica 1`.

The reason for running the replica with `--log-replica-updates=OFF` is to prevent replicas from receiving updates twice in case you cause one of the replicas to become the new source. If `Replica 1` has `--log-replica-updates` enabled, which is the default, it writes any updates that it receives from

`Source` in its own binary log. This means that, when `Replica 2` changes from `Source` to `Replica 1` as its source, it may receive updates from `Replica 1` that it has already received from `Source`.

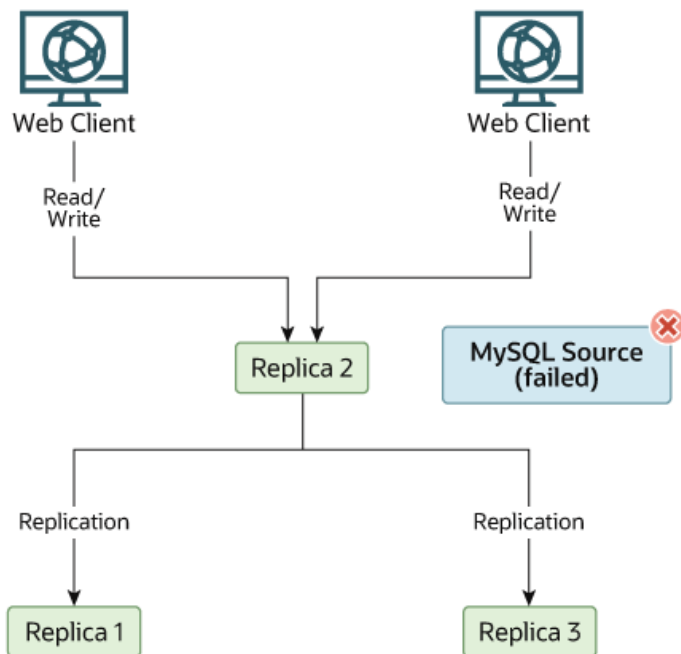

Make sure that all replicas have processed any statements in their relay log. On each replica, issue `STOP REPLICATION IO_THREAD`, then check the output of `SHOW PROCESSLIST` until you see `Has read all relay log`. When this is true for all replicas, they can be reconfigured to the new setup. On the replica `Replica 1` being promoted to become the source, issue `STOP REPLICATION` and `RESET BINARY LOGS AND GTIDS`.

On the other replicas `Replica 2` and `Replica 3`, use `STOP REPLICATION` and `CHANGE REPLICATION SOURCE TO SOURCE_HOST='Replica1'` (where `'Replica1'` represents the real host name of `Replica 1`). To use `CHANGE REPLICATION SOURCE TO`, add all information about how to connect to `Replica 1` from `Replica 2` or `Replica 3` (`user`, `password`, `port`). When issuing the statement in this scenario, there is no need to specify the name of the `Replica 1` binary log file or log position to read from, since the first binary log file and position 4 are the defaults. Finally, execute `START REPLICATION` on `Replica 2` and `Replica 3`.

Once the new replication setup is in place, you need to tell each `Web Client` to direct its statements to `Replica 1`. From that point on, all updates sent by `Web Client` to `Replica 1` are written to the binary log of `Replica 1`, which then contains every update sent to `Replica 1` since `Source` became unavailable.

The resulting server structure is shown in [Figure 19.5, “Redundancy Using Replication, After Source Failure”](#).

**Figure 19.5 Redundancy Using Replication, After Source Failure**

When `Source` becomes available again, you should make it a replica of `Replica 1`. To do this, issue on `Source` the same `CHANGE REPLICATION SOURCE TO` statement as that issued on `Replica 2` and `Replica 3` previously. `Source` then becomes a replica of `Replica 1` and picks up the `Web Client` writes that it missed while it was offline.

To make `Source` a source again, use the preceding procedure as if `Replica 1` were unavailable and `Source` were to be the new source. During this procedure, do not forget to run `RESET BINARY LOGS`

`AND GTIDS` on `Source` before making `Replica 1`, `Replica 2`, and `Replica 3` replicas of `Source`. If you fail to do this, the replicas may pick up stale writes from the `Web Client` applications dating from before the point at which `Source` became unavailable.

You should be aware that there is no synchronization between replicas, even when they share the same source, and thus some replicas might be considerably ahead of others. This means that in some cases the procedure outlined in the previous example might not work as expected. In practice, however, relay logs on all replicas should be relatively close together.

One way to keep applications informed about the location of the source is to have a dynamic DNS entry for the source host. With `BIND`, you can use `nsupdate` to update the DNS dynamically.

## 19.4.9 Switching Sources and Replicas with Asynchronous Connection Failover

You can use the asynchronous connection failover mechanism to establish an asynchronous (source-to-replica) replication connection to a new source automatically, after the existing connection from a replica to its source fails. The asynchronous connection failover mechanism can be used to keep a replica synchronized with multiple MySQL servers or groups of servers that share data. The list of potential source servers is stored on the replica, and in the event of a connection failure, a new source is selected from the list based on a weighted priority that you set.

The asynchronous connection failover mechanism also supports Group Replication topologies, by automatically monitoring changes to group membership and distinguishing between primary and secondary servers. When you add a group member to the source list and define it as part of a managed group, the asynchronous connection failover mechanism updates the source list to keep it in line with membership changes, adding and removing group members automatically as they join or leave. Only online group members that are in the majority are used for connections and obtaining status. The last remaining member of a managed group is not removed automatically even if it leaves the group, so that the configuration of the managed group is kept. However, you can delete a managed group manually if it is no longer needed.

The asynchronous connection failover mechanism also enables a replica that is part of a managed replication group to automatically reconnect to the sender if the current receiver (the primary of the group) fails. This feature works with Group Replication, on a group configured in single-primary mode, where the group's primary is a replica that has a replication channel using the mechanism. The feature is designed for a group of senders and a group of receivers to keep synchronized with each other even when some members are temporarily unavailable. It also synchronizes a group of receivers with one or more senders that are not part of a managed group. A replica that is not part of a replication group cannot use this feature.

The requirements for using the asynchronous connection failover mechanism are as follows:

- GTIDs must be in use on the source and the replica (`gtid_mode=ON`), and the `SOURCE_AUTO_POSITION` option of the `CHANGE REPLICATION SOURCE TO` statement must be enabled on the replica, so that GTID auto-positioning is used for the connection to the source.
- The same replication user account and password must exist on all the source servers in the source list for the channel. This account is used for the connection to each of the sources. You can set up different accounts for different channels.
- The replication user account must be given `SELECT` permissions on the Performance Schema tables, for example, by issuing `GRANT SELECT ON performance_schema.* TO 'repl_user';`
- The replication user account and password cannot be specified on the statement used to start replication, because they need to be available on the automatic restart for the connection to the

alternative source. They must be set for the channel using the `CHANGE REPLICATION SOURCE TO` statement on the replica, and recorded in the replication metadata repositories.

- If the channel where the asynchronous connection failover mechanism is in use is on the primary of a Group Replication single-primary mode group, asynchronous connection failover between replicas is also active by default. In this situation, the replication channel and the replication user account and password for the channel must be set up on all the secondary servers in the replication group, and on any new joining members. If the new servers are provisioned using MySQL's clone functionality, this all happens automatically.

#### Important

If you do not want asynchronous connection failover to take place between replicas in this situation, disable it by disabling the member action `mysql_start_failover_channels_if_primary` for the group, using the `group_replication_disable_member_action` function. When the feature is disabled, you do not need to configure the replication channel on the secondary group members, but if the primary goes offline or into an error state, replication stops for the channel.

MySQL InnoDB ClusterSet is available to provide disaster tolerance for InnoDB Cluster deployments by linking a primary InnoDB Cluster with one or more replicas of itself in alternate locations, such as different datacenters. Consider using this solution instead to simplify the setup of a new multi-group deployment for replication, failover, and disaster recovery. You can adopt an existing Group Replication deployment as an InnoDB Cluster.

InnoDB ClusterSet and InnoDB Cluster are designed to abstract and simplify the procedures for setting up, managing, monitoring, recovering, and repairing replication groups. InnoDB ClusterSet automatically manages replication from a primary cluster to replica clusters using a dedicated ClusterSet replication channel. You can use administrator commands to trigger a controlled switchover or emergency failover between groups if the primary cluster is not functioning normally. Servers and groups can easily be added to or removed from the InnoDB ClusterSet deployment after the initial setup when demand changes. For more information, see [MySQL InnoDB ClusterSet](#).

### 19.4.9.1 Asynchronous Connection Failover for Sources

To activate asynchronous connection failover for a replication channel set `SOURCE_CONNECTION_AUTO_FAILOVER=1` in a `CHANGE REPLICATION SOURCE TO` statement for this channel. GTID auto-positioning must be in use for the channel (`SOURCE_AUTO_POSITION = 1`).

#### Important

When the existing connection to a source fails, the replica first retries the same connection the number of times specified by the `SOURCE_RETRY_COUNT` option of the `CHANGE REPLICATION SOURCE TO`. The interval between attempts is set by the `SOURCE_CONNECT_RETRY` option. When these attempts are exhausted, the asynchronous connection failover mechanism takes over. Note that the defaults for these options, which were designed for a connection to a single source, make the replica retry the same connection for 60 days. To ensure that the asynchronous connection failover mechanism can be activated promptly, set `SOURCE_RETRY_COUNT` and `SOURCE_CONNECT_RETRY` to minimal numbers that just allow a few retry attempts with the same source, in case the connection failure is caused by a transient network outage. Suitable values are `SOURCE_RETRY_COUNT=3` and `SOURCE_CONNECT_RETRY=10`, which make the replica retry the connection 3 times with 10-second intervals between.

You also need to set the source list for the replication channel, to specify the sources that are available for failover. You set and manage source lists using the `asynchronous_connection_failover_add_source` and `asynchronous_connection_failover_delete_source` functions to add and remove single replication source servers. To add and remove managed groups of servers, use the `asynchronous_connection_failover_add_managed` and `asynchronous_connection_failover_delete_managed` functions instead.

The functions name the relevant replication channel and specify the host name, port number, network namespace, and weighted priority (1-100, with 100 being the highest priority) of a MySQL instance to add to or delete from the channel's source list. For a managed group, you also specify the type of managed service (currently only Group Replication is available), and the identifier of the managed group (for Group Replication, this is the value of the `group_replication_group_name` system variable). When you add a managed group, you only need to add one group member, and the replica automatically adds the rest from the current group membership. When you delete a managed group, you delete the entire group together.

The asynchronous connection failover mechanism also fails over the connection if another available server on the source list has a higher priority (weight) setting. This feature ensures that the replica stays connected to the most suitable source server at all times, and it applies to both managed groups and single (non-managed) servers. For a managed group, a source's weight is assigned depending on whether it is a primary or a secondary server. So assuming that you set up the managed group to give a higher weight to a primary and a lower weight to a secondary, when the primary changes, the higher weight is assigned to the new primary, so the replica changes over the connection to it. The asynchronous connection failover mechanism additionally changes connection if the currently connected managed source server leaves the managed group, or is no longer in the majority in the managed group.

When failing over a connection, the source with the highest priority (weight) setting among the alternative sources listed in the source list for the channel is chosen for the first connection attempt. The replica checks first that it can connect to the source server, or in the case of a managed group, that the source server has `ONLINE` status in the group (not `RECOVERING` or unavailable). If the highest weighted source is not available, the replica tries with all the listed sources in descending order of weight, then starts again from the highest weighted source. If multiple sources have the same weight, the replica orders them randomly. If the replica needs to start working through the list again, it includes and retries the source to which the original connection failure occurred.

The source lists are stored in the `mysql.replication_asynchronous_connection_failover` and `mysql.replication_asynchronous_connection_failover_managed` tables, and can be viewed in the Performance Schema `replication_asynchronous_connection_failover` and `replication_asynchronous_connection_failover_managed` tables. The replica uses a monitor thread to track the membership of managed groups and update the source list (`thread/sql/replica_monitor`). The setting for the `SOURCE_CONNECTION_AUTO_FAILOVER` option of the `CHANGE REPLICATION SOURCE TO` statement, and the source list, are transferred to a clone of the replica during a remote cloning operation.

### 19.4.9.2 Asynchronous Connection Failover for Replicas

Asynchronous connection failover for replicas is activated automatically for a replication channel on a Group Replication primary when you set `SOURCE_CONNECTION_AUTO_FAILOVER=1` in the `CHANGE REPLICATION SOURCE TO` statement for the channel. The feature is designed for a group of senders and a group of receivers to keep synchronized with each other even when some members are temporarily unavailable. When the feature is active and correctly configured, if the primary that is replicating goes offline or into an error state, the new primary starts replication on the same channel when it is elected.

The new primary uses the source list for the channel to select the source with the highest priority (weight) setting, which might not be the same as the original source.

To configure this feature, the replication channel and the replication user account and password for the channel must be set up on all the member servers in the replication group, and on any new joining members. Ensure that `SOURCE_RETRY_COUNT` and `SOURCE_CONNECT_RETRY` are set to minimal numbers that just allow a few retry attempts, for example 3 and 10. You can set up the replication channel using `CHANGE REPLICATION SOURCE TO`, or if the new servers are provisioned using MySQL's clone functionality, this all happens automatically. The `SOURCE_CONNECTION_AUTO_FAILOVER` setting for the channel is broadcast to group members from the primary when they join. If you later disable `SOURCE_CONNECTION_AUTO_FAILOVER` for the channel on the primary, this is also broadcast to the secondary servers, and they change the status of the channel to match.

Asynchronous connection failover for replicas is activated and deactivated using the Group Replication member action `mysql_start_failover_channels_if_primary`, which is enabled by default. You can disable it for the whole group by disabling that member action on the primary, using the `group_replication_disable_member_action` function, as in this example:

```
mysql> SELECT group_replication_disable_member_action("mysql_start_failover_channels_if_primary", "AFTER_PRIMA
```

The function can only be changed on a primary, and must be enabled or disabled for the whole group, so you cannot have some members providing failover and others not. When the `mysql_start_failover_channels_if_primary` member action is disabled, the channel does not need to be configured on secondary members, but if the primary goes offline or into an error state, replication stops for the channel. Note that if there is more than one channel with `SOURCE_CONNECTION_AUTO_FAILOVER=1`, the member action covers all the channels, so they cannot be individually enabled and disabled by that method. Set `SOURCE_CONNECTION_AUTO_FAILOVER=0` on the primary to disable an individual channel.

The source list for a channel with `SOURCE_CONNECTION_AUTO_FAILOVER=1` is broadcast to all group members when they join, and also when it changes. This is the case whether the sources are a managed group for which the membership is updated automatically, or whether they are added or changed manually using `asynchronous_connection_failover_add_source()`, `asynchronous_connection_failover_delete_source()`, `asynchronous_connection_failover_add_managed()`, or `asynchronous_connection_failover_delete_managed()`. All group members receive the current source list as recorded in the `mysql.replication_asynchronous_connection_failover` and `mysql.replication_asynchronous_connection_failover_managed` tables. Because the sources do not have to be in a managed group, you can set up the function to synchronize a group of receivers with one or more alternative standalone senders, or even a single sender. A standalone replica that is not part of a replication group cannot use this feature.

## 19.4.10 Semisynchronous Replication

In addition to the built-in asynchronous replication, MySQL 9.1 supports an interface to semisynchronous replication that is implemented by plugins. This section discusses what semisynchronous replication is and how it works. The following sections cover the administrative interface to semisynchronous replication and how to install, configure, and monitor it.

MySQL replication by default is asynchronous. The source writes events to its binary log and replicas request them when they are ready. The source does not know whether or when a replica has retrieved and processed the transactions, and there is no guarantee that any event ever reaches any replica. With asynchronous replication, if the source crashes, transactions that it has committed might not have been transmitted to any replica. Failover from source to replica in this case might result in failover to a server that is missing transactions relative to the source.

With fully synchronous replication, when a source commits a transaction, all replicas have also committed the transaction before the source returns to the session that performed the transaction. Fully synchronous replication means failover from the source to any replica is possible at any time. The drawback of fully synchronous replication is that there might be a lot of delay to complete a transaction.

Semisynchronous replication falls between asynchronous and fully synchronous replication. The source waits until at least one replica has received and logged the events (the required number of replicas is configurable), and then commits the transaction. The source does not wait for all replicas to acknowledge receipt, and it requires only an acknowledgement from the replicas, not that the events have been fully executed and committed on the replica side. Semisynchronous replication therefore guarantees that if the source crashes, all the transactions that it has committed have been transmitted to at least one replica.

Compared to asynchronous replication, semisynchronous replication provides improved data integrity, because when a commit returns successfully, it is known that the data exists in at least two places. Until a semisynchronous source receives acknowledgment from the required number of replicas, the transaction is on hold and not committed.

Compared to fully synchronous replication, semisynchronous replication is faster, because it can be configured to balance your requirements for data integrity (the number of replicas acknowledging receipt of the transaction) with the speed of commits, which are slower due to the need to wait for replicas.

### Important

With semisynchronous replication, if the source crashes and a failover to a replica is carried out, the failed source should not be reused as the replication source, and should be discarded. It could have transactions that were not acknowledged by any replica, which were therefore not committed before the failover.

If your goal is to implement a fault-tolerant replication topology where all the servers receive the same transactions in the same order, and a server that crashes can rejoin the group and be brought up to date automatically, you can use Group Replication to achieve this. For information, see [Chapter 20, Group Replication](#).

The performance impact of semisynchronous replication compared to asynchronous replication is the tradeoff for increased data integrity. The amount of slowdown is at least the TCP/IP roundtrip time to send the commit to the replica and wait for the acknowledgment of receipt by the replica. This means that semisynchronous replication works best for close servers communicating over fast networks, and worst for distant servers communicating over slow networks. Semisynchronous replication also places a rate limit on busy sessions by constraining the speed at which binary log events can be sent from source to replica. When one user is too busy, this slows it down, which can be useful in some deployment situations.

Semisynchronous replication between a source and its replicas operates as follows:

- A replica indicates whether it is semisynchronous-capable when it connects to the source.
- If semisynchronous replication is enabled on the source side and there is at least one semisynchronous replica, a thread that performs a transaction commit on the source blocks and waits until at least one semisynchronous replica acknowledges that it has received all events for the transaction, or until a timeout occurs.
- The replica acknowledges receipt of a transaction's events only after the events have been written to its relay log and flushed to disk.
- If a timeout occurs without any replica having acknowledged the transaction, the source reverts to asynchronous replication. When at least one semisynchronous replica catches up, the source returns to semisynchronous replication.

- Semisynchronous replication must be enabled on both the source and replica sides. If semisynchronous replication is disabled on the source, or enabled on the source but on no replicas, the source uses asynchronous replication.

While the source is blocking (waiting for acknowledgment from a replica), it does not return to the session that performed the transaction. When the block ends, the source returns to the session, which then can proceed to execute other statements. At this point, the transaction has committed on the source side, and receipt of its events has been acknowledged by at least one replica. The number of replica acknowledgments the source must receive per transaction before returning to the session is configurable, and defaults to one acknowledgement (see [Section 19.4.10.2, “Configuring Semisynchronous Replication”](#)).

Blocking also occurs after rollbacks that are written to the binary log, which occurs when a transaction that modifies nontransactional tables is rolled back. The rolled-back transaction is logged even though it has no effect for transactional tables because the modifications to the nontransactional tables cannot be rolled back and must be sent to replicas.

For statements that do not occur in transactional context (that is, when no transaction has been started with `START TRANSACTION` or `SET autocommit = 0`), autocommit is enabled and each statement commits implicitly. With semisynchronous replication, the source blocks for each such statement, just as it does for explicit transaction commits.

By default, the source waits for replica acknowledgment of the transaction receipt after syncing the binary log to disk, but before committing the transaction to the storage engine. As an alternative, you can configure the source so that the source waits for replica acknowledgment after committing the transaction to the storage engine, using the `rpl_semi_sync_source_wait_point` system variable. This setting affects the replication characteristics and the data that clients can see on the source. For more information, see [Section 19.4.10.2, “Configuring Semisynchronous Replication”](#).

You can improve the performance of semisynchronous replication by enabling the system variables `replication_sender_observe_commit_only`, which limits callbacks, and `replication_optimize_for_static_plugin_config`, which adds shared locks and avoids unnecessary lock acquisitions. These settings help as the number of replicas increases, because contention for locks can slow down performance. Semisynchronous replication source servers can also get performance benefits from enabling these system variables, because they use the same locking mechanisms as the replicas.

### 19.4.10.1 Installing Semisynchronous Replication

Semisynchronous replication is implemented using plugins, which must be installed on the source and on the replicas to make semisynchronous replication available on the instances. There are different plugins for a source and for a replica. After a plugin has been installed, you control it by means of the system variables associated with it. These system variables are available only when the associated plugin has been installed.

This section describes how to install the semisynchronous replication plugins. For general information about installing plugins, see [Section 7.6.1, “Installing and Uninstalling Plugins”](#).

To use semisynchronous replication, the following requirements must be satisfied:

- The capability of installing plugins requires a MySQL server that supports dynamic loading. To verify this, check that the value of the `have_dynamic_loading` system variable is `YES`. Binary distributions should support dynamic loading.
- Replication must already be working, see [Section 19.1, “Configuring Replication”](#).

- There must not be multiple replication channels configured. Semisynchronous replication is only compatible with the default replication channel. See [Section 19.2.2, “Replication Channels”](#).

The file name suffix for the plugin library files differs per platform (for example, `.so` for Unix and Unix-like systems, and `.dll` for Windows). The plugin and library file names are as follows:

- Source server: `rpl_semi_sync_source` plugin (`semisync_source.so` or `semisync_source.dll` library)
- Replica: `rpl_semi_sync_replica` plugin (`semisync_replica.so` or `semisync_replica.dll` library)

To be usable by a source or replica server, the appropriate plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup. The source plugin library file must be present in the plugin directory of the source server. The replica plugin library file must be present in the plugin directory of each replica server.

To set up semisynchronous replication, use the following instructions. The `INSTALL PLUGIN`, `SET GLOBAL`, `STOP REPLICA`, and `START REPLICA` statements mentioned here require the `REPLICATION_SLAVE_ADMIN` privilege (or the deprecated `SUPER` privilege).

To load the plugins, use the `INSTALL PLUGIN` statement on the source and on each replica that is to be semisynchronous, adjusting the `.so` suffix for your platform as necessary.

On the source:

```
INSTALL PLUGIN rpl_semi_sync_source SONAME 'semisync_source.so';
```

On each replica:

```
INSTALL PLUGIN rpl_semi_sync_replica SONAME 'semisync_replica.so';
```

If an attempt to install a plugin results in an error on Linux similar to that shown here, you must install `libimf`:

```
mysql> INSTALL PLUGIN rpl_semi_sync_source SONAME 'semisync_source.so';
ERROR 1126 (HY000): Can't open shared library
'/usr/local/mysql/lib/plugin/semisync_source.so'
(errno: 22 libimf.so: cannot open shared object file:
No such file or directory)
```

You can obtain `libimf` from <https://dev.mysql.com/downloads/os-linux.html>.

To verify plugin installation, examine the Information Schema `PLUGINS` table or use the `SHOW PLUGINS` statement (see [Section 7.6.2, “Obtaining Server Plugin Information”](#)). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
FROM INFORMATION_SCHEMA.PLUGINS
WHERE PLUGIN_NAME LIKE '%semi%';
+-----+-----+
| PLUGIN_NAME | PLUGIN_STATUS |
+-----+-----+
| rpl_semi_sync_source | ACTIVE |
+-----+-----+
```

If a plugin fails to initialize, check the server error log for diagnostic messages.

After a semisynchronous replication plugin has been installed, it is disabled by default. The plugins must be enabled both on the source side and the replica side to enable semisynchronous replication. If only one

side is enabled, replication is asynchronous. To enable the plugins, set the appropriate system variable either at runtime using `SET GLOBAL`, or at server startup on the command line or in an option file. For example:

```
SET GLOBAL rpl_semi_sync_source_enabled = 1;
```

```
SET GLOBAL rpl_semi_sync_replica_enabled = 1;
```

If you enable semisynchronous replication on a replica at runtime, you must also start the replication I/O (receiver) thread (stopping it first if it is already running) to cause the replica to connect to the source and register as a semisynchronous replica:

```
STOP REPLICATION IO_THREAD;
START REPLICATION IO_THREAD;
```

If the replication I/O (receiver) thread is already running and you do not restart it, the replica continues to use asynchronous replication.

A setting listed in an option file takes effect each time the server starts. For example, you can set the variables in `my.cnf` files on the source and replica servers as follows. On the source:

```
[mysqld]
rpl_semi_sync_source_enabled=1
```

On each replica:

```
[mysqld]
rpl_semi_sync_replica_enabled=1
```

You can configure the behavior of the semisynchronous replication plugins using the system variables that become available when you install the plugins. For information on key system variables, see [Section 19.4.10.2, “Configuring Semisynchronous Replication”](#).

## 19.4.10.2 Configuring Semisynchronous Replication

When you install the source and replica plugins for semisynchronous replication (see [Section 19.4.10.1, “Installing Semisynchronous Replication”](#)), system variables become available to control plugin behavior.

To check the current values of the status variables for semisynchronous replication, use `SHOW VARIABLES`:

```
mysql> SHOW VARIABLES LIKE 'rpl_semi_sync%';
```

All the `rpl_semi_sync_XXX` system variables are described at [Section 19.1.6.2, “Replication Source Options and Variables”](#) and [Section 19.1.6.3, “Replica Server Options and Variables”](#). Some key system variables are:

`rpl_semi_sync_source_enabled` Controls whether semisynchronous replication is enabled on the source server. To enable or disable the plugin, set this variable to 1 or 0, respectively. The default is 0 (off).

`rpl_semi_sync_replica_enabled` Controls whether semisynchronous replication is enabled on the replica.

`rpl_semi_sync_source_timeout` A value in milliseconds that controls how long the source waits on a commit for acknowledgment from a replica before timing out and reverting to asynchronous replication. The default value is 10000 (10 seconds).

`rpl_semi_sync_source_wait_count` Controls the number of replica acknowledgments the source must receive per transaction before returning to the session. The default is

1, meaning that the source only waits for one replica to acknowledge receipt of the transaction's events.

The `rpl_semi_sync_source_wait_point` system variable controls the point at which a semisynchronous source server waits for replica acknowledgment of transaction receipt before returning a status to the client that committed the transaction. These values are permitted:

- `AFTER_SYNC` (the default): The source writes each transaction to its binary log and the replica, and syncs the binary log to disk. The source waits for replica acknowledgment of transaction receipt after the sync. Upon receiving acknowledgment, the source commits the transaction to the storage engine and returns a result to the client, which then can proceed.
- `AFTER_COMMIT`: The source writes each transaction to its binary log and the replica, syncs the binary log, and commits the transaction to the storage engine. The source waits for replica acknowledgment of transaction receipt after the commit. Upon receiving acknowledgment, the source returns a result to the client, which then can proceed.

The replication characteristics of these settings differ as follows:

- With `AFTER_SYNC`, all clients see the committed transaction at the same time, which is after it has been acknowledged by the replica and committed to the storage engine on the source. Thus, all clients see the same data on the source.

In the event of source failure, all transactions committed on the source have been replicated to the replica (saved to its relay log). An unexpected exit of the source and failover to the replica is lossless because the replica is up to date. As noted above, the source should not be reused after the failover.

- With `AFTER_COMMIT`, the client issuing the transaction gets a return status only after the server commits to the storage engine and receives replica acknowledgment. After the commit and before replica acknowledgment, other clients can see the committed transaction before the committing client.

If something goes wrong such that the replica does not process the transaction, then in the event of an unexpected source exit and failover to the replica, it is possible for such clients to see a loss of data relative to what they saw on the source.

You can improve the performance of semisynchronous replication by enabling the system variables `replication_sender_observe_commit_only`, which limits callbacks, and `replication_optimize_for_static_plugin_config`, which adds shared locks and avoids unnecessary lock acquisitions. These settings help as the number of replicas increases, because contention for locks can slow down performance. Semisynchronous replication source servers can also get performance benefits from enabling these system variables, because they use the same locking mechanisms as the replicas.

### 19.4.10.3 Semisynchronous Replication Monitoring

The plugins for semisynchronous replication expose a number of status variables that enable you to monitor their operation. To check the current values of the status variables, use `SHOW STATUS`:

```
mysql> SHOW STATUS LIKE 'Rpl_semi_sync%';
```

All `Rpl_semi_sync_xxx` status variables are described at [Section 7.1.10, “Server Status Variables”](#). Some examples are:

- `Rpl_semi_sync_source_clients`

The number of semisynchronous replicas that are connected to the source server.

- `Rpl_semi_sync_source_status`

Whether semisynchronous replication currently is operational on the source server. The value is 1 if the plugin has been enabled and a commit acknowledgment has not occurred. It is 0 if the plugin is not enabled or the source has fallen back to asynchronous replication due to commit acknowledgment timeout.

- `Rpl_semi_sync_source_no_tx`

The number of commits that were not acknowledged successfully by a replica.

- `Rpl_semi_sync_source_yes_tx`

The number of commits that were acknowledged successfully by a replica.

- `Rpl_semi_sync_replica_status`

Whether semisynchronous replication currently is operational on the replica. This is 1 if the plugin has been enabled and the replication I/O (receiver) thread is running, 0 otherwise.

When the source switches between asynchronous or semisynchronous replication due to commit-blocking timeout or a replica catching up, it sets the value of the `Rpl_semi_sync_source_status` status variable appropriately. Automatic fallback from semisynchronous to asynchronous replication on the source means that it is possible for the `rpl_semi_sync_source_enabled` system variable to have a value of 1 on the source side even when semisynchronous replication is in fact not operational at the moment. You can monitor the `Rpl_semi_sync_source_status` status variable to determine whether the source currently is using asynchronous or semisynchronous replication.

## 19.4.11 Delayed Replication

MySQL supports delayed replication such that a replica server deliberately executes transactions later than the source by at least a specified amount of time. This section describes how to configure a replication delay on a replica, and how to monitor replication delay.

In MySQL 9.1, the method of delaying replication depends on two timestamps, `immediate_commit_timestamp` and `original_commit_timestamp` (see [Replication Delay Timestamps](#)); delayed replication is measured using these timestamps. If either the immediate source or replica is not using these timestamps, the implementation of delayed replication from MySQL 5.7 is used (see [Delayed Replication](#)). This section describes delayed replication between servers which are all using these timestamps.

The default replication delay is 0 seconds. Use a `CHANGE REPLICATION SOURCE TO SOURCE_DELAY=N` statement to set the delay to *N* seconds. A transaction received from the source is not executed until at least *N* seconds later than its commit on the immediate source. The delay happens per transaction (not event as in previous MySQL versions) and the actual delay is imposed only on `gtid_log_event` or `anonymous_gtid_log_event`. The other events in the transaction always follow these events without any waiting time imposed on them.

### Note

`START REPLICATION` and `STOP REPLICATION` take effect immediately and ignore any delay. `RESET REPLICATION` resets the delay to 0.

The `replication_applier_configuration` Performance Schema table contains the `DESIRED_DELAY` column which shows the delay configured using the `SOURCE_DELAY` option. The `replication_applier_status` Performance Schema table contains the `REMAINING_DELAY` column which shows the number of delay seconds remaining.

Delayed replication can be used for several purposes:

- To protect against user mistakes on the source. With a delay you can roll back a delayed replica to the time just before the mistake.
- To test how the system behaves when there is a lag. For example, in an application, a lag might be caused by a heavy load on the replica. However, it can be difficult to generate this load level. Delayed replication can simulate the lag without having to simulate the load. It can also be used to debug conditions related to a lagging replica.
- To inspect what the database looked like in the past, without having to reload a backup. For example, by configuring a replica with a delay of one week, if you then need to see what the database looked like before the last few days' worth of development, the delayed replica can be inspected.

## Replication Delay Timestamps

MySQL 9.1 provides a new method for measuring delay (also referred to as replication lag) in replication topologies that depends on the following timestamps associated with the GTID of each transaction (instead of each event) written to the binary log.

- `original_commit_timestamp`: the number of microseconds since epoch when the transaction was written (committed) to the binary log of the original source.
- `immediate_commit_timestamp`: the number of microseconds since epoch when the transaction was written (committed) to the binary log of the immediate source.

The output of `mysqlbinlog` displays these timestamps in two formats, microseconds from epoch and also `TIMESTAMP` format, which is based on the user defined time zone for better readability. For example:

```
#170404 10:48:05 server id 1 end_log_pos 233 CRC32 0x016ce647 GTID last_committed=0
\ sequence_number=1 original_committed_timestamp=1491299285661130 immediate_commit_timestamp=1491299285661130
original_commit_timestamp=1491299285661130 (2017-04-04 10:48:05.661130 WEST)
immediate_commit_timestamp=1491299285843771 (2017-04-04 10:48:05.843771 WEST)
/*!80001 SET @@SESSION.original_commit_timestamp=1491299285661130/*!*/;
SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa-aaaa-aaaa-aaaaaaaaaaaa:1'/*!*/;
at 233
```

As a rule, the `original_commit_timestamp` is always the same on all replicas where the transaction is applied. In source-replica replication, the `original_commit_timestamp` of a transaction in the (original) source's binary log is always the same as its `immediate_commit_timestamp`. In the replica's relay log, the `original_commit_timestamp` and `immediate_commit_timestamp` of the transaction are the same as in the source's binary log; whereas in its own binary log, the transaction's `immediate_commit_timestamp` corresponds to when the replica committed the transaction.

In a Group Replication setup, when the original source is a member of a group, the `original_commit_timestamp` is generated when the transaction is ready to be committed. In other words, when it finished executing on the original source and its write set is ready to be sent to all members of the group for certification. When the original source is a server outside the group, the `original_commit_timestamp` is preserved. The same `original_commit_timestamp` for a particular transaction is replicated to all servers in the group, and to any replica outside the group that is replicating from a member. Each recipient of the transaction also stores the local commit time in its binary log using `immediate_commit_timestamp`.

View change events, which are exclusive to Group Replication, are a special case. Transactions containing these events are generated by each group member but share the same GTID (so, they are not first executed in a source and then replicated to the group, but all members of the group execute and apply the same transaction). Group members set local timestamp values for transactions associated with view change events.

## Monitoring Replication Delay

One of the most common ways to monitor replication delay (lag) in previous MySQL versions was by relying on the `Seconds_Behind_Master` field in the output of `SHOW REPLICA STATUS`. However, this metric is not suitable when using replication topologies more complex than the traditional source-replica setup, such as Group Replication. The addition of `immediate_commit_timestamp` and `original_commit_timestamp` to MySQL 8 provides a much finer degree of information about replication delay. The recommended method to monitor replication delay in a topology that supports these timestamps is using the following Performance Schema tables.

- `replication_connection_status`: current status of the connection to the source, provides information on the last and current transaction the connection thread queued into the relay log.
- `replication_applier_status_by_coordinator`: current status of the coordinator thread that only displays information when using a multithreaded replica, provides information on the last transaction buffered by the coordinator thread to a worker's queue, as well as the transaction it is currently buffering.
- `replication_applier_status_by_worker`: current status of the thread(s) applying transactions received from the source, provides information about the transactions applied by the replication SQL thread, or by each worker thread when using a multithreaded replica.

Using these tables you can monitor information about the last transaction the corresponding thread processed and the transaction that thread is currently processing. This information comprises:

- a transaction's GTID
- a transaction's `original_commit_timestamp` and `immediate_commit_timestamp`, retrieved from the replica's relay log
- the time a thread started processing a transaction
- for the last processed transaction, the time the thread finished processing it

In addition to the Performance Schema tables, the output of `SHOW REPLICA STATUS` has three fields that show:

- `SQL_Delay`: A nonnegative integer indicating the replication delay configured using `CHANGE REPLICATION SOURCE TO SOURCE_DELAY=N`, where `N` is measured in seconds.
- `SQL_Remaining_Delay`: When `Replica_SQL_Running_State` is `Waiting until SOURCE_DELAY seconds after master executed event`, this field contains an integer indicating the number of seconds left of the delay. At other times, this field is `NULL`.
- `Replica_SQL_Running_State`: A string indicating the state of the SQL thread (analogous to `Replica_IO_State`). The value is identical to the `State` value of the SQL thread as displayed by `SHOW PROCESSLIST`.

When the replication SQL thread is waiting for the delay to elapse before executing an event, `SHOW PROCESSLIST` displays its `State` value as `Waiting until SOURCE_DELAY seconds after master executed event`.

## 19.5 Replication Notes and Tips

### 19.5.1 Replication Features and Issues

The following sections provide information about what is supported and what is not in MySQL replication, and about specific issues and situations that may occur when replicating certain statements.

Statement-based replication depends on compatibility at the SQL level between the source and replica. In other words, successful statement-based replication requires that any SQL features used be supported by both the source and the replica servers. If you use a feature on the source server that is available only in the current version of MySQL, you cannot replicate to a replica that uses an earlier version of MySQL. Such incompatibilities can also occur within a release series as well as between versions.

If you are planning to use statement-based replication between MySQL 9.1 and a previous MySQL release series, it is a good idea to consult the edition of the *MySQL Reference Manual* corresponding to the earlier release series for information regarding the replication characteristics of that series.

With MySQL's statement-based replication, there may be issues with replicating stored routines or triggers. You can avoid these issues by using MySQL's row-based replication instead. For a detailed list of issues, see [Section 27.8, “Stored Program Binary Logging”](#). For more information about row-based logging and row-based replication, see [Section 7.4.4.1, “Binary Logging Formats”](#), and [Section 19.2.1, “Replication Formats”](#).

For additional information specific to replication and [InnoDB](#), see [Section 17.19, “InnoDB and MySQL Replication”](#). For information relating to replication with NDB Cluster, see [Section 25.7, “NDB Cluster Replication”](#).

### 19.5.1.1 Replication and AUTO\_INCREMENT

Statement-based replication of [AUTO\\_INCREMENT](#), [LAST\\_INSERT\\_ID\(\)](#), and [TIMESTAMP](#) values is carried out subject to the following exceptions:

- A statement invoking a trigger or function that causes an update to an [AUTO\\_INCREMENT](#) column is not replicated correctly using statement-based replication. These statements are marked as unsafe. (Bug #45677)
- An [INSERT](#) into a table that has a composite primary key that includes an [AUTO\\_INCREMENT](#) column that is not the first column of this composite key is not safe for statement-based logging or replication. These statements are marked as unsafe. (Bug #11754117, Bug #45670)

This issue does not affect tables using the [InnoDB](#) storage engine, since an [InnoDB](#) table with an [AUTO\\_INCREMENT](#) column requires at least one key where the auto-increment column is the only or leftmost column.

- Adding an [AUTO\\_INCREMENT](#) column to a table with [ALTER TABLE](#) might not produce the same ordering of the rows on the replica and the source. This occurs because the order in which the rows are numbered depends on the specific storage engine used for the table and the order in which the rows were inserted. If it is important to have the same order on the source and replica, the rows must be ordered before assigning an [AUTO\\_INCREMENT](#) number. Assuming that you want to add an [AUTO\\_INCREMENT](#) column to a table `t1` that has columns `col1` and `col2`, the following statements produce a new table `t2` identical to `t1` but with an [AUTO\\_INCREMENT](#) column:

```
CREATE TABLE t2 LIKE t1;
ALTER TABLE t2 ADD id INT AUTO_INCREMENT PRIMARY KEY;
INSERT INTO t2 SELECT * FROM t1 ORDER BY col1, col2;
```

#### Important

To guarantee the same ordering on both source and replica, the [ORDER BY](#) clause must name *all* columns of `t1`.

The instructions just given are subject to the limitations of [CREATE TABLE ... LIKE](#): Foreign key definitions are ignored, as are the [DATA DIRECTORY](#) and [INDEX DIRECTORY](#) table options. If a table

definition includes any of those characteristics, create `t2` using a `CREATE TABLE` statement that is identical to the one used to create `t1`, but with the addition of the `AUTO_INCREMENT` column.

Regardless of the method used to create and populate the copy having the `AUTO_INCREMENT` column, the final step is to drop the original table and then rename the copy:

```
DROP t1;
ALTER TABLE t2 RENAME t1;
```

See also [Section B.3.6.1, “Problems with ALTER TABLE”](#).

### 19.5.1.2 Replication and BLACKHOLE Tables

The `BLACKHOLE` storage engine accepts data but discards it and does not store it. When performing binary logging, all inserts to such tables are always logged, regardless of the logging format in use. Updates and deletes are handled differently depending on whether statement based or row based logging is in use. With the statement based logging format, all statements affecting `BLACKHOLE` tables are logged, but their effects ignored. When using row-based logging, updates and deletes to such tables are simply skipped—they are not written to the binary log. A warning is logged whenever this occurs.

For this reason we recommend when you replicate to tables using the `BLACKHOLE` storage engine that you have the `binlog_format` server variable set to `STATEMENT`, and not to either `ROW` or `MIXED`.

### 19.5.1.3 Replication and Character Sets

The following applies to replication between MySQL servers that use different character sets:

- If the source has databases with a character set different from the global `character_set_server` value, you should design your `CREATE TABLE` statements so that they do not implicitly rely on the database default character set. A good workaround is to state the character set and collation explicitly in `CREATE TABLE` statements.

### 19.5.1.4 Replication and CHECKSUM TABLE

`CHECKSUM TABLE` returns a checksum that is calculated row by row, using a method that depends on the table row storage format. The storage format is not guaranteed to remain the same between MySQL versions, so the checksum value might change following an upgrade.

### 19.5.1.5 Replication of CREATE SERVER, ALTER SERVER, and DROP SERVER

The statements `CREATE SERVER`, `ALTER SERVER`, and `DROP SERVER` are not written to the binary log, regardless of the binary logging format that is in use.

### 19.5.1.6 Replication of CREATE ... IF NOT EXISTS Statements

MySQL applies these rules when various `CREATE ... IF NOT EXISTS` statements are replicated:

- Every `CREATE DATABASE IF NOT EXISTS` statement is replicated, whether or not the database already exists on the source.
- Similarly, every `CREATE TABLE IF NOT EXISTS` statement without a `SELECT` is replicated, whether or not the table already exists on the source. This includes `CREATE TABLE IF NOT EXISTS ... LIKE`. Replication of `CREATE TABLE IF NOT EXISTS ... SELECT` follows somewhat different rules; see [Section 19.5.1.7, “Replication of CREATE TABLE ... SELECT Statements”](#), for more information.
- `CREATE EVENT IF NOT EXISTS` is always replicated, whether or not the event named in the statement already exists on the source.

- `CREATE USER` is written to the binary log only if successful. If the statement includes `IF NOT EXISTS`, it is considered successful, and is logged as long as at least one user named in the statement is created; in such cases, the statement is logged as written; this includes references to existing users that were not created. See [CREATE USER Binary Logging](#), for more information.
- `CREATE PROCEDURE IF NOT EXISTS`, `CREATE FUNCTION IF NOT EXISTS`, or `CREATE TRIGGER IF NOT EXISTS`, if successful, is written in its entirety to the binary log (including the `IF NOT EXISTS` clause), whether or not the statement raised a warning because the object (procedure, function, or trigger) already existed.

### 19.5.1.7 Replication of `CREATE TABLE ... SELECT` Statements

MySQL applies these rules when `CREATE TABLE ... SELECT` statements are replicated:

- `CREATE TABLE ... SELECT` always performs an implicit commit ([Section 15.3.3, “Statements That Cause an Implicit Commit”](#)).
- If the destination table does not exist, logging occurs as follows. It does not matter whether `IF NOT EXISTS` is present.
  - `STATEMENT` or `MIXED` format: The statement is logged as written.
  - `ROW` format: The statement is logged as a `CREATE TABLE` statement followed by a series of insert-row events.

With storage engines that support atomic DDL, the statement is logged as one transaction. For more information, see [Section 15.1.1, “Atomic Data Definition Statement Support”](#).

- If the `CREATE TABLE ... SELECT` statement fails, nothing is logged. This includes the case that the destination table exists and `IF NOT EXISTS` is not given.
- If the destination table exists and `IF NOT EXISTS` is given, MySQL 9.1 ignores the statement completely; nothing is inserted or logged.

MySQL 9.1 does not allow a `CREATE TABLE ... SELECT` statement to make any changes in tables other than the table that is created by the statement.

### 19.5.1.8 Replication of `CURRENT_USER()`

The following statements support use of the `CURRENT_USER()` function to take the place of the name of, and possibly the host for, an affected user or a definer:

- `DROP USER`
- `RENAME USER`
- `GRANT`
- `REVOKE`
- `CREATE FUNCTION`
- `CREATE PROCEDURE`
- `CREATE TRIGGER`
- `CREATE EVENT`

- `CREATE VIEW`
- `ALTER EVENT`
- `ALTER VIEW`
- `SET PASSWORD`

When binary logging is enabled and `CURRENT_USER( )` or `CURRENT_USER` is used as the definer in any of these statements, MySQL Server ensures that the statement is applied to the same user on both the source and the replica when the statement is replicated. In some cases, such as statements that change passwords, the function reference is expanded before it is written to the binary log, so that the statement includes the user name. For all other cases, the name of the current user on the source is replicated to the replica as metadata, and the replica applies the statement to the current user named in the metadata, rather than to the current user on the replica.

### 19.5.1.9 Replication with Differing Table Definitions on Source and Replica

Source and target tables for replication do not have to be identical. A table on the source can have more or fewer columns than the replica's copy of the table. In addition, corresponding table columns on the source and the replica can use different data types, subject to certain conditions.

#### Note

Replication between tables which are partitioned differently from one another is not supported. See [Section 19.5.1.25, “Replication and Partitioning”](#).

In all cases where the source and target tables do not have identical definitions, the database and table names must be the same on both the source and the replica. Additional conditions are discussed, with examples, in the following two sections.

### Replication with More Columns on Source or Replica

You can replicate a table from the source to the replica such that the source and replica copies of the table have differing numbers of columns, subject to the following conditions:

- Columns common to both versions of the table must be defined in the same order on the source and the replica. (This is true even if both tables have the same number of columns.)
- Columns common to both versions of the table must be defined before any additional columns.

This means that executing an `ALTER TABLE` statement on the replica where a new column is inserted into the table within the range of columns common to both tables causes replication to fail, as shown in the following example:

Suppose that a table `t`, existing on the source and the replica, is defined by the following `CREATE TABLE` statement:

```
CREATE TABLE t (
 c1 INT,
 c2 INT,
 c3 INT
);
```

Suppose that the `ALTER TABLE` statement shown here is executed on the replica:

```
ALTER TABLE t ADD COLUMN cnew1 INT AFTER c3;
```

The previous `ALTER TABLE` is permitted on the replica because the columns `c1`, `c2`, and `c3` that are common to both versions of table `t` remain grouped together in both versions of the table, before any columns that differ.

However, the following `ALTER TABLE` statement cannot be executed on the replica without causing replication to break:

```
ALTER TABLE t ADD COLUMN cnew2 INT AFTER c2;
```

Replication fails after execution on the replica of the `ALTER TABLE` statement just shown, because the new column `cnew2` comes between columns common to both versions of `t`.

- Each “extra” column in the version of the table having more columns must have a default value.

A column's default value is determined by a number of factors, including its type, whether it is defined with a `DEFAULT` option, whether it is declared as `NULL`, and the server SQL mode in effect at the time of its creation; for more information, see [Section 13.6, “Data Type Default Values”](#)).

In addition, when the replica's copy of the table has more columns than the source's copy, each column common to the tables must use the same data type in both tables.

**Examples.** The following examples illustrate some valid and invalid table definitions:

**More columns on the source.** The following table definitions are valid and replicate correctly:

```
source> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
replica> CREATE TABLE t1 (c1 INT, c2 INT);
```

The following table definitions would raise an error because the definitions of the columns common to both versions of the table are in a different order on the replica than they are on the source:

```
source> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
replica> CREATE TABLE t1 (c2 INT, c1 INT);
```

The following table definitions would also raise an error because the definition of the extra column on the source appears before the definitions of the columns common to both versions of the table:

```
source> CREATE TABLE t1 (c3 INT, c1 INT, c2 INT);
replica> CREATE TABLE t1 (c1 INT, c2 INT);
```

**More columns on the replica.** The following table definitions are valid and replicate correctly:

```
source> CREATE TABLE t1 (c1 INT, c2 INT);
replica> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
```

The following definitions raise an error because the columns common to both versions of the table are not defined in the same order on both the source and the replica:

```
source> CREATE TABLE t1 (c1 INT, c2 INT);
replica> CREATE TABLE t1 (c2 INT, c1 INT, c3 INT);
```

The following table definitions also raise an error because the definition for the extra column in the replica's version of the table appears before the definitions for the columns which are common to both versions of the table:

```
source> CREATE TABLE t1 (c1 INT, c2 INT);
replica> CREATE TABLE t1 (c3 INT, c1 INT, c2 INT);
```

The following table definitions fail because the replica's version of the table has additional columns compared to the source's version, and the two versions of the table use different data types for the common column `c2`:

```
source> CREATE TABLE t1 (c1 INT, c2 BIGINT);
replica> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
```

## Replication of Columns Having Different Data Types

Corresponding columns on the source's and the replica's copies of the same table ideally should have the same data type. However, this is not always strictly enforced, as long as certain conditions are met.

It is usually possible to replicate from a column of a given data type to another column of the same type and same size or width, where applicable, or larger. For example, you can replicate from a `CHAR(10)` column to another `CHAR(10)`, or from a `CHAR(10)` column to a `CHAR(25)` column without any problems. In certain cases, it is also possible to replicate from a column having one data type (on the source) to a column having a different data type (on the replica); when the data type of the source's version of the column is promoted to a type that is the same size or larger on the replica, this is known as *attribute promotion*.

Attribute promotion can be used with both statement-based and row-based replication, and is not dependent on the storage engine used by either the source or the replica. However, the choice of logging format does have an effect on the type conversions that are permitted; the particulars are discussed later in this section.

### Important

Whether you use statement-based or row-based replication, the replica's copy of the table cannot contain more columns than the source's copy if you wish to employ attribute promotion.

**Statement-based replication.** When using statement-based replication, a simple rule of thumb to follow is, "If the statement run on the source would also execute successfully on the replica, it should also replicate successfully". In other words, if the statement uses a value that is compatible with the type of a given column on the replica, the statement can be replicated. For example, you can insert any value that fits in a `TINYINT` column into a `BIGINT` column as well; it follows that, even if you change the type of a `TINYINT` column in the replica's copy of a table to `BIGINT`, any insert into that column on the source that succeeds should also succeed on the replica, since it is impossible to have a legal `TINYINT` value that is large enough to exceed a `BIGINT` column.

**Row-based replication: attribute promotion and demotion.** Row-based replication supports attribute promotion and demotion between smaller data types and larger types. It is also possible to specify whether or not to permit lossy (truncated) or non-lossy conversions of demoted column values, as explained later in this section.

**Lossy and non-lossy conversions.** In the event that the target type cannot represent the value being inserted, a decision must be made on how to handle the conversion. If we permit the conversion but truncate (or otherwise modify) the source value to achieve a "fit" in the target column, we make what is known as a *lossy conversion*. A conversion which does not require truncation or similar modifications to fit the source column value in the target column is a *non-lossy conversion*.

**Type conversion modes.** The global value of the system variable `replica_type_conversions` controls the type conversion mode used on the replica. This variable takes a set of values from the following list, which describes the effects of each mode on the replica's type-conversion behavior:

`ALL_LOSSY`

In this mode, type conversions that would mean loss of information are permitted.

	This does not imply that non-lossy conversions are permitted, merely that only cases requiring either lossy conversions or no conversion at all are permitted; for example, enabling <i>only</i> this mode permits an <code>INT</code> column to be converted to <code>TINYINT</code> (a lossy conversion), but not a <code>TINYINT</code> column to an <code>INT</code> column (non-lossy). Attempting the latter conversion in this case would cause replication to stop with an error on the replica.
<code>ALL_NON_LOSSY</code>	<p>This mode permits conversions that do not require truncation or other special handling of the source value; that is, it permits conversions where the target type has a wider range than the source type.</p> <p>Setting this mode has no bearing on whether lossy conversions are permitted; this is controlled with the <code>ALL_LOSSY</code> mode. If only <code>ALL_NON_LOSSY</code> is set, but not <code>ALL_LOSSY</code>, then attempting a conversion that would result in the loss of data (such as <code>INT</code> to <code>TINYINT</code>, or <code>CHAR(25)</code> to <code>VARCHAR(20)</code>) causes the replica to stop with an error.</p>
<code>ALL_LOSSY,ALL_NON_LOSSY</code>	When this mode is set, all supported type conversions are permitted, whether or not they are lossy conversions.
<code>ALL_SIGNED</code>	Treat promoted integer types as signed values (the default behavior).
<code>ALL_UNSIGNED</code>	Treat promoted integer types as unsigned values.
<code>ALL_SIGNED,ALL_UNSIGNED</code>	Treat promoted integer types as signed if possible, otherwise as unsigned.
<code>[empty]</code>	<p>When <code>replica_type_conversions</code> is not set, no attribute promotion or demotion is permitted; this means that all columns in the source and target tables must be of the same types.</p> <p>This mode is the default.</p>

When an integer type is promoted, its signedness is not preserved. By default, the replica treats all such values as signed. You can control this behavior using `ALL_SIGNED`, `ALL_UNSIGNED`, or both. `ALL_SIGNED` tells the replica to treat all promoted integer types as signed; `ALL_UNSIGNED` instructs it to treat these as unsigned. Specifying both causes the replica to treat the value as signed if possible, otherwise to treat it as unsigned; the order in which they are listed is not significant. Neither `ALL_SIGNED` nor `ALL_UNSIGNED` has any effect if at least one of `ALL_LOSSY` or `ALL_NONLOSSY` is not also used.

Changing the type conversion mode requires restarting the replica with the new `replica_type_conversions` setting.

**Supported conversions.** Supported conversions between different but similar data types are shown in the following list:

- Between any of the integer types `TINYINT`, `SMALLINT`, `MEDIUMINT`, `INT`, and `BIGINT`.

This includes conversions between the signed and unsigned versions of these types.

Lossy conversions are made by truncating the source value to the maximum (or minimum) permitted by the target column. For ensuring non-lossy conversions when going from unsigned to signed types, the target column must be large enough to accommodate the range of values in the source column. For example, you can demote `TINYINT UNSIGNED` non-lossily to `SMALLINT`, but not to `TINYINT`.

- Between any of the decimal types `DECIMAL`, `FLOAT`, `DOUBLE`, and `NUMERIC`.

`FLOAT` to `DOUBLE` is a non-lossy conversion; `DOUBLE` to `FLOAT` can only be handled lossily. A conversion from `DECIMAL(M,D)` to `DECIMAL(M',D')` where  $D' \geq D$  and  $(M' - D') \geq (M - D)$  is non-lossy; for any case where  $M' < M$ ,  $D' < D$ , or both, only a lossy conversion can be made.

For any of the decimal types, if a value to be stored cannot be fit in the target type, the value is rounded down according to the rounding rules defined for the server elsewhere in the documentation. See [Section 14.25.4, “Rounding Behavior”](#), for information about how this is done for decimal types.

- Between any of the string types `CHAR`, `VARCHAR`, and `TEXT`, including conversions between different widths.

Conversion of a `CHAR`, `VARCHAR`, or `TEXT` to a `CHAR`, `VARCHAR`, or `TEXT` column the same size or larger is never lossy. Lossy conversion is handled by inserting only the first *N* characters of the string on the replica, where *N* is the width of the target column.

#### Important

Replication between columns using different character sets is not supported.

- Between any of the binary data types `BINARY`, `VARBINARY`, and `BLOB`, including conversions between different widths.

Conversion of a `BINARY`, `VARBINARY`, or `BLOB` to a `BINARY`, `VARBINARY`, or `BLOB` column the same size or larger is never lossy. Lossy conversion is handled by inserting only the first *N* bytes of the string on the replica, where *N* is the width of the target column.

- Between any 2 `BIT` columns of any 2 sizes.

When inserting a value from a `BIT(M)` column into a `BIT(M')` column, where  $M' > M$ , the most significant bits of the `BIT(M')` columns are cleared (set to zero) and the *M* bits of the `BIT(M)` value are set as the least significant bits of the `BIT(M')` column.

When inserting a value from a source `BIT(M)` column into a target `BIT(M')` column, where  $M' < M$ , the maximum possible value for the `BIT(M')` column is assigned; in other words, an “all-set” value is assigned to the target column.

Conversions between types not in the previous list are not permitted.

### 19.5.1.10 Replication and `DIRECTORY` Table Options

If a `DATA DIRECTORY` or `INDEX DIRECTORY` table option is used in a `CREATE TABLE` statement on the source server, the table option is also used on the replica. This can cause problems if no corresponding directory exists in the replica host file system or if it exists but is not accessible to the replica MySQL server. This can be overridden by using the `NO_DIR_IN_CREATE` server SQL mode on the replica, which causes the replica to ignore the `DATA DIRECTORY` and `INDEX DIRECTORY` table options when replicating `CREATE TABLE` statements. The result is that `MyISAM` data and index files are created in the table's database directory.

For more information, see [Section 7.1.11, “Server SQL Modes”](#).

### 19.5.1.11 Replication of `DROP ... IF EXISTS` Statements

The `DROP DATABASE IF EXISTS`, `DROP TABLE IF EXISTS`, and `DROP VIEW IF EXISTS` statements are always replicated, even if the database, table, or view to be dropped does not exist on the

source. This is to ensure that the object to be dropped no longer exists on either the source or the replica, once the replica has caught up with the source.

`DROP ... IF EXISTS` statements for stored programs (stored procedures and functions, triggers, and events) are also replicated, even if the stored program to be dropped does not exist on the source.

### 19.5.1.12 Replication and Floating-Point Values

With statement-based replication, values are converted from decimal to binary. Because conversions between decimal and binary representations of them may be approximate, comparisons involving floating-point values are inexact. This is true for operations that use floating-point values explicitly, or that use values that are converted to floating-point implicitly. Comparisons of floating-point values might yield different results on source and replica servers due to differences in computer architecture, the compiler used to build MySQL, and so forth. See [Section 14.3, “Type Conversion in Expression Evaluation”](#), and [Section B.3.4.8, “Problems with Floating-Point Values”](#).

### 19.5.1.13 Replication and FLUSH

Some forms of the `FLUSH` statement are not logged because they could cause problems if replicated to a replica: `FLUSH LOGS` and `FLUSH TABLES WITH READ LOCK`. For a syntax example, see [Section 15.7.8.3, “FLUSH Statement”](#). The `FLUSH TABLES`, `ANALYZE TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` statements are written to the binary log and thus replicated to replicas. This is not normally a problem because these statements do not modify table data.

However, this behavior can cause difficulties under certain circumstances. If you replicate the privilege tables in the `mysql` database and update those tables directly without using `GRANT`, you must issue a `FLUSH PRIVILEGES` on the replicas to put the new privileges into effect. In addition, if you use `FLUSH TABLES` when renaming a `MyISAM` table that is part of a `MERGE` table, you must issue `FLUSH TABLES` manually on the replicas. These statements are written to the binary log unless you specify `NO_WRITE_TO_BINLOG` or its alias `LOCAL`.

### 19.5.1.14 Replication and System Functions

Certain functions do not replicate well under some conditions:

- The `USER()`, `CURRENT_USER()` (or `CURRENT_USER`), `UUID()`, `VERSION()`, and `LOAD_FILE()` functions are replicated without change and thus do not work reliably on the replica unless row-based replication is enabled. (See [Section 19.2.1, “Replication Formats”](#).)

`USER()` and `CURRENT_USER()` are automatically replicated using row-based replication when using `MIXED` mode, and generate a warning in `STATEMENT` mode. (See also [Section 19.5.1.8, “Replication of CURRENT\\_USER\(\)”](#).) This is also true for `VERSION()` and `RAND()`.

- For `NOW()`, the binary log includes the timestamp. This means that the value *as returned by the call to this function on the source* is replicated to the replica. To avoid unexpected results when replicating between MySQL servers in different time zones, set the time zone on both source and replica. For more information, see [Section 19.5.1.34, “Replication and Time Zones”](#).

To explain the potential problems when replicating between servers which are in different time zones, suppose that the source is located in New York, the replica is located in Stockholm, and both servers are using local time. Suppose further that, on the source, you create a table `mytable`, perform an `INSERT` statement on this table, and then select from the table, as shown here:

```
mysql> CREATE TABLE mytable (mycol TEXT);
Query OK, 0 rows affected (0.06 sec)
```

```
mysql> INSERT INTO mytable VALUES (NOW());
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM mytable;
+-----+
| mycol |
+-----+
| 2009-09-01 12:00:00 |
+-----+
1 row in set (0.00 sec)
```

Local time in Stockholm is 6 hours later than in New York; so, if you issue `SELECT NOW()` on the replica at that exact same instant, the value `2009-09-01 18:00:00` is returned. For this reason, if you select from the replica's copy of `mytable` after the `CREATE TABLE` and `INSERT` statements just shown have been replicated, you might expect `mycol` to contain the value `2009-09-01 18:00:00`. However, this is not the case; when you select from the replica's copy of `mytable`, you obtain exactly the same result as on the source:

```
mysql> SELECT * FROM mytable;
+-----+
| mycol |
+-----+
| 2009-09-01 12:00:00 |
+-----+
1 row in set (0.00 sec)
```

Unlike `NOW()`, the `SYSDATE()` function is not replication-safe because it is not affected by `SET TIMESTAMP` statements in the binary log and is nondeterministic if statement-based logging is used. This is not a problem if row-based logging is used.

An alternative is to use the `--sysdate-is-now` option to cause `SYSDATE()` to be an alias for `NOW()`. This must be done on the source and the replica to work correctly. In such cases, a warning is still issued by this function, but can safely be ignored as long as `--sysdate-is-now` is used on both the source and the replica.

`SYSDATE()` is automatically replicated using row-based replication when using `MIXED` mode, and generates a warning in `STATEMENT` mode.

See also [Section 19.5.1.34, "Replication and Time Zones"](#).

- *The following restriction applies to statement-based replication only, not to row-based replication.* The `GET_LOCK()`, `RELEASE_LOCK()`, `IS_FREE_LOCK()`, and `IS_USED_LOCK()` functions that handle user-level locks are replicated without the replica knowing the concurrency context on the source. Therefore, these functions should not be used to insert into a source table because the content on the replica would differ. For example, do not issue a statement such as `INSERT INTO mytable VALUES (GET_LOCK(...))`.

These functions are automatically replicated using row-based replication when using `MIXED` mode, and generate a warning in `STATEMENT` mode.

As a workaround for the preceding limitations when statement-based replication is in effect, you can use the strategy of saving the problematic function result in a user variable and referring to the variable in a later statement. For example, the following single-row `INSERT` is problematic due to the reference to the `UUID()` function:

```
INSERT INTO t VALUES(UUID());
```

To work around the problem, do this instead:

```
SET @my_uuid = UUID();
```

```
INSERT INTO t VALUES(@my_uuid);
```

That sequence of statements replicates because the value of `@my_uuid` is stored in the binary log as a user-variable event prior to the `INSERT` statement and is available for use in the `INSERT`.

The same idea applies to multiple-row inserts, but is more cumbersome to use. For a two-row insert, you can do this:

```
SET @my_uuid1 = UUID(); @my_uuid2 = UUID();
INSERT INTO t VALUES(@my_uuid1),(@my_uuid2);
```

However, if the number of rows is large or unknown, the workaround is difficult or impracticable. For example, you cannot convert the following statement to one in which a given individual user variable is associated with each row:

```
INSERT INTO t2 SELECT UUID(), * FROM t1;
```

Within a stored function, `RAND()` replicates correctly as long as it is invoked only once during the execution of the function. (You can consider the function execution timestamp and random number seed as implicit inputs that are identical on the source and replica.)

The `FOUND_ROWS()` and `ROW_COUNT()` functions are not replicated reliably using statement-based replication. A workaround is to store the result of the function call in a user variable, and then use that in the `INSERT` statement. For example, if you wish to store the result in a table named `mytable`, you might normally do so like this:

```
SELECT SQL_CALC_FOUND_ROWS FROM mytable LIMIT 1;
INSERT INTO mytable VALUES(FOUND_ROWS());
```

However, if you are replicating `mytable`, you should use `SELECT ... INTO`, and then store the variable in the table, like this:

```
SELECT SQL_CALC_FOUND_ROWS INTO @found_rows FROM mytable LIMIT 1;
INSERT INTO mytable VALUES(@found_rows);
```

In this way, the user variable is replicated as part of the context, and applied on the replica correctly.

These functions are automatically replicated using row-based replication when using `MIXED` mode, and generate a warning in `STATEMENT` mode. (Bug #12092, Bug #30244)

### 19.5.1.15 Replication and Fractional Seconds Support

MySQL 9.1 permits fractional seconds for `TIME`, `DATETIME`, and `TIMESTAMP` values, with up to microseconds (6 digits) precision. See [Section 13.2.6, “Fractional Seconds in Time Values”](#).

### 19.5.1.16 Replication of Invoked Features

Replication of invoked features such as loadable functions and stored programs (stored procedures and functions, triggers, and events) provides the following characteristics:

- The effects of the feature are always replicated.
- The following statements are replicated using statement-based replication:
  - `CREATE EVENT`
  - `ALTER EVENT`
  - `DROP EVENT`

- `CREATE PROCEDURE`
- `DROP PROCEDURE`
- `CREATE FUNCTION`
- `DROP FUNCTION`
- `CREATE TRIGGER`
- `DROP TRIGGER`

However, the *effects* of features created, modified, or dropped using these statements are replicated using row-based replication.

#### Note

Attempting to replicate invoked features using statement-based replication produces the warning `Statement is not safe to log in statement format`. For example, trying to replicate a loadable function with statement-based replication generates this warning because it currently cannot be determined by the MySQL server whether the function is deterministic. If you are absolutely certain that the invoked feature's effects are deterministic, you can safely disregard such warnings.

- In the case of `CREATE EVENT` and `ALTER EVENT`:
  - The status of the event is set to `REPLICA_SIDE_DISABLED` on the replica regardless of the state specified (this does not apply to `DROP EVENT`).
  - The source on which the event was created is identified on the replica by its server ID. The `ORIGINATOR` column in `INFORMATION_SCHEMA.EVENTS` stores this information. See [Section 15.7.7.19, “SHOW EVENTS Statement”](#), for more information.
  - The feature implementation resides on the replica in a renewable state so that if the source fails, the replica can be used as the source without loss of event processing.

To determine whether there are any scheduled events on a MySQL server that were created on a different server (that was acting as a source), query the Information Schema `EVENTS` table in a manner similar to what is shown here:

```
SELECT EVENT_SCHEMA, EVENT_NAME
FROM INFORMATION_SCHEMA.EVENTS
WHERE STATUS = 'REPLICA_SIDE_DISABLED';
```

Alternatively, you can use the `SHOW EVENTS` statement, like this:

```
SHOW EVENTS
WHERE STATUS = 'REPLICA_SIDE_DISABLED';
```

When promoting a replica having such events to a source, you must enable each event using `ALTER EVENT event_name ENABLE`, where *event\_name* is the name of the event.

If more than one source was involved in creating events on this replica, and you wish to identify events that were created only on a given source having the server ID *source\_id*, modify the previous query on the `EVENTS` table to include the `ORIGINATOR` column, as shown here:

```
SELECT EVENT_SCHEMA, EVENT_NAME, ORIGINATOR
```

```
FROM INFORMATION_SCHEMA.EVENTS
WHERE STATUS = 'REPLICA_SIDE_DISABLED'
AND ORIGINATOR = 'source_id'
```

You can employ `ORIGINATOR` with the `SHOW EVENTS` statement in a similar fashion:

```
SHOW EVENTS
WHERE STATUS = 'REPLICA_SIDE_DISABLED'
AND ORIGINATOR = 'source_id'
```

#### Note

`REPLICA_SIDE_DISABLED` replaces `SLAVESIDE_DISABLED`, which is deprecated.

Before enabling events that were replicated from the source, you should disable the MySQL Event Scheduler on the replica (using a statement such as `SET GLOBAL event_scheduler = OFF;`), run any necessary `ALTER EVENT` statements, restart the server, then re-enable the Event Scheduler on the replica afterward (using a statement such as `SET GLOBAL event_scheduler = ON;`)-

If you later demote the new source back to being a replica, you must disable manually all events enabled by the `ALTER EVENT` statements. You can do this by storing in a separate table the event names from the `SELECT` statement shown previously, or using `ALTER EVENT` statements to rename the events with a common prefix such as `replicated_` to identify them.

If you rename the events, then when demoting this server back to being a replica, you can identify the events by querying the `EVENTS` table, as shown here:

```
SELECT CONCAT(EVENT_SCHEMA, '.', EVENT_NAME) AS 'Db.Event'
FROM INFORMATION_SCHEMA.EVENTS
WHERE INSTR(EVENT_NAME, 'replicated_') = 1;
```

### 19.5.1.17 Replication of JSON Documents

In MySQL 9.1, it is possible to log partial updates to JSON documents (see [Partial Updates of JSON Values](#)). The logging behavior depends on the format used, as described here:

**Statement-based replication.** JSON partial updates are always logged as partial updates. This cannot be disabled when using statement-based logging.

**Row-based replication.** JSON partial updates are not logged as such by default, but instead are logged as complete documents. To enable logging of partial updates, set `binlog_row_value_options=PARTIAL_JSON`. If a replication source has this variable set, partial updates received from that source are handled and applied by a replica regardless of the replica's own setting for the variable.

### 19.5.1.18 Replication and JavaScript Stored Programs

MySQL Replication is compatible with JavaScript stored programs, provided that the MLE component is installed on every server in the topology, due to the following issues:

- A replica without the component installed accepts `CREATE FUNCTION` and `CREATE PROCEDURE` statements containing JavaScript code from the source, but the replica cannot execute the stored programs thus created.
- A JavaScript stored program created on a server without the component installed is not checked for validity.

This means that, when a `CREATE FUNCTION` or `CREATE PROCEDURE` statement which contains invalid JavaScript code is executed on a server without the MLE component installed, the statement always succeeds, and thus is replicated. If the replica which has the MLE component installed, an error is raised when the replica attempts to execute it, leading to a break in replication.

For installing (or uninstalling) the MLE component on MySQL servers used in replication, it is recommended that you stop replication, install (or uninstall) the component on every server in the topology, and only then allow replication to resume. Replicating between servers in a mixed setting (that is, in which some servers have the MLE component installed and some do not) is not supported for the reasons stated in the previous paragraph.

For more information about JavaScript stored programs in MySQL, see [Section 27.3, “JavaScript Stored Programs”](#). For information about the MLE component, see [Section 7.5.7, “Multilingual Engine Component \(MLE\)”](#).

### 19.5.1.19 Replication and LIMIT

Statement-based replication of `LIMIT` clauses in `DELETE`, `UPDATE`, and `INSERT ... SELECT` statements is unsafe since the order of the rows affected is not defined. (Such statements can be replicated correctly with statement-based replication only if they also contain an `ORDER BY` clause.) When such a statement is encountered:

- When using `STATEMENT` mode, a warning that the statement is not safe for statement-based replication is now issued.

When using `STATEMENT` mode, warnings are issued for DML statements containing `LIMIT` even when they also have an `ORDER BY` clause (and so are made deterministic). This is a known issue. (Bug #42851)

- When using `MIXED` mode, the statement is now automatically replicated using row-based mode.

### 19.5.1.20 Replication and LOAD DATA

`LOAD DATA` is considered unsafe for statement-based logging (see [Section 19.2.1.3, “Determination of Safe and Unsafe Statements in Binary Logging”](#)). When `binlog_format=MIXED` is set, the statement is logged in row-based format. When `binlog_format=STATEMENT` is set, note that `LOAD DATA` does not generate a warning, unlike other unsafe statements.

If you use `LOAD DATA` with `binlog_format=STATEMENT`, each replica on which the changes are to be applied creates a temporary file containing the data. The replica then uses a `LOAD DATA` statement to apply the changes. This temporary file is not encrypted, even if binary log encryption is active on the source. If encryption is required, use row-based or mixed binary logging format instead, for which replicas do not create the temporary file.

If a `PRIVILEGE_CHECKS_USER` account has been used to help secure the replication channel (see [Section 19.3.3, “Replication Privilege Checks”](#)), it is strongly recommended that you log `LOAD DATA` operations using row-based binary logging (`binlog_format=ROW`). If `REQUIRE_ROW_FORMAT` is set for the channel, row-based binary logging is required. With this logging format, the `FILE` privilege is not needed to execute the event, so do not give the `PRIVILEGE_CHECKS_USER` account this privilege. If you need to recover from a replication error involving a `LOAD DATA INFILE` operation logged in statement format, and the replicated event is trusted, you could grant the `FILE` privilege to the `PRIVILEGE_CHECKS_USER` account temporarily, removing it after the replicated event has been applied.

When `mysqlbinlog` reads log events for `LOAD DATA` statements logged in statement-based format, a generated local file is created in a temporary directory. These temporary files are not automatically

removed by `mysqlbinlog` or any other MySQL program. If you do use `LOAD DATA` statements with statement-based binary logging, you should delete the temporary files yourself after you no longer need the statement log. For more information, see [Section 6.6.9, “mysqlbinlog — Utility for Processing Binary Log Files”](#).

### 19.5.1.21 Replication and `max_allowed_packet`

`max_allowed_packet` sets an upper limit on the size of any single message between the MySQL server and clients, including replicas. If you are replicating large column values (such as might be found in `TEXT` or `BLOB` columns) and `max_allowed_packet` is too small on the source, the source fails with an error, and the replica shuts down the replication I/O (receiver) thread. If `max_allowed_packet` is too small on the replica, this also causes the replica to stop the I/O thread.

Row-based replication sends all columns and column values for updated rows from the source to the replica, including values of columns that were not actually changed by the update. This means that, when you are replicating large column values using row-based replication, you must take care to set `max_allowed_packet` large enough to accommodate the largest row in any table to be replicated, even if you are replicating updates only, or you are inserting only relatively small values.

On a multi-threaded replica (with `replica_parallel_workers > 0`), ensure that the system variable `replica_pending_jobs_size_max` is set to a value equal to or greater than the setting for the `max_allowed_packet` system variable on the source. The default setting for `replica_pending_jobs_size_max`, 128M, is twice the default setting for `max_allowed_packet`, which is 64M. `max_allowed_packet` limits the packet size that the source can send, but the addition of an event header can produce a binary log event exceeding this size. Also, in row-based replication, a single event can be significantly larger than the `max_allowed_packet` size, because the value of `max_allowed_packet` only limits each column of the table.

The replica actually accepts packets up to the limit set by its `replica_max_allowed_packet` setting, which default to the maximum setting of 1GB, to prevent a replication failure due to a large packet. However, the value of `replica_pending_jobs_size_max` controls the memory that is made available on the replica to hold incoming packets. The specified memory is shared among all the replica worker queues.

The value of `replica_pending_jobs_size_max` is a soft limit, and if an unusually large event (consisting of one or multiple packets) exceeds this size, the transaction is held until all the replica workers have empty queues, and then processed. All subsequent transactions are held until the large transaction has been completed. So although unusual events larger than `replica_pending_jobs_size_max` can be processed, the delay to clear the queues of all the replica workers and the wait to queue subsequent transactions can cause lag on the replica and decreased concurrency of the replica workers. `replica_pending_jobs_size_max` should therefore be set high enough to accommodate most expected event sizes.

### 19.5.1.22 Replication and `MEMORY` Tables

When a replication source server shuts down and restarts, its `MEMORY` tables become empty. To replicate this effect to replicas, the first time that the source uses a given `MEMORY` table after startup, it logs an event that notifies replicas that the table must be emptied by writing a `DELETE` or `TRUNCATE TABLE` statement for that table to the binary log. This generated event is identifiable by a comment in the binary log, and if GTIDs are in use on the server, it has a GTID assigned. The statement is always logged in statement format, even if the binary logging format is set to `ROW`, and it is written even if `read_only` or `super_read_only` mode is set on the server. Note that the replica still has outdated data in a `MEMORY` table during the interval between the source's restart and its first use of the table. To avoid this interval when a direct query to the replica could return stale data, you can set the `init_file` system variable to name a file containing statements that populate the `MEMORY` table on the source at startup.

When a replica server shuts down and restarts, its `MEMORY` tables become empty. This causes the replica to be out of synchrony with the source and may lead to other failures or cause the replica to stop:

- Row-format updates and deletes received from the source may fail with `Can't find record in 'memory_table'`.
- Statements such as `INSERT INTO ... SELECT FROM memory_table` may insert a different set of rows on the source and replica.

The replica also writes a `DELETE` or `TRUNCATE TABLE` statement to its own binary log, which is passed on to any downstream replicas, causing them to empty their own `MEMORY` tables.

The safe way to restart a replica that is replicating `MEMORY` tables is to first drop or delete all rows from the `MEMORY` tables on the source and wait until those changes have replicated to the replica. Then it is safe to restart the replica.

An alternative restart method may apply in some cases. When `binlog_format=ROW`, you can prevent the replica from stopping if you set `replica_exec_mode=IDEMPOTENT` before you start the replica again. This allows the replica to continue to replicate, but its `MEMORY` tables still differ from those on the source. This is acceptable if the application logic is such that the contents of `MEMORY` tables can be safely lost (for example, if the `MEMORY` tables are used for caching). `replica_exec_mode=IDEMPOTENT` applies globally to all tables, so it may hide other replication errors in non-`MEMORY` tables.

(The method just described is not applicable in NDB Cluster, where `replica_exec_mode` is always `IDEMPOTENT`, and cannot be changed.)

The size of `MEMORY` tables is limited by the value of the `max_heap_table_size` system variable, which is not replicated (see [Section 19.5.1.40, “Replication and Variables”](#)). A change in `max_heap_table_size` takes effect for `MEMORY` tables that are created or updated using `ALTER TABLE ... ENGINE = MEMORY` or `TRUNCATE TABLE` following the change, or for all `MEMORY` tables following a server restart. If you increase the value of this variable on the source without doing so on the replica, it becomes possible for a table on the source to grow larger than its counterpart on the replica, leading to inserts that succeed on the source but fail on the replica with `Table is full` errors. This is a known issue (Bug #48666). In such cases, you must set the global value of `max_heap_table_size` on the replica as well as on the source, then restart replication. It is also recommended that you restart both the source and replica MySQL servers, to ensure that the new value takes complete (global) effect on each of them.

See [Section 18.3, “The MEMORY Storage Engine”](#), for more information about `MEMORY` tables.

### 19.5.1.23 Replication of the mysql System Schema

Data modification statements made to tables in the `mysql` schema are replicated according to the value of `binlog_format`; if this value is `MIXED`, these statements are replicated using row-based format. However, statements that would normally update this information indirectly—such as `GRANT`, `REVOKE`, and statements manipulating triggers, stored routines, and views—are replicated to replicas using statement-based replication.

### 19.5.1.24 Replication and the Query Optimizer

It is possible for the data on the source and replica to become different if a statement is written in such a way that the data modification is nondeterministic; that is, left up to the query optimizer. (In general, this is not a good practice, even outside of replication.) Examples of nondeterministic statements include `DELETE` or `UPDATE` statements that use `LIMIT` with no `ORDER BY` clause; see [Section 19.5.1.19, “Replication and LIMIT”](#), for a detailed discussion of these.

### 19.5.1.25 Replication and Partitioning

Replication is supported between partitioned tables as long as they use the same partitioning scheme and otherwise have the same structure, except where an exception is specifically allowed (see [Section 19.5.1.9, “Replication with Differing Table Definitions on Source and Replica”](#)).

Replication between tables that have different partitioning is generally not supported. This because statements (such as `ALTER TABLE ... DROP PARTITION`) that act directly on partitions in such cases might produce different results on the source and the replica. In the case where a table is partitioned on the source but not on the replica, any statements that operate on partitions on the source's copy of the replica fail on the replica. When the replica's copy of the table is partitioned but the source's copy is not, statements that act directly on partitions cannot be run on the source without causing errors there. To avoid stopping replication or creating inconsistencies between the source and replica, always ensure that a table on the source and the corresponding replicated table on the replica are partitioned in the same way.

### 19.5.1.26 Replication and REPAIR TABLE

When used on a corrupted or otherwise damaged table, it is possible for the `REPAIR TABLE` statement to delete rows that cannot be recovered. However, any such modifications of table data performed by this statement are not replicated, which can cause source and replica to lose synchronization. For this reason, in the event that a table on the source becomes damaged and you use `REPAIR TABLE` to repair it, you should first stop replication (if it is still running) before using `REPAIR TABLE`, then afterward compare the source's and replica's copies of the table and be prepared to correct any discrepancies manually, before restarting replication.

### 19.5.1.27 Replication and Reserved Words

You can encounter problems when you attempt to replicate from an older source to a newer replica and you make use of identifiers on the source that are reserved words in the newer MySQL version running on the replica. For example, a table column named `rank` on a MySQL 5.7 source that is replicating to a MySQL 9.1 replica could cause a problem because `RANK` became a reserved word in MySQL 8.0.

Replication can fail in such cases with Error 1064 *You have an error in your SQL syntax..., even if a database or table named using the reserved word or a table having a column named using the reserved word is excluded from replication*. This is due to the fact that each SQL event must be parsed by the replica prior to execution, so that the replica knows which database object or objects would be affected. Only after the event is parsed can the replica apply any filtering rules defined by `--replicate-do-db`, `--replicate-do-table`, `--replicate-ignore-db`, and `--replicate-ignore-table`.

To work around the problem of database, table, or column names on the source which would be regarded as reserved words by the replica, do one of the following:

- Use one or more `ALTER TABLE` statements on the source to change the names of any database objects where these names would be considered reserved words on the replica, and change any SQL statements that use the old names to use the new names instead.
- In any SQL statements using these database object names, write the names as quoted identifiers using backtick characters (```).

For listings of reserved words by MySQL version, see [Keywords and Reserved Words in MySQL 8.0](#), in the *MySQL Server Version Reference*. For identifier quoting rules, see [Section 11.2, “Schema Object Names”](#).

### 19.5.1.28 Replication and Row Searches

When a replica using row-based replication format applies an `UPDATE` or `DELETE` operation, it must search the relevant table for the matching rows. The algorithm used to carry out this process uses one of the table's indexes to carry out the search as the first choice, and a hash table if there are no suitable indexes.

The algorithm first assesses the available indexes in the table definition to see if there is any suitable index to use, and if there are multiple possibilities, which index is the best fit for the operation. The algorithm ignores the following types of index:

- Fulltext indexes.
- Hidden indexes.
- Generated indexes.
- Multi-valued indexes.
- Any index where the before-image of the row event does not contain all the columns of the index.

If there are no suitable indexes after ruling out these index types, the algorithm does not use an index for the search. If there are suitable indexes, one index is selected from the candidates, in the following priority order:

1. A primary key.
2. A unique index where every column in the index has a NOT NULL attribute. If more than one such index is available, the algorithm chooses the leftmost of these indexes.
3. Any other index. If more than one such index is available, the algorithm chooses the leftmost of these indexes.

If the algorithm is able to select a primary key or a unique index where every column in the index has a NOT NULL attribute, it uses this index to iterate over the rows in the UPDATE or DELETE operation. For each row in the row event, the algorithm looks up the row in the index to locate the table record to update. If no matching record is found, it returns the error `ER_KEY_NOT_FOUND` and stops the replication applier thread.

If the algorithm was not able to find a suitable index, or was only able to find an index that was non-unique or contained nulls, a hash table is used to assist in identifying the table records. The algorithm creates a hash table containing the rows in the UPDATE or DELETE operation, with the key as the full before-image of the row. The algorithm then iterates over all the records in the target table, using the selected index if it found one, or else performing a full table scan. For each record in the target table, it determines whether that row exists in the hash table. If the row is found in the hash table, the record in the target table is updated, and the row is deleted from the hash table. When all the records in the target table have been checked, the algorithm verifies whether the hash table is now empty. If there are any unmatched rows remaining in the hash table, the algorithm returns the error `ER_KEY_NOT_FOUND` and stops the replication applier thread.

### 19.5.1.29 Replication and Source or Replica Shutdowns

It is safe to shut down a replication source server and restart it later. When a replica loses its connection to the source, the replica tries to reconnect immediately and retries periodically if that fails. The default is to retry every 60 seconds. This may be changed with the `CHANGE REPLICATION SOURCE TO` statement. A replica also is able to deal with network connectivity outages. However, the replica notices the network outage only after receiving no data from the source for `replica_net_timeout` seconds. If your outages are short, you may want to decrease the value of `replica_net_timeout`. See [Section 19.4.2, “Handling an Unexpected Halt of a Replica”](#).

An unclean shutdown (for example, a crash) on the source side can result in the source's binary log having a final position less than the most recent position read by the replica, due to the source's binary log file not being flushed. This can cause the replica not to be able to replicate when the source

comes back up. Setting `sync_binlog=1` in the source server's `my.cnf` file helps to minimize this problem because it causes the source to flush its binary log more frequently. For the greatest possible durability and consistency in a replication setup using `InnoDB` with transactions, you should also set `innodb_flush_log_at_trx_commit=1`. With this setting, the contents of the `InnoDB` redo log buffer are written out to the log file at each transaction commit and the log file is flushed to disk. Note that the durability of transactions is still not guaranteed with this setting, because operating systems or disk hardware may tell `mysqld` that the flush-to-disk operation has taken place, even though it has not.

Shutting down a replica cleanly is safe because it keeps track of where it left off. However, be careful that the replica does not have temporary tables open; see [Section 19.5.1.32, “Replication and Temporary Tables”](#). Unclean shutdowns might produce problems, especially if the disk cache was not flushed to disk before the problem occurred:

- For transactions, the replica commits and then updates `relay-log.info`. If an unexpected exit occurs between these two operations, relay log processing proceeds further than the information file indicates and the replica re-executes the events from the last transaction in the relay log after it has been restarted.
- A similar problem can occur if the replica updates `relay-log.info` but the server host crashes before the write has been flushed to disk. To minimize the chance of this occurring, set `sync_relay_log_info=1` in the replica `my.cnf` file. Setting `sync_relay_log_info` to 0 causes no writes to be forced to disk and the server relies on the operating system to flush the file from time to time.

The fault tolerance of your system for these types of problems is greatly increased if you have a good uninterruptible power supply.

### 19.5.1.30 Replica Errors During Replication

If a statement produces the same error (identical error code) on both the source and the replica, the error is logged, but replication continues.

If a statement produces different errors on the source and the replica, the replication SQL thread terminates, and the replica writes a message to its error log and waits for the database administrator to decide what to do about the error. This includes the case that a statement produces an error on the source or the replica, but not both. To address the issue, connect to the replica manually and determine the cause of the problem. `SHOW REPLICATION STATUS` is useful for this. Then fix the problem and run `START REPLICATION`. For example, you might need to create a nonexistent table before you can start the replica again.

#### Note

If a temporary error is recorded in the replica's error log, you do not necessarily have to take any action suggested in the quoted error message. Temporary errors should be handled by the client retrying the transaction. For example, if the replication SQL thread records a temporary error relating to a deadlock, you do not need to restart the transaction manually on the replica, unless the replication SQL thread subsequently terminates with a nontemporary error message.

If this error code validation behavior is not desirable, some or all errors can be masked out (ignored) with the `--replica-skip-errors` option.

For nontransactional storage engines such as `MyISAM`, it is possible to have a statement that only partially updates a table and returns an error code. This can happen, for example, on a multiple-row insert that has one row violating a key constraint, or if a long update statement is killed after updating some of the rows. If that happens on the source, the replica expects execution of the statement to result in the same error code. If it does not, the replication SQL thread stops as described previously.

If you are replicating between tables that use different storage engines on the source and replica, keep in mind that the same statement might produce a different error when run against one version of the table, but not the other, or might cause an error for one version of the table, but not the other. For example, since [MyISAM](#) ignores foreign key constraints, an [INSERT](#) or [UPDATE](#) statement accessing an [InnoDB](#) table on the source might cause a foreign key violation but the same statement performed on a [MyISAM](#) version of the same table on the replica would produce no such error, causing replication to stop.

Replication filter rules are applied first, prior to making any privilege or row format checks, making it possible to filter out any transactions that fail validation; no checks are performed and thus no errors are raised for transactions which have been filtered out. This means that the replica can accept only that part of the database to which a given user has been granted access (as long as any updates to this part of the database use the row-based replication format). This may be helpful when performing an upgrade or when migrating to a system or application that uses administration tables to which the inbound replication user does not have access. See also [Section 19.2.5, “How Servers Evaluate Replication Filtering Rules”](#).

### 19.5.1.31 Replication and Server SQL Mode

Using different server SQL mode settings on the source and the replica may cause the same [INSERT](#) statements to be handled differently on the source and the replica, leading the source and replica to diverge. For best results, you should always use the same server SQL mode on the source and on the replica. This advice applies whether you are using statement-based or row-based replication.

If you are replicating partitioned tables, using different SQL modes on the source and the replica is likely to cause issues. At a minimum, this is likely to cause the distribution of data among partitions to be different in the source's and replica's copies of a given table. It may also cause inserts into partitioned tables that succeed on the source to fail on the replica.

For more information, see [Section 7.1.11, “Server SQL Modes”](#).

### 19.5.1.32 Replication and Temporary Tables

In MySQL 9.1, when [binlog\\_format](#) is set to [ROW](#) or [MIXED](#), statements that exclusively use temporary tables are not logged on the source, and therefore the temporary tables are not replicated. Statements that involve a mix of temporary and nontemporary tables are logged on the source only for the operations on nontemporary tables, and the operations on temporary tables are not logged. This means that there are never any temporary tables on the replica to be lost in the event of an unplanned shutdown by the replica. For more information about row-based replication and temporary tables, see [Row-based logging of temporary tables](#).

When [binlog\\_format](#) is set to [STATEMENT](#), operations on temporary tables are logged on the source and replicated on the replica, provided that the statements involving temporary tables can be logged safely using statement-based format. In this situation, loss of replicated temporary tables on the replica can be an issue. In statement-based replication mode, [CREATE TEMPORARY TABLE](#) and [DROP TEMPORARY TABLE](#) statements cannot be used inside a transaction, procedure, function, or trigger when GTIDs are in use on the server (that is, when the [enforce\\_gtid\\_consistency](#) system variable is set to [ON](#)). They can be used outside these contexts when GTIDs are in use, provided that [autocommit=1](#) is set.

Because of the differences in behavior between row-based or mixed replication mode and statement-based replication mode regarding temporary tables, you cannot switch the replication format at runtime, if the change applies to a context (global or session) that contains any open temporary tables. For more details, see the description of the [binlog\\_format](#) option.

**Safe replica shutdown when using temporary tables.** In statement-based replication mode, temporary tables are replicated except in the case where you stop the replica server (not just the replication threads) and you have replicated temporary tables that are open for use in updates that have

not yet been executed on the replica. If you stop the replica server, the temporary tables needed by those updates are no longer available when the replica is restarted. To avoid this problem, do not shut down the replica while it has temporary tables open. Instead, use the following procedure:

1. Issue a `STOP REPLICATION SQL_THREAD` statement.
2. Use `SHOW STATUS` to check the value of the `Replica_open_temp_tables` status variable.
3. If the value is not 0, restart the replication SQL thread with `START REPLICATION SQL_THREAD` and repeat the procedure later.
4. When the value is 0, issue a `mysqladmin shutdown` command to stop the replica.

**Temporary tables and replication options.** By default, with statement-based replication, all temporary tables are replicated; this happens whether or not there are any matching `--replicate-do-db`, `--replicate-do-table`, or `--replicate-wild-do-table` options in effect. However, the `--replicate-ignore-table` and `--replicate-wild-ignore-table` options are honored for temporary tables. The exception is that to enable correct removal of temporary tables at the end of a session, a replica always replicates a `DROP TEMPORARY TABLE IF EXISTS` statement, regardless of any exclusion rules that would normally apply for the specified table.

A recommended practice when using statement-based replication is to designate a prefix for exclusive use in naming temporary tables that you do not want replicated, then employ a `--replicate-wild-ignore-table` option to match that prefix. For example, you might give all such tables names beginning with `norep` (such as `norepmytable`, `norepyourtable`, and so on), then use `--replicate-wild-ignore-table=norep%` to prevent them from being replicated.

### 19.5.1.33 Replication Retries and Timeouts

The global value of the system variable `replica_transaction_retries` sets the maximum number of times for applier threads on a single-threaded or multithreaded replica to automatically retry failed transactions before stopping. Transactions are automatically retried when the SQL thread fails to execute them because of an `InnoDB` deadlock, or when the transaction's execution time exceeds the `InnoDB innodb_lock_wait_timeout` value. If a transaction has a non-temporary error that prevents it from succeeding, it is not retried.

The default setting for `replica_transaction_retries` is 10, meaning that a failing transaction with an apparently temporary error is retried 10 times before the applier thread stops. Setting the variable to 0 disables automatic retrying of transactions. On a multithreaded replica, the specified number of transaction retries can take place on all applier threads of all channels. The Performance Schema table `replication_applier_status` shows the total number of transaction retries that took place on each replication channel, in the `COUNT_TRANSACTIONS_RETRIES` column.

The process of retrying transactions can cause lag on a replica or on a Group Replication group member, which can be configured as a single-threaded or multithreaded replica. The Performance Schema table `replication_applier_status_by_worker` shows detailed information on transaction retries by the applier threads on a single-threaded or multithreaded replica. This data includes timestamps showing how long it took the applier thread to apply the last transaction from start to finish (and when the transaction currently in progress was started), and how long this was after the commit on the original source and the immediate source. The data also shows the number of retries for the last transaction and the transaction currently in progress, and enables you to identify the transient errors that caused the transactions to be retried. You can use this information to see whether transaction retries are the cause of replication lag, and investigate the root cause of the failures that led to the retries.

### 19.5.1.34 Replication and Time Zones

By default, source and replica servers assume that they are in the same time zone. If you are replicating between servers in different time zones, the time zone must be set on both source and replica. Otherwise, statements depending on the local time on the source are not replicated properly, such as statements that use the `NOW()` or `FROM_UNIXTIME()` functions.

Verify that your combination of settings for the system time zone (`system_time_zone`), server current time zone (the global value of `time_zone`), and per-session time zones (the session value of `time_zone`) on the source and replica is producing the correct results. In particular, if the `time_zone` system variable is set to the value `SYSTEM`, indicating that the server time zone is the same as the system time zone, this can cause the source and replica to apply different time zones. For example, a source could write the following statement in the binary log:

```
SET @@session.time_zone='SYSTEM';
```

If this source and its replica have a different setting for their system time zones, this statement can produce unexpected results on the replica, even if the replica's global `time_zone` value has been set to match the source's. For an explanation of MySQL Server's time zone settings, and how to change them, see [Section 7.1.15, “MySQL Server Time Zone Support”](#).

See also [Section 19.5.1.14, “Replication and System Functions”](#).

### 19.5.1.35 Replication and Transaction Inconsistencies

Inconsistencies in the sequence of transactions that have been executed from the relay log can occur depending on your replication configuration. This section explains how to avoid inconsistencies and solve any problems they cause.

The following types of inconsistencies can exist:

- *Half-applied transactions.* A transaction which updates non-transactional tables has applied some but not all of its changes.
- *Gaps.* A gap in the externalized transaction set appears when, given an ordered sequence of transactions, a transaction that is later in the sequence is applied before some other transaction that is prior in the sequence. Gaps can only appear when using a multithreaded replica.

To avoid gaps occurring on a multithreaded replica, set `replica_preserve_commit_order=ON`. This is the default, because all replicas are multithreaded by default.

Binary logging and replica update logging are not required on the replica to set `replica_preserve_commit_order=ON`, and can be disabled if wanted.

Setting `replica_preserve_commit_order=ON` requires that `replica_parallel_type` is set to `LOGICAL_CLOCK`. In MySQL 9.1, this is the default.

In some specific situations, as listed in the description for `replica_preserve_commit_order`, setting `replica_preserve_commit_order=ON` cannot preserve commit order on the replica, so in these cases gaps might still appear in the sequence of transactions that have been executed from the replica's relay log.

Setting `replica_preserve_commit_order=ON` does not prevent source binary log position lag.

- *Source binary log position lag.* Even in the absence of gaps, it is possible that transactions after `Exec_master_log_pos` have been applied. That is, all transactions up to point `N` have been applied, and no transactions after `N` have been applied, but `Exec_master_log_pos` has a value smaller than `N`. In this situation, `Exec_master_log_pos` is a “low-water mark” of the transactions applied, and lags

behind the position of the most recently applied transaction. This can only happen on multithreaded replicas. Enabling `replica_preserve_commit_order` does not prevent source binary log position lag.

The following scenarios are relevant to the existence of half-applied transactions, gaps, and source binary log position lag:

1. While replication threads are running, there may be gaps and half-applied transactions.
2. `mysqld` shuts down. Both clean and unclean shutdown abort ongoing transactions and may leave gaps and half-applied transactions.
3. `KILL` of replication threads (the SQL thread when using a single-threaded replica, the coordinator thread when using a multithreaded replica). This aborts ongoing transactions and may leave gaps and half-applied transactions.
4. Error in applier threads. This may leave gaps. If the error is in a mixed transaction, that transaction is half-applied. When using a multithreaded replica, workers which have not received an error complete their queues, so it may take time to stop all threads.
5. `STOP REPLICATION` when using a multithreaded replica. After issuing `STOP REPLICATION`, the replica waits for any gaps to be filled and then updates `Exec_master_log_pos`. This ensures it never leaves gaps or source binary log position lag, unless any of the cases above applies, in other words, before `STOP REPLICATION` completes, either an error happens, or another thread issues `KILL`, or the server restarts. In these cases, `STOP REPLICATION` returns successfully.
6. If the last transaction in the relay log is only half-received and the multithreaded replica's coordinator thread has started to schedule the transaction to a worker, then `STOP REPLICATION` waits up to 60 seconds for the transaction to be received. After this timeout, the coordinator gives up and aborts the transaction. If the transaction is mixed, it may be left half-completed.
7. `STOP REPLICATION` when the ongoing transaction updates transactional tables only, in which case it is rolled back and `STOP REPLICATION` stops immediately. If the ongoing transaction is mixed, `STOP REPLICATION` waits up to 60 seconds for the transaction to complete. After this timeout, it aborts the transaction, so it may be left half-completed.

The global setting for the system variable `rpl_stop_replica_timeout` is unrelated to the process of stopping the replication threads. It only makes the client that issues `STOP REPLICATION` return to the client, but the replication threads continue to try to stop.

If a replication channel has gaps, it has the following consequences:

1. The replica database is in a state that may never have existed on the source.
2. The field `Exec_master_log_pos` in `SHOW REPLICATION STATUS` is only a “low-water mark”. In other words, transactions appearing before the position are guaranteed to have committed, but transactions after the position may have committed or not.
3. `CHANGE REPLICATION SOURCE TO` statements for that channel fail with an error, unless the applier threads are running and the statement only sets receiver options.
4. If `mysqld` is started with `--relay-log-recovery`, no recovery is done for that channel, and a warning is printed.
5. If `mysqldump` is used with `--dump-replica`, it does not record the existence of gaps; thus it prints `CHANGE REPLICATION SOURCE TO` with `RELAY_LOG_POS` set to the “low-water mark” position in `Exec_master_log_pos`.

After applying the dump on another server, and starting the replication threads, transactions appearing after the position are replicated again. Note that this is harmless if GTIDs are enabled (however, in that case it is not recommended to use `--dump-replica`).

If a replication channel has source binary log position lag but no gaps, cases 2 to 5 above apply, but case 1 does not.

The source binary log position information is persisted in binary format in the internal table `mysql.slave_worker_info`. `START REPLICA [SQL_THREAD]` always consults this information so that it applies only the correct transactions. This remains true even if `replica_parallel_workers` has been changed to 0 before `START REPLICA`, and even if `START REPLICA` is used with `UNTIL`. `START REPLICA UNTIL SQL_AFTER_MTS_GAPS` applies only as many transactions as needed in order to fill in the gaps. If `START REPLICA` is used with `UNTIL` clauses that tell it to stop before it has consumed all the gaps, then it leaves remaining gaps.

### Warning

`RESET REPLICA` removes the relay logs and resets the replication position. Thus issuing `RESET REPLICA` on a multithreaded replica with gaps means the replica loses any information about the gaps, without correcting the gaps. In this situation, if binary log position based replication is in use, the recovery process fails.

When GTID-based replication is in use (`GTID_MODE=ON`) and `SOURCE_AUTO_POSITION` is set for the replication channel using the `CHANGE REPLICATION SOURCE TO` statement, the old relay logs are not required for the recovery process. Instead, the replica can use GTID auto-positioning to calculate what transactions it is missing compared to the source. The process used for binary log position based replication to resolve gaps on a multithreaded replica is skipped entirely when GTID-based replication is in use. When the process is skipped, a `START REPLICA UNTIL SQL_AFTER_MTS_GAPS` statement behaves differently, and does not attempt to check for gaps in the sequence of transactions. You can also issue `CHANGE REPLICATION SOURCE TO` statements, which are not permitted on a non-GTID replica where there are gaps.

## 19.5.1.36 Replication and Transactions

**Mixing transactional and nontransactional statements within the same transaction.** In MySQL 9.3 (and later), transactions that update both transactional tables and tables which are nontransactional or noncomposable are deprecated, and causes a deprecation warning to be written to both the client and the error log. In MySQL 9.3 only the `InnoDB` and `BLACKHOLE` storage engines are transactional and composable; `NDBCLUSTER` is transactional but not composable. This means that the only combinations of storage engines that do *not* raise the deprecation warning are those listed here:

- `InnoDB` and `BLACKHOLE`
- `MyISAM` and `Merge`
- `performance_schema` and any other storage engine
- `TempTable` and any other storage engine

In general, you should avoid transactions that update both transactional and nontransactional tables in a replication environment. You should also avoid using any statement that accesses both transactional (or temporary) and nontransactional tables and writes to any of them.

The server uses these rules for binary logging:

- If the initial statements in a transaction are nontransactional, they are written to the binary log immediately. The remaining statements in the transaction are cached and not written to the binary log

until the transaction is committed. (If the transaction is rolled back, the cached statements are written to the binary log only if they make nontransactional changes that cannot be rolled back. Otherwise, they are discarded.)

- For statement-based logging, logging of nontransactional statements is affected by the `binlog_direct_non_transactional_updates` system variable. When this variable is `OFF` (the default), logging is as just described. When this variable is `ON`, logging occurs immediately for nontransactional statements occurring anywhere in the transaction (not just initial nontransactional statements). Other statements are kept in the transaction cache and logged when the transaction commits. `binlog_direct_non_transactional_updates` has no effect for row-format or mixed-format binary logging.

### Transactional, nontransactional, and mixed statements.

To apply those rules, the server considers a statement nontransactional if it changes only nontransactional tables, and transactional if it changes only transactional tables. A statement that references both nontransactional and transactional tables and updates *any* of the tables involved is considered a “mixed” statement. Mixed statements, like transactional statements, are cached and logged when the transaction commits.

A mixed statement that updates a transactional table is considered unsafe if the statement also performs either of the following actions:

- Updates or reads a temporary table
- Reads a nontransactional table and the transaction isolation level is less than `REPEATABLE_READ`

A mixed statement following the update of a transactional table within a transaction is considered unsafe if it performs either of the following actions:

- Updates any table and reads from any temporary table
- Updates a nontransactional table and `binlog_direct_non_transactional_updates` is `OFF`

For more information, see [Section 19.2.1.3, “Determination of Safe and Unsafe Statements in Binary Logging”](#).

### Note

A mixed statement is unrelated to mixed binary logging format.

In situations where transactions mix updates to transactional and nontransactional tables, the order of statements in the binary log is correct, and all needed statements are written to the binary log even in case of a `ROLLBACK`. However, when a second connection updates the nontransactional table before the first connection transaction is complete, statements can be logged out of order because the second connection update is written immediately after it is performed, regardless of the state of the transaction being performed by the first connection.

**Using different storage engines on source and replica.** It is possible to replicate transactional tables on the source using nontransactional tables on the replica. For example, you can replicate an `InnoDB` source table as a `MyISAM` replica table. However, if you do this, there are problems if the replica is stopped in the middle of a `BEGIN ... COMMIT` block because the replica restarts at the beginning of the `BEGIN` block.

It is also safe to replicate transactions from `MyISAM` tables on the source to transactional tables, such as tables that use the `InnoDB` storage engine, on the replica. In such cases, an `AUTOCOMMIT=1` statement issued on the source is replicated, thus enforcing `AUTOCOMMIT` mode on the replica.

When the storage engine type of the replica is nontransactional, transactions on the source that mix updates of transactional and nontransactional tables should be avoided because they can cause inconsistency of the data between the source transactional table and the replica nontransactional table. That is, such transactions can lead to source storage engine-specific behavior with the possible effect of replication going out of synchrony. MySQL does not issue a warning about this, so extra care should be taken when replicating transactional tables from the source to nontransactional tables on the replicas.

**Changing the binary logging format within transactions.** The `binlog_format` and `binlog_checksum` system variables are read-only as long as a transaction is in progress.

Every transaction (including `autocommit` transactions) is recorded in the binary log as though it starts with a `BEGIN` statement, and ends with either a `COMMIT` or a `ROLLBACK` statement. This is even true for statements affecting tables that use a nontransactional storage engine (such as `MyISAM`).

#### Note

For restrictions that apply specifically to XA transactions, see [Section 15.3.8.3, “Restrictions on XA Transactions”](#).

### 19.5.1.37 Replication and Triggers

With statement-based replication, triggers executed on the source also execute on the replica. With row-based replication, triggers executed on the source do not execute on the replica. Instead, the row changes on the source resulting from trigger execution are replicated and applied on the replica.

This behavior is by design. If under row-based replication the replica applied the triggers as well as the row changes caused by them, the changes would in effect be applied twice on the replica, leading to different data on the source and the replica.

If you want triggers to execute on both the source and the replica, perhaps because you have different triggers on the source and replica, you must use statement-based replication. However, to enable replica-side triggers, it is not necessary to use statement-based replication exclusively. It is sufficient to switch to statement-based replication only for those statements where you want this effect, and to use row-based replication the rest of the time.

A statement invoking a trigger (or function) that causes an update to an `AUTO_INCREMENT` column is not replicated correctly using statement-based replication. MySQL 9.1 marks such statements as unsafe. (Bug #45677)

A trigger can have triggers for different combinations of trigger event (`INSERT`, `UPDATE`, `DELETE`) and action time (`BEFORE`, `AFTER`), and multiple triggers are permitted.

For brevity, “multiple triggers” here is shorthand for “multiple triggers that have the same trigger event and action time.”

**Upgrades.** Multiple triggers are not supported in versions earlier than MySQL 5.7. If you upgrade servers in a replication topology that use a version earlier than MySQL 5.7, upgrade the replicas first and then upgrade the source. If an upgraded replication source server still has old replicas using MySQL versions that do not support multiple triggers, an error occurs on those replicas if a trigger is created on the source for a table that already has a trigger with the same trigger event and action time.

**Downgrades.** If you downgrade a server that supports multiple triggers to an older version that does not, the downgrade has these effects:

- For each table that has triggers, all trigger definitions are in the `.TRG` file for the table. However, if there are multiple triggers with the same trigger event and action time, the server executes only one of them

when the trigger event occurs. For information about `.TRG` files, see the Table Trigger Storage section of the MySQL Server Doxygen documentation, available at <https://dev.mysql.com/doc/index-other.html>.

- If triggers for the table are added or dropped subsequent to the downgrade, the server rewrites the table's `.TRG` file. The rewritten file retains only one trigger per combination of trigger event and action time; the others are lost.

To avoid these problems, modify your triggers before downgrading. For each table that has multiple triggers per combination of trigger event and action time, convert each such set of triggers to a single trigger as follows:

1. For each trigger, create a stored routine that contains all the code in the trigger. Values accessed using `NEW` and `OLD` can be passed to the routine using parameters. If the trigger needs a single result value from the code, you can put the code in a stored function and have the function return the value. If the trigger needs multiple result values from the code, you can put the code in a stored procedure and return the values using `OUT` parameters.
2. Drop all triggers for the table.
3. Create one new trigger for the table that invokes the stored routines just created. The effect for this trigger is thus the same as the multiple triggers it replaces.

### 19.5.1.38 Replication and TRUNCATE TABLE

`TRUNCATE TABLE` is normally regarded as a DML statement, and so would be expected to be logged and replicated using row-based format when the binary logging mode is `ROW` or `MIXED`. However this caused issues when logging or replicating, in `STATEMENT` or `MIXED` mode, tables that used transactional storage engines such as `InnoDB` when the transaction isolation level was `READ COMMITTED` or `READ UNCOMMITTED`, which precludes statement-based logging.

`TRUNCATE TABLE` is treated for purposes of logging and replication as DDL rather than DML so that it can be logged and replicated as a statement. However, the effects of the statement as applicable to `InnoDB` and other transactional tables on replicas still follow the rules described in [Section 15.1.37, “TRUNCATE TABLE Statement”](#) governing such tables. (Bug #36763)

### 19.5.1.39 Replication and User Name Length

The maximum length for user names in MySQL 9.1 is 32 characters. Replication of user names longer than 16 characters fails when the replica runs a version of MySQL previous to 5.7, because those versions support only shorter user names. This occurs only when replicating from a newer source to an older replica, which is not a recommended configuration.

### 19.5.1.40 Replication and Variables

System variables are not replicated correctly when using `STATEMENT` mode, except for the following variables when they are used with session scope:

- `auto_increment_increment`
- `auto_increment_offset`
- `character_set_client`
- `character_set_connection`
- `character_set_database`

- `character_set_server`
- `collation_connection`
- `collation_database`
- `collation_server`
- `foreign_key_checks`
- `identity`
- `last_insert_id`
- `lc_time_names`
- `pseudo_thread_id`
- `sql_auto_is_null`
- `time_zone`
- `timestamp`
- `unique_checks`

When `MIXED` mode is used, the variables in the preceding list, when used with session scope, cause a switch from statement-based to row-based logging. See [Section 7.4.4.3, “Mixed Binary Logging Format”](#).

`sql_mode` is also replicated except for the `NO_DIR_IN_CREATE` mode; the replica always preserves its own value for `NO_DIR_IN_CREATE`, regardless of changes to it on the source. This is true for all replication formats.

However, when `mysqlbinlog` parses a `SET @@sql_mode = mode` statement, the full `mode` value, including `NO_DIR_IN_CREATE`, is passed to the receiving server. For this reason, replication of such a statement may not be safe when `STATEMENT` mode is in use.

The `default_storage_engine` system variable is not replicated, regardless of the logging mode; this is intended to facilitate replication between different storage engines.

The `read_only` system variable is not replicated. In addition, the enabling this variable has different effects with regard to temporary tables, table locking, and the `SET PASSWORD` statement in different MySQL versions.

The `max_heap_table_size` system variable is not replicated. Increasing the value of this variable on the source without doing so on the replica can lead eventually to `Table is full` errors on the replica when trying to execute `INSERT` statements on a `MEMORY` table on the source that is thus permitted to grow larger than its counterpart on the replica. For more information, see [Section 19.5.1.22, “Replication and MEMORY Tables”](#).

In statement-based replication, session variables are not replicated properly when used in statements that update tables. For example, the following sequence of statements does not insert the same data on the source and the replica:

```
SET max_join_size=1000;
INSERT INTO mytable VALUES(@@max_join_size);
```

This does not apply to the common sequence:

```
SET time_zone=...;
INSERT INTO mytable VALUES(CONVERT_TZ(..., ..., @@time_zone));
```

Replication of session variables is not a problem when row-based replication is being used, in which case, session variables are always replicated safely. See [Section 19.2.1, “Replication Formats”](#).

The following session variables are written to the binary log and honored by the replica when parsing the binary log, regardless of the logging format:

- `sql_mode`
- `foreign_key_checks`
- `unique_checks`
- `character_set_client`
- `collation_connection`
- `collation_database`
- `collation_server`
- `sql_auto_is_null`

#### Important

Even though session variables relating to character sets and collations are written to the binary log, replication between different character sets is not supported.

To help reduce possible confusion, we recommend that you always use the same setting for the `lower_case_table_names` system variable on both source and replica, especially when you are running MySQL on platforms with case-sensitive file systems. The `lower_case_table_names` setting can only be configured when initializing the server.

### 19.5.1.41 Replication and Views

Views are always replicated to replicas. Views are filtered by their own name, not by the tables they refer to. This means that a view can be replicated to the replica even if the view contains a table that would normally be filtered out by `replication-ignore-table` rules. Care should therefore be taken to ensure that views do not replicate table data that would normally be filtered for security reasons.

Replication from a table to a same-named view is supported using statement-based logging, but not when using row-based logging. Trying to do so when row-based logging is in effect causes an error.

## 19.5.2 Replication Compatibility Between MySQL Versions

MySQL supports replication from an older source to a newer replica for version combinations where we support upgrades from the source version to the replica version as described at [Section 1.3, “MySQL Releases: Innovation and LTS”](#) and [Section 3.2, “Upgrade Paths”](#). However, you might encounter difficulties when replicating from an older source to a newer replica if the source uses statements or relies on behavior no longer supported in the version of MySQL used on the replica.

The use of more than two MySQL Server versions is not supported in replication setups involving multiple sources, regardless of the number of source or replica MySQL servers. For example, if you are using a chained or circular replication setup, you cannot use MySQL X.Y.1, MySQL X.Y.2, and MySQL X.Y.3 concurrently, although you could use any two of these releases together.

**Important**

It is strongly recommended to use the most recent release available within a given MySQL release series because replication (and other) capabilities are continually being improved. It is also recommended to upgrade sources and replicas that use early releases of a release series of MySQL to GA (production) releases when the latter become available for that release series.

The server version is recorded in the binary log for each transaction for the server that originally committed the transaction ([original\\_server\\_version](#)), and for the server that is the immediate source of the current server in the replication topology ([immediate\\_server\\_version](#)).

Replication from newer sources to older replicas might be possible, but is generally not supported. This is due to a number of factors:

- **Binary log format changes.** The binary log format can change between major releases. While we attempt to maintain backward compatibility, this is not always possible. A source might also have optional features enabled that are not understood by older replicas, such as binary log transaction compression, where the resulting compressed transaction payloads cannot be read by a replica from a release prior to MySQL 8.0.20.

This also has significant implications for upgrading replication servers; see [Section 19.5.3, “Upgrading or Downgrading a Replication Topology”](#), for more information.

- **SQL incompatibilities.** You cannot replicate from a newer source to an older replica using statement-based replication if the statements to be replicated use SQL features available on the source but not on the replica.

However, if both the source and the replica support row-based replication, and there are no data definition statements to be replicated that depend on SQL features found on the source but not on the replica, you can use row-based replication to replicate the effects of data modification statements even if the DDL run on the source is not supported on the replica.

For more information about row-based replication, see [Section 19.2.1, “Replication Formats”](#).

For more information on potential replication issues, see [Section 19.5.1, “Replication Features and Issues”](#).

## 19.5.3 Upgrading or Downgrading a Replication Topology

When you upgrade servers that participate in a replication topology, you need to take into account each server's role in the topology and look out for issues specific to replication. For general information and instructions for upgrading a MySQL Server instance, see [Chapter 3, \*Upgrading MySQL\*](#).

As explained in [Section 19.5.2, “Replication Compatibility Between MySQL Versions”](#), MySQL supports replication from an older source to a newer replica for version combinations where we support upgrades from the source version to the replica version as described at [Section 1.3, “MySQL Releases: Innovation and LTS”](#) and [Section 3.2, “Upgrade Paths”](#), but does not support replication from a source running a later release to a replica running an earlier release. A replica at an earlier release might not have the required capability to process transactions that can be handled by the source at a later release. You must therefore upgrade all of the replicas in a replication topology to the target MySQL Server release, before you upgrade the source server to the target release. In this way you will never be in the situation where a replica still at the earlier release is attempting to handle transactions from a source at the later release.

In a replication topology where there are multiple sources (multi-source replication), the use of more than two MySQL Server versions is not supported, regardless of the number of source or replica MySQL

servers. For example, you cannot use MySQL X.Y.1, MySQL X.Y.2, and MySQL X.Y.3 concurrently in such a setup, although you could use any two of these releases together.

## Pre-Check Servers before Upgrade

It is possible to encounter replication difficulties when replicating from a source at an earlier release that has not yet been upgraded, to a replica at a later release that has been upgraded. This can happen if the source uses statements or relies on behavior that is no longer supported in the later release installed on the replica. You can use the MySQL Shell upgrade checker utility `util.checkForServerUpgrade()` to check MySQL 8.0 server instances for upgrade to a MySQL 8.4 release. This utility identifies configuration and stored data that is known to potentially cause upgrade problems, including features and behaviors that are no longer available in the later release. See [Upgrade Checker Utility](#) for information on the upgrade checker utility.

## Standard Upgrade Procedure

To upgrade a replication topology, follow the instructions in [Chapter 3, Upgrading MySQL](#) for each individual MySQL Server instance, using this overall procedure:

1. Upgrade the replicas first. On each replica instance:
  - Carry out the preliminary checks and steps described in [Section 3.6, “Preparing Your Installation for Upgrade”](#).
  - Shut down MySQL Server.
  - Upgrade the MySQL Server binaries or packages.
  - Restart MySQL Server.
  - MySQL Server performs the entire MySQL upgrade procedure automatically, disabling binary logging during the upgrade.
  - Restart replication using a `START REPLICA`.
2. If there are multiple layers of replicas (replicas-of-replicas) start upgrading the replicas that are farthest away from the source, performing the upgrade in a bottom-up fashion.
3. When all replicas have upgraded and only the source remains, perform a switch-over to one of the replicas. In other words, stop client updates on the source, wait for at least one replica to apply all changes, reconfigure the replication topology so that replica becomes the source and that the source is left outside the replication topology. Upgrade the old source according to the procedure for a single server, and then reinsert it into the topology.

If you need to downgrade the servers in a replication topology, the source must be downgraded before the replicas are downgraded. On the replicas, you must ensure that the binary log and relay log have been fully processed, and purge them before proceeding with the downgrade.

## Rolling Downgrade Procedure

1. Stop the updates.
2. Wait for replicas to receive all updates. It is not necessary to wait for them to apply all changes. If they have not applied all changes, leave their applier running so they can process the received transactions in the background.
3. Downgrade the source server, following the instructions for single server downgrade.

4. Insert the downgraded source server in the topology again.
5. Allow updates again.
6. Wait until all replicas have applied all remaining transactions from the previous primary.
7. For each replica, take out the replica from the topology, wait for it to apply all its relay log, downgrade it following the instructions for a single server downgrade, and reinsert it back into the topology. If there are multiple levels of replicas (replicas-of-replicas) then downgrade top-down starting with the replicas nearest to the source server.

## 19.5.4 Troubleshooting Replication

If you have followed the instructions but your replication setup is not working, the first thing to do is *check the error log for messages*. Many users have lost time by not doing this soon enough after encountering problems.

If you cannot tell from the error log what the problem was, try the following techniques:

- Verify that the source has binary logging enabled by issuing a `SHOW BINARY LOG STATUS` statement. Binary logging is enabled by default. If binary logging is enabled, `Position` is nonzero. If binary logging is not enabled, verify that you are not running the source with any settings that disable binary logging, such as the `--skip-log-bin` option.
- Verify that the `server_id` system variable was set at startup on both the source and replica and that the ID value is unique on each server.
- Verify that the replica is running. Use `SHOW REPLICA STATUS` to check whether the `Replica_IO_Running` and `Replica_SQL_Running` values are both `Yes`. If not, verify the options that were used when starting the replica server. For example, `--skip-replica-start` prevents the replication threads from starting until you issue a `START REPLICA` statement.
- If the replica is running, check whether it established a connection to the source. Use `SHOW PROCESSLIST`, find the I/O (receiver) and SQL (applier) threads and check their `State` column to see what they display. See [Section 19.2.3, “Replication Threads”](#). If the receiver thread state says `Connecting to master`, check the following:
  - Verify the privileges for the replication user on the source.
  - Check that the host name of the source is correct and that you are using the correct port to connect to the source. The port used for replication is the same as used for client network communication (the default is `3306`). For the host name, ensure that the name resolves to the correct IP address.
  - Check the configuration file to see whether the `skip_networking` system variable has been enabled on the source or replica to disable networking. If so, comment the setting or remove it.
  - If the source has a firewall or IP filtering configuration, ensure that the network port being used for MySQL is not being filtered.
  - Check that you can reach the source by using `ping` or `traceroute/tracert` to reach the host.
- If the replica was running previously but has stopped, the reason usually is that some statement that succeeded on the source failed on the replica. This should never happen if you have taken a proper snapshot of the source, and never modified the data on the replica outside of the replication threads. If the replica stops unexpectedly, it is a bug or you have encountered one of the known replication limitations described in [Section 19.5.1, “Replication Features and Issues”](#). If it is a bug, see [Section 19.5.5, “How to Report Replication Bugs or Problems”](#), for instructions on how to report it.

- If a statement that succeeded on the source refuses to run on the replica, try the following procedure if it is not feasible to do a full database resynchronization by deleting the replica's databases and copying a new snapshot from the source:

1. Determine whether the affected table on the replica is different from the source table. Try to understand how this happened. Then make the replica's table identical to the source's and run `START REPLICA`.
2. If the preceding step does not work or does not apply, try to understand whether it would be safe to make the update manually (if needed) and then ignore the next statement from the source.
3. If you decide that the replica can skip the next statement from the source, issue the following statements:

```
mysql> SET GLOBAL sql_replica_skip_counter = N;
mysql> START REPLICA;
```

The value of `N` should be 1 if the next statement from the source does not use `AUTO_INCREMENT` or `LAST_INSERT_ID()`. Otherwise, the value should be 2. The reason for using a value of 2 for statements that use `AUTO_INCREMENT` or `LAST_INSERT_ID()` is that they take two events in the binary log of the source.

4. If you are sure that the replica started out perfectly synchronized with the source, and that no one has updated the tables involved outside of the replication threads, then presumably the discrepancy is the result of a bug. If you are running the most recent version of MySQL, please report the problem. If you are running an older version, try upgrading to the latest production release to determine whether the problem persists.

## 19.5.5 How to Report Replication Bugs or Problems

When you have determined that there is no user error involved, and replication still either does not work at all or is unstable, it is time to send us a bug report. We need to obtain as much information as possible from you to be able to track down the bug. Please spend some time and effort in preparing a good bug report.

If you have a repeatable test case that demonstrates the bug, please enter it into our bugs database using the instructions given in [Section 1.6, “How to Report Bugs or Problems”](#). If you have a “phantom” problem (one that you cannot duplicate at will), use the following procedure:

1. Verify that no user error is involved. For example, if you update the replica outside of the replication threads, the data goes out of synchrony, and you can have unique key violations on updates. In this case, the replication thread stops and waits for you to clean up the tables manually to bring them into synchrony. *This is not a replication problem. It is a problem of outside interference causing replication to fail.*
2. Ensure that the replica is running with binary logging enabled (the `log_bin` system variable), and with the `--log-replica-updates` option enabled, which causes the replica to log the updates that it receives from the source into its own binary logs. These settings are the defaults.
3. Save all evidence before resetting the replication state. If we have no information or only sketchy information, it becomes difficult or impossible for us to track down the problem. The evidence you should collect is:
  - All binary log files from the source
  - All binary log files from the replica

- The output of `SHOW BINARY LOG STATUS` from the source at the time you discovered the problem
  - The output of `SHOW REPLICATION STATUS` from the replica at the time you discovered the problem
  - Error logs from the source and the replica
4. Use `mysqlbinlog` to examine the binary logs. The following should be helpful to find the problem statement. `log_file` and `log_pos` are the `Master_Log_File` and `Read_Master_Log_Pos` values from `SHOW REPLICATION STATUS`.

```
$> mysqlbinlog --start-position=log_pos log_file | head
```

After you have collected the evidence for the problem, try to isolate it as a separate test case first. Then enter the problem with as much information as possible into our bugs database using the instructions at [Section 1.6, “How to Report Bugs or Problems”](#).

---

This chapter explains Group Replication in MySQL 9.1, and how to install, configure and monitor groups. MySQL Group Replication enables you to create elastic, highly-available, fault-tolerant replication topologies.

Groups can operate in a single-primary mode with automatic primary election, where only one server accepts updates at a time. Alternatively, groups can be deployed in multi-primary mode, where all servers can accept updates, even if they are issued concurrently.

There is a built-in group membership service that keeps the view of the group consistent and available for all servers at any given point in time. Servers can leave and join the group and the view is updated accordingly. Sometimes servers can leave the group unexpectedly, in which case the failure detection mechanism detects this and notifies the group that the view has changed. This is all automatic.

Group Replication guarantees that the database service is continuously available. However, it is important to understand that if one of the group members becomes unavailable, the clients connected to that group member must be redirected, or failed over, to a different server in the group, using a connector, load balancer, router, or some form of middleware. Group Replication does not have an inbuilt method to do this. For example, see [MySQL Router 9.1](#).

Group Replication is provided as a plugin to MySQL Server. You can follow the instructions in this chapter to configure the plugin on each of the server instances that you want in the group, start up the group, and monitor and administer the group. An alternative way to deploy a group of MySQL server instances is by using InnoDB Cluster.

#### Tip

To deploy multiple instances of MySQL, you can use [InnoDB Cluster](#) which enables you to easily administer a group of MySQL server instances in [MySQL Shell](#). InnoDB Cluster wraps MySQL Group Replication in a programmatic environment that enables you easily deploy a cluster of MySQL instances to achieve high availability. In addition, InnoDB Cluster interfaces seamlessly with [MySQL Router](#), which enables your applications to connect to the cluster without writing your own failover process. For similar use cases that do not require high availability, however, you can use [InnoDB ReplicaSet](#). Installation instructions for MySQL Shell can be found [here](#).

MySQL 9.1 and later support a number of MySQL components for use with MySQL Group Replication. See [Section 7.5.6, “Replication Components”](#), for more information.

This chapter is structured as follows:

- [Section 20.1, “Group Replication Background”](#) provides an introduction to groups and how Group Replication works.
- [Section 20.2, “Getting Started”](#) explains how to configure multiple MySQL Server instances to create a group.
- [Section 20.3, “Requirements and Limitations”](#) explains architecture and setup requirements and limitations for Group Replication.
- [Section 20.4, “Monitoring Group Replication”](#) explains how to monitor a group.
- [Section 20.5, “Group Replication Operations”](#) explains how to work with a group.
- [Section 20.6, “Group Replication Security”](#) explains how to secure a group.
- [Section 20.7, “Group Replication Performance and Troubleshooting”](#) explains how to fine tune performance for a group.

- [Section 20.8, “Upgrading Group Replication”](#) explains how to upgrade a group.
- [Section 20.9, “Group Replication Variables”](#) is a reference for the system variables specific to Group Replication.
- [Section 20.10, “Frequently Asked Questions”](#) provides answers to some technical questions about deploying and operating Group Replication.

## 20.1 Group Replication Background

This section provides background information on MySQL Group Replication.

The most common way to create a fault-tolerant system is to resort to making components redundant, in other words the component can be removed and the system should continue to operate as expected. This creates a set of challenges that raise complexity of such systems to a whole different level. Specifically, replicated databases have to deal with the fact that they require maintenance and administration of several servers instead of just one. Moreover, as servers are cooperating together to create the group several other classic distributed systems problems have to be dealt with, such as network partitioning or split brain scenarios.

Therefore, the ultimate challenge is to fuse the logic of the database and data replication with the logic of having several servers coordinated in a consistent and simple way. In other words, to have multiple servers agreeing on the state of the system and the data on each and every change that the system goes through. This can be summarized as having servers reaching agreement on each database state transition, so that they all progress as one single database or alternatively that they eventually converge to the same state. Meaning that they need to operate as a (distributed) state machine.

MySQL Group Replication provides distributed state machine replication with strong coordination between servers. Servers coordinate themselves automatically when they are part of the same group. The group can operate in a single-primary mode with automatic primary election, where only one server accepts updates at a time. Alternatively, for more advanced users the group can be deployed in multi-primary mode, where all servers can accept updates, even if they are issued concurrently. This power comes at the expense of applications having to work around the limitations imposed by such deployments.

There is a built-in group membership service that keeps the view of the group consistent and available for all servers at any given point in time. Servers can leave and join the group and the view is updated accordingly. Sometimes servers can leave the group unexpectedly, in which case the failure detection mechanism detects this and notifies the group that the view has changed. This is all automatic.

For a transaction to commit, the majority of the group have to agree on the order of a given transaction in the global sequence of transactions. Deciding to commit or abort a transaction is done by each server individually, but all servers make the same decision. If there is a network partition, resulting in a split where members are unable to reach agreement, then the system does not progress until this issue is resolved. Hence there is also a built-in, automatic, split-brain protection mechanism.

All of this is powered by the provided Group Communication System (GCS) protocols. These provide a failure detection mechanism, a group membership service, and safe and completely ordered message delivery. All these properties are key to creating a system which ensures that data is consistently replicated across the group of servers. At the very core of this technology lies an implementation of the Paxos algorithm. It acts as the group communication engine.

### 20.1.1 Replication Technologies

Before getting into the details of MySQL Group Replication, this section introduces some background concepts and an overview of how things work. This provides some context to help understand what is required for Group Replication and what the differences are between classic asynchronous MySQL Replication and Group Replication.

### 20.1.1.1 Source to Replica Replication

Traditional MySQL [Replication](#) provides a simple source to replica approach to replication. The source is the primary, and there are one or more replicas, which are secondaries. The source applies transactions, commits them and then they are later (thus asynchronously) sent to the replicas to be either re-executed (in statement-based replication) or applied (in row-based replication). It is a shared-nothing system, where all servers have a full copy of the data by default.

**Figure 20.1 MySQL Asynchronous Replication**

There is also semisynchronous replication, which adds one synchronization step to the protocol. This means that the primary waits, at apply time, for the secondary to acknowledge that it has *received* the transaction. Only then does the primary resume the commit operation.

**Figure 20.2 MySQL Semisynchronous Replication**

**Key**

ACK = Acknowledged

In the two pictures there is a diagram of the classic asynchronous MySQL Replication protocol (and its semisynchronous variant as well). The arrows between the different instances represent messages exchanged between servers or messages exchanged between servers and the client application.

### 20.1.1.2 Group Replication

Group Replication is a technique that can be used to implement fault-tolerant systems. A replication group is a set of servers, each of which has a complete copy of the data (a shared-nothing replication scheme), which interact with each other through message passing. The communication layer provides a set of guarantees such as atomic message and total order message delivery. These are very powerful properties that translate into very useful abstractions that one can resort to build more advanced database replication solutions.

MySQL Group Replication builds on top of such properties and abstractions and implements a multi-source update everywhere replication protocol. A replication group is formed by multiple servers; each server in the group may execute transactions independently at any time. Read/write transactions commit only after they have been approved by the group. In other words, for any read/write transaction the group needs to decide whether it commits or not, so the commit operation is not a unilateral decision from the originating server. Read-only transactions need no coordination within the group and commit immediately.

When a read/write transaction is ready to commit at the originating server, the server atomically broadcasts the write values (the rows that were changed) and the corresponding write set (the unique identifiers of the rows that were updated). Because the transaction is sent through an atomic broadcast, either all servers in the group receive the transaction or none do. If they receive it, then they all receive it in the same order with respect to other transactions that were sent before. All servers therefore receive the same set of transactions in the same order, and a global total order is established for the transactions.

However, there may be conflicts between transactions that execute concurrently on different servers. Such conflicts are detected by inspecting and comparing the write sets of two different and concurrent transactions, in a process called *certification*. During certification, conflict detection is carried out at row level: if two concurrent transactions, that executed on different servers, update the same row, then there is a conflict. The conflict resolution procedure states that the transaction that was ordered first commits on all servers, and the transaction ordered second aborts, and is therefore rolled back on the originating server and dropped by the other servers in the group. For example, if t1 and t2 execute concurrently at different sites, both changing the same row, and t2 is ordered before t1, then t2 wins the conflict and t1 is rolled back. This is in fact a distributed first commit wins rule. Note that if two transactions are bound to conflict more often than not, then it is a good practice to start them on the same server, where they have a chance to synchronize on the local lock manager instead of being rolled back as a result of certification.

For applying and externalizing the certified transactions, Group Replication permits servers to deviate from the agreed order of the transactions if this does not break consistency and validity. Group Replication is an eventual consistency system, meaning that as soon as the incoming traffic slows down or stops, all group members have the same data content. While traffic is flowing, transactions can be externalized in a slightly different order, or externalized on some members before the others. For example, in multi-primary mode, a local transaction might be externalized immediately following certification, although a remote transaction that is earlier in the global order has not yet been applied. This is permitted when the certification process has established that there is no conflict between the transactions. In single-primary mode, on the primary server, there is a small chance that concurrent, non-conflicting local transactions might be committed and externalized in a different order from the global order agreed by Group Replication. On the secondaries, which do not accept writes from clients, transactions are always committed and externalized in the agreed order.

The following figure depicts the MySQL Group Replication protocol and by comparing it to MySQL Replication (or even MySQL semisynchronous replication) you can see some differences. Some underlying consensus and Paxos related messages are missing from this picture for the sake of clarity.

Figure 20.3 MySQL Group Replication Protocol

## 20.1.2 Group Replication Use Cases

Group Replication enables you to create fault-tolerant systems with redundancy by replicating the system state to a set of servers. Even if some of the servers subsequently fail, as long it is not all or a majority, the system is still available. Depending on the number of servers which fail the group might have degraded performance or scalability, but it is still available. Server failures are isolated and independent. They are tracked by a group membership service which relies on a distributed failure detector that is able to signal when any servers leave the group, either voluntarily or due to an unexpected halt. There is a distributed recovery procedure to ensure that when servers join the group they are brought up to date automatically. There is no need for server failover, and the multi-source update everywhere nature ensures that even updates are not blocked in the event of a single server failure. To summarize, MySQL Group Replication guarantees that the database service is continuously available.

It is important to understand that although the database service is available, in the event of an unexpected server exit, those clients connected to it must be redirected, or failed over, to a different server. This is not something Group Replication attempts to resolve. A connector, load balancer, router, or some form of middleware are more suitable to deal with this issue. For example see [MySQL Router 9.1](#).

To summarize, MySQL Group Replication provides a highly available, highly elastic, dependable MySQL service.

### Tip

To deploy multiple instances of MySQL, you can use [InnoDB Cluster](#) which enables you to easily administer a group of MySQL server instances in [MySQL Shell](#). InnoDB Cluster wraps MySQL Group Replication in a programmatic environment that enables you easily deploy a cluster of MySQL instances to achieve high availability. In addition, InnoDB Cluster interfaces seamlessly with [MySQL Router](#), which enables your applications to connect to the cluster without writing your own failover process. For similar use cases that do not require high availability, however, you can use [InnoDB ReplicaSet](#). Installation instructions for MySQL Shell can be found [here](#).

## Example Use Cases

The following examples are typical use cases for Group Replication.

- *Elastic Replication* - Environments that require a very fluid replication infrastructure, where the number of servers has to grow or shrink dynamically and with as few side-effects as possible. For instance, database services for the cloud.
- *Highly Available Shards* - Sharding is a popular approach to achieve write scale-out. Use MySQL Group Replication to implement highly available shards, where each shard maps to a replication group.
- *Alternative to asynchronous Source-Replica replication* - In certain situations, using a single source server makes it a single point of contention. Writing to an entire group may prove more scalable under certain circumstances.
- *Autonomic Systems* - Additionally, you can deploy MySQL Group Replication purely for the automation that is built into the replication protocol (described already in this and previous chapters).

### 20.1.3 Multi-Primary and Single-Primary Modes

Group Replication operates either in single-primary mode or in multi-primary mode. The group's mode is a group-wide configuration setting, specified by the `group_replication_single_primary_mode` system variable, which must be the same on all members. `ON` means single-primary mode, which is the default mode, and `OFF` means multi-primary mode. It is not possible to have members of the group deployed in different modes, for example one member configured in multi-primary mode while another member is in single-primary mode.

You cannot change the value of `group_replication_single_primary_mode` manually while Group Replication is running. You can use the `group_replication_switch_to_single_primary_mode()` and `group_replication_switch_to_multi_primary_mode()` functions to move a group from one mode to another while Group Replication is still running. These functions manage the process of changing the group's mode and ensure the safety and consistency of your data. In earlier releases, to change the group's mode you must stop Group Replication and change the value of `group_replication_single_primary_mode` on all members. Then carry out a full reboot of the group (a bootstrap by a server with `group_replication_bootstrap_group=ON`) to implement the change to the new operating configuration. You do not need to restart the servers.

Regardless of the deployed mode, Group Replication does not handle client-side failover. That must be handled by a middleware framework such as [MySQL Router 9.1](#), a proxy, a connector, or the application itself.

#### 20.1.3.1 Single-Primary Mode

In single-primary mode (`group_replication_single_primary_mode=ON`) the group has a single primary server that is set to read/write mode. All the other members in the group are set to read-only mode (with `super_read_only=ON`). The primary typically bootstraps the entire group. All other servers that join the group learn about the primary server and are automatically set to read-only mode.

In single-primary mode, Group Replication enforces that only a single server writes to the group, so compared to multi-primary mode, consistency checking can be less strict and DDL statements do not need to be handled with any extra care. The option `group_replication_enforce_update_everywhere_checks` enables or disables strict consistency checks for a group. When deploying in single-primary mode, or changing the group to single-primary mode, this system variable must be set to `OFF`.

The member that is designated as the primary server can change in the following ways:

- If the existing primary leaves the group, whether voluntarily or unexpectedly, a new primary is elected automatically.

- You can appoint a specific member as the new primary using the `group_replication_set_as_primary()` function.
- If you use the `group_replication_switch_to_single_primary_mode()` function to change a group that was running in multi-primary mode to run in single-primary mode, a new primary is elected automatically, or you can appoint the new primary by specifying it with the function.

When a new primary server is elected (automatically or manually), it is automatically set to read/write, and the other group members remain as secondaries, and as such, read-only. The following diagram shows this process:

**Figure 20.4 New Primary Election**

When a new primary is chosen, it might have a backlog of changes that had been applied on the old primary but have not yet been applied on the new one. In this case, until the new primary catches up with the old one, read/write transactions might result in conflicts and be rolled back, and read-only transactions might result in stale reads. The Group Replication flow control mechanism minimizes the difference between fast and slow members, and so reduces the chances of this happening if it is activated and properly tuned. For more information, see [Section 20.7.2, “Flow Control”](#). You can also use the `group_replication_consistency` system variable to set the group's level of transaction consistency to prevent this issue. Setting this variable to `BEFORE_ON_PRIMARY_FAILOVER` (the default) or any higher consistency level holds new transactions on a newly elected primary until the backlog has been applied.

For more information on transaction consistency, see [Section 20.5.3, “Transaction Consistency Guarantees”](#). If flow control and transaction consistency guarantees are not used for a group, it is a good practice to wait for the new primary to apply its replication-related relay log before re-routing client applications to it.

## Primary Election Algorithm

The automatic primary member election process involves each member looking at the new view of the group, ordering the potential new primary members, and choosing the member that qualifies as the most suitable. Each member makes its own decision locally, following the primary election algorithm in its MySQL Server release. Because all members must reach the same decision, members adapt their primary election algorithm if other group members are running lower MySQL Server versions, so that they have the same behavior as the member with the lowest MySQL Server version in the group.

The factors considered by members when electing a primary, in order, are as follows:

1. The first factor considered is which member or members are running the lowest MySQL Server version. All group members are first ordered by the patch version of their release.
2. If more than one member is running the lowest MySQL Server version, the second factor considered is the member weight of each of those members, as specified by the `group_replication_member_weight` system variable on the member.

The `group_replication_member_weight` system variable specifies a number in the range 0-100. All members default to a weight of 50, so set a weight below this to lower their ordering, and a weight above it to increase their ordering. You can use this weighting function to prioritize the use of better hardware or to ensure failover to a specific member during scheduled maintenance of the primary.

3. If more than one member is running the lowest MySQL Server version, and more than one of those members has the highest member weight (or member weighting is being ignored), the third factor considered is the lexicographical order of the generated server UUIDs of each member, as specified by the `server_uuid` system variable. The member with the lowest server UUID is chosen as the primary. This factor acts as a guaranteed and predictable tie-breaker so that all group members reach the same decision if it cannot be determined by any important factors.

## Finding the Primary

To find out which server is currently the primary when deployed in single-primary mode, use the `MEMBER_ROLE` column in the `performance_schema.replication_group_members` table. For example:

```
mysql> SELECT MEMBER_HOST, MEMBER_ROLE FROM performance_schema.replication_group_members;
```

MEMBER_HOST	MEMBER_ROLE
remote1.example.com	PRIMARY
remote2.example.com	SECONDARY
remote3.example.com	SECONDARY

### 20.1.3.2 Multi-Primary Mode

In multi-primary mode (`group_replication_single_primary_mode=OFF`) no member has a special role. Any member that is compatible with the other group members is set to read/write mode when joining the group, and can process write transactions, even if they are issued concurrently.

If a member stops accepting write transactions, for example, in the event of an unexpected server exit, clients connected to it can be redirected, or failed over, to any other member that is in read/write mode. Group Replication does not handle client-side failover itself, so you need to arrange this using a middleware framework such as [MySQL Router 9.1](#), a proxy, a connector, or the application itself. [Figure 20.5, “Client Failover”](#) shows how clients can reconnect to an alternative group member if a member leaves the group.

**Figure 20.5 Client Failover**

Group Replication is an eventual consistency system. This means that as soon as the incoming traffic slows down or stops, all group members have the same data content. While traffic is flowing, transactions can be externalized on some members before the others, especially if some members have less write throughput than others, creating the possibility of stale reads. In multi-primary mode, slower members can also build up an excessive backlog of transactions to certify and apply, leading to a greater risk of conflicts and certification failure. To limit these issues, you can activate and tune Group Replication's flow control mechanism to minimize the difference between fast and slow members. For more information on flow control, see [Section 20.7.2, "Flow Control"](#).

If you want transaction consistency guaranteed for every transaction in the group, you can do this using the `group_replication_consistency` system variable. You can choose a setting that suits the workload of your group and your priorities for data reads and writes, taking into account the performance impact of the synchronization required to increase consistency. You can also set the system variable for individual sessions to protect particularly concurrency-sensitive transactions. For more information on transaction consistency, see [Section 20.5.3, "Transaction Consistency Guarantees"](#).

## Transaction Checks

When a group is deployed in multi-primary mode, transactions are checked to ensure they are compatible with the mode. The following strict consistency checks are made when Group Replication is deployed in multi-primary mode:

- If a transaction is executed under the `SERIALIZABLE` isolation level, then its commit fails when synchronizing itself with the group.
- If a transaction executes against a table that has foreign keys with cascading constraints, then its commit fails when synchronizing itself with the group.

The checks are controlled by the `group_replication_enforce_update_everywhere_checks` system variable. In multi-primary mode, the system variable should normally be set to `ON`, but the checks can optionally be deactivated by setting the system variable to `OFF`. When deploying in single-primary mode, the system variable must be set to `OFF`.

## Data Definition Statements

In a Group Replication topology in multi-primary mode, care needs to be taken when executing data definition statements, also commonly known as data definition language (DDL).

MySQL 9.1 supports atomic Data Definition Language (DDL) statements, where the complete DDL statement is either committed or rolled back as a single atomic transaction. DDL statements, atomic or otherwise, implicitly end any transaction that is active in the current session, as if you had done a `COMMIT` before executing the statement. This means that DDL statements cannot be performed within another transaction, within transaction control statements such as `START TRANSACTION ... COMMIT`, or combined with other statements within the same transaction.

Group Replication is based on an optimistic replication paradigm, where statements are optimistically executed and rolled back later if necessary. Each server executes without securing group agreement first. Therefore, more care needs to be taken when replicating DDL statements in multi-primary mode. If you make schema changes (using DDL) and changes to the data that an object contains (using DML) for the same object, the changes need to be handled through the same server while the schema operation has not yet completed and replicated everywhere. Failure to do so can result in data inconsistency when operations are interrupted or only partially completed. If the group is deployed in single-primary mode this issue does not occur, because all changes are performed through the same server, the primary.

For more information about atomic DDL support, see [Section 15.1.1, “Atomic Data Definition Statement Support”](#).

## Version Compatibility

For optimal compatibility and performance, all members of a group should run the same version of MySQL Server and therefore of Group Replication. In multi-primary mode, this is more significant because all members would normally join the group in read/write mode. If a group includes members running more than one MySQL Server version, there is a potential for some members to be incompatible with others, because they support functions others do not, or lack functions others have. To guard against this, when a new member joins (including a former member that has been upgraded and restarted), the member carries out compatibility checks against the rest of the group.

One result of these compatibility checks is particularly important in multi-primary mode. If a joining member is running a higher MySQL Server version than the lowest version that the existing group members are running, it joins the group but remains in read-only mode. (In a group that is running in single-primary mode, new members default to read-only in any case.) Members take into account the major.minor.release version of the MySQL software (and thus, of the Group Replication plugin) when checking their compatibility.

In a group running in multi-primary mode with members that use different MySQL Server versions, Group Replication automatically manages their read/write and read-only status. If a member leaves the group, the members running the version that is now the lowest are automatically set to read/write mode. When you change a group that was running in single-primary mode to run in multi-primary mode, using the function `group_replication_switch_to_multi_primary_mode()`, Group Replication automatically sets members to the correct mode. Members are automatically placed in read-only mode if they are running a higher MySQL server version than the lowest version present in the group, and members running the lowest version are placed in read/write mode.

For full information on version compatibility in a group and how this influences the behavior of a group during an upgrade process, see [Section 20.8.1, “Combining Different Member Versions in a Group”](#).

## 20.1.4 Group Replication Services

This section introduces some of the services that Group Replication builds on.

### 20.1.4.1 Group Membership

In MySQL Group Replication, a set of servers forms a replication group. A group has a name, which takes the form of a UUID. The group is dynamic and servers can leave (either voluntarily or involuntarily) and join it at any time. The group adjusts itself whenever servers join or leave.

If a server joins the group, it automatically brings itself up to date by fetching the missing state from an existing server. If a server leaves the group, for instance it was taken down for maintenance, the remaining servers notice that it has left and reconfigure the group automatically.

Group Replication has a group membership service that defines which servers are online and participating in the group. The list of online servers is referred to as a *view*. Every server in the group has a consistent view of which servers are the members participating actively in the group at a given moment in time.

Group members must agree not only on transaction commits, but also on which is the current view. If existing members agree that a new server should become part of the group, the group is reconfigured to integrate that server in it, which triggers a view change. If a server leaves the group, either voluntarily or not, the group dynamically rearranges its configuration and a view change is triggered.

In the case where a member leaves the group voluntarily, it first initiates a dynamic group reconfiguration, during which all members have to agree on a new view without the leaving server. However, if a member leaves the group involuntarily, for example because it has stopped unexpectedly or the network connection is down, it cannot initiate the reconfiguration. In this situation, Group Replication's failure detection mechanism recognizes after a short period of time that the member has left, and a reconfiguration of the group without the failed member is proposed. As with a member that leaves voluntarily, the reconfiguration requires agreement from the majority of servers in the group. However, if the group is not able to reach agreement, for example because it partitioned in such a way that there is no majority of servers online, the system is not able to dynamically change the configuration, and blocks to prevent a split-brain situation. This situation requires intervention from an administrator.

It is possible for a member to go offline for a short time, then attempt to rejoin the group again before the failure detection mechanism has detected its failure, and before the group has been reconfigured to remove the member. In this situation, the rejoining member forgets its previous state, but if other members send it messages that are intended for its pre-crash state, this can cause issues including possible data inconsistency. If a member in this situation participates in XCom's consensus protocol, it could potentially cause XCom to deliver different values for the same consensus round, by making a different decision before and after failure.

To counter this possibility, MySQL Group Replication checks for the situation where a new incarnation of the same server is trying to join the group while its old incarnation (with the same address and port number) is still listed as a member. The new incarnation is blocked from joining the group until the old incarnation can be removed by a reconfiguration. Note that if a waiting period has been added by the `group_replication_member_expel_timeout` system variable to allow additional time for members to reconnect with the group before they are expelled, a member under suspicion can become active in the group again as its current incarnation if it reconnects to the group before the suspicion times out. When a member exceeds the expel timeout and is expelled from the group, or when Group Replication is stopped on the server by a `STOP GROUP_REPLICATION` statement or a server failure, it must rejoin as a new incarnation.

### 20.1.4.2 Failure Detection

Group Replication's failure detection mechanism is a distributed service which is able to identify that a server in the group is not communicating with the others, and is therefore suspected of being out of service. If the group's consensus is that the suspicion is probably true, the group takes a coordinated decision to expel the member. Expelling a member that is not communicating is necessary because the group needs a majority of its members to agree on a transaction or view change. If a member is not

participating in these decisions, the group must remove it to increase the chance that the group contains a majority of correctly working members, and can therefore continue to process transactions.

In a replication group, each member has a point-to-point communication channel to each other member, creating a fully connected graph. These connections are managed by the group communication engine (XCom, a Paxos variant) and use TCP/IP sockets. One channel is used to send messages to the member and the other channel is used to receive messages from the member. If a member does not receive messages from another member for 5 seconds, it suspects that the member has failed, and lists the status of that member as `UNREACHABLE` in its own Performance Schema table `replication_group_members`. Usually, two members will suspect each other of having failed because they are each not communicating with the other. It is possible, though less likely, that member A suspects member B of having failed but member B does not suspect member A of having failed - perhaps due to a routing or firewall issue. A member can also create a suspicion of itself. A member that is isolated from the rest of the group suspects that all the others have failed.

If a suspicion lasts for more than 10 seconds, the suspecting member tries to propagate its view that the suspect member is faulty to the other members of the group. A suspecting member only does this if it is a notifier, as calculated from its internal XCom node number. If a member is actually isolated from the rest of the group, it might attempt to propagate its view, but that will have no consequences as it cannot secure a quorum of the other members to agree on it. A suspicion only has consequences if a member is a notifier, and its suspicion lasts long enough to be propagated to the other members of the group, and the other members agree on it. In that case, the suspect member is marked for expulsion from the group in a coordinated decision, and is expelled after the waiting period set by the `group_replication_member_expel_timeout` system variable expires and the expelling mechanism detects and implements the expulsion.

Where the network is unstable and members frequently lose and regain connection to each other in different combinations, it is theoretically possible for a group to end up marking all its members for expulsion, after which the group would cease to exist and have to be set up again. To counter this possibility, the Group Replication Group Communication System (GCS) tracks the group members that have been marked for expulsion, and treats them as if they were in the group of suspected members when deciding if there is a majority. This ensures at least one member remains in the group and the group can continue to exist. When an expelled member has actually been removed from the group, GCS removes its record of having marked the member for expulsion, so that the member can rejoin the group if it is able to do so.

For information on the Group Replication system variables that you can configure to specify the responses of working group members to failure situations, and the actions taken by group members that are suspected of having failed, see [Section 20.7.7, “Responses to Failure Detection and Network Partitioning”](#).

### 20.1.4.3 Fault-tolerance

MySQL Group Replication builds on an implementation of the Paxos distributed algorithm to provide distributed coordination between servers. As such, it requires a majority of servers to be active to reach quorum and thus make a decision. This has direct impact on the number of failures the system can tolerate without compromising itself and its overall functionality. The number of servers ( $n$ ) needed to tolerate  $f$  failures is then  $n = 2 \times f + 1$ .

In practice this means that to tolerate one failure the group must have three servers in it. As such if one server fails, there are still two servers to form a majority (two out of three) and allow the system to continue to make decisions automatically and progress. However, if a second server fails *involuntarily*, then the group (with one server left) blocks, because there is no majority to reach a decision.

The following is a small table illustrating the formula above.

Group Size	Majority	Instant Failures Tolerated
1	1	0
2	2	0
3	2	1
4	3	1
5	3	2
6	4	2
7	4	3

#### 20.1.4.4 Observability

There is a lot of automation built into the Group Replication plugin. Nonetheless, you might sometimes need to understand what is happening behind the scenes. This is where the instrumentation of Group Replication and Performance Schema becomes important. The entire state of the system (including the view, conflict statistics and service states) can be queried through Performance Schema tables. The distributed nature of the replication protocol and the fact that server instances agree and thus synchronize on transactions and metadata makes it simpler to inspect the state of the group. For example, you can connect to a single server in the group and obtain both local and global information by issuing select statements on the Group Replication related Performance Schema tables. For more information, see [Section 20.4, “Monitoring Group Replication”](#).

#### 20.1.5 Group Replication Plugin Architecture

MySQL Group Replication is a MySQL plugin and it builds on the existing MySQL replication infrastructure, taking advantage of features such as the binary log, row-based logging, and global transaction identifiers. It integrates with current MySQL frameworks, such as the performance schema or plugin and service infrastructures. The following figure presents a block diagram depicting the overall architecture of MySQL Group Replication.

Figure 20.6 Group Replication Plugin Block Diagram

The MySQL Group Replication plugin includes a set of APIs for capture, apply, and lifecycle, which control how the plugin interacts with MySQL Server. There are interfaces to make information flow from the server to the plugin and vice versa. These interfaces isolate the MySQL Server core from the Group Replication plugin, and are mostly hooks placed in the transaction execution pipeline. In one direction, from server to the plugin, there are notifications for events such as the server starting, the server recovering, the server being ready to accept connections, and the server being about to commit a transaction. In the other direction, the plugin instructs the server to perform actions such as committing or aborting ongoing transactions, or queuing transactions in the relay log.

The next layer of the Group Replication plugin architecture is a set of components that react when a notification is routed to them. The capture component is responsible for keeping track of context related to transactions that are executing. The applier component is responsible for executing remote transactions

on the database. The recovery component manages distributed recovery, and is responsible for getting a server that is joining the group up to date by selecting the donor, managing the catch up procedure and reacting to donor failures.

Continuing down the stack, the replication protocol module contains the specific logic of the replication protocol. It handles conflict detection, and receives and propagates transactions to the group.

The final two layers of the Group Replication plugin architecture are the Group Communication System (GCS) API, and an implementation of a Paxos-based group communication engine (XCom). The GCS API is a high level API that abstracts the properties required to build a replicated state machine (see [Section 20.1, “Group Replication Background”](#)). It therefore decouples the implementation of the messaging layer from the remaining upper layers of the plugin. The group communication engine handles communications with the members of the replication group.

## 20.2 Getting Started

MySQL Group Replication is provided as a plugin for the MySQL server; each server in a group requires configuration and installation of the plugin. This section provides a detailed tutorial with the steps required to create a replication group with at least three members.

### Tip

To deploy multiple instances of MySQL, you can use [InnoDB Cluster](#) which enables you to easily administer a group of MySQL server instances in [MySQL Shell](#). InnoDB Cluster wraps MySQL Group Replication in a programmatic environment that enables you easily deploy a cluster of MySQL instances to achieve high availability. In addition, InnoDB Cluster interfaces seamlessly with [MySQL Router](#), which enables your applications to connect to the cluster without writing your own failover process. For similar use cases that do not require high availability, however, you can use [InnoDB ReplicaSet](#). Installation instructions for MySQL Shell can be found [here](#).

### 20.2.1 Deploying Group Replication in Single-Primary Mode

Each of the MySQL server instances in a group can run on an independent physical host machine, which is the recommended way to deploy Group Replication. This section explains how to create a replication group with three MySQL Server instances, each running on a different host machine. See [Section 20.2.2, “Deploying Group Replication Locally”](#) for information about deploying multiple MySQL server instances running Group Replication on the same host machine, for example for testing purposes.

**Figure 20.7 Group Architecture**

This tutorial explains how to get and deploy MySQL Server with the Group Replication plugin, how to configure each server instance before creating a group, and how to use Performance Schema monitoring to verify that everything is working correctly.

### 20.2.1.1 Deploying Instances for Group Replication

The first step is to deploy at least three instances of MySQL Server, this procedure demonstrates using multiple hosts for the instances, named s1, s2, and s3. It is assumed that MySQL Server is installed on each host (see [Chapter 2, \*Installing MySQL\*](#)). The Group Replication plugin is provided with MySQL Server 9.1; no additional software is required, although the plugin must be installed in the running MySQL server. See [Section 20.2.1.1, “Deploying Instances for Group Replication”](#); for additional information, see [Section 7.6, “MySQL Server Plugins”](#).

In this example, three instances are used for the group, which is the minimum number of instances to create a group. Adding more instances increases the fault tolerance of the group. For example if the group consists of three members, in event of failure of one instance the group can continue. But in the event of another failure the group can no longer continue processing write transactions. By adding more instances, the number of servers which can fail while the group continues to process transactions also

increases. The maximum number of instances which can be used in a group is nine. For more information see [Section 20.1.4.2, “Failure Detection”](#).

### 20.2.1.2 Configuring an Instance for Group Replication

This section explains the configuration settings required for MySQL Server instances that you want to use for Group Replication. For background information, see [Section 20.3, “Requirements and Limitations”](#).

- [Storage Engines](#)
- [Replication Framework](#)
- [Group Replication Settings](#)

#### Storage Engines

For Group Replication, data must be stored in the InnoDB transactional storage engine (for details of why, see [Section 20.3.1, “Group Replication Requirements”](#)). The use of other storage engines, including the temporary `MEMORY` storage engine, might cause errors in Group Replication. Set the `disabled_storage_engines` system variable as follows to prevent their use:

```
disabled_storage_engines="MyISAM,BLACKHOLE,FEDERATED,ARCHIVE,MEMORY"
```

#### Replication Framework

The following settings configure replication according to the MySQL Group Replication requirements.

```
server_id=1
gtid_mode=ON
enforce_gtid_consistency=ON
```

These settings configure the server to use the unique identifier number 1, to enable [Section 19.1.3, “Replication with Global Transaction Identifiers”](#), and to allow execution of only statements that can be safely logged using a GTID.

This setting disables checksums for events written to the binary log, which default to being enabled. Group Replication in MySQL 9.1 supports the presence of checksums in the binary log and can use them to verify the integrity of events on some channels, so you can use the default setting. For more details, see [Section 20.3.2, “Group Replication Limitations”](#).

See also [Section 20.3.1, “Group Replication Requirements”](#).

#### Group Replication Settings

At this point the option file ensures that the server is configured and is instructed to instantiate the replication infrastructure under a given configuration. The following section configures the Group Replication settings for the server.

```
plugin_load_add='group_replication.so'
group_replication_group_name="aaaaaaaa-aaaa-aaaa-aaaa-aaaaaaaaaaaaa"
group_replication_start_on_boot=off
group_replication_local_address= "s1:33061"
group_replication_group_seeds= "s1:33061,s2:33061,s3:33061"
group_replication_bootstrap_group=off
```

- `plugin-load-add` adds the Group Replication plugin to the list of plugins which the server loads at startup. This is preferable in a production deployment to installing the plugin manually.
- Configuring `group_replication_group_name` tells the plugin that the group that it is joining, or creating, is named "aaaaaaaa-aaaa-aaaa-aaaa-aaaaaaaaaaaaa".

The value of `group_replication_group_name` must be a valid UUID. You can use `SELECT UUID( )` to generate one. This UUID forms part of the GTIDs that are used when transactions received by group members from clients, and view change events that are generated internally by the group members, are written to the binary log.

- Configuring the `group_replication_start_on_boot` variable to `off` instructs the plugin to not start operations automatically when the server starts. This is important when setting up Group Replication as it ensures you can configure the server before manually starting the plugin. Once the member is configured you can set `group_replication_start_on_boot` to `on` so that Group Replication starts automatically upon server boot.
- Configuring `group_replication_local_address` sets the network address and port which the member uses for internal communication with other members in the group. Group Replication uses this address for internal member-to-member connections involving remote instances of the group communication engine (XCom, a Paxos variant).

**Important**

The group replication local address must be different to the host name and port used for SQL client connections, which are defined by MySQL Server's `hostname` and `port` system variables. It must not be used for client applications. It must be only be used for internal communication between the members of the group while running Group Replication.

The network address configured by `group_replication_local_address` must be resolvable by all group members. For example, if each server instance is on a different machine with a fixed network address, you could use the IP address of the machine, such as 10.0.0.1. If you use a host name, you must use a fully qualified name, and ensure it is resolvable through DNS, correctly configured `/etc/hosts` files, or other name resolution processes. IPv6 addresses (or host names that resolve to them) can be used as well as IPv4 addresses; a group can contain a mix of members using IPv6 and members using IPv4. For more information on Group Replication support for IPv6 networks and on mixed IPv4 and IPv6 groups, see [Section 20.5.5, “Support For IPv6 And For Mixed IPv6 And IPv4 Groups”](#).

The recommended port for `group_replication_local_address` is 33061. This is used by Group Replication as the unique identifier for a group member within the replication group. You can use the same port for all members of a replication group as long as the host names or IP addresses are all different, as demonstrated in this tutorial. Alternatively you can use the same host name or IP address for all members as long as the ports are all different, for example as shown in [Section 20.2.2, “Deploying Group Replication Locally”](#).

The connection that an existing member offers to a joining member for Group Replication's distributed recovery process is not the network address configured by `group_replication_local_address`. Group members offer their standard SQL client connection to joining members for distributed recovery, as specified by MySQL Server's `hostname` and `port`; they may (also) advertise an alternative list of distributed recovery endpoints as dedicated client connections for joining members. For more details, see [Section 20.5.4.1, “Connections for Distributed Recovery”](#).

**Important**

Distributed recovery can fail if a joining member cannot correctly identify the other members using the host name as defined by MySQL Server's `hostname` system variable. It is recommended that operating systems running MySQL have a properly configured unique host name, either using DNS or local settings. The host name that the server is using for SQL client connections can be verified in the `Member_host` column of the Performance Schema

table `replication_group_members`. If multiple group members externalize a default host name set by the operating system, there is a chance of the joining member not resolving it to the correct member address and not being able to connect for distributed recovery. In this situation you can use MySQL Server's `report_host` system variable to configure a unique host name to be externalized by each of the servers.

- Configuring `group_replication_group_seeds` sets the hostname and port of the group members which are used by the new member to establish its connection to the group. These members are called the seed members. Once the connection is established, the group membership information is listed in the Performance Schema table `replication_group_members`. Usually the `group_replication_group_seeds` list contains the `hostname:port` of each of the group member's `group_replication_local_address`, but this is not obligatory and a subset of the group members can be chosen as seeds.

#### Important

The `hostname:port` listed in `group_replication_group_seeds` is the seed member's internal network address, configured by `group_replication_local_address` and not the `hostname:port` used for SQL client connections, which is shown for example in the Performance Schema table `replication_group_members`.

The server that starts the group does not make use of this option, since it is the initial server and as such, it is in charge of bootstrapping the group. In other words, any existing data which is on the server bootstrapping the group is what is used as the data for the next joining member. The second server joining asks the one and only member in the group to join, any missing data on the second server is replicated from the donor data on the bootstrapping member, and then the group expands. The third server joining can ask any of these two to join, data is synchronized to the new member, and then the group expands again. Subsequent servers repeat this procedure when joining.

#### Warning

When joining multiple servers at the same time, make sure that they point to seed members that are already in the group. Do not use members that are also joining the group as seeds, because they might not yet be in the group when contacted.

It is good practice to start the bootstrap member first, and let it create the group. Then make it the seed member for the rest of the members that are joining. This ensures that there is a group formed when joining the rest of the members.

Creating a group and joining multiple members at the same time is not supported. It might work, but chances are that the operations race and then the act of joining the group ends up in an error or a time out.

A joining member must communicate with a seed member using the same protocol (IPv4 or IPv6) that the seed member advertises in the `group_replication_group_seeds` option. For the purpose of IP address permissions for Group Replication, the allowlist on the seed member must include an IP address for the joining member for the protocol offered by the seed member, or a host name that resolves to an address for that protocol. This address or host name must be set up and permitted in addition to the joining member's `group_replication_local_address` if the protocol for that address does not match the seed member's advertised protocol. If a joining member does not have a permitted address for the appropriate protocol, its connection attempt is refused. For more information, see [Section 20.6.4, “Group Replication IP Address Permissions”](#).

- Configuring `group_replication_bootstrap_group` instructs the plugin whether to bootstrap the group or not. In this case, even though s1 is the first member of the group we set this variable to off in the option file. Instead we configure `group_replication_bootstrap_group` when the instance is running, to ensure that only one member actually bootstraps the group.

**Important**

The `group_replication_bootstrap_group` variable must only be enabled on one server instance belonging to a group at any time, usually the first time you bootstrap the group (or in case the entire group is brought down and back up again). If you bootstrap the group multiple times, for example when multiple server instances have this option set, then they could create an artificial split brain scenario, in which two distinct groups with the same name exist. Always set `group_replication_bootstrap_group=off` after the first server instance comes online.

The system variables described in this tutorial are the required configuration settings to start a new member, but further system variables are also available to configure group members. These are listed in [Section 20.9, “Group Replication Variables”](#).

**Important**

A number of system variables, some specific to Group Replication and others not, are group-wide configuration settings that must have the same value on all group members. If the group members have a value set for one of these system variables, and a joining member has a different value set for it, the joining member cannot join the group and an error message is returned. If the group members have a value set for this system variable, and the joining member does not support the system variable, it cannot join the group. These system variables are all identified in [Section 20.9, “Group Replication Variables”](#).

### 20.2.1.3 User Credentials For Distributed Recovery

Group Replication uses a distributed recovery process to synchronize group members when joining them to the group. Distributed recovery involves transferring transactions from a donor's binary log to a joining member using a replication channel named `group_replication_recovery`. You must therefore set up a replication user with the correct permissions so that Group Replication can establish direct member-to-member replication channels. If group members have been set up to support the use of a remote cloning operation as part of distributed recovery, this replication user is also used as the clone user on the donor, and requires the correct permissions for this role too. For a complete description of distributed recovery, see [Section 20.5.4, “Distributed Recovery”](#).

The same replication user must be used for distributed recovery on every group member. The process of creating the replication user for distributed recovery can be captured in the binary log, and then you can rely on distributed recovery to replicate the statements used to create the user. Alternatively, you can disable binary logging before creating the replication user, and then create the user manually on each member, for example if you want to avoid the changes being propagated to other server instances. If you do this, ensure you re-enable binary logging once you have configured the user.

**Important**

If distributed recovery connections for your group use SSL, the replication user must be created on each server *before* the joining member connects to the donor. For instructions to set up SSL for distributed recovery connections and create a replication user that requires SSL, see [Section 20.6.3, “Securing Distributed Recovery Connections”](#)

### Important

By default, users created in MySQL 8 use [Section 8.4.1.1, “Caching SHA-2 Pluggable Authentication”](#). If the replication user for distributed recovery uses the caching SHA-2 authentication plugin, and you are *not* using SSL for distributed recovery connections, RSA key-pairs are used for password exchange. You can either copy the public key of the replication user to the joining member, or configure the donors to provide the public key when requested. For instructions to do this, see [Section 20.6.3.1, “Secure User Credentials for Distributed Recovery”](#).

To create the replication user for distributed recovery, follow these steps:

1. Start the MySQL server instance, then connect a client to it.
2. If you want to disable binary logging in order to create the replication user separately on each instance, do so by issuing the following statement:

```
mysql> SET SQL_LOG_BIN=0;
```

3. Create a MySQL user with the following privileges:
  - [REPLICATION SLAVE](#), which is required for making a distributed recovery connection to a donor to retrieve data.
  - [CONNECTION\\_ADMIN](#), which ensures that Group Replication connections are not terminated if one of the servers involved is placed in offline mode.
  - [BACKUP\\_ADMIN](#), if the servers in the replication group are set up to support cloning (see [Section 20.5.4.2, “Cloning for Distributed Recovery”](#)). This privilege is required for a member to act as the donor in a cloning operation for distributed recovery.
  - [GROUP\\_REPLICATION\\_STREAM](#), if the MySQL communication stack is in use for the replication group (see [Section 20.6.1, “Communication Stack for Connection Security Management”](#)). This privilege is required for the user account to be able to establish and maintain connections for Group Replication using the MySQL communication stack.

In this example the user `rpl_user` with the password `password` is shown. When configuring your servers use a suitable user name and password:

```
mysql> CREATE USER rpl_user@%' IDENTIFIED BY 'password';
mysql> GRANT REPLICATION SLAVE ON *.* TO rpl_user@'%';
mysql> GRANT CONNECTION_ADMIN ON *.* TO rpl_user@'%';
mysql> GRANT BACKUP_ADMIN ON *.* TO rpl_user@'%';
mysql> GRANT GROUP_REPLICATION_STREAM ON *.* TO rpl_user@'%';
mysql> FLUSH PRIVILEGES;
```

4. If you disabled binary logging, enable it again as soon as you have created the user, by issuing the following statement:

```
mysql> SET SQL_LOG_BIN=1;
```

5. When you have created the replication user, you must supply the user credentials to the server for use with distributed recovery. You can do this by setting the user credentials as the credentials for the `group_replication_recovery` channel, using a [CHANGE REPLICATION SOURCE TO](#) statement. Alternatively, you can specify the user credentials for distributed recovery in a [START GROUP\\_REPLICATION](#) statement.
  - User credentials set using [CHANGE REPLICATION SOURCE TO](#) are stored in plain text in the replication metadata repositories on the server. They are applied whenever Group Replication is

started, including automatic starts if the `group_replication_start_on_boot` system variable is set to `ON`.

- User credentials specified on `START GROUP_REPLICATION` are saved in memory only, and are removed by a `STOP GROUP_REPLICATION` statement or server shutdown. You must issue a `START GROUP_REPLICATION` statement to provide the credentials again, so you cannot start Group Replication automatically with these credentials. This method of specifying the user credentials helps to secure the Group Replication servers against unauthorized access.

For more information on the security implications of each method of providing the user credentials, see [Providing Replication User Credentials Securely](#). If you choose to provide the user credentials using a `CHANGE REPLICATION SOURCE TO` statement, issue the following statement on the server instance now, replacing `rpl_user` and `password` with the values used when creating the user:

```
mysql> CHANGE REPLICATION SOURCE TO SOURCE_USER='rpl_user',
-> SOURCE_PASSWORD='password'
-> FOR CHANNEL 'group_replication_recovery';
```

### 20.2.1.4 Launching Group Replication

It is first necessary to ensure that the Group Replication plugin is installed on server s1. If you used `plugin_load_add='group_replication.so'` in the option file then the Group Replication plugin is already installed, and you can proceed to the next step. Otherwise, you must install the plugin manually; to do this, connect to the server using the `mysql` client, and issue the SQL statement shown here:

```
mysql> INSTALL PLUGIN group_replication SONAME 'group_replication.so';
```

To check that the plugin was installed successfully, issue `SHOW PLUGINS;` and check the output. It should show something like this:

```
mysql> SHOW PLUGINS;
```

Name	Status	Type	Library	License
binlog	ACTIVE	STORAGE ENGINE	NULL	PROPRIETARY
(...)				
group_replication	ACTIVE	GROUP REPLICATION	group_replication.so	PROPRIETARY

### 20.2.1.5 Bootstrapping the Group

The process of starting a group for the first time is called bootstrapping. You use the `group_replication_bootstrap_group` system variable to bootstrap a group. The bootstrap should only be done by a single server, the one that starts the group and only once. This is why the value of the `group_replication_bootstrap_group` option was not stored in the instance's option file. If it is saved in the option file, upon restart the server automatically bootstraps a second group with the same name. This would result in two distinct groups with the same name. The same reasoning applies to stopping and restarting the plugin with this option set to `ON`. Therefore to safely bootstrap the group, connect to s1 and issue the following statements:

```
mysql> SET GLOBAL group_replication_bootstrap_group=ON;
mysql> START GROUP_REPLICATION;
mysql> SET GLOBAL group_replication_bootstrap_group=OFF;
```

Or if you are providing user credentials for distributed recovery in the `START GROUP_REPLICATION` statement, issue the following statements:

```
mysql> SET GLOBAL group_replication_bootstrap_group=ON;
```

```
mysql> START GROUP_REPLICATION USER='rpl_user', PASSWORD='password';
mysql> SET GLOBAL group_replication_bootstrap_group=OFF;
```

Once the `START GROUP_REPLICATION` statement returns, the group has been started. You can check that the group is now created and that there is one member in it:

```
mysql> SELECT * FROM performance_schema.replication_group_members;
```

CHANNEL_NAME	MEMBER_ID	MEMBER_HOST	MEMBER_PORT	MEMBER_STATE
group_replication_applier	ce9be252-2b71-11e6-b8f4-00212844f856	s1	3306	ONLINE

1 row in set (0.0108 sec)

The information in this table confirms that there is a member in the group with the unique identifier `ce9be252-2b71-11e6-b8f4-00212844f856`, that it is `ONLINE` and is at `s1` listening for client connections on port `3306`.

For the purpose of demonstrating that the server is indeed in a group and that it is able to handle load, create a table and add some content to it.

```
mysql> CREATE DATABASE test;
mysql> USE test;
mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY, c2 TEXT NOT NULL);
mysql> INSERT INTO t1 VALUES (1, 'Luis');
```

Check the content of table `t1` and the binary log.

```
mysql> SELECT * FROM t1;
```

c1	c2
1	Luis

```
mysql> SHOW BINLOG EVENTS;
```

Log_name	Pos	Event_type	Server_id	End_log_pos	Info
binlog.000001	4	Format_desc	1	123	Server ver: 9.1.0-log, Binlog ver: 4
binlog.000001	123	Previous_gtid	1	150	
binlog.000001	150	Gtid	1	211	SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa-aaa'
binlog.000001	211	Query	1	270	BEGIN
binlog.000001	270	View_change	1	369	view_id=14724817264259180:1
binlog.000001	369	Query	1	434	COMMIT
binlog.000001	434	Gtid	1	495	SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa-aaa'
binlog.000001	495	Query	1	585	CREATE DATABASE test
binlog.000001	585	Gtid	1	646	SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa-aaa'
binlog.000001	646	Query	1	770	use `test`; CREATE TABLE t1 (c1 INT PRIMARY
binlog.000001	770	Gtid	1	831	SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa-aaa'
binlog.000001	831	Query	1	899	BEGIN
binlog.000001	899	Table_map	1	942	table_id: 108 (test.t1)
binlog.000001	942	Write_rows	1	984	table_id: 108 flags: STMT_END_F
binlog.000001	984	Xid	1	1011	COMMIT /* xid=38 */

As seen above, the database and the table objects were created and their corresponding DDL statements were written to the binary log. Also, the data was inserted into the table and written to the binary log, so it can be used for distributed recovery by state transfer from a donor's binary log.

### 20.2.1.6 Adding Instances to the Group

At this point, the group has one member in it, server `s1`, which has some data in it. It is now time to expand the group by adding the other two servers configured previously.

## Adding a Second Instance

In order to add a second instance, server s2, first create the configuration file for it. The configuration is similar to the one used for server s1, except for things such as the `server_id`.

```
[mysqld]

#
Disable other storage engines
#
disabled_storage_engines="MyISAM,BLACKHOLE,FEDERATED,ARCHIVE,MEMORY"

#
Replication configuration parameters
#
server_id=2
gtid_mode=ON
enforce_gtid_consistency=ON

#
Group Replication configuration
#
plugin_load_add='group_replication.so'
group_replication_group_name="aaaaaaaa-aaaa-aaaa-aaaa-aaaaaaaaaaaaa"
group_replication_start_on_boot=off
group_replication_local_address= "s2:33061"
group_replication_group_seeds= "s1:33061,s2:33061,s3:33061"
group_replication_bootstrap_group= off
```

Similar to the procedure for server s1, with the option file in place you launch the server. Then configure the distributed recovery credentials as follows. The commands are the same as used when setting up server s1 as the user is shared within the group. This member needs to have the same replication user configured in [Section 20.2.1.3, "User Credentials For Distributed Recovery"](#). If you are relying on distributed recovery to configure the user on all members, when s2 connects to the seed s1 the replication user is replicated or cloned to s1. If you did not have binary logging enabled when you configured the user credentials on s1, and a remote cloning operation is not used for state transfer, you must create the replication user on s2. In this case, connect to s2 and issue:

```
SET SQL_LOG_BIN=0;
CREATE USER rpl_user@%' IDENTIFIED BY 'password';
GRANT REPLICATION SLAVE ON *.* TO rpl_user@'%';
GRANT CONNECTION_ADMIN ON *.* TO rpl_user@'%';
GRANT BACKUP_ADMIN ON *.* TO rpl_user@'%';
GRANT GROUP_REPLICATION_STREAM ON *.* TO rpl_user@'%';
FLUSH PRIVILEGES;
SET SQL_LOG_BIN=1;
```

If you are providing user credentials using a `CHANGE REPLICATION SOURCE TO`, issue the following statement after that:

```
CHANGE REPLICATION SOURCE TO SOURCE_USER='rpl_user', SOURCE_PASSWORD='password' \
FOR CHANNEL 'group_replication_recovery';
```

### Tip

If you are using the caching SHA-2 authentication plugin (the default), see [Replication User With The Caching SHA-2 Authentication Plugin](#).

If necessary, install the Group Replication plugin, see [Section 20.2.1.4, "Launching Group Replication"](#).

Start Group Replication and s2 starts the process of joining the group.

```
mysql> START GROUP_REPLICATION;
```

If you are providing user credentials for distributed recovery as part of `START GROUP_REPLICATION`, you can do so like this:

```
mysql> START GROUP_REPLICATION USER='rpl_user', PASSWORD='password';
```

Unlike the previous steps that were the same as those executed on s1, here there is a difference in that you do *not* need to bootstrap the group because the group already exists. In other words on s2 `group_replication_bootstrap_group` is set to `OFF`, and you do not issue `SET GLOBAL group_replication_bootstrap_group=ON`; before starting Group Replication, because the group has already been created and bootstrapped by server s1. At this point server s2 only needs to be added to the already existing group.

### Tip

When Group Replication starts successfully and the server joins the group it checks the `super_read_only` variable. By setting `super_read_only` to `ON` in the member's configuration file, you can ensure that servers which fail when starting Group Replication for any reason do not accept transactions. If the server should join the group as a read/write instance, for example as the primary in a single-primary group or as a member of a multi-primary group, when `super_read_only` is set to `ON` then it is set to `OFF` upon joining the group.

Checking the `performance_schema.replication_group_members` table again shows that there are now two `ONLINE` servers in the group.

```
mysql> SELECT * FROM performance_schema.replication_group_members;
```

CHANNEL_NAME	MEMBER_ID	MEMBER_HOST	MEMBER_PORT	MEMBER_STATE
group_replication_applier	395409e1-6dfa-11e6-970b-00212844f856	s1	3306	ONLINE
group_replication_applier	ac39f1e6-6dfa-11e6-a69d-00212844f856	s2	3306	ONLINE

When s2 attempted to join the group, [Section 20.5.4, “Distributed Recovery”](#) ensured that s2 applied the same transactions which s1 had applied. Once this process completed, s2 could join the group as a member, and at this point it is marked as `ONLINE`. In other words it must have already caught up with server s1 automatically. Once s2 is `ONLINE`, it then begins to process transactions with the group. Verify that s2 has indeed synchronized with server s1 as follows.

```
mysql> SHOW DATABASES LIKE 'test';
```

Database (test)
test

```
mysql> SELECT * FROM test.t1;
```

c1	c2
1	Luis

```
mysql> SHOW BINLOG EVENTS;
```

Log_name	Pos	Event_type	Server_id	End_log_pos	Info
binlog.000001	4	Format_desc	2	123	Server ver: 9.1.0-log, Binlog ver: 4
binlog.000001	123	Previous_gtid	2	150	
binlog.000001	150	Gtid	1	211	SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa-aa
binlog.000001	211	Query	1	270	BEGIN
binlog.000001	270	View_change	1	369	view_id=14724832985483517:1

binlog.000001	369	Query	1	434	COMMIT
binlog.000001	434	Gtid	1	495	SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaa
binlog.000001	495	Query	1	585	CREATE DATABASE test
binlog.000001	585	Gtid	1	646	SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaa
binlog.000001	646	Query	1	770	use `test`; CREATE TABLE t1 (c1 INT PR
binlog.000001	770	Gtid	1	831	SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaa
binlog.000001	831	Query	1	890	BEGIN
binlog.000001	890	Table_map	1	933	table_id: 108 (test.t1)
binlog.000001	933	Write_rows	1	975	table_id: 108 flags: STMT_END_F
binlog.000001	975	Xid	1	1002	COMMIT /* xid=30 */
binlog.000001	1002	Gtid	1	1063	SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaa
binlog.000001	1063	Query	1	1122	BEGIN
binlog.000001	1122	View_change	1	1261	view_id=14724832985483517:2
binlog.000001	1261	Query	1	1326	COMMIT

As seen above, the second server has been added to the group and it has replicated the changes from server s1 automatically. In other words, the transactions applied on s1 up to the point in time that s2 joined the group have been replicated to s2.

## Adding Additional Instances

Adding additional instances to the group is essentially the same sequence of steps as adding the second server, except that the configuration has to be changed as it had to be for server s2. To summarise the required commands:

1. Create the configuration file.

```
[mysqld]

#
Disable other storage engines
#
disabled_storage_engines="MyISAM,BLACKHOLE,FEDERATED,ARCHIVE,MEMORY"

#
Replication configuration parameters
#
server_id=3
gtid_mode=ON
enforce_gtid_consistency=ON

#
Group Replication configuration
#
plugin_load_add='group_replication.so'
group_replication_group_name="aaaaaaaa-aaaa-aaaa-aaaa-aaaaaaaaaaaaaa"
group_replication_start_on_boot=off
group_replication_local_address= "s3:33061"
group_replication_group_seeds= "s1:33061,s2:33061,s3:33061"
group_replication_bootstrap_group= off
```

2. Start the server and connect to it. Create the replication user for distributed recovery.

```
SET SQL_LOG_BIN=0;
CREATE USER rpl_user@'%' IDENTIFIED BY 'password';
GRANT REPLICATION SLAVE ON *.* TO rpl_user@'%';
GRANT CONNECTION_ADMIN ON *.* TO rpl_user@'%';
GRANT BACKUP_ADMIN ON *.* TO rpl_user@'%';
GRANT GROUP_REPLICATION_STREAM ON *.* TO rpl_user@'%';
FLUSH PRIVILEGES;
SET SQL_LOG_BIN=1;
```

If you are providing user credentials using a `CHANGE REPLICATION SOURCE TO` statement, issue the following statement after that:

```
mysql> CHANGE REPLICATION SOURCE TO SOURCE_USER='rpl_user',
-> SOURCE_PASSWORD='password'
-> FOR CHANNEL 'group_replication_recovery';
```

3. Install the Group Replication plugin if necessary, like this:

```
mysql> INSTALL PLUGIN group_replication SONAME 'group_replication.so';
```

4. Start Group Replication:

```
mysql> START GROUP_REPLICATION;
```

If you are providing user credentials for distributed recovery in the `START GROUP_REPLICATION` statement, you can do so like this:

```
mysql> START GROUP_REPLICATION USER='rpl_user', PASSWORD='password';
```

At this point server s3 is booted and running, has joined the group and caught up with the other servers in the group. Consulting the `performance_schema.replication_group_members` table again confirms this is the case.

```
mysql> SELECT * FROM performance_schema.replication_group_members;
```

CHANNEL_NAME	MEMBER_ID	MEMBER_HOST	MEMBER_PORT	MEMBER_STATE
group_replication_applier	395409e1-6dfa-11e6-970b-00212844f856	s1	3306	ONLINE
group_replication_applier	7eb217ff-6df3-11e6-966c-00212844f856	s3	3306	ONLINE
group_replication_applier	ac39f1e6-6dfa-11e6-a69d-00212844f856	s2	3306	ONLINE

Issuing this same query on server s2 or server s1 yields the same result. Also, you can verify that server s3 has caught up:

```
mysql> SHOW DATABASES LIKE 'test';
```

Database (test)
test

```
mysql> SELECT * FROM test.t1;
```

c1	c2
1	Luis

```
mysql> SHOW BINLOG EVENTS;
```

Log_name	Pos	Event_type	Server_id	End_log_pos	Info
binlog.000001	4	Format_desc	3	123	Server ver: 9.1.0-log, Binlog ver: 4

## 20.2.2 Deploying Group Replication Locally

The most common way to deploy Group Replication is using multiple server instances, to provide high availability. It is also possible to deploy Group Replication locally, for example for testing purposes. This section explains how you can deploy Group Replication locally.

### Important

Group Replication is usually deployed on multiple hosts because this ensures that high-availability is provided. The instructions in this section are not suitable for production deployments because all MySQL server instances are running on the same single host. In the event of failure of this host, the whole group fails. Therefore this information should be used for testing purposes and it should not be used in a production environments.

This section explains how to create a replication group with three MySQL Server instances on one physical machine. This means that three data directories are needed, one per server instance, and that you need to configure each instance independently. This - procedure assumes that MySQL Server was downloaded and unpacked - into the directory named `mysql-9.1`. Each MySQL server instance requires a specific data directory. Create a directory named `data`, then in that directory create a subdirectory for each server instance, for example `s1`, `s2` and `s3`, and initialize each one.

```
mysql-9.1/bin/mysqld --initialize-insecure --basedir=$PWD/mysql-9.1 --datadir=$PWD/data/s1
mysql-9.1/bin/mysqld --initialize-insecure --basedir=$PWD/mysql-9.1 --datadir=$PWD/data/s2
mysql-9.1/bin/mysqld --initialize-insecure --basedir=$PWD/mysql-9.1 --datadir=$PWD/data/s3
```

Inside `data/s1`, `data/s2`, `data/s3` is an initialized data directory, containing the mysql system database and related tables and much more. To learn more about the initialization procedure, see [Section 2.9.1, “Initializing the Data Directory”](#).

### Warning

Do not use `--initialize-insecure` in production environments, it is only used here to simplify the tutorial. For more information on security settings, see [Section 20.6, “Group Replication Security”](#).

## Configuration of Local Group Replication Members

When you are following [Section 20.2.1.2, “Configuring an Instance for Group Replication”](#), you need to add configuration for the data directories added in the previous section. For example:

```
[mysqld]

server configuration
datadir=<full_path_to_data>/data/s1
basedir=<full_path_to_bin>/mysql-9.1/

port=24801
socket=<full_path_to_sock_dir>/s1.sock
```

These settings configure MySQL server to use the data directory created earlier and which port the server should open and start listening for incoming connections.

#### Note

The non-default port of 24801 is used because in this tutorial the three server instances use the same hostname. In a setup with three different machines this would not be required.

Group Replication requires a network connection between the members, which means that each member must be able to resolve the network address of all of the other members. For example in this tutorial all three instances run on one machine, so to ensure that the members can contact each other you could add a line to the option file such as `report_host=127.0.0.1`.

Then each member needs to be able to connect to the other members on their `group_replication_local_address`. For example in the option file of member s1 add:

```
group_replication_local_address= "127.0.0.1:24901"
group_replication_group_seeds= "127.0.0.1:24901,127.0.0.1:24902,127.0.0.1:24903"
```

This configures s1 to use port 24901 for internal group communication with seed members. For each server instance you want to add to the group, make these changes in the option file of the member. For each member you must ensure a unique address is specified, so use a unique port per instance for `group_replication_local_address`. Usually you want all members to be able to serve as seeds for members that are joining the group and have not got the transactions processed by the group. In this case, add all of the ports to `group_replication_group_seeds` as shown above.

The remaining steps of [Section 20.2.1, “Deploying Group Replication in Single-Primary Mode”](#) apply equally to a group which you have deployed locally in this way.

## 20.3 Requirements and Limitations

This section lists and explains the requirements and limitations of Group Replication.

### 20.3.1 Group Replication Requirements

- [Infrastructure](#)
- [Server Instance Configuration](#)

Server instances that you want to use for Group Replication must satisfy the following requirements.

#### Infrastructure

- **InnoDB Storage Engine.** Data must be stored in the [InnoDB](#) transactional storage engine. Transactions are executed optimistically and then, at commit time, are checked for conflicts. If there are conflicts, in order to maintain consistency across the group, some transactions are rolled back. This means that a transactional storage engine is required. Moreover, [InnoDB](#) provides some additional functionality that enables better management and handling of conflicts when operating together with Group Replication. The use of other storage engines, including the temporary [MEMORY](#) storage engine, might cause errors in Group Replication. Convert any tables in other storage engines to use [InnoDB](#) before using the instance with Group Replication. You can prevent the use of other storage engines by setting the `disabled_storage_engines` system variable on group members, for example:

```
disabled_storage_engines="MyISAM,BLACKHOLE,FEDERATED,ARCHIVE,MEMORY"
```

- **Primary Keys.** Every table that is to be replicated by the group must have a defined primary key, or primary key equivalent where the equivalent is a non-null unique key. Such keys are

required as a unique identifier for every row within a table, enabling the system to determine which transactions conflict by identifying exactly which rows each transaction has modified. Group Replication has its own built-in set of checks for primary keys or primary key equivalents, and does not use the checks carried out by the `sql_require_primary_key` system variable. You may set `sql_require_primary_key=ON` for a server instance where Group Replication is running, and you may set the `REQUIRE_TABLE_PRIMARY_KEY_CHECK` option of the `CHANGE REPLICATION SOURCE TO` statement to `ON` for a Group Replication channel. However, be aware that you might find some transactions that are permitted under Group Replication's built-in checks are not permitted under the checks carried out when you set `sql_require_primary_key=ON` or `REQUIRE_TABLE_PRIMARY_KEY_CHECK=ON`.

- **Network Performance.** MySQL Group Replication is designed to be deployed in a cluster environment where server instances are very close to each other. The performance and stability of a group can be impacted by both network latency and network bandwidth. Bi-directional communication must be maintained at all times between all group members. If either inbound or outbound communication is blocked for a server instance (for example, by a firewall, or by connectivity issues), the member cannot function in the group, and the group members (including the member with issues) might not be able to report the correct member status for the affected server instance.

You can use a network infrastructure based on IPv4, IPv6, or a mix of the two, for TCP communication between remote Group Replication servers. There is also nothing preventing Group Replication from operating over a virtual private network (VPN).

Where Group Replication server instances are co-located and share a local group communication engine (XCom) instance, a dedicated input channel with lower overhead is used for communication where possible instead of the TCP socket. For certain Group Replication tasks that require communication between remote XCom instances, such as joining a group, the TCP network is still used, so network performance influences the group's performance.

## Server Instance Configuration

The following options must be configured as shown on server instances that are members of a group.

- **Unique Server Identifier.** Use the `server_id` system variable to configure the server with a unique server ID, as required for all servers in replication topologies. The server ID must be a positive integer between 1 and  $(2^{32})-1$ , and it must be different from every other server ID in use by any other server in the replication topology.
- **Binary Log Active.** In MySQL 9.1, binary logging is enabled by default. You can optionally specify the names of the binary log files using `--log-bin[=log_file_name]`. Group Replication replicates the binary log's contents, therefore the binary log needs to be on for it to operate. See [Section 7.4.4, “The Binary Log”](#).
- **Replica Updates Logged.** Set `log_replica_updates=ON` if it is not already enabled. (In MySQL 9.1, this is the default.) Group members need to log transactions that are received from their donors at joining time and applied through the replication applier, and to log all transactions that they receive and apply from the group. This enables Group Replication to carry out distributed recovery by state transfer from an existing group member's binary log.
- **Binary Log Row Format.** Set `binlog_format=ROW` if necessary; in MySQL 9.1, this is the default. Group Replication relies on the row-based replication format to propagate changes consistently among the servers in the group, and extract the necessary information to detect conflicts among transactions that execute concurrently in different servers in the group. The setting for `REQUIRE_ROW_FORMAT` is automatically added to Group Replication's channels to enforce the use of row-based replication when the transactions are applied. See [Section 19.2.1, “Replication Formats”](#) and [Section 19.3.3, “Replication Privilege Checks”](#).

- **Global Transaction Identifiers On.** Set `gtid_mode=ON` and `enforce_gtid_consistency=ON`. These settings are not the defaults. GTID-based replication is required for Group Replication, which uses global transaction identifiers to track the transactions that have been committed on every server instance in the group. See [Section 19.1.3, “Replication with Global Transaction Identifiers”](#).
- **Default Table Encryption.** Set `default_table_encryption` to the same value on all group members. Default schema and tablespace encryption can be either enabled (`ON`) or disabled (`OFF`, the default) as long as the setting is the same on all members.
- **Lower Case Table Names.** Set `lower_case_table_names` to the same value on all group members. A setting of 1 is correct for the use of the `InnoDB` storage engine, which is required for Group Replication. Note that this setting is not the default on all platforms.
- **Multithreaded Appliers.** Group Replication members can be configured as multithreaded replicas, enabling transactions to be applied in parallel. All replicas are configured as multithreaded by default. A nonzero value for `replica_parallel_workers` enables the multithreaded applier on the member. The default is 4 parallel applier threads; up to 1024 parallel applier threads can be specified.

Setting `replica_parallel_workers=0` disables parallel execution and gives the replica a single applier thread and no coordinator thread. With that setting, the `replica_parallel_type` and `replica_preserve_commit_order` options have no effect and are ignored. If parallel execution is disabled when GTIDs are in use on a replica, the replica actually uses one parallel worker, to take advantage of the method for retrying transactions without accessing the file positions. However, this behavior does not change anything for the user.

- **Detached XA transactions.** MySQL 9.1 and later supports detached XA transactions. A detached transaction is one which, once prepared, is no longer connected to the current session. This happens automatically as part of executing `XA PREPARE`. The prepared XA transaction can be committed or rolled back by another connection, and the current session can then initiate another XA transaction or local transaction without waiting for the transaction that was just prepared to complete.

When detached XA transaction support is enabled (`xa_detach_on_prepare = ON`) it is possible for any connection to this server to list (using `XA RECOVER`), roll back, or commit any prepared XA transaction. In addition, you cannot use temporary tables within detached XA transactions.

You can disable support for detached XA transactions by setting `xa_detach_on_prepare` to `OFF`, but this is not recommended. In particular, if this server is being set up as an instance in MySQL group replication, you should leave this variable set to its default value (`ON`).

See [Section 15.3.8.2, “XA Transaction States”](#), for more information.

## 20.3.2 Group Replication Limitations

- [Limit on Group Size](#)
- [Limits on Transaction Size](#)

The following known limitations exist for Group Replication. Note that the limitations and issues described for multi-primary mode groups can also apply in single-primary mode clusters during a failover event, while the newly elected primary flushes out its applier queue from the old primary.

### Tip

Group Replication is built on GTID based replication, therefore you should also be aware of [Section 19.1.3.7, “Restrictions on Replication with GTIDs”](#).

- **--upgrade=MINIMAL option.** Group Replication cannot be started following a MySQL Server upgrade that uses the MINIMAL option (`--upgrade=MINIMAL`), which does not upgrade system tables on which the replication internals depend.
- **Gap Locks.** Group Replication's certification process for concurrent transactions does not take into account [gap locks](#), as information about gap locks is not available outside of [InnoDB](#). See [Gap Locks](#) for more information.

**Note**

For a group in multi-primary mode, unless you rely on [REPEATABLE READ](#) semantics in your applications, we recommend using the [READ COMMITTED](#) isolation level with Group Replication. InnoDB does not use gap locks in [READ COMMITTED](#), which aligns the local conflict detection within InnoDB with the distributed conflict detection performed by Group Replication. For a group in single-primary mode, only the primary accepts writes, so the [READ COMMITTED](#) isolation level is not important to Group Replication.

- **Table Locks and Named Locks.** The certification process does not take into account table locks (see [Section 15.3.6, “LOCK TABLES and UNLOCK TABLES Statements”](#)) or named locks (see [GET\\_LOCK\(\)](#)).
- **Binary Log Checksums.** Group Replication in MySQL 9.1 supports checksums, so group members may use the default setting `binlog_checksum=CRC32`. The setting for `binlog_checksum` does not have to be the same for all members of a group.

When checksums are available, Group Replication does not use them to verify incoming events on the `group_replication_applier` channel, because events are written to that relay log from multiple sources and before they are actually written to the originating server's binary log, which is when a checksum is generated. Checksums are used to verify the integrity of events on the `group_replication_recovery` channel and on any other replication channels on group members.

- **SERIALIZABLE Isolation Level.** [SERIALIZABLE](#) isolation level is not supported in multi-primary groups by default. Setting a transaction isolation level to [SERIALIZABLE](#) configures Group Replication to refuse to commit the transaction.
- **Concurrent DDL versus DML Operations.** Concurrent data definition statements and data manipulation statements executing against the same object but on different servers is not supported when using multi-primary mode. During execution of Data Definition Language (DDL) statements on an object, executing concurrent Data Manipulation Language (DML) on the same object but on a different server instance has the risk of conflicting DDL executing on different instances not being detected.
- **Foreign Keys with Cascading Constraints.** Multi-primary mode groups (members all configured with `group_replication_single_primary_mode=OFF`) do not support tables with multi-level foreign key dependencies, specifically tables that have defined [CASCADING foreign key constraints](#). This is because foreign key constraints that result in cascading operations executed by a multi-primary mode group can result in undetected conflicts and lead to inconsistent data across the members of the group. Therefore we recommend setting `group_replication_enforce_update_everywhere_checks=ON` on server instances used in multi-primary mode groups to avoid undetected conflicts.

In single-primary mode this is not a problem as it does not allow concurrent writes to multiple members of the group and thus there is no risk of undetected conflicts.

- **Multi-primary Mode Deadlock.** When a group is operating in multi-primary mode, [SELECT .. FOR UPDATE](#) statements can result in a deadlock. This is because the lock is not shared across the members of the group, therefore the expectation for such a statement might not be reached.

- **Replication Filters.** Global replication filters cannot be used on a MySQL server instance that is configured for Group Replication, because filtering transactions on some servers would make the group unable to reach agreement on a consistent state. Channel specific replication filters can be used on replication channels that are not directly involved with Group Replication, such as where a group member also acts as a replica to a source that is outside the group. They cannot be used on the `group_replication_applier` or `group_replication_recovery` channels.
- **Encrypted Connections.** Support for the TLSv1.3 protocol is available in MySQL, provided that it was compiled using OpenSSL 1.1.1 or higher. Group Replication supports TLSv1.3, where it can be used for group communication connections and distributed recovery connections.

`group_replication_recovery_tls_version` and `group_replication_recovery_tls_ciphersuites` can be used to configure client support for any selection of ciphersuites, including only non-default ciphersuites if desired. See [Section 8.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#).

- **Cloning Operations.** Group Replication initiates and manages cloning operations for distributed recovery, but group members that have been set up to support cloning may also participate in cloning operations that a user initiates manually. You can initiate a cloning operation manually if the operation involves a group member on which Group Replication is running, provided that the cloning operation does not remove and replace the data on the recipient. The statement to initiate the cloning operation must therefore include the `DATA DIRECTORY` clause if Group Replication is running. See [Cloning for Other Purposes](#).

## Limit on Group Size

The maximum number of MySQL servers that can be members of a single replication group is 9. If further members attempt to join the group, their request is refused. This limit has been identified from testing and benchmarking as a safe boundary where the group performs reliably on a stable local area network.

## Limits on Transaction Size

If an individual transaction results in message contents which are large enough that the message cannot be copied between group members over the network within a 5-second window, members can be suspected of having failed, and then expelled, just because they are busy processing the transaction. Large transactions can also cause the system to slow due to problems with memory allocation. To avoid these issues use the following mitigations:

- If unnecessary expulsions occur due to large messages, use the system variable `group_replication_member_expel_timeout` to allow additional time before a member under suspicion of having failed is expelled. You can allow up to an hour after the initial 5-second detection period before a suspect member is expelled from the group. An additional 5 seconds is allowed by default.
- Where possible, try and limit the size of your transactions before they are handled by Group Replication. For example, split up files used with `LOAD DATA` into smaller chunks.
- Use the system variable `group_replication_transaction_size_limit` to specify a maximum transaction size that the group accepts. The default maximum transaction size is 150000000 bytes (approximately 143 MB); transactions above this size are rolled back and are not sent to Group Replication's Group Communication System (GCS) for distribution to the group. Adjust the value of this variable depending on the maximum message size that you need the group to tolerate, bearing in mind that the time taken to process a transaction is proportional to its size.
- Use the system variable `group_replication_compression_threshold` to specify a message size above which compression is applied. This system variable defaults to 1000000

bytes (1 MB), so large messages are automatically compressed. Compression is carried out by Group Replication's Group Communication System (GCS) when it receives a message that was permitted by the `group_replication_transaction_size_limit` setting but exceeds the `group_replication_compression_threshold` setting. For more information, see [Section 20.7.4, “Message Compression”](#).

- Use the system variable `group_replication_communication_max_message_size` to specify a message size above which messages are fragmented. This system variable defaults to 10485760 bytes (10 MiB), so large messages are automatically fragmented. GCS carries out fragmentation after compression if the compressed message still exceeds the `group_replication_communication_max_message_size` limit. For more information, see [Section 20.7.5, “Message Fragmentation”](#).

The maximum transaction size, message compression, and message fragmentation can all be deactivated by specifying a zero value for the relevant system variable. If you have deactivated all these safeguards, the upper size limit for a message that can be handled by the applier thread on a member of a replication group is the value of the member's `replica_max_allowed_packet` system variable, which has a default and maximum value of 1073741824 bytes (1 GB). A message that exceeds this limit fails when the receiving member attempts to handle it. The upper size limit for a message that a group member can originate and attempt to transmit to the group is 4294967295 bytes (approximately 4 GB). This is a hard limit on the packet size that is accepted by the group communication engine for Group Replication (XCom, a Paxos variant), which receives messages after GCS has handled them. A message that exceeds this limit fails when the originating member attempts to broadcast it.

## 20.4 Monitoring Group Replication

You can use the MySQL [Performance Schema](#) to monitor Group Replication. These Performance Schema tables display information specific to Group Replication:

- `replication_group_member_stats`: See [Section 20.4.4, “The replication\\_group\\_member\\_stats Table”](#).
- `replication_group_members`: See [Section 20.4.3, “The replication\\_group\\_members Table”](#).
- `replication_group_communication_information`: See [Section 29.12.11.14, “The replication\\_group\\_communication\\_information Table”](#).

These Performance Schema replication tables also show information relating to Group Replication:

- `replication_connection_status` shows information regarding Group Replication, such as transactions received from the group and queued in the applier queue (relay log).
- `replication_applier_status` shows the states of channels and threads relating to Group Replication. These can also be used to monitor what individual worker threads are doing.

Replication channels created by the Group Replication plugin are listed here:

- `group_replication_recovery`: Used for replication changes related to distributed recovery.
- `group_replication_applier`: Used for the incoming changes from the group, to apply transactions coming directly from the group.

For information about system variables affecting Group Replication, see [Section 20.9.1, “Group Replication System Variables”](#). See [Section 20.9.2, “Group Replication Status Variables”](#), for status variables providing information about Group Replication.

Messages relating to Group Replication lifecycle events other than errors are classified as system messages; these are always written to the replication group member's error log. You can use this information to review the history of a given server's membership in a replication group.

Some lifecycle events that affect the whole group are logged on every group member, such as a new member entering [ONLINE](#) status in the group or a primary election. Other events are logged only on the member where they take place, such as super read only mode being enabled or disabled on the member, or the member leaving the group. A number of lifecycle events that can indicate an issue if they occur frequently are logged as warning messages, including a member becoming unreachable and then reachable again, and a member starting distributed recovery by state transfer from the binary log or by a remote cloning operation.

**Note**

If you are monitoring one or more secondary instances using [mysqladmin](#), you should be aware that a [FLUSH STATUS](#) statement executed by this utility creates a GTID event on the local instance which may impact future group operations.

## 20.4.1 GTIDs and Group Replication

Group Replication uses GTIDs (global transaction identifiers) to track exactly which transactions have been committed on every server instance. The settings [gtid\\_mode=ON](#) and [enforce\\_gtid\\_consistency=ON](#) are required on all group members. Incoming transactions from clients are assigned a GTID by the group member that receives them. Any replicated transactions that are received by group members on asynchronous replication channels from source servers outside the group retain the GTIDs that they have when they arrive on the group member.

The GTIDs that are assigned to incoming transactions from clients use the group name specified by the [group\\_replication\\_group\\_name](#) system variable as the UUID part of the identifier, rather than the server UUID of the individual group member that received the transaction. All the transactions received directly by the group can therefore be identified and are grouped together in GTID sets, and it does not matter which member originally received them. Each group member has a block of consecutive GTIDs reserved for its use, and when these are consumed it reserves more. The [group\\_replication\\_gtid\\_assignment\\_block\\_size](#) system variable sets the size of the blocks, with a default of 1 million GTIDs in each block.

View change events ([View\\_change\\_log\\_event](#)), which are generated by the group itself when a new member joins, are given GTIDs when they are recorded in the binary log. By default, the GTIDs for these events also use the group name specified by the [group\\_replication\\_group\\_name](#) system variable as the UUID part of the identifier. You can set the Group Replication system variable [group\\_replication\\_view\\_change\\_uuid](#) to use an alternative UUID in the GTIDs for view change events, so that they are easy to distinguish from transactions received by the group from clients. This can be useful if your setup allows for failover between groups, and you need to identify and discard transactions that were specific to the backup group. The alternative UUID must be different from the server UUIDs of the members. It must also be different from any UUIDs in the GTIDs applied to anonymous transactions using the [ASSIGN\\_GTIDS\\_TO\\_ANONYMOUS\\_TRANSACTIONS](#) option of the [CHANGE REPLICATION SOURCE TO](#) statement.

[GTID\\_ONLY=1](#), [REQUIRE\\_ROW\\_FORMAT = 1](#), and [SOURCE\\_AUTO\\_POSITION = 1](#) are applied for the Group Replication channels [group\\_replication\\_applier](#) and [group\\_replication\\_recovery](#). The settings are made automatically on the Group Replication channels when they are created, or when a member server in a replication group is upgraded. These options are normally set using a [CHANGE REPLICATION SOURCE TO](#) statement, but note that you cannot disable them for a Group Replication channel. With these options set, the group member does not persist file names and file positions in the replication metadata repositories for these channels. GTID auto-positioning and GTID auto-skip are used to locate the correct receiver and applier positions when necessary.

## Extra Transactions

If a joining member has transactions in its GTID set that are not present on the existing members of the group, it is not allowed to complete the distributed recovery process, and cannot join the group. If a remote cloning operation was carried out, these transactions would be deleted and lost, because the data directory on the joining member is erased. If state transfer from a donor's binary log was carried out, these transactions could conflict with the group's transactions.

Extra transactions might be present on a member if an administrative transaction is carried out on the instance while Group Replication is stopped. To avoid introducing new transactions in that way, always set the value of the `sql_log_bin` system variable to `OFF` before issuing administrative statements, and back to `ON` afterwards:

```
SET SQL_LOG_BIN=0;
<administrator action>
SET SQL_LOG_BIN=1;
```

Setting this system variable to `OFF` means that the transactions that occur from that point until you set it back to `ON` are not written to the binary log and do not have GTIDs assigned to them.

If an extra transaction is present on a joining member, check the binary log for the affected server to see what the extra transaction actually contains. The safest method to reconcile the joining member's data and GTID set with the members currently in the group is to use MySQL's cloning functionality to transfer the content from a server in the group to the affected server. For instructions to do this, see [Section 7.6.7.3, "Cloning Remote Data"](#). If the transaction is required, rerun it after the member has successfully rejoined.

## 20.4.2 Group Replication Server States

The state of a Group Replication group member shows its current role in the group. The Performance Schema table `replication_group_members` shows the state for each member in a group. If the group is fully functional and all members are communicating properly, all members report the same state for all other members. However, a member that has left the group or is part of a network partition cannot report accurate information on the other servers. In this situation, the member does not attempt to guess the status of the other servers, and instead reports them as unreachable.

A group member can be in the following states:

### ONLINE

The server is an active member of a group and in a fully functioning state. Other group members can connect to it, as can clients if applicable. A member is only fully synchronized with the group, and participating in it, when it is in the `ONLINE` state.

### RECOVERING

The server has joined a group and is in the process of becoming an active member. Distributed recovery is currently taking place, where the member is receiving state transfer from a donor using a remote cloning operation or the donor's binary log. This state is

For more information, see [Section 20.5.4, "Distributed Recovery"](#).

### OFFLINE

The Group Replication plugin is loaded but the member does not belong to any group. This status may briefly occur while a member is joining or rejoining a group.

### ERROR

The member is in an error state and is not functioning correctly as a group member. A member can enter error state either while applying transactions or during the recovery phase. A member in this state does not participate in the group's transactions. For more information on

possible reasons for error states, see [Section 20.7.7, “Responses to Failure Detection and Network Partitioning”](#).

Depending on the exit action set by `group_replication_exit_state_action`, the member is in read-only mode (`super_read_only=ON`) and could also be in offline mode (`offline_mode=ON`). Note that a server in offline mode following the `OFFLINE_MODE` exit action is displayed with `ERROR` status, not `OFFLINE`. A server with the exit action `ABORT_SERVER` shuts down and is removed from the view of the group. For more information, see [Section 20.7.7.4, “Exit Action”](#).

While a member is joining or rejoining a replication group, its status can be displayed as `ERROR` before the group completes the compatibility checks and accepts it as a member.

#### UNREACHABLE

The local failure detector suspects that the member cannot be contacted, because the group's messages are timing out. This can happen if a member is disconnected involuntarily, for example. If you see this status for other servers, it can also mean that the member where you query this table is part of a partition, where a subset of the group's servers can contact each other but cannot contact the other servers in the group. For more information, see [Section 20.7.8, “Handling a Network Partition and Loss of Quorum”](#).

See [Section 20.4.3, “The replication\\_group\\_members Table”](#) for an example of the Performance Schema table contents.

## 20.4.3 The replication\_group\_members Table

The `performance_schema.replication_group_members` table is used for monitoring the status of the different server instances that are members of the group. The information in the table is updated whenever there is a view change, for example when the configuration of the group is dynamically changed when a new member joins. At that point, servers exchange some of their metadata to synchronize themselves and continue to cooperate together. The information is shared between all the server instances that are members of the replication group, so information on all the group members can be queried from any member. This table can be used to get a high level view of the state of a replication group, for example by issuing:

```
SELECT * FROM performance_schema.replication_group_members;
```

CHANNEL_NAME	MEMBER_ID	MEMBER_HOST	MEMBER_PORT	MEMBER_STATE
group_replication_applier	d391e9ee-2691-11ec-bf61-00059a3c7a00	example1	4410	ONLINE
group_replication_applier	e059ce5c-2691-11ec-8632-00059a3c7a00	example2	4420	ONLINE
group_replication_applier	ecd9ad06-2691-11ec-91c7-00059a3c7a00	example3	4430	ONLINE

3 rows in set (0.0007 sec)

Based on this result we can see that the group consists of three members. Shown in the table is each member's `server_uuid`, as well as the member's host name and port number, which clients use to connect to it. The `MEMBER_STATE` column shows one of the [Section 20.4.2, “Group Replication Server States”](#), in this case it shows that all three members in this group are `ONLINE`, and the `MEMBER_ROLE` column shows that there are two secondaries, and a single primary. Therefore this group must be running in single-primary mode. The `MEMBER_VERSION` column can be useful when you are upgrading a group and are combining members running different MySQL versions. The `MEMBER_COMMUNICATION_STACK` column shows the communication stack used for the group.

For more information about the [MEMBER\\_HOST](#) value and its impact on the distributed recovery process, see [Section 20.2.1.3, “User Credentials For Distributed Recovery”](#).

## 20.4.4 The replication\_group\_member\_stats Table

Each member in a replication group certifies and applies transactions received by the group. Statistics regarding the certifier and applier procedures are useful to understand how the applier queue is growing, how many conflicts have been found, how many transactions were checked, which transactions are committed everywhere, and so on.

The `performance_schema.replication_group_member_stats` table provides group-level information related to the certification process, and also statistics for the transactions received and originated by each individual member of the replication group. The information is shared between all the server instances that are members of the replication group, so information on all the group members can be queried from any member. Note that refreshing of statistics for remote members is controlled by the message period specified in the `group_replication_flow_control_period` option, so these can differ slightly from the locally collected statistics for the member where the query is made. To use this table to monitor a Group Replication member, issue the following statement:

```
mysql> SELECT * FROM performance_schema.replication_group_member_stats\G
```

You can also use the following statement:

```
mysql> TABLE performance_schema.replication_group_member_stats\G
```

These columns are important for monitoring the performance of the members connected in the group. Suppose that one of the group's members always reports a large number of transactions in its queue compared to other members. This means that the member is delayed and is not able to keep up to date with the other members of the group. Based on this information, you could decide to either remove the member from the group, or delay the processing of transactions on the other members of the group in order to reduce the number of queued transactions. This information can also help you to decide how to adjust the flow control of the Group Replication plugin, see [Section 20.7.2, “Flow Control”](#).

## 20.5 Group Replication Operations

This section explains common operations for managing groups.

### 20.5.1 Configuring an Online Group

You can configure an online group while Group Replication is running by using a set of functions, which rely on a group action coordinator. These functions are installed by the Group Replication plugin. This section describes how changes are made to a running group, and the available functions.

#### Important

For the coordinator to be able to configure group wide actions on a running group, all members must have the functions installed.

To use the functions, connect to a member of the running group and invoke the function with the `SELECT` statement. The Group Replication plugin processes the action and its parameters and the coordinator sends it to all members which are visible to the member where you invoked the function. If the action is accepted, all members execute the action and send a termination message when completed. Once all members declare the action as finished, the invoking member returns the result to the client.

When configuring a whole group, the distributed nature of the operations means that they interact with many processes of the Group Replication plugin, and therefore you should observe the following:

**You can issue configuration operations everywhere.** If you want to make member A the new primary you do not need to invoke the operation on member A. All operations are sent and executed in a coordinated way on all group members. Also, this distributed execution of an operation has a different ramification: if the invoking member dies, any already running configuration process continues to run on other members. In the unlikely event that the invoking member dies, you can still use the monitoring features to ensure other members complete the operation successfully.

**All members must be online.** To simplify the migration or election processes and guarantee they are as fast as possible, the group must not contain any member currently in the distributed recovery process, otherwise the configuration action is rejected by the member where you issue the statement.

**No members can join a group during a configuration change.** Any member that attempts to join the group during a coordinated configuration change leaves the group and cancels its join process.

**Only one configuration at once.** A group which is executing a configuration change cannot accept any other group configuration change, because concurrent configuration operations could lead to member divergence.

### 20.5.1.1 Changing the Primary

This section explains how to change which member of a single-primary group is the primary, using the `group_replication_set_as_primary()` function, which can be run on any member of the group. When this is done, the current primary becomes a read-only secondary, and the specified group member becomes the read/write primary; this replaces the usual primary election process (see [Section 20.1.3.1, “Single-Primary Mode”](#)).

If a standard source-to-replica replication channel is running on the existing primary member in addition to the Group Replication channels, you must stop that replication channel before you can change the primary member. You can identify the current primary using the `MEMBER_ROLE` column in the Performance Schema `replication_group_members` table.

If all members are not running the same MySQL Server version, you can specify a new primary member that is running the lowest MySQL Server version in the group only. This safeguard is applied to ensure the group maintains compatibility with new functions.

Any uncommitted transactions that the group is waiting on must be committed, rolled back, or terminated before the operation can complete. You can specify a timeout from 1 to 3600 seconds (60 minutes) for transactions that are running when you use the function. Specify 0 for no timeout (or do not specify a timeout value), in which case the group waits indefinitely. If you do not set the timeout, there is no upper limit to the wait time, and new transactions can start during that time.

When the timeout expires, for any transactions that did not yet reach their commit phase, the client session is disconnected so that the transaction does not proceed. Transactions that reached their commit phase are allowed to complete. When you set a timeout, it also prevents new transactions starting on the primary from that point on. Explicitly defined transactions (with a `START TRANSACTION` or `BEGIN` statement) are subject to the timeout, disconnection, and incoming transaction blocking even if they do not modify any data. To allow inspection of the primary while the function is operating, single statements that do not modify data, as listed in [Permitted Queries Under Consistency Rules](#), are permitted to proceed.

Pass in the `server_uuid` of the member which you want to become the new primary of the group by issuing the following statement:

```
SELECT group_replication_set_as_primary(member_uuid);
```

You can add a timeout as shown here:

```
SELECT group_replication_set_as_primary('00371d66-3c45-11ea-804b-080027337932', 300)
```

To check the status of the timeout, use the `PROCESSLIST_INFO` column in the Performance Schema `threads` table, like this:

```
mysql> SELECT NAME, PROCESSLIST_INFO FROM performance_schema.threads
-> WHERE NAME="thread/group_rpl/THD_transaction_monitor"\G
***** 1. row *****
NAME: thread/group_rpl/THD_transaction_monitor
PROCESSLIST_INFO: Group replication transaction monitor: Stopped client connections
```

The status shows when the transaction monitoring thread has been created, when new transactions have been stopped, when the client connections with uncommitted transactions have been disconnected, and finally, when the process is complete and new transactions are allowed again.

While the action runs, you can check its progress by issuing the statement shown here:

```
mysql> SELECT event_name, work_completed, work_estimated
-> FROM performance_schema.events_stages_current
-> WHERE event_name LIKE "%stage/group_rpl%\G
***** 1. row *****
EVENT_NAME: stage/group_rpl/Primary Election: Waiting for members to turn on super_read_only
WORK_COMPLETED: 3
WORK_ESTIMATED: 5
```

### 20.5.1.2 Changing the Group Mode

This section explains how to change the mode which a group is running in, either single or multi-primary. The functions used to change a group's mode can be run on any member.

#### Changing to Single-Primary Mode

Use the `group_replication_switch_to_single_primary_mode()` function to change a group running in multi-primary mode to single-primary mode by issuing:

```
SELECT group_replication_switch_to_single_primary_mode();
```

When you change to single-primary mode, strict consistency checks are also disabled on all group members, as required in single-primary mode (`group_replication_enforce_update_everywhere_checks=OFF`).

If no string is passed in, the election of the new primary in the resulting single-primary group follows the election policies described in [Section 20.1.3.1, “Single-Primary Mode”](#). To override the election process and configure a specific member of the multi-primary group as the new primary in the process, get the `server_uuid` of the member and pass it to `group_replication_switch_to_single_primary_mode()`. For example, issue:

```
SELECT group_replication_switch_to_single_primary_mode(member_uuid);
```

#### Changing to Multi-Primary Mode

Use the `group_replication_switch_to_multi_primary_mode()` function to change a group running in single-primary mode to multi-primary mode by issuing:

```
SELECT group_replication_switch_to_multi_primary_mode();
```

After some coordinated group operations to ensure the safety and consistency of your data, all members which belong to the group become primaries.

When you change a group from single-primary mode to multi-primary mode, members are automatically placed in read-only mode if they are running a later MySQL server version than the lowest version present in the group.

While the action runs, you can check its progress by issuing the following `SELECT` statement:

```
SELECT event_name, work_completed, work_estimated FROM performance_schema.events_stages_current WHERE event_name = 'stage/group_rpl/Multi-primary Switch: applying buffered transactions'
```

event_name	work_completed	work_estimated
stage/group_rpl/Multi-primary Switch: applying buffered transactions	0	1

### 20.5.1.3 Using Group Replication Group Write Consensus

This section explains how to inspect and configure the maximum number of consensus instances at any time for a group. This maximum is referred to as the event horizon for a group, and is the maximum number of consensus instances that the group can execute in parallel. This enables you to fine tune the performance of your Group Replication deployment. For example, the default value of 10 is suitable for a group running on a LAN, but for groups operating over a slower network such as a WAN, increase this number to improve performance.

#### Inspecting a Group's Write Concurrency

Use the `group_replication_get_write_concurrency()` function to inspect a group's event horizon value at runtime by issuing:

```
SELECT group_replication_get_write_concurrency();
```

#### Configuring a Group's Write Concurrency

Use the `group_replication_set_write_concurrency()` function to set the maximum number of consensus instances that the system can execute in parallel by issuing:

```
SELECT group_replication_set_write_concurrency(instances);
```

where *instances* is the new maximum number of consensus instances. The `GROUP_REPLICATION_ADMIN` privilege is required to use this function.

### 20.5.1.4 Setting a Group's Communication Protocol Version

Group Replication in MySQL 9.1 uses the concept of a group communication protocol whose version can be managed explicitly, and set to accommodate the oldest MySQL Server version that you want the group to support. This enables groups to be formed from members using different MySQL Server versions while ensuring backward compatibility.

- MySQL 5.7.14 and later allows compression of messages (see [Section 20.7.4, “Message Compression”](#)).
- MySQL 8.0.16 and later also allows fragmentation of messages (see [Section 20.7.5, “Message Fragmentation”](#)).
- MySQL 8.0.27 and later also allow the group communication engine to operate with a single consensus leader when the group is in single-primary mode and `group_replication_paxos_single_leader` is set to true (see [Section 20.7.3, “Single Consensus Leader”](#)).

All members of the group must use the same communication protocol version, so that group members can be at different MySQL Server releases but only send messages that can be understood by all group members.

A MySQL server at version X can only join and reach `ONLINE` status in a replication group if the group's communication protocol version is less than or equal to X. When a new member joins a replication group, it checks the communication protocol version that is announced by the existing members of the group. If the joining member supports that version, it joins the group and uses the communication protocol that the group has announced, even if the member supports additional communication capabilities. If the joining member does not support the communication protocol version, it is expelled from the group.

If two members attempt to join in the same membership change event, they can only join if the communication protocol version for both members is already compatible with the group's communication protocol version. Members with different communication protocol versions from the group must join in isolation. For example:

- One MySQL Server 8.0.16 instance can successfully join a group that uses the communication protocol version 5.7.24.
- One MySQL Server 5.7.24 instance cannot successfully join a group that uses the communication protocol version 8.0.16.
- Two MySQL Server 8.0.16 instances cannot simultaneously join a group that uses the communication protocol version 5.7.24.
- Two MySQL Server 8.0.16 instances can simultaneously join a group that uses the communication protocol version 8.0.16.

You can inspect the communication protocol in use by a group by using the `group_replication_get_communication_protocol()` function, which returns the oldest MySQL Server version that the group supports. All existing members of the group return the same communication protocol version. For example:

```
SELECT group_replication_get_communication_protocol();
+-----+
| group_replication_get_communication_protocol() |
+-----+
| 8.0.16 |
+-----+
```

Note that the `group_replication_get_communication_protocol()` function returns the minimum MySQL version that the group supports, which might differ from the version number that was passed to the `group_replication_set_communication_protocol()` function, and from the MySQL Server version that is installed on the member where you use the function.

If you need to change the communication protocol version of a group so that members at earlier releases can join, use the `group_replication_set_communication_protocol()` function to specify the MySQL Server version of the oldest member that you want to allow. This makes the group fall back to a compatible communication protocol version if possible. The `GROUP_REPLICATION_ADMIN` privilege is required to use this function, and all existing group members must be online when you issue the statement, with no loss of majority. For example:

```
SELECT group_replication_set_communication_protocol("5.7.25");
```

If you upgrade all the members of a replication group to a new MySQL Server release, the group's communication protocol version is not automatically upgraded to match.

If you no longer need to support members at earlier releases, you can use the `group_replication_set_communication_protocol()` function to set the communication protocol version to the new MySQL Server version to which you have upgraded the members. For example:

```
SELECT group_replication_set_communication_protocol("8.0.16");
```

The `group_replication_set_communication_protocol()` function is implemented as a group action, so it is executed at the same time on all members of the group. The group action starts buffering messages and waits for delivery of any outgoing messages that were already in progress to complete, then changes the communication protocol version and sends the buffered messages. If a member attempts to join the group at any time after you change the communication protocol version, the group members announce the new protocol version.

MySQL InnoDB cluster automatically and transparently manages the communication protocol versions of its members, whenever the cluster topology is changed using AdminAPI operations. An InnoDB cluster always uses the most recent communication protocol version that is supported by all the instances that are currently part of the cluster or joining it. For details, see [InnoDB Cluster and Group Replication Protocol](#).

### 20.5.1.5 Configuring Member Actions

Group Replication has the ability to set actions for the members of a group to take in specified situations. Member actions can be enabled and disabled individually using functions. The member actions configuration for a server can also be reset to the default after it has left the group.

Administrators (with the `GROUP_REPLICATION_ADMIN` privilege) can configure a member action on the group's primary using the `group_replication_enable_member_action` or `group_replication_disable_member_action` function. The member actions configuration, consisting of all the member actions and whether they are enabled or disabled, is then propagated to other group members and joining members using Group Replication's group messages. All group members therefore have the same member actions configuration. You can also configure member actions on a server that is not part of a group, as long as the Group Replication plugin is installed. In that case, the member actions configuration is not propagated to any other servers.

If the server where you use the functions to configure a member action is part of a group, it must be the current primary in a group in single-primary mode, and it must be part of the majority. The configuration change is tracked internally by Group Replication, but it is not given a GTID and is not written to the binary log, so it is not propagated to any servers outside the group, such as downstream replicas. Group Replication increments the version number for its member actions configuration each time a member action is enabled or disabled.

The member actions configuration is propagated to members as follows:

- When starting a group, the member actions configuration of the server that bootstraps the group becomes the configuration for the group.
- If a group's lowest MySQL Server version supports member actions, joining members receive the group's member actions configuration during the state exchange process that takes place when they join. In that case, the joining member replaces its own member actions configuration with the group's.
- If a joining member that supports member actions joins a group where the lowest MySQL Server version does not support member actions, it does not receive a member actions configuration when it joins. In that case, the joining member resets its own configuration to the default.

A member that does not support member actions cannot join a group that has a member actions configuration, because its MySQL Server version is lower than the lowest version that the existing group members are running.

The Performance Schema table `replication_group_member_actions` lists the member actions that are available in the configuration, the events that trigger them, and whether or not they are currently enabled. Member actions have a priority from 1 to 100, with lower values being actioned first. If an error occurs when the member action is being carried out, the failure of the member action can be logged but otherwise ignored. If the failure of the member action is considered critical, it can be handled according to the policy specified by the `group_replication_exit_state_action` system variable.

The `mysql.replication_group_configuration_version` table, which can be viewed using the Performance Schema table `replication_group_configuration_version`, records the current version of the member actions configuration. Whenever a member action is enabled or disabled using the functions, the version number is incremented.

The `group_replication_reset_member_actions` function can only be used on a server that is not part of a group. It resets the member actions configuration to the default settings, and resets its version number to 1. The server must be writeable (with the `read_only` system variable set to `OFF`) and have the Group Replication plugin installed. You can use this function to remove the member actions configuration that a server used when it was part of a group, if you intend to use it as a standalone server with no member actions or different member actions.

The member action `mysql_disable_super_read_only_if_primary` can be set so that a group in single-primary mode stay in super read-only mode when a new primary is elected; this means that the group accepts replicated transactions only, and does not accept any direct writes from clients. This setup means that when a group's is intended to provide a secondary backup to another group for disaster tolerance, you can ensure that the secondary group remains synchronized with the first.

By default, super read-only mode is disabled on the primary when it is elected, so that the primary becomes read/write, and accepts updates from a replication source server and from clients. This is the situation when the member action `mysql_disable_super_read_only_if_primary` is enabled, which is its default setting. If you set the action to disabled using the `group_replication_disable_member_action()` function, the primary remains in super read-only mode after election. In this state, it does not accept updates from any clients, even users who have the `CONNECTION_ADMIN` or `SUPER` privilege. It does continue to accept updates performed by replication threads.

## 20.5.2 Restarting a Group

Group Replication is designed to ensure that the database service is continuously available, even if some of the servers that form the group are currently unable to participate in it due to planned maintenance or unplanned issues. As long as the remaining members are a majority of the group they can elect a new primary and continue to function as a group. However, if every member of a replication group leaves the group, and Group Replication is stopped on every member by a `STOP GROUP_REPLICATION` statement or system shutdown, the group now only exists in theory, as a configuration on the members. In that situation, to re-create the group, it must be started by bootstrapping as if it was being started for the first time.

The difference between bootstrapping a group for the first time and doing it for the second or subsequent times is that in the latter situation, the members of a group that was shut down might have different transaction sets from each other, depending on the order in which they were stopped or failed. A member cannot join a group if it has transactions that are not present on the other group members. For Group Replication, this includes both transactions that have been committed and applied, which are in the `gtid_executed` GTID set, and transactions that have been certified but not yet applied, which are in the `group_replication_applier` channel. The exact point at which a transaction is committed depends on the transaction consistency level that is set for the group (see [Section 20.5.3, “Transaction Consistency Guarantees”](#)). However, a Group Replication group member never removes a transaction that has been certified, which is a declaration of the member's intent to commit the transaction.

The replication group must therefore be restarted beginning with the most up to date member, that is, the member that has the most transactions executed and certified. The members with fewer transactions can then join and catch up with the transactions they are missing through distributed recovery. It is not correct to assume that the last known primary member of the group is the most up to date member of the group, because a member that was shut down later than the primary might have more transactions. You must therefore restart each member to check the transactions, compare all the transaction sets, and identify the most up to date member. This member can then be used to bootstrap the group.

Follow this procedure to restart a replication group safely after every member shuts down.

1. For each group member in turn, in any order:

- a. Connect a client to the group member. If Group Replication is not already stopped, issue a `STOP GROUP_REPLICATION` statement and wait for Group Replication to stop.
- b. Edit the MySQL Server configuration file (typically named `my.cnf` on Linux and Unix systems, or `my.ini` on Windows systems) and set the system variable `group_replication_start_on_boot=OFF`. This setting prevents Group Replication from starting when MySQL Server is started, which is the default.

If you cannot change that setting on the system, you can just allow the server to attempt to start Group Replication, which will fail because the group has been fully shut down and not yet bootstrapped. If you take that approach, do not set `group_replication_bootstrap_group=ON` on any server at this stage.

- c. Start the MySQL Server instance, and verify that Group Replication has not been started (or has failed to start). Do not start Group Replication at this stage.
- d. Collect the following information from the group member:
  - The contents of the `gtid_executed` GTID set. You can get this by issuing the following statement:

```
mysql> SELECT @@GLOBAL.GTID_EXECUTED
```

- The set of certified transactions on the `group_replication_applier` channel. You can get this by issuing the following statement:

```
mysql> SELECT received_transaction_set FROM \
performance_schema.replication_connection_status WHERE \
channel_name="group_replication_applier";
```

2. When you have collected the transaction sets from all the group members, compare them to find which member has the biggest transaction set overall, including both the executed transactions (`gtid_executed`) and the certified transactions (on the `group_replication_applier` channel). You can do this manually by looking at the GTIDs, or you can compare the GTID sets using stored functions, as described in [Section 19.1.3.8, "Stored Function Examples to Manipulate GTIDs"](#).
3. Use the member that has the biggest transaction set to bootstrap the group, by connecting a client to the group member and issuing the following statements:

```
mysql> SET GLOBAL group_replication_bootstrap_group=ON;
mysql> START GROUP_REPLICATION;
mysql> SET GLOBAL group_replication_bootstrap_group=OFF;
```

It is important not to store the setting `group_replication_bootstrap_group=ON` in the configuration file, otherwise when the server is restarted again, a second group with the same name is set up.

4. To verify that the group now exists with this founder member in it, issue this statement on the member that bootstrapped it:

```
mysql> SELECT * FROM performance_schema.replication_group_members;
```

5. Add each of the other members back into the group, in any order, by issuing a `START GROUP_REPLICATION` statement on each of them:

```
mysql> START GROUP_REPLICATION;
```

6. To verify that each member has joined the group, issue this statement on any member:

```
mysql> SELECT * FROM performance_schema.replication_group_members;
```

7. When the members have rejoined the group, if you edited their configuration files to set `group_replication_start_on_boot=OFF`, you can edit them again to set `ON` (or remove the system variable, since `ON` is the default).

## 20.5.3 Transaction Consistency Guarantees

One of the major implications of a distributed system such as Group Replication is the consistency guarantees that it provides as a group. In other words, the consistency of the global synchronization of transactions distributed across the members of the group. This section describes how Group Replication handles consistency guarantees depending on the events that occur in a group, and how to best configure your group's consistency guarantees.

### 20.5.3.1 Understanding Transaction Consistency Guarantees

In terms of distributed consistency guarantees, either in normal or failure repair operations, Group Replication has always been an eventual consistency system. This means that as soon as the incoming traffic slows down or stops, all group members have the same data content. The events that relate to the consistency of a system can be split into control operations, either manual or automatically triggered by failures; and data flow operations.

For Group Replication, the control operations that can be evaluated in terms of consistency are:

- a member joining or leaving, which is covered by Group Replication's [Section 20.5.4, “Distributed Recovery”](#) and write protection.
- network failures, which are covered by the fencing modes.
- in single-primary groups, primary failover, which can also be an operation triggered by `group_replication_set_as_primary()`.

### Consistency Guarantees and Primary Failover

In a single-primary group, in the event of a primary failover when a secondary is promoted to primary, the new primary can either be made available to application traffic immediately, regardless of how large the replication backlog is, or alternatively access to it can be restricted until the backlog has been applied.

With the first approach, the group takes the minimum time possible to secure a stable group membership after a primary failure by electing a new primary and then allowing data access immediately while it is still applying any possible backlog from the old primary. Write consistency is ensured, but reads can temporarily retrieve stale data while the new primary applies the backlog. For example, if client C1 wrote `A=2 WHERE A=1` on the old primary just before its failure, when client C1 is reconnected to the new primary it could potentially read `A=1` until the new primary applies its backlog and catches up with the state of the old primary before it left the group.

With the second alternative, the system secures a stable group membership after the primary failure and elects a new primary in the same way as the first alternative, but in this case the group then waits until the new primary applies all backlog and only then does it permit data access. This ensures that in a situation as described previously, when client C1 is reconnected to the new primary it reads `A=2`. However, the trade-off is that the time required to failover is then proportional to the size of the backlog, which on a correctly configured group should be small.

You can determine the level of transaction consistency guarantees provided by members during primary failover using the `group_replication_consistency` variable. See [Impact of Consistency on Primary Election](#).

## Data Flow Operations

Data flow is relevant to group consistency guarantees due to the reads and writes executed against a group, especially when these operations are distributed across all members. Data flow operations apply to both modes of Group Replication: single-primary and multi-primary, however to make this explanation clearer it is restricted to single-primary mode. The usual way to split incoming read or write transactions across a single-primary group's members is to route writes to the primary and evenly distribute reads to the secondaries. Since the group should behave as a single entity, it is reasonable to expect that writes on the primary are instantaneously available on the secondaries. Although Group Replication is written using Group Communication System (GCS) protocols that implement the Paxos algorithm, some parts of Group Replication are asynchronous, which implies that data is asynchronously applied to secondaries. This means that a client C2 can write `B=2 WHERE B=1` on the primary, immediately connect to a secondary and read `B=1`. This is because the secondary is still applying backlog, and has not applied the transaction which was applied by the primary.

## Transaction Synchronization Points

You configure a group's consistency guarantee based on the point at which you want to synchronize transactions across the group. To help you understand the concept, this section simplifies the points of synchronizing transactions across a group to be at the time of a read operation or at the time of a write operation. If data is synchronized at the time of a read, the current client session waits until a given point, which is the point in time that all preceding update transactions have been applied, before it can start executing. With this approach, only this session is affected, all other concurrent data operations are not affected.

If data is synchronized at the time of write, the writing session waits until all secondaries have written their data. Group Replication uses a total order on writes, and therefore this implies waiting for this and all preceding writes that are in secondaries' queues to be applied. Therefore when using this synchronization point, the writing session waits for all secondaries queues to be applied.

Any alternative ensures that in the situation described for client C2 would always read `B=2` even if immediately connected to a secondary. Each alternative has its advantages and disadvantages, which are directly related to your system workload. The following examples describe different types of workloads and advise which point of synchronization is appropriate.

Imagine the following situations:

- You want to load-balance reads without deploying additional restrictions on which server you read from to avoid reading stale data, group writes are much less common than group reads.
- For a group that has predominantly read-only data, you want read/write transactions to be applied everywhere once they commit, so that subsequent reads are done on up-to-date data that includes the latest write. This ensures that you do not pay the synchronization cost for every read-only transaction, but only for read/write transactions.

In these cases, you should choose to synchronize on writes.

Imagine the following situations:

- You want to load balance your reads without deploying additional restrictions on which server you read from to avoid reading stale data, group writes are much more common than group reads.
- You want specific transactions in your workload to always read up-to-date data from the group, for example whenever sensitive data is updated (such as credentials for a file or similar data) and you want to enforce that reads retrieve the most up to date value.

In these cases, you should choose to synchronize on reads.

### 20.5.3.2 Configuring Transaction Consistency Guarantees

Although the [Transaction Synchronization Points](#) section explains that conceptually there are two synchronization points from which you can choose: on read or on write, these terms were a simplification and the terms used in Group Replication are: *before* and *after* transaction execution. The consistency level can have different effects on read-only and read/write transactions processed by the group as demonstrated in this section.

- [How to Choose a Consistency Level](#)
- [Impacts of Consistency Levels](#)
- [Impact of Consistency on Primary Election](#)
- [Permitted Queries Under Consistency Rules](#)

The following list shows the possible consistency levels that you can configure in Group Replication using the `group_replication_consistency` variable, in order of increasing transaction consistency guarantee:

- `EVENTUAL`

Neither read-only nor read/write transactions wait for preceding transactions to be applied before executing. This was the behavior of Group Replication before the `group_replication_consistency` variable was added. A read/write transaction does not wait for other members to apply a transaction. This means that a transaction could be externalized on one member before the others. This also means that in the event of a primary failover, the new primary can accept new read-only and read/write transactions before the previous primary transactions are all applied. Read-only transactions could result in outdated values, read/write transactions could result in a rollback due to conflicts.

- `BEFORE_ON_PRIMARY_FAILOVER`

New read-only or read/write transactions with a newly elected primary that is applying a backlog from the old primary are not applied until any backlog has been applied. This ensures that when a primary failover happens, intentionally or not, clients always see the latest value on the primary. This guarantees consistency, but means that clients must be able to handle the delay in the event that a backlog is being applied. Usually this delay should be minimal, but it does depend on the size of the backlog.

- `BEFORE`

A read/write transaction waits for all preceding transactions to complete before being applied. A read-only transaction waits for all preceding transactions to complete before being executed. This ensures that this transaction reads the latest value by only affecting the latency of the transaction. This reduces the overhead of synchronization on every read/write transaction, by ensuring synchronization is used only on read-only transactions. This consistency level also includes the consistency guarantees provided by `BEFORE_ON_PRIMARY_FAILOVER`.

- `AFTER`

A read/write transaction waits until its changes have been applied to all of the other members. This value has no effect on read-only transactions. This mode ensures that when a transaction is committed on the local member, any subsequent transaction reads the written value or a more recent value on any group member. Use this mode with a group that is used for predominantly read-only operations to ensure that applied read/write transactions are applied everywhere once they commit. This could be used by your application to ensure that subsequent reads fetch the latest data which includes the latest writes. This reduces the overhead of synchronization on every read-only transaction, by ensuring synchronization is

used only on read/write transactions. This consistency level also includes the consistency guarantees provided by [BEFORE\\_ON\\_PRIMARY\\_FAILOVER](#).

- [BEFORE\\_AND\\_AFTER](#)

A read/write transaction waits for 1) all preceding transactions to complete before being applied and 2) until its changes have been applied on other members. A read-only transaction waits for all preceding transactions to complete before execution takes place. This consistency level also includes the consistency guarantees provided by [BEFORE\\_ON\\_PRIMARY\\_FAILOVER](#).

The [BEFORE](#) and [BEFORE\\_AND\\_AFTER](#) consistency levels can be used on both read-only and read/write transactions. The [AFTER](#) consistency level has no impact on read-only transactions, because they do not generate changes.

### How to Choose a Consistency Level

The different consistency levels provide flexibility to both DBAs, who can use them to set up their infrastructure; and to developers who can use the consistency level that best suits their application's requirements. The following scenarios show how to choose a consistency guarantee level based on how you use your group:

- *Scenario 1:* You want to balance reads without being concerned about stale reads, and group write operations are considerably fewer than group read operations. In this case, you should choose [AFTER](#).
- *Scenario 2:* For a data set that applies many writes, you want to perform occasional reads without concerns about reading stale data. In this case, you should choose [BEFORE](#).
- *Scenario 3:* You want specific transactions to read only up-to-date data from the group, so that whenever sensitive data such as credentials for a file is updated, reads always use the most recent value. In this case, you should choose [BEFORE](#).
- *Scenario 4:* For a group that has predominantly read-only data, you want read/write transactions to be applied everywhere once they commit, so that subsequent reads are done on data that includes your latest writes and you do not incur the cost of synchronization for every read-only transaction, but only for read/write transactions. In this case, you should choose [AFTER](#).
- *Scenario 5:* For a group that works predominantly with read-only data, you want read/write transactions to read up-to-date data from the group and to be applied everywhere once they commit, so that subsequent reads are performed on data that includes the latest write and you do not incur the cost of synchronization for every read-only transaction, but only for read/write transactions. In this case, you should choose [BEFORE\\_AND\\_AFTER](#).

You can choose the scope for which the consistency level is enforced by setting [group\\_replication\\_consistency](#) with session or global scope. This is important because consistency levels can have a negative impact on group performance they apply globally.

To enforce the consistency level for the current session, use session scope, like this:

```
> SET @@SESSION.group_replication_consistency= 'BEFORE';
```

To enforce the consistency level for all sessions, use global scope, as shown here:

```
> SET @@GLOBAL.group_replication_consistency= 'BEFORE';
```

The possibility of setting the consistency level on specific sessions enables you to take advantage of scenarios such as those listed here:

- *Scenario 6:* A given system handles several instructions that do not require a strong consistency level, but one kind of instruction does require strong consistency: managing

access permissions to documents;. In this scenario, the system changes access permissions and it wants to be sure that all clients see the correct permission. You only need to `SET @@SESSION.group_replication_consistency= 'AFTER'`, on those instructions and leave the other instructions to run with `EVENTUAL` set at the global scope.

- *Scenario 7:* On the same system as described in Scenario 6, a command that performs analytics needs to be executed daily, using the most up-to-date data. To achieve this, you need only run the SQL statement `SET @@SESSION.group_replication_consistency= 'BEFORE'` prior to executing the command.

In sum, you do not need to run all transactions with the same specific consistency level, especially if only some transactions actually require it.

You should be aware that all read/write transactions are always ordered in Group Replication, so even when you set the consistency level to `AFTER` for the current session, this transaction waits until its changes are applied on all members, which means waiting for this and all preceding transactions that could be in the secondaries' queues. In other words, the consistency level `AFTER` waits for everything up to and including this transaction.

## Impacts of Consistency Levels

Another way to classify the consistency levels is in terms of impact on the group, that is, the repercussions that the consistency levels have on the other members.

The `BEFORE` consistency level, apart from being ordered on the transaction stream, only impacts on the local member. That is, it does not require coordination with the other members and does not have repercussions on their transactions. In other words, `BEFORE` only impacts the transactions on which it is used.

The `AFTER` and `BEFORE_AND_AFTER` consistency levels do have side-effects on concurrent transactions executed on other members. These consistency levels make the other members transactions wait if transactions with the `EVENTUAL` consistency level start while a transaction with `AFTER` or `BEFORE_AND_AFTER` is executing. The other members wait until the `AFTER` transaction is committed on that member, even if the other member's transactions have the `EVENTUAL` consistency level. In other words, `AFTER` and `BEFORE_AND_AFTER` impact *all* `ONLINE` group members.

To illustrate this further, imagine a group with 3 members, M1, M2 and M3. On member M1 a client issues:

```
> SET @@SESSION.group_replication_consistency= AFTER;
> BEGIN;
> INSERT INTO t1 VALUES (1);
> COMMIT;
```

Then, while the above transaction is being applied, on member M2 a client issues:

```
> SET SESSION group_replication_consistency= EVENTUAL;
```

In this situation, even though the second transaction's consistency level is `EVENTUAL`, because it starts executing while the first transaction is already in the commit phase on M2, the second transaction has to wait for the first transaction to finish the commit and only then can it execute.

You can only use the consistency levels `BEFORE`, `AFTER` and `BEFORE_AND_AFTER` on `ONLINE` members, attempting to use them on members in other states causes a session error.

Transactions whose consistency level is not `EVENTUAL` hold execution until a timeout, configured by `wait_timeout` value is reached, which defaults to 8 hours. If the timeout is reached an `ER_GR_HOLD_WAIT_TIMEOUT` error is thrown.

## Impact of Consistency on Primary Election

This section describes how a group's consistency level impacts on a single-primary group that has elected a new primary. Such a group automatically detects failures and adjusts the view of the members that are active, in other words the membership configuration. Furthermore, if a group is deployed in single-primary mode, whenever the group's membership changes there is a check performed to detect if there is still a primary member in the group. If there is none, a new one is selected from the list of secondary members. Typically, this is known as the secondary promotion.

Given the fact that the system detects failures and reconfigures itself automatically, the user may also expect that once the promotion takes place, the new primary is in the exact state, data-wise, as that of the old one. In other words, the user may expect that there is no backlog of replicated transactions to be applied on the new primary once he is able to read from and write to it. In practical terms, the user may expect that once his application fails-over to the new primary, there would be no chance, even if temporarily, to read old data or write into old data records.

When flow control is activated and properly tuned on a group, there is only a small chance of transiently reading stale data from a newly elected primary immediately after the promotion, as there should not be a backlog, or if there is one it should be small. Moreover, you might have a proxy or middleware layers that govern application accesses to the primary after a promotion and enforce the consistency criteria at that level. You can specify the behavior of the new primary once it is promoted using the `group_replication_consistency` variable, which controls whether a newly elected primary blocks both reads and writes until after the backlog is fully applied. If the `group_replication_consistency` variable was set to `BEFORE_ON_PRIMARY_FAILOVER` on a newly elected primary which has backlog to apply, and transactions are issued against the new primary while it is still applying the backlog, incoming transactions are blocked until the backlog is fully applied. This prevents the following anomalies:

- No stale reads for read-only and read/write transactions. This prevents stale reads from being externalized to the application by the new primary.
- No spurious rollbacks for read/write transactions, due to write-write conflicts with replicated read/write transactions still in the backlog waiting to be applied.
- No read skew on read/write transactions, such as this one:

```
> BEGIN;
> SELECT x FROM t1; -- x=1 because x=2 is in the backlog;
> INSERT x INTO t2;
> COMMIT;
```

This query should not cause a conflict but writes outdated values.

To summarize, when `group_replication_consistency` is set to `BEFORE_ON_PRIMARY_FAILOVER` you are choosing to prioritize consistency over availability, because reads and writes are held whenever a new primary is elected. This is the trade-off you have to consider when configuring your group. It should also be remembered that if flow control is working correctly, backlog should be minimal. Note that the higher consistency levels `BEFORE`, `AFTER`, and `BEFORE_AND_AFTER` also include the consistency guarantees provided by `BEFORE_ON_PRIMARY_FAILOVER`.

To guarantee that the group provides the same consistency level regardless of which member is promoted to primary, all members of the group should have `BEFORE_ON_PRIMARY_FAILOVER` (or a higher consistency level) persisted to their configuration. For example, on each member issue:

```
> SET PERSIST group_replication_consistency='BEFORE_ON_PRIMARY_FAILOVER';
```

This ensures that the members all behave in the same way, and that the configuration is persisted after a restart of the member.

A transaction cannot be on-hold forever, and if the time held exceeds `wait_timeout` it returns an `ER_GR_HOLD_WAIT_TIMEOUT` error.

## Permitted Queries Under Consistency Rules

Although all writes are held when using `BEFORE_ON_PRIMARY_FAILOVER` consistency level, not all reads are blocked to ensure that you can still inspect the server while it is applying backlog after a promotion took place. This is useful for debugging, monitoring, observability and troubleshooting. Some queries that do not modify data are allowed, such as the following:

- `SHOW` statements: These are restricted to those that do not depend on data, only on status and configuration.

The `SHOW` statements that are allowed are `SHOW VARIABLES`, `SHOW PROCESSLIST`, `SHOW STATUS`, `SHOW ENGINE INNODB LOGS`, `SHOW ENGINE INNODB STATUS`, `SHOW ENGINE INNODB MUTEX`, `SHOW BINARY LOG STATUS`, `SHOW REPLICA STATUS`, `SHOW CHARACTER SET`, `SHOW COLLATION`, `SHOW BINARY LOGS`, `SHOW OPEN TABLES`, `SHOW REPLICAS`, `SHOW BINLOG EVENTS`, `SHOW WARNINGS`, `SHOW ERRORS`, `SHOW ENGINES`, `SHOW PRIVILEGES`, `SHOW PROCEDURE STATUS`, `SHOW FUNCTION STATUS`, `SHOW PLUGINS`, `SHOW EVENTS`, `SHOW PROFILE`, `SHOW PROFILES`, and `SHOW RELAYLOG EVENTS`.

- `SET` statements
- `DO` statements that do not use tables or loadable functions
- `EMPTY` statements
- `USE` statements
- Using `SELECT` statements against the `performance_schema` and `sys` databases
- Using `SELECT` statements against the `PROCESSLIST` table from the `infoschema` database
- `SELECT` statements that do not use tables or loadable functions
- `STOP GROUP_REPLICATION` statements
- `SHUTDOWN` statements
- `RESET PERSIST` statements

## 20.5.4 Distributed Recovery

Whenever a member joins or rejoins a replication group, it must catch up with the transactions that were applied by the group members before it joined, or while it was away. This process is called distributed recovery.

The joining member begins by checking the relay log for its `group_replication_applier` channel for any transactions that it already received from the group but did not yet apply. If the joining member was in the group previously, it might find unapplied transactions from before it left, in which case it applies these as a first step. A member that is new to the group does not have anything to apply.

After this, the joining member connects to an online existing member to carry out state transfer. The joining member transfers all the transactions that took place in the group before it joined or while it was away, which are provided by the existing member (called the *donor*). Next, the joining member applies the transactions that took place in the group while this state transfer was in progress. When this process is complete, the joining member has caught up with the remaining servers in the group, and it begins to participate normally in the group.

Group Replication uses a combination of these methods for state transfer during distributed recovery:

- A remote cloning operation using the clone plugin's function. To enable this method of state transfer, you must install the clone plugin on the group members and the joining member. Group Replication automatically configures the required clone plugin settings and manages the remote cloning operation.
- Replicating from a donor's binary log and applying the transactions on the joining member. This method uses a standard asynchronous replication channel named `group_replication_recovery` that is established between the donor and the joining member.

Group Replication automatically selects the best combination of these methods for state transfer after you issue `START GROUP_REPLICATION` on the joining member. To do this, Group Replication checks which existing members are suitable as donors, how many transactions the joining member needs from a donor, and whether any required transactions are no longer present in the binary log files on any group member. If the transaction gap between the joining member and a suitable donor is large, or if some required transactions are not in any donor's binary log files, Group Replication begins distributed recovery with a remote cloning operation. If there is not a large transaction gap, or if the clone plugin is not installed, Group Replication proceeds directly to state transfer from a donor's binary log.

- During a remote cloning operation, the existing data on the joining member is removed, and replaced with a copy of the donor's data. When the remote cloning operation is complete and the joining member has restarted, state transfer from a donor's binary log is carried out to get the transactions that the group applied while the remote cloning operation was in progress.
- During state transfer from a donor's binary log, the joining member replicates and applies the required transactions from the donor's binary log, applying the transactions as they are received, up to the point where the binary log records that the joining member joined the group (a view change event). While this is in progress, the joining member buffers the new transactions that the group applies. When state transfer from the binary log is complete, the joining member applies the buffered transactions.

When the joining member is up to date with all the group's transactions, it is declared online and can participate in the group as a normal member, and distributed recovery is complete.

#### Tip

State transfer from the binary log is Group Replication's base mechanism for distributed recovery, and if the donors and joining members in your replication group are not set up to support cloning, this is the only available option. As state transfer from the binary log is based on classic asynchronous replication, it might take a very long time if the server joining the group does not have the group's data at all, or has data taken from a very old backup image. In this situation, it is therefore recommended that before adding a server to the group, you should set it up with the group's data by transferring a fairly recent snapshot of a server already in the group. This minimizes the time taken for distributed recovery, and reduces the impact on donor servers, since they have to retain and transfer fewer binary log files.

### 20.5.4.1 Connections for Distributed Recovery

When a joining member connects to an online existing member for state transfer during distributed recovery, the joining member acts as a client on the connection and the existing member acts as a server. When state transfer from the donor's binary log is in progress over this connection (using the asynchronous replication channel `group_replication_recovery`), the joining member acts as the replica and the existing member acts as the source. When a remote cloning operation is in progress over this connection, the joining member acts as a recipient and the existing member acts as a donor. Configuration settings that

apply to those roles outside the Group Replication context can apply for Group Replication also, unless they are overridden by a Group Replication-specific configuration setting or behavior.

The connection that an existing member offers to a joining member for distributed recovery is not the same connection that is used by Group Replication for communication between online members of the group.

- The connection used by the group communication engine for Group Replication (XCom, a Paxos variant) for TCP communication between remote XCom instances is specified by the `group_replication_local_address` system variable. This connection is used for TCP/IP messages between online members. Communication with the local instance is over an input channel using shared memory.
- For distributed recovery, by default, group members offer their standard SQL client connection to joining members, as specified by `hostname` and `port`. If an alternative port number is specified by `report_port`, that one is used instead.
- Group members may instead advertise an alternative list of distributed recovery endpoints as dedicated client connections for joining members, allowing you to control distributed recovery traffic separately from connections by regular client users of the member. A member transmits the list of distributed recovery endpoints specified by `group_replication_advertise_recovery_endpoints` to the group when it joins. By default, the member continues to offer the standard SQL client connection as in earlier releases.

#### Important

Distributed recovery can fail if a joining member cannot correctly identify the other members using the host name as defined by MySQL Server's `hostname` system variable. It is recommended that operating systems running MySQL have a properly configured unique host name, either using DNS or local settings. The host name that the server is using for SQL client connections can be verified in the `Member_host` column of the Performance Schema table `replication_group_members`. If multiple group members externalize a default host name set by the operating system, there is a chance of the joining member not resolving it to the correct member address and not being able to connect for distributed recovery. In this situation you can use MySQL Server's `report_host` system variable to configure a unique host name to be externalized by each of the servers.

The steps for a joining member to establish a connection for distributed recovery are as follows:

1. When the member joins the group, it connects with one of the seed members included in the list in its `group_replication_group_seeds` system variable, initially using the `group_replication_local_address` connection as specified in that list. The seed members might be a subset of the group.
2. Over this connection, the seed member uses Group Replication's membership service to provide the joining member with a list of all the members that are online in the group, in the form of a view. The membership information includes the details of the distributed recovery endpoints or standard SQL client connection offered by each member for distributed recovery.
3. The joining member selects a suitable group member from this list to be its donor for distributed recovery, following the behaviors described in [Section 20.5.4.4, “Fault Tolerance for Distributed Recovery”](#).
4. The joining member then attempts to connect to the donor using the donor's advertised distributed recovery endpoints, trying each in turn in the order they are specified in the list. If the donor provides no endpoints, the joining member attempts to connect using the donor's standard

SQL client connection. The SSL requirements for the connection are as specified by the `group_replication_recovery_ssl_*` options described in [SSL and Authentication for Distributed Recovery](#).

5. If the joining member is not able to connect to the selected donor, it retries with other suitable donors, following the behaviors described in [Section 20.5.4.4, “Fault Tolerance for Distributed Recovery”](#). Note that if the joining member exhausts the list of advertised endpoints without making a connection, it does not fall back to the donor's standard SQL client connection, but switches to another donor.
6. When the joining member establishes a distributed recovery connection with a donor, it uses that connection for state transfer as described in [Section 20.5.4, “Distributed Recovery”](#). The host and port for the connection that is used are shown in the joining member's log. Note that if a remote cloning operation is used, when the joining member has restarted at the end of the operation, it establishes a connection with a new donor for state transfer from the binary log. This might be a connection to a different member from the original donor used for the remote cloning operation, or it might be a different connection to the original donor. In any case, the distributed recovery process continues in the same way as it would have with the original donor.

### Selecting addresses for distributed recovery endpoints

IP addresses supplied by the `group_replication_advertise_recovery_endpoints` system variable as distributed recovery endpoints do not have to be configured for MySQL Server (that is, they do not have to be specified by the `admin_address` system variable or in the list for the `bind_address` system variable). They do have to be assigned to the server. Any host names used must resolve to a local IP address. IPv4 and IPv6 addresses can be used.

The ports supplied for the distributed recovery endpoints do have to be configured for MySQL Server, so they must be specified by the `port`, `report_port`, or `admin_port` system variable. The server must listen for TCP/IP connections on these ports. If you specify the `admin_port`, the replication user for distributed recovery needs the `SERVICE_CONNECTION_ADMIN` privilege to connect. Selecting the `admin_port` keeps distributed recovery connections separate from regular MySQL client connections.

Joining members try each of the endpoints in turn in the order they are specified on the list. If `group_replication_advertise_recovery_endpoints` is set to `DEFAULT` rather than a list of endpoints, the standard SQL client connection is offered. Note that the standard SQL client connection is not automatically included on a list of distributed recovery endpoints, and is not offered as a fallback if the donor's list of endpoints is exhausted without a connection. If you want to offer the standard SQL client connection as one of a number of distributed recovery endpoints, you must include it explicitly in the list specified by `group_replication_advertise_recovery_endpoints`. You can put it in the last place so that it acts as a last resort for connection.

A group member's distributed recovery endpoints (or standard SQL client connection if endpoints are not provided) do not need to be added to the Group Replication allowlist specified by the `group_replication_ip_allowlist` system variable. The allowlist is only for the address specified by `group_replication_local_address` for each member. A joining member must have its initial connection to the group permitted by the allowlist in order to retrieve the address or addresses for distributed recovery.

The distributed recovery endpoints that you list are validated when the system variable is set and when a `START GROUP_REPLICATION` statement has been issued. If the list cannot be parsed correctly, or if any of the endpoints cannot be accessed on the host because the server is not listening on them, Group Replication logs an error and does not start.

### Compression for Distributed Recovery

You can optionally configure compression for distributed recovery by the method of state transfer from a donor's binary log. Compression can benefit distributed recovery where

network bandwidth is limited and the donor has to transfer many transactions to the joining member. The `group_replication_recovery_compression_algorithms` and `group_replication_recovery_zstd_compression_level` system variables determine permitted compression algorithms, and the `zstd` compression level used when carrying out state transfer from a donor's binary log. For more information, see [Section 6.2.8, “Connection Compression Control”](#).

These compression settings do not apply to remote cloning operations. When a remote cloning operation is used for distributed recovery, the clone plugin's setting for `clone_enable_compression` applies.

## Replication User for Distributed Recovery

Distributed recovery requires a replication user that has the correct permissions so that Group Replication can establish direct member-to-member replication channels. The replication user must also have the correct permissions to act as the clone user on the donor for a remote cloning operation. The same replication user must be used for distributed recovery on every group member. For instructions to set up this replication user, see [Section 20.2.1.3, “User Credentials For Distributed Recovery”](#). For instructions to secure the replication user credentials, see [Section 20.6.3.1, “Secure User Credentials for Distributed Recovery”](#).

## SSL and Authentication for Distributed Recovery

SSL for distributed recovery is configured separately from SSL for normal group communications, which is determined by the server's SSL settings and the `group_replication_ssl_mode` system variable. For distributed recovery connections, dedicated Group Replication distributed recovery SSL system variables are available to configure the use of certificates and ciphers specifically for distributed recovery.

By default, SSL is not used for distributed recovery connections. To activate it, set `group_replication_recovery_use_ssl=ON`, and configure the Group Replication distributed recovery SSL system variables as described in [Section 20.6.3, “Securing Distributed Recovery Connections”](#). You need a replication user that is set up to use SSL.

When distributed recovery is configured to use SSL, Group Replication applies this setting for remote cloning operations, as well as for state transfer from a donor's binary log. Group Replication automatically configures the settings for the clone SSL options (`clone_ssl_ca`, `clone_ssl_cert`, and `clone_ssl_key`) to match your settings for the corresponding Group Replication distributed recovery options (`group_replication_recovery_ssl_ca`, `group_replication_recovery_ssl_cert`, and `group_replication_recovery_ssl_key`).

If you are not using SSL for distributed recovery (so `group_replication_recovery_use_ssl` is set to `OFF`), and the replication user account for Group Replication authenticates with the `caching_sha2_password` plugin (the default) or the `sha256_password` plugin (deprecated), RSA key pairs are used for password exchange. In this case, either use the `group_replication_recovery_public_key_path` system variable to specify the RSA public key file, or use the `group_replication_recovery_get_public_key` system variable to request the public key from the source, as described in [Replication User With The Caching SHA-2 Authentication Plugin](#).

### 20.5.4.2 Cloning for Distributed Recovery

If you want to use remote cloning operations for distributed recovery in a group, you must set up existing members and joining members beforehand to support this function. If you do not want to use this function in a group, do not set it up, in which case Group Replication only uses state transfer from the binary log.

To use cloning, at least one existing group member and the joining member must be set up beforehand to support remote cloning operations. As a minimum, you must install the clone plugin on the donor and joining member, grant the `BACKUP_ADMIN` permission to the replication user for distributed recovery, and

set the `group_replication_clone_threshold` system variable to an appropriate level. To ensure the maximum availability of donors, it is advisable to set up all current and future group members to support remote cloning operations.

Be aware that a remote cloning operation removes user-created tablespaces and data from the joining member before transferring the data from the donor. If the operation is stopped while in progress, the joining member might be left with partial data or no data. This can be repaired by retrying the remote cloning operation, which Group Replication does automatically.

## Prerequisites for Cloning

For full instructions to set up and configure the clone plugin, see [Section 7.6.7, “The Clone Plugin”](#). Detailed prerequisites for a remote cloning operation are covered in [Section 7.6.7.3, “Cloning Remote Data”](#). For Group Replication, note the following key points and differences:

- The donor (an existing group member) and the recipient (the joining member) must have the clone plugin installed and active. For instructions to do this, see [Section 7.6.7.1, “Installing the Clone Plugin”](#).
- The donor and the recipient must run on the same operating system, and must use the same MySQL Server release series. Cloning is therefore not suitable for groups where members run different minor MySQL Server versions, such as MySQL 8.0 and 8.4.
- The donor and the recipient must have the Group Replication plugin installed and active, and any other plugins that are active on the donor (such as a keyring plugin) must also be active on the recipient.
- If distributed recovery is configured to use SSL (`group_replication_recovery_use_ssl=ON`), Group Replication applies this setting for remote cloning operations. Group Replication automatically configures the settings for the clone SSL options (`clone_ssl_ca`, `clone_ssl_cert`, and `clone_ssl_key`) to match your settings for the corresponding Group Replication distributed recovery options (`group_replication_recovery_ssl_ca`, `group_replication_recovery_ssl_cert`, and `group_replication_recovery_ssl_key`).
- You do not need to set up a list of valid donors in the `clone_valid_donor_list` system variable for the purpose of joining a replication group. Group Replication configures this setting automatically for you after it selects a donor from the existing group members. Note that remote cloning operations use the server's SQL protocol hostname and port.
- The clone plugin has a number of system variables to manage the network load and performance impact of the remote cloning operation. Group Replication does not configure these settings, so you can review them and set them if you want to, or allow them to default. Note that when a remote cloning operation is used for distributed recovery, the clone plugin's `clone_enable_compression` setting applies to the operation, rather than the Group Replication compression setting.
- To invoke the remote cloning operation on the recipient, Group Replication uses the internal `mysql.session` user, which already has the `CLONE_ADMIN` privilege, so you do not need to set this up.
- As the clone user on the donor for the remote cloning operation, Group Replication uses the replication user that you set up for distributed recovery (which is covered in [Section 20.2.1.3, “User Credentials For Distributed Recovery”](#)). You must therefore give the `BACKUP_ADMIN` privilege to this replication user on all group members that support cloning. Also give the privilege to the replication user on joining members when you are configuring them for Group Replication, because they can act as donors after they join the group. The same replication user is used for distributed recovery on every group member. To give this privilege to the replication user on existing members, you can issue this statement on each group member individually with binary logging disabled, or on one group member with binary logging enabled:

```
GRANT BACKUP_ADMIN ON *.* TO rpl_user@'%' ;
```

- If you use `START GROUP_REPLICATION` to specify the replication user credentials on a server that previously supplied the user credentials using `CHANGE REPLICATION SOURCE TO`, ensure that you remove the user credentials from the replication metadata repositories before any remote cloning operations take place. Also ensure that `group_replication_start_on_boot=OFF` is set on the joining member. For instructions, see [Section 20.6.3, “Securing Distributed Recovery Connections”](#). If you do not unset the user credentials, they are transferred to the joining member during remote cloning operations. The `group_replication_recovery` channel could then be inadvertently started with the stored credentials, on either the original member or members that were cloned from it. An automatic start of Group Replication on server boot (including after a remote cloning operation) would use the stored user credentials, and they would also be used if an operator did not specify the distributed recovery credentials on a `START GROUP_REPLICATION` command.

## Threshold for Cloning

When group members have been set up to support cloning, the `group_replication_clone_threshold` system variable specifies a threshold, expressed as a number of transactions, for the use of a remote cloning operation in distributed recovery. If the gap between the transactions on the donor and the transactions on the joining member is larger than this number, a remote cloning operation is used for state transfer to the joining member when this is technically possible. Group Replication calculates whether the threshold has been exceeded based on the `gtid_executed` sets of the existing group members. Using a remote cloning operation in the event of a large transaction gap lets you add new members to the group without transferring the group's data to the server manually beforehand, and also enables a member that is very out of date to catch up more efficiently.

The default setting for the `group_replication_clone_threshold` Group Replication system variable is extremely high (the maximum permitted sequence number for a transaction in a GTID), so it effectively deactivates cloning wherever state transfer from the binary log is possible. To enable Group Replication to select a remote cloning operation for state transfer where this is more appropriate, set the system variable to specify a number of transactions as the transaction gap above which you want cloning to take place.

### Warning

Do not use a low setting for `group_replication_clone_threshold` in an active group. If a number of transactions above the threshold takes place in the group while the remote cloning operation is in progress, the joining member triggers a remote cloning operation again after restarting, and could continue this indefinitely. To avoid this situation, ensure that you set the threshold to a number higher than the number of transactions that you would expect to occur in the group during the time taken for the remote cloning operation.

Group Replication attempts to execute a remote cloning operation regardless of your threshold when state transfer from a donor's binary log is impossible, for example because the transactions needed by the joining member are not available in the binary log on any existing group member. Group Replication identifies this based on the `gtid_purged` sets of the existing group members. You cannot use the `group_replication_clone_threshold` system variable to deactivate cloning when the required transactions are not available in any member's binary log files, because in that situation cloning is the only alternative to transferring data to the joining member manually.

## Cloning Operations

When group members and joining members are set up for cloning, Group Replication manages remote cloning operations for you. A remote cloning operation might take some time to complete, depending on

the size of the data. See [Section 7.6.7.10, “Monitoring Cloning Operations”](#) for information on monitoring the process.

**Note**

When state transfer is complete, Group Replication restarts the joining member to complete the process. If `group_replication_start_on_boot=OFF` is set on the joining member, for example because you specify the replication user credentials on the `START GROUP_REPLICATION` statement, you must issue `START GROUP_REPLICATION` manually again following this restart. If `group_replication_start_on_boot=ON` and other settings required to start Group Replication were set in a configuration file or using a `SET PERSIST` statement, you do not need to intervene and the process continues automatically to bring the joining member online.

A remote cloning operation clones settings that are persisted in tables from the donor to the recipient, as well as the data. Group Replication manages the settings that relate specifically to Group Replication channels. Group Replication member settings that are persisted in configuration files, such as the group replication local address, are not cloned and are not changed on the joining member. Group Replication also preserves the channel settings that relate to the use of SSL, so these are unique to the individual member.

If the replication user credentials used by the donor for the `group_replication_recovery` replication channel have been stored in the replication metadata repositories using a `CHANGE REPLICATION SOURCE TO` statement, they are transferred to and used by the joining member after cloning, and they must be valid there. With stored credentials, all group members that received state transfer by a remote cloning operation therefore automatically receive the replication user and password for distributed recovery. If you specify the replication user credentials on the `START GROUP_REPLICATION` statement, these are used to start the remote cloning operation, but they are not transferred to and used by the joining member after cloning. If you do not want the credentials transferred to new joiners and recorded there, ensure that you unset them before remote cloning operations take place, as described in [Section 20.6.3, “Securing Distributed Recovery Connections”](#), and use `START GROUP_REPLICATION` to supply them instead.

If a `PRIVILEGE_CHECKS_USER` account has been used to help secure the replication appliers (see [Section 19.3.3.2, “Privilege Checks For Group Replication Channels”](#)), the `PRIVILEGE_CHECKS_USER` account and related settings from the donor are cloned to the joining member. If the joining member is set to start Group Replication on boot, it automatically uses the account for privilege checks on the appropriate replication channels.

## Cloning for Other Purposes

Group Replication initiates and manages cloning operations for distributed recovery. Group members that have been set up to support cloning may also participate in cloning operations that a user initiates manually. For example, you might want to create a new server instance by cloning from a group member as the donor, but you do not want the new server instance to join the group immediately, or maybe not ever.

In all releases that support cloning, you can initiate a cloning operation manually involving a group member on which Group Replication is stopped. Note that because cloning requires that the active plugins on a donor and recipient must match, the Group Replication plugin must be installed and active on the other server instance, even if you do not intend that server instance to join a group. You can install the plugin by issuing this statement:

```
INSTALL PLUGIN group_replication SONAME 'group_replication.so';
```

You can initiate a cloning operation manually if the operation involves a group member on which Group Replication is running, provided that the cloning operation does not remove and replace the data on the recipient. The statement to initiate the cloning operation must therefore include the `DATA DIRECTORY` clause if Group Replication is running.

### 20.5.4.3 Configuring Distributed Recovery

Several aspects of Group Replication's distributed recovery process can be configured to suit your system.

#### Number of Connection Attempts

For state transfer from the binary log, Group Replication limits the number of attempts a joining member makes when trying to connect to a donor from the pool of donors. If the connection retry limit is reached without a successful connection, the distributed recovery procedure terminates with an error. Note that this limit specifies the total number of attempts that the joining member makes to connect to a donor. For example, if 2 group members are suitable donors, and the connection retry limit is set to 4, the joining member makes 2 attempts to connect to each of the donors before reaching the limit.

The default connection retry limit is 10. You can configure this setting using the `group_replication_recovery_retry_count` system variable. The following command sets the maximum number of attempts to connect to a donor to 5:

```
mysql> SET GLOBAL group_replication_recovery_retry_count= 5;
```

For remote cloning operations, this limit does not apply. Group Replication makes only one connection attempt to each suitable donor for cloning, before starting to attempt state transfer from the binary log.

#### Sleep Interval for Connection Attempts

For state transfer from the binary log, the `group_replication_recovery_reconnect_interval` system variable defines how much time the distributed recovery process should sleep between donor connection attempts. Note that distributed recovery does not sleep after every donor connection attempt. As the joining member is connecting to different servers and not to the same one repeatedly, it can assume that the problem that affects server A does not affect server B. Distributed recovery therefore suspends only when it has gone through all the possible donors. Once the server joining the group has made one attempt to connect to each of the suitable donors in the group, the distributed recovery process sleeps for the number of seconds configured by the `group_replication_recovery_reconnect_interval` system variable. For example, if 2 group members are suitable donors, and the connection retry limit is set to 4, the joining member makes one attempt to connect to each of the donors, then sleeps for the connection retry interval, then makes one further attempt to connect to each of the donors before reaching the limit.

The default connection retry interval is 60 seconds, and you can change this value dynamically. The following command sets the distributed recovery donor connection retry interval to 120 seconds:

```
mysql> SET GLOBAL group_replication_recovery_reconnect_interval= 120;
```

For remote cloning operations, this interval does not apply. Group Replication makes only one connection attempt to each suitable donor for cloning, before starting to attempt state transfer from the binary log.

#### Marking the Joining Member Online

When distributed recovery has successfully completed state transfer from the donor to the joining member, the joining member can be marked as online in the group and ready to participate. This is done after the new member has received and applied all the transactions that it missed prior to joining the group.

#### 20.5.4.4 Fault Tolerance for Distributed Recovery

Group Replication's distributed recovery process has a number of built-in measures to ensure fault tolerance in the event of any problems during the process.

The donor for distributed recovery is selected randomly from the existing list of suitable online group members in the current view. Selecting a random donor means that there is a good chance that the same server is not selected more than once when multiple members enter the group. For state transfer from the binary log, the joiner selects a donor that is running a lower or equal patch version of MySQL Server compared to itself. For earlier releases, all of the online members are allowed to be a donor. For a remote cloning operation, the joiner selects a donor that is running the same patch version as itself. When the member joining has restarted at the end of the operation, it establishes a connection with a new donor for state transfer from the binary log, which might be a different member from the original donor used for the remote cloning operation.

In the following situations, Group Replication detects an error in distributed recovery, automatically switches over to a new donor, and retries the state transfer:

- *Connection error* - There is an authentication issue or another problem with making the connection to a candidate donor.
- *Replication errors* - One of the replication threads (the receiver or applier threads) being used for state transfer from the binary log fails. Because this method of state transfer uses the existing MySQL replication framework, it is possible that some transient errors could cause errors in the receiver or applier threads.
- *Remote cloning operation errors* - A remote cloning operation fails or is stopped before it completes.
- *Donor leaves the group* - The donor leaves the group, or Group Replication is stopped on the donor, while state transfer is in progress.

The Performance Schema table `replication_applier_status_by_worker` displays the error that caused the last retry. In these situations, the new connection following the error is attempted with a new candidate donor. Selecting a different donor in the event of an error means that there is a chance the new candidate donor does not have the same error. If the clone plugin is installed, Group Replication attempts a remote cloning operation with each of the suitable online clone-supporting donors first. If all those attempts fail, Group Replication attempts state transfer from the binary log with all the suitable donors in turn, if that is possible.

##### Warning

For a remote cloning operation, user-created tablespaces and data on the recipient (the joining member) are dropped before the remote cloning operation begins to transfer the data from the donor. If the remote cloning operation starts but does not complete, the joining member might be left with a partial set of its original data files, or with no user data. Data transferred by the donor is removed from the recipient if the cloning operation is stopped before the data is fully cloned. This situation can be repaired by retrying the cloning operation, which Group Replication does automatically.

In the following situations, the distributed recovery process cannot be completed, and the joining member leaves the group:

- *Purged transactions* - Transactions that are required by the joining member are not present in any online group member's binary log files, and the data cannot be obtained by a remote cloning operation

(because the clone plugin is not installed, or because cloning was attempted with all possible donors but failed). The joining member is therefore unable to catch up with the group.

- *Extra transactions* - The joining member already contains some transactions that are not present in the group. If a remote cloning operation was carried out, these transactions would be deleted and lost, because the data directory on the joining member is erased. If state transfer from a donor's binary log was carried out, these transactions could conflict with the group's transactions. For advice on dealing with this situation, see [Extra Transactions](#).
- *Connection retry limit reached* - The joining member has made all the connection attempts allowed by the connection retry limit. You can configure this using the `group_replication_recovery_retry_count` system variable (see [Section 20.5.4.3, "Configuring Distributed Recovery"](#)).
- *No more donors* - The joining member has unsuccessfully attempted a remote cloning operation with each of the online clone-supporting donors in turn (if the clone plugin is installed), then has unsuccessfully attempted state transfer from the binary log with each of the suitable online donors in turn, if possible.
- *Joining member leaves the group* - The joining member leaves the group or Group Replication is stopped on the joining member while state transfer is in progress.

If the joining member left the group unintentionally, so in any situation listed above except the last, it proceeds to take the action specified by the `group_replication_exit_state_action` system variable.

### 20.5.4.5 How Distributed Recovery Works

When Group Replication's distributed recovery process is carrying out state transfer from the binary log, to synchronize the joining member with the donor up to a specific point in time, the joining member and donor make use of GTIDs (see [Section 19.1.3, "Replication with Global Transaction Identifiers"](#)). However, GTIDs only provide a means to realize which transactions the joining member is missing. They do not help marking a specific point in time to which the server joining the group must catch up, nor do they convey certification information. This is the job of binary log view markers, which mark view changes in the binary log stream, and also contain additional metadata information, supplying the joining member with missing certification-related data.

This topic explains the role of view changes and the view change identifier, and the steps to carry out state transfer from the binary log.

#### View and View Changes

A *view* corresponds to a group of members participating actively in the current configuration, in other words at a specific point in time. They are functioning correctly and online in the group.

A *view change* occurs when a modification to the group configuration happens, such as a member joining or leaving. Any group membership change results in an independent view change communicated to all members at the same logical point in time.

A *view identifier* uniquely identifies a view. It is generated whenever a view change happens.

At the group communication layer, view changes with their associated view identifiers mark boundaries between the data exchanged before and after a member joins. This concept is implemented through a binary log event: the "view change log event" (VCLE). The view identifier is recorded to demarcate transactions transmitted before and after changes happen in the group membership.

The view identifier itself is built from two parts: a randomly generated part, and a monotonically increasing integer. The randomly generated part is generated when the group is created, and remains unchanged while there is at least one member in the group. The integer is incremented every time a view change happens. Using these two different parts enables the view identifier to identify incremental group changes caused by members joining or leaving, and also to identify the situation where all members leave the group in a full group shutdown, so no information remains of what view the group was in. Randomly generating part of the identifier when the group is started from the beginning ensures that the data markers in the binary log remain unique, and an identical identifier is not reused after a full group shutdown, as this would cause issues with distributed recovery in the future.

## Begin: Stable Group

All servers are online and processing incoming transactions from the group. Some servers may be a little behind in terms of transactions replicated, but eventually they converge. The group acts as one distributed and replicated database.

**Figure 20.8 Stable Group**

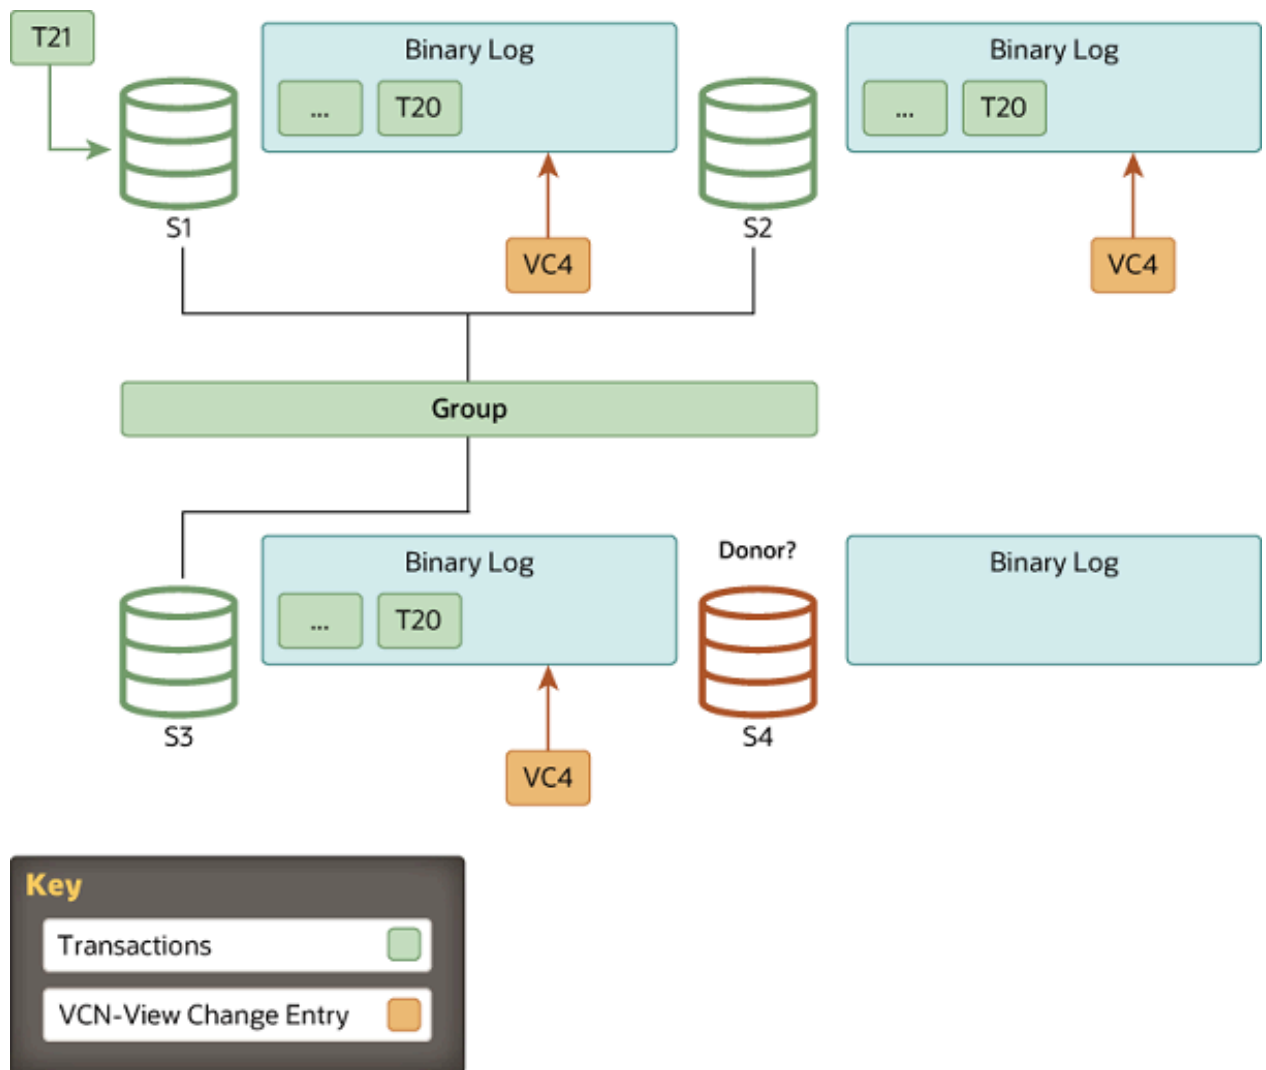

## View Change: a Member Joins

Whenever a new member joins the group and therefore a view change is performed, every online server queues a view change log event for execution. This is queued because before the view change, several

transactions can be queued on the server to be applied and as such, these belong to the old view. Queuing the view change event after them guarantees a correct marking of when this happened.

Meanwhile, the joining member selects a suitable donor from the list of online servers as stated by the membership service through the view abstraction. A member joins on view 4 and the online members write a view change event to the binary log.

**Figure 20.9 A Member Joins**

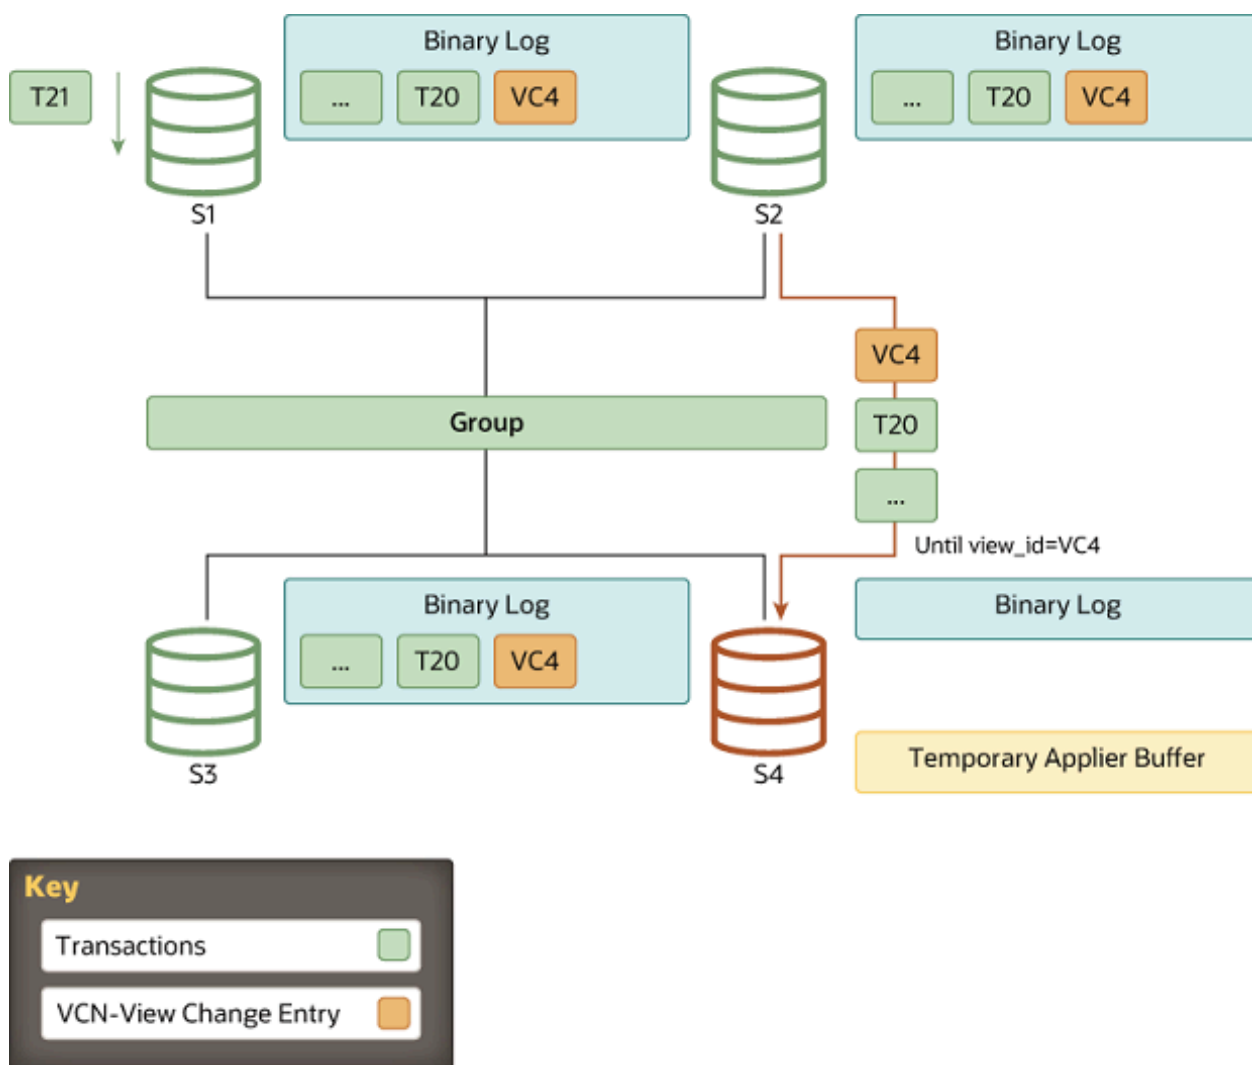

### State Transfer: Catching Up

If group members and the joining member are set up with the clone plugin (see [Section 20.5.4.2, “Cloning for Distributed Recovery”](#)), and the difference in transactions between the joining member and the group exceeds the threshold set for a remote cloning operation (`group_replication_clone_threshold`), Group Replication begins distributed recovery with a remote cloning operation. A remote cloning operation is also carried out if required transactions are no longer present in any group member's binary log files. During a remote cloning operation, the existing data on the joining member is removed, and replaced with a copy of the donor's data. When the remote cloning operation is complete and the joining member has restarted, state transfer from a donor's binary log is carried out to get the transactions that the group

applied while the remote cloning operation was in progress. If there is not a large transaction gap, or if the clone plugin is not installed, Group Replication proceeds directly to state transfer from a donor's binary log.

For state transfer from a donor's binary log, a connection is established between the joining member and the donor and state transfer begins. This interaction with the donor continues until the server joining the group's applier thread processes the view change log event that corresponds to the view change triggered when the server joining the group came into the group. In other words, the server joining the group replicates from the donor, until it gets to the marker with the view identifier which matches the view marker it is already in.

**Figure 20.10 State Transfer: Catching Up**

As view identifiers are transmitted to all members in the group at the same logical time, the server joining the group knows at which view identifier it should stop replicating. This avoids complex GTID set calculations because the view identifier clearly marks which data belongs to each group view.

While the server joining the group is replicating from the donor, it is also caching incoming transactions from the group. Eventually, it stops replicating from the donor and switches to applying those that are cached.

Figure 20.11 Queued Transactions

### Finish: Caught Up

When the server joining the group recognizes a view change log event with the expected view identifier, the connection to the donor is terminated and it starts applying the cached transactions. Although it acts as a marker in the binary log, delimiting view changes, the view change log event also plays another role. It conveys the certification information as perceived by all servers when the server joining the group entered the group, in other words the last view change. Without it, the server joining the group would not have the necessary information to be able to certify (detect conflicts) subsequent transactions.

The duration of the catch up is not deterministic, because it depends on the workload and the rate of incoming transactions to the group. This process is completely online and the server joining the group does not block any other server in the group while it is catching up. Therefore the number of transactions the server joining the group is behind when it moves to this stage can, for this reason, vary and thus increase or decrease according to the workload.

When the server joining the group reaches zero queued transactions and its stored data is equal to the other members, its public state changes to online.

**Figure 20.12 Instance Online**

## 20.5.5 Support For IPv6 And For Mixed IPv6 And IPv4 Groups

Group Replication group members can use IPv6 addresses as an alternative to IPv4 addresses for communications within the group. To use IPv6 addresses, the operating system on the server host and the MySQL Server instance must both be configured to support IPv6. For instructions to set up IPv6 support for a server instance, see [Section 7.1.13, “IPv6 Support”](#).

IPv6 addresses, or host names that resolve to them, can be specified as the network address that the member provides in the `group_replication_local_address` option for connections from other members. When specified with a port number, an IPv6 address must be specified in square brackets, for example:

```
group_replication_local_address= "[2001:db8:85a3:8d3:1319:8a2e:370:7348]:33061"
```

The network address or host name specified in `group_replication_local_address` is used by Group Replication as the unique identifier for a group member within the replication group. If a host name specified as the Group Replication local address for a server instance resolves to both an IPv4 and an IPv6 address, the IPv4 address is always used for Group Replication connections. The address or host name specified as the Group Replication local address is not the same as the MySQL server SQL protocol host and port, and is not specified in the `bind_address` system variable for the server instance. For the purpose of IP address permissions for Group Replication (see [Section 20.6.4, “Group Replication IP Address Permissions”](#)), the address that you specify for each group member in `group_replication_local_address` must be added to the list for the `group_replication_ip_allowlist` system variable on the other servers in the replication group.

A replication group can contain a combination of members that present an IPv6 address as their Group Replication local address, and members that present an IPv4 address. When a server joins such a mixed group, it must make the initial contact with the seed member using the protocol that the seed member advertises in the `group_replication_group_seeds` option, whether that is IPv4 or IPv6. If any of the seed members for the group are listed in the `group_replication_group_seeds` option with an IPv6 address when a joining member has an IPv4 Group Replication local address, or the reverse, you must also set up and permit an alternative address for the joining member for the required protocol (or a host name that resolves to an address for that protocol). If a joining member does not have a permitted address for the appropriate protocol, its connection attempt is refused. The alternative address or host name only needs to be added to the `group_replication_ip_allowlist` system variable on the other servers in the replication group, not to the `group_replication_local_address` value for the joining member (which can only contain a single address).

For example, server A is a seed member for a group, and has the following configuration settings for Group Replication, so that it is advertising an IPv6 address in the `group_replication_group_seeds` option:

```
group_replication_bootstrap_group=on
group_replication_local_address= "[2001:db8:85a3:8d3:1319:8a2e:370:7348]:33061"
group_replication_group_seeds= "[2001:db8:85a3:8d3:1319:8a2e:370:7348]:33061"
```

Server B is a joining member for the group, and has the following configuration settings for Group Replication, so that it has an IPv4 Group Replication local address:

```
group_replication_bootstrap_group=off
group_replication_local_address= "203.0.113.21:33061"
group_replication_group_seeds= "[2001:db8:85a3:8d3:1319:8a2e:370:7348]:33061"
```

Server B also has an alternative IPv6 address `2001:db8:8b0:40:3d9c:cc43:e006:19e8`. For Server B to join the group successfully, both its IPv4 Group Replication local address, and its alternative IPv6 address, must be listed in Server A's allowlist, as in the following example:

```
group_replication_ip_allowlist=
"203.0.113.0/24,2001:db8:85a3:8d3:1319:8a2e:370:7348,
2001:db8:8b0:40:3d9c:cc43:e006:19e8"
```

As a best practice for Group Replication IP address permissions, Server B (and all other group members) should have the same allowlist as Server A, unless security requirements demand otherwise.

If any or all members of a replication group are using an older MySQL Server version that does not support the use of IPv6 addresses for Group Replication, a member cannot participate in the group using an IPv6 address (or a host name that resolves to one) as its Group Replication local address. This applies both in the case where at least one existing member uses an IPv6 address and a new member that does not support this attempts to join, and in the case where a new member attempts to join using an IPv6 address but the group includes at least one member that does not support this. In each situation, the new member

cannot join. To make a joining member present an IPv4 address for group communications, you can either change the value of `group_replication_local_address` to an IPv4 address, or configure your DNS to resolve the joining member's existing host name to an IPv4 address. After you have upgraded every group member to a MySQL Server version that supports IPv6 for Group Replication, you can change the `group_replication_local_address` value for each member to an IPv6 address, or configure your DNS to present an IPv6 address. Changing the value of `group_replication_local_address` takes effect only when you stop and restart Group Replication.

IPv6 addresses can also be used as distributed recovery endpoints, which can be specified using the `group_replication_advertise_recovery_endpoints` system variable. The same rules apply to addresses used in this list. See [Section 20.5.4.1, “Connections for Distributed Recovery”](#).

## 20.5.6 Using MySQL Enterprise Backup with Group Replication

[MySQL Enterprise Backup](#) is a commercially-licensed backup utility for MySQL Server, available with [MySQL Enterprise Edition](#). This section explains how to back up and subsequently restore a Group Replication member using MySQL Enterprise Backup. The same technique can be used to quickly add a new member to a group.

### Backing up a Group Replication Member Using MySQL Enterprise Backup

Backing up a Group Replication member is similar to backing up a stand-alone MySQL instance. The following instructions assume that you are already familiar with how to use MySQL Enterprise Backup to perform a backup; if that is not the case, please review [Backing Up a Database Server](#). Also note the requirements described in [Grant MySQL Privileges to Backup Administrator](#) and [Using MySQL Enterprise Backup with Group Replication](#).

Consider the following group with three members, `s1`, `s2`, and `s3`, running on hosts with the same names:

```
mysql> SELECT member_host, member_port, member_state FROM performance_schema.replication_group_members;
```

member_host	member_port	member_state
s1	3306	ONLINE
s2	3306	ONLINE
s3	3306	ONLINE

Using MySQL Enterprise Backup, create a backup of `s2` by issuing on its host, for example, the following command:

```
s2> mysqlbackup --defaults-file=/etc/my.cnf --backup-image=/backups/my.mbi_`date +%d%m_%H%M` \
--backup-dir=/backups/backup_`date +%d%m_%H%M` --user=root -p \
--host=127.0.0.1 backup-to-image
```

### Restoring a Failed Member

Assume one of the members (`s3` in the following example) is irreconcilably corrupted. The most recent backup of group member `s2` can be used to restore `s3`. Here are the steps for performing the restore:

1. *Copy the backup of s2 onto the host for s3.* The exact way to copy the backup depends on the operating system and tools available to you. In this example, we assume the hosts are both Linux servers and use SCP to copy the files between them:

```
s2/backups> scp my.mbi_2206_1429 s3:/backups
```

2. *Restore the backup.* Connect to the target host (the host for `s3` in this case), and restore the backup using MySQL Enterprise Backup. Here are the steps:

- a. Stop the corrupted server, if it is still running. For example, on Linux distributions that use systemd:

```
s3> systemctl stop mysqld
```

- b. Preserve the two configuration files in the corrupted server's data directory, `auto.cnf` and `mysqld-auto.cnf` (if it exists), by copying them to a safe location outside of the data directory. This is for preserving the [server's UUID](#) and [Section 7.1.9.3, "Persisted System Variables"](#) (if used), which are needed in the steps below.
- c. Delete all contents in the data directory of `s3`. For example:

```
s3> rm -rf /var/lib/mysql/*
```

If the system variables `innodb_data_home_dir`, `innodb_log_group_home_dir`, and `innodb_undo_directory` point to any directories other than the data directory, they should also be made empty; otherwise, the restore operation fails.

- d. Restore backup of `s2` onto the host for `s3`:

```
s3> mysqlbackup --defaults-file=/etc/my.cnf \
--datadir=/var/lib/mysql \
--backup-image=/backups/my.mbi_2206_1429 \
--backup-dir=/tmp/restore_`date +%d%m_%H%M` copy-back-and-apply-log
```

#### Note

The command above assumes that the binary logs and relay logs on `s2` and `s3` have the same base name and are at the same location on the two servers. If these conditions are not met, you should use the `--log-bin` and `--relay-log` options to restore the binary log and relay log to their original file paths on `s3`. For example, if you know that on `s3` the binary log's base name is `s3-bin` and the relay-log's base name is `s3-relay-bin`, your restore command should look like:

```
mysqlbackup --defaults-file=/etc/my.cnf \
--datadir=/var/lib/mysql \
--backup-image=/backups/my.mbi_2206_1429 \
--log-bin=s3-bin --relay-log=s3-relay-bin \
--backup-dir=/tmp/restore_`date +%d%m_%H%M` copy-back-and-apply-log
```

Being able to restore the binary log and relay log to the right file paths makes the restore process easier; if that is impossible for some reason, see [Rebuild the Failed Member to Rejoin as a New Member](#).

3. Restore the `auto.cnf` file for `s3`. To rejoin the replication group, the restored member *must* have the same `server_uuid` it used to join the group before. Supply the old server UUID by copying the `auto.cnf` file preserved in step 2 above into the data directory of the restored member.

#### Note

If you cannot supply the failed member's original `server_uuid` to the restored member by restoring its old `auto.cnf` file, you must let the restored member join the group as a new member; see instructions in [Rebuild the Failed Member to Rejoin as a New Member](#) below on how to do that.

4. Restore the `mysqld-auto.cnf` file for `s3` (only required if `s3` used persistent system variables). The settings for the [Section 7.1.9.3, "Persisted System Variables"](#) that were used to configure the failed member must be provided to the restored member. These settings are to be found in the `mysqld-`

`auto.cnf` file of the failed server, which you should have preserved in step 2 above. Restore the file to the data directory of the restored server. See [Restoring Persisted System Variables](#) on what to do if you do not have a copy of the file.

5. *Start the restored server.* For example, on Linux distributions that use `systemd`:

```
systemctl start mysqld
```

#### Note

If the server you are restoring is a primary member, perform the steps described in [Restoring a Primary Member](#) before starting the restored server.

6. *Restart Group Replication.* Connect to the restarted `s3` using, for example, a `mysql` client, and issue the following command:

```
mysql> START GROUP_REPLICATION;
```

Before the restored instance can become an online member of the group, it needs to apply any transactions that have happened to the group after the backup was taken; this is achieved using Group Replication's [distributed recovery](#) mechanism, and the process starts after the [START GROUP\\_REPLICATION](#) statement has been issued. To check the member status of the restored instance, issue:

```
mysql> SELECT member_host, member_port, member_state FROM performance_schema.replication_group_members;
```

member_host	member_port	member_state
s1	3306	ONLINE
s2	3306	ONLINE
s3	3306	RECOVERING

This shows that `s3` is applying transactions to catch up with the group. Once it has caught up with the rest of the group, its `member_state` changes to `ONLINE`:

```
mysql> SELECT member_host, member_port, member_state FROM performance_schema.replication_group_members;
```

member_host	member_port	member_state
s1	3306	ONLINE
s2	3306	ONLINE
s3	3306	ONLINE

#### Note

If the server you are restoring is a primary member, once it has gained synchrony with the group and become `ONLINE`, perform the steps described at the end of [Restoring a Primary Member](#) to revert the configuration changes you had made to the server before you started it.

The member has now been fully restored from the backup and functions as a regular member of the group.

## Rebuild the Failed Member to Rejoin as a New Member

Sometimes, the steps outlined above in [Restoring a Failed Member](#) cannot be carried out because, for example, the binary log or relay log is corrupted, or it is just missing from the backup. In such a situation, use the backup to rebuild the member, and then add it to the group as a new member. In the steps below,

we assume the rebuilt member is named `s3`, like the failed member, and that it runs on the same host as `s3`:

1. *Copy the backup of `s2` onto the host for `s3`.* The exact way to copy the backup depends on the operating system and tools available to you. In this example we assume the hosts are both Linux servers and use SCP to copy the files between them:

```
s2/backups> scp my.mbi_2206_1429 s3:/backups
```

2. *Restore the backup.* Connect to the target host (the host for `s3` in this case), and restore the backup using MySQL Enterprise Backup. Here are the steps:

- a. Stop the corrupted server, if it is still running. For example, on Linux distributions that use systemd:

```
s3> systemctl stop mysqld
```

- b. Preserve the configuration file `mysqld-auto.cnf`, if it is found in the corrupted server's data directory, by copying it to a safe location outside of the data directory. This is for preserving the server's [Section 7.1.9.3, "Persisted System Variables"](#), which are needed later.

- c. Delete all contents in the data directory of `s3`. For example:

```
s3> rm -rf /var/lib/mysql/*
```

If the system variables `innodb_data_home_dir`, `innodb_log_group_home_dir`, and `innodb_undo_directory` point to any directories other than the data directory, they should also be made empty; otherwise, the restore operation fails.

- d. Restore the backup of `s2` onto the host of `s3`. With this approach, we are rebuilding `s3` as a new member, for which we do not need or do not want to use the old binary and relay logs in the backup; therefore, if these logs have been included in your backup, exclude them using the `--skip-binlog` and `--skip-relaylog` options:

```
s3> mysqlbackup --defaults-file=/etc/my.cnf \
--datadir=/var/lib/mysql \
--backup-image=/backups/my.mbi_2206_1429 \
--backup-dir=/tmp/restore_`date +%d%m_%H%M` \
--skip-binlog --skip-relaylog \
copy-back-and-apply-log
```

#### Note

If you have healthy binary log and relay logs in the backup that you can transfer onto the target host with no issues, you are recommended to follow the easier procedure as described in [Restoring a Failed Member](#) above.

3. *Restore the `mysqld-auto.cnf` file for `s3` (only required if `s3` used persistent system variables).* The settings for the [Section 7.1.9.3, "Persisted System Variables"](#) that were used to configure the failed member must be provided to the restored server. These settings are to be found in the `mysqld-auto.cnf` file of the failed server, which you should have preserved in step 2 above. Restore the file to the data directory of the restored server. See [Restoring Persisted System Variables](#) on what to do if you do not have a copy of the file.

#### Note

Do NOT restore the corrupted server's `auto.cnf` file to the data directory of the new member—when the rebuilt `s3` joins the group as a new member, it is going to be assigned a new server UUID.

4. *Start the restored server.* For example, on Linux distributions that use systemd:

```
systemctl start mysqld
```

#### Note

If the server you are restoring is a primary member, perform the steps described in [Restoring a Primary Member](#) before starting the restored server.

5. *Reconfigure the restored member to join Group Replication.* Connect to the restored server with a `mysql` client and reset the source and replica information with the following statements:

```
mysql> RESET BINARY LOGS AND GTIDS;
mysql> RESET REPLICA ALL;
```

For the restored server to be able to recover automatically using Group Replication's built-in mechanism for [distributed recovery](#), configure the server's `gtid_executed` variable. To do this, use the `backup_gtid_executed.sql` file included in the backup of `s2`, which is usually restored under the restored member's data directory. Disable binary logging, use the `backup_gtid_executed.sql` file to configure `gtid_executed`, and then re-enable binary logging by issuing the following statements with your `mysql` client:

```
mysql> SET SQL_LOG_BIN=OFF;
mysql> SOURCE datadir/backup_gtid_executed.sql
mysql> SET SQL_LOG_BIN=ON;
```

Then, configure the [Group Replication user credentials](#) on the member using the SQL statements shown here:

```
mysql> CHANGE REPLICATION SOURCE TO SOURCE_USER='rpl_user',
-> SOURCE_PASSWORD='password'
-> FOR CHANNEL 'group_replication_recovery';
```

6. *Restart Group Replication.* Issue the following command to the restored server with your `mysql` client:

```
mysql> START GROUP_REPLICATION;
```

Before the restored instance can become an online member of the group, it needs to apply any transactions that have happened to the group after the backup was taken; this is achieved using Group Replication's [distributed recovery](#) mechanism, and the process starts after the [START GROUP\\_REPLICATION](#) statement has been issued. To check the member status of the restored instance, issue:

```
mysql> SELECT member_host, member_port, member_state FROM performance_schema.replication_group_members;
+-----+-----+-----+
| member_host | member_port | member_state |
+-----+-----+-----+
| s3 | 3306 | RECOVERING |
| s2 | 3306 | ONLINE |
| s1 | 3306 | ONLINE |
+-----+-----+-----+
```

This shows that `s3` is applying transactions to catch up with the group. Once it has caught up with the rest of the group, its `member_state` changes to `ONLINE`:

```
mysql> SELECT member_host, member_port, member_state FROM performance_schema.replication_group_members;
+-----+-----+-----+
| member_host | member_port | member_state |
+-----+-----+-----+
| s3 | 3306 | ONLINE |
+-----+-----+-----+
```

s2	3306	ONLINE
s1	3306	ONLINE

**Note**

If the server you are restoring is a primary member, once it has gained synchrony with the group and become **ONLINE**, perform the steps described at the end of [Restoring a Primary Member](#) to revert the configuration changes you had made to the server before you started it.

The member has now been restored to the group as a new member.

**Restoring Persisted System Variables.** `mysqlbackup` does not provide support for backing up or preserving [Section 7.1.9.3, “Persisted System Variables”](#)—the file `mysqld-auto.cnf` is not included in a backup. To start the restored member with its persisted variable settings, you need to do one of the following:

- Preserve a copy of the `mysqld-auto.cnf` file from the corrupted server, and copy it to the restored server's data directory.
- Copy the `mysqld-auto.cnf` file from another member of the group into the restored server's data directory, if that member has the same persisted system variable settings as the corrupted member.
- After the restored server is started and before you restart Group Replication, set all the system variables manually to their persisted values through a `mysql` client.

**Restoring a Primary Member.** If the restored member is a primary in the group, care must be taken to prevent writes to the restored database during the Group Replication distributed recovery process. Depending on how the group is accessed by clients, there is a possibility of DML statements being executed on the restored member once it becomes accessible on the network, prior to the member finishing its catch-up on the activities it has missed while off the group. To avoid this, *before starting the restored server*, configure the following system variables in the server option file:

```
group_replication_start_on_boot=OFF
super_read_only=ON
event_scheduler=OFF
```

These settings ensure that the member becomes read-only at startup, and that the event scheduler is turned off while the member catches up with the group during the distributed recovery process. Adequate error handling must also be provided for on the clients, since they are unable to perform DML operations during this period on the member being restored.

Once the restoration process is fully completed and the restored member is synchronized with the rest of the group, you can revert these changes. First, restart the event scheduler using the statement shown here:

```
mysql> SET global event_scheduler=ON;
```

After this, you should set the following system variables in the member's option file, so that they have the necessary values for the next time that the member is started:

```
group_replication_start_on_boot=ON
super_read_only=OFF
event_scheduler=ON
```

## 20.6 Group Replication Security

This section explains how to secure a group, securing the connections between members of a group, or by establishing a security perimeter using an IP address allowlist.

## 20.6.1 Communication Stack for Connection Security Management

MySQL 9.1 Group Replication can secure group communication connections between members by one of the following methods:

- Using its own implementation of the security protocols, including TLS/SSL and the use of an allowlist for incoming Group Communication System (GCS) connections.
- Using MySQL Server's own connection security in place of Group Replication's implementation. Using the MySQL protocol means that standard methods of user authentication can be used for granting (or revoking) access to the group in place of the allowlist, and the latest functionality of the server's protocol is always available on release.

The choice is made by setting the system variable `group_replication_communication_stack` to `XCOM` to use Group Replication's own implementation (this is the default choice), or to `MYSQL` to use MySQL Server's connection security.

The following additional configuration is required for a replication group to use the MySQL communication stack. It is especially important to make sure these requirements are all fulfilled when you switch from using the XCom communication stack to the MySQL communication stack for your group.

### Group Replication Requirements For The MySQL Communication Stack

- The network address configured by the `group_replication_local_address` system variable for each group member must be set to one of the IP addresses and ports that MySQL Server is listening on, as specified by the `bind_address` system variable for the server. The combination of IP address and port for each member must be unique in the group. It is recommended that the `group_replication_group_seeds` system variable for each group member be configured to contain all the local addresses for all the group members.
- The MySQL communication stack supports network namespaces, which the XCom communication stack does not support. If network namespaces are used with the Group Replication local addresses for the group members (`group_replication_local_address`), these must be configured for each group member using the `CHANGE REPLICATION SOURCE TO` statement. Also, the `report_host` server system variable for each group member must be set to report the namespace. All group members must use the same namespace to avoid possible issues with address resolution during distributed recovery.
- The `group_replication_ssl_mode` system variable must be set to the required setting for group communications. This system variable controls whether TLS/SSL is enabled or disabled for group communications. When the MySQL communication stack is used, the TLS/SSL configuration is taken from Group Replication's distributed recovery settings. This setting should be the same on all the group members, to avoid potential conflicts.
- The `require_secure_transport` server system variable value should be the same on all the group members, to avoid potential conflicts. If `group_replication_ssl_mode` is set to `REQUIRED`, `VERIFY_CA`, or `VERIFY_IDENTITY`, use `require_secure_transport=ON`. If `group_replication_ssl_mode` is set to `DISABLED`, use `require_secure_transport=OFF`.
- If TLS/SSL is enabled for group communications, Group Replication's settings for securing distributed recovery must be configured if they are not already in place, or validated if they already are. The MySQL communication stack uses these settings not just for member-to-member distributed recovery connections, but also for TLS/SSL configuration in general group communications. `group_replication_recovery_use_ssl` and the other `group_replication_recovery_*` system variables are explained in [Section 20.6.3.2, "Secure Socket Layer \(SSL\) Connections for Distributed Recovery"](#).

- The Group Replication allowlist is not used when the group is using the MySQL communication stack, so the `group_replication_ip_allowlist` system variable is ignored and need not be set.
- The replication user account that Group Replication uses for distributed recovery, as configured using the `CHANGE REPLICATION SOURCE TO` statement, is used for authentication by the MySQL communication stack when setting up Group Replication connections. This user account, which is the same on all group members, must be given the following privileges:
  - `GROUP_REPLICATION_STREAM`. This privilege is required for the user account to be able to establish connections for Group Replication using the MySQL communication stack.
  - `CONNECTION_ADMIN`. This privilege is required so that Group Replication connections are not terminated if one of the servers involved is placed in offline mode. If the MySQL communication stack is in use without this privilege, a member that is placed in offline mode is expelled from the group.

These are in addition to the privileges `REPLICATION SLAVE` and `BACKUP_ADMIN` that all replication user accounts must have (see [Section 20.2.1.3, “User Credentials For Distributed Recovery”](#)). When you add the new privileges, ensure that you skip binary logging on each group member by issuing `SET SQL_LOG_BIN=0` before you issue the `GRANT` statements, and `SET SQL_LOG_BIN=1` after them, so that the local transaction does not interfere with restarting Group Replication.

`group_replication_communication_stack` is effectively a group-wide configuration setting, and the setting must be the same on all group members. However, this is not policed by Group Replication’s own checks for group-wide configuration settings. A member with a different value from the rest of the group cannot communicate with the other members at all, because the communication protocols are incompatible, so it cannot exchange information about its configuration settings.

This means that although the value of the system variable can be changed while Group Replication is running, and takes effect after you restart Group Replication on the group member, the member still cannot rejoin the group until the setting has been changed on all the members. You must therefore stop Group Replication on all of the members and change the value of the system variable on them all before you can restart the group. Because all of the members are stopped, a full reboot of the group (a bootstrap by a server with `group_replication_bootstrap_group=ON`) is required in order for the value change to take effect. You can make the other required changes to settings on the group members while they are stopped.

For a running group, follow this procedure to change the value of `group_replication_communication_stack` and the other required settings to migrate a group from the XCom communication stack to the MySQL communication stack, or from the MySQL communication stack to the XCom communication stack:

1. Stop Group Replication on each of the group members, using a `STOP GROUP_REPLICATION` statement. Stop the primary member last, so that you do not trigger a new primary election and have to wait for that to complete.
2. On each of the group members, set the system variable `group_replication_communication_stack` to the new communication stack, `MYSQL` or `XCOM` as appropriate. You can do this by editing the MySQL Server configuration file (typically named `my.cnf` on Linux and Unix systems, or `my.ini` on Windows systems), or by using a `SET` statement. For example:

```
SET PERSIST group_replication_communication_stack="MYSQL";
```

3. If you are migrating the replication group from the XCom communication stack (the default) to the MySQL communication stack, on each of the group members, configure or reconfigure the required system variables to appropriate settings, as described in the listing above. For example, the

`group_replication_local_address` system variable must be set to one of the IP addresses and ports that MySQL Server is listening on. Also configure any network namespaces using a `CHANGE REPLICATION SOURCE TO` statement.

4. If you are migrating the replication group from the XCom communication stack (the default) to the MySQL communication stack, on each of the group members, issue `GRANT` statements to give the replication user account the `GROUP_REPLICATION_STREAM` and `CONNECTION_ADMIN` privileges. You will need to take the group members out of the read-only state that is applied when Group Replication is stopped. Also ensure that you skip binary logging on each group member by issuing `SET SQL_LOG_BIN=0` before you issue the `GRANT` statements, and `SET SQL_LOG_BIN=1` after them, so that the local transaction does not interfere with restarting Group Replication. For example:

```
SET GLOBAL SUPER_READ_ONLY=OFF;
SET SQL_LOG_BIN=0;
GRANT GROUP_REPLICATION_STREAM ON *.* TO rpl_user@'%';
GRANT CONNECTION_ADMIN ON *.* TO rpl_user@'%';
SET SQL_LOG_BIN=1;
```

5. If you are migrating the replication group from the MySQL communication stack back to the XCom communication stack, on each of the group members, reconfigure the system variables in the requirements listing above to settings suitable for the XCom communication stack. [Section 20.9, “Group Replication Variables”](#) lists the system variables with their defaults and requirements for the XCom communication stack.

#### Note

- The XCom communication stack does not support network namespaces, so the Group Replication local address (`group_replication_local_address` system variable) cannot use these. Unset them by issuing a `CHANGE REPLICATION SOURCE TO` statement.
- When you move back to the XCom communication stack, the settings specified by `group_replication_recovery_use_ssl` and the other `group_replication_recovery_*` system variables are not used to secure group communications. Instead, the Group Replication system variable `group_replication_ssl_mode` is used to activate the use of SSL for group communication connections and specify the security mode for the connections, and the remainder of the configuration is taken from the server's SSL configuration. For details, see [Section 20.6.2, “Securing Group Communication Connections with Secure Socket Layer \(SSL\)”](#).

6. To restart the group, follow the process in [Section 20.5.2, “Restarting a Group”](#), which explains how to safely bootstrap a group where transactions have been executed and certified. A bootstrap by a server with `group_replication_bootstrap_group=ON` is necessary to change the communication stack, because all of the members must be shut down.
7. Members now connect to each other using the new communication stack. Any server that has `group_replication_communication_stack` set (or defaulted, in the case of XCom) to the previous communication stack is no longer able to join the group. It is important to note that because Group Replication cannot even see the joining attempt, it does not check and reject the joining member with an error message. Instead, the attempted join fails silently when the previous communication stack gives up trying to contact the new one.

## 20.6.2 Securing Group Communication Connections with Secure Socket Layer (SSL)

Secure sockets can be used for group communication connections between members of a group.

The Group Replication system variable `group_replication_ssl_mode` is used to activate the use of SSL for group communication connections and specify the security mode for the connections. The default setting means that SSL is not used. The option has the following possible values:

**Table 20.1** `group_replication_ssl_mode` configuration values

Value	Description
<code>DISABLED</code>	Establish an unencrypted connection (the default).
<code>REQUIRED</code>	Establish a secure connection if the server supports secure connections.
<code>VERIFY_CA</code>	Like <code>REQUIRED</code> , but additionally verify the server TLS certificate against the configured Certificate Authority (CA) certificates.
<code>VERIFY_IDENTITY</code>	Like <code>VERIFY_CA</code> , but additionally verify that the server certificate matches the host to which the connection is attempted.

If SSL is used, the means for configuring the secure connection depends on whether the XCom or the MySQL communication stack is used for group communication.

#### When using the XCom communication stack

(`group_replication_communication_stack=XCOM`): The remainder of the configuration for Group Replication's group communication connections is taken from the server's SSL configuration. For more information on the options for configuring the server SSL, see [Command Options for Encrypted Connections](#). The server SSL options that are applied to Group Replication's group communication connections are as follows:

**Table 20.2** SSL Options

Server Configuration	Description
<code>ssl_key</code>	The path name of the SSL private key file in PEM format. On the client side, this is the client private key. On the server side, this is the server private key.
<code>ssl_cert</code>	The path name of the SSL public key certificate file in PEM format. On the client side, this is the client public key certificate. On the server side, this is the server public key certificate.
<code>ssl_ca</code>	The path name of the Certificate Authority (CA) certificate file in PEM format.
<code>ssl_cacpath</code>	The path name of the directory that contains trusted SSL certificate authority (CA) certificate files in PEM format.
<code>ssl_crl</code>	The path name of the file containing certificate revocation lists in PEM format.
<code>ssl_crlpath</code>	The path name of the directory that contains certificate revocation list files in PEM format.

Server Configuration	Description
<code>ssl_cipher</code>	A list of permissible ciphers for encrypted connections.
<code>tls_version</code>	A list of the TLS protocols the server permits for encrypted connections.
<code>tls_ciphersuites</code>	Which TLSv1.3 ciphersuites the server permits for encrypted connections.

### Important

- Support for the TLSv1 and TLSv1.1 connection protocols was removed in MySQL 8.0. MySQL clients, including Group Replication server instances acting as clients, do not return warnings to the user if a deprecated TLS protocol version is used. See [Removal of Support for the TLSv1 and TLSv1.1 Protocols](#) for more information.
- MySQL 9.1 supports the TLSv1.3 protocol, provided that the MySQL Server was compiled using OpenSSL 1.1.1. The server checks the version of OpenSSL at startup; if it is lower than 1.1.1, TLSv1.3 is removed from the default values for all server system variables relating to TLS versions, including `group_replication_recovery_tls_version`.
- MySQL 9.1 Group Replication supports TLSv1.3.
- Use `group_replication_recovery_tls_version` and `group_replication_recovery_tls_ciphersuites` to configure client support for any selection of ciphersuites, including only non-default ciphersuites if desired.
- In the list of TLS protocols specified in the `tls_version` system variable, ensure the specified versions are contiguous (for example, `TLSv1.2,TLSv1.3`). If there are any gaps in the list of protocols (for example, if you specified `TLSv1,TLSv1.2`, omitting TLS 1.1) Group Replication might be unable to make group communication connections.

In a replication group, OpenSSL negotiates the use of the highest TLS protocol that is supported by all members. A joining member that is configured to use only TLSv1.3 (`tls_version=TLSv1.3`) cannot join a replication group where any existing member does not support TLSv1.3, because the group members in that case are using a lower TLS protocol version. To join the member to the group, you must configure the joining member to also permit the use of lower TLS protocol versions supported by the existing group members. Conversely, if a joining member does not support TLSv1.3, but the existing group members all do and are using that version for connections to each other, the member can join if the existing group members already permit the use of a suitable lower TLS protocol version, or if you configure them to do so. In that situation, OpenSSL uses a lower TLS protocol version for the connections from each member to the joining member. Each member's connections to other existing members continue to use the highest available protocol that both members support.

You can change the `tls_version` system variable at runtime to alter the list of permitted TLS protocol versions for the server. For Group Replication, the `ALTER INSTANCE RELOAD TLS` statement, which reconfigures the server's TLS context from the current values of the system variables that define the context, does not change the TLS context for Group Replication's group communication connection while Group Replication is running. To apply the reconfiguration to these connections, you must execute `STOP GROUP_REPLICATION` followed by `START GROUP_REPLICATION` to restart Group Replication on the member or members where you changed the `tls_version` system variable. Similarly, if you

want to make all members of a group change to using a higher or lower TLS protocol version, you must carry out a rolling restart of Group Replication on the members after changing the list of permitted TLS protocol versions, so that OpenSSL negotiates the use of the higher TLS protocol version when the rolling restart is completed. For instructions to change the list of permitted TLS protocol versions at runtime, see [Section 8.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#) and [Server-Side Runtime Configuration and Monitoring for Encrypted Connections](#).

The following example shows a section from a `my.cnf` file that configures SSL on a server, and activates SSL for Group Replication group communication connections:

```
[mysqld]
ssl_ca = "cacert.pem"
ssl_capath = "/.../ca_directory"
ssl_cert = "server-cert.pem"
ssl_cipher = "DHE-RSA-AES256-SHA"
ssl_crl = "crl-server-revoked.crl"
ssl_crlpath = "/.../crl_directory"
ssl_key = "server-key.pem"
group_replication_ssl_mode= REQUIRED
```

### Important

The `ALTER INSTANCE RELOAD TLS` statement, which reconfigures the server's TLS context from the current values of the system variables that define the context, does not change the TLS context for Group Replication's group communication connections while Group Replication is running. To apply the reconfiguration to these connections, you must execute `STOP GROUP_REPLICATION` followed by `START GROUP_REPLICATION` to restart Group Replication.

Connections made between a joining member and an existing member for distributed recovery are not covered by the options described above. These connections use Group Replication's dedicated distributed recovery SSL options, which are described in [Section 20.6.3.2, “Secure Socket Layer \(SSL\) Connections for Distributed Recovery”](#).

### When using the MySQL communication stack

**(group\_replication\_communication\_stack=MYSQL):** The security settings for distributed recovery of the group are applied to the normal communications between group members. See [Section 20.6.3, “Securing Distributed Recovery Connections”](#) on how to configure the security settings.

## 20.6.3 Securing Distributed Recovery Connections

### Important

When using the MySQL communication stack (`group_replication_communication_stack=MYSQL`) AND secure connections between members (`group_replication_ssl_mode` is not set to `DISABLED`), the security settings discussed in this section are applied not just to distributed recovery connections, but to group communications between members in general.

When a member joins the group, distributed recovery is carried out using a combination of a remote cloning operation, if available and appropriate, and an asynchronous replication connection. For a full description of distributed recovery, see [Section 20.5.4, “Distributed Recovery”](#).

Group members offer their standard SQL client connection to joining members for distributed recovery, as specified by MySQL Server's `hostname` and `port` system variables, and may (also) advertise an alternative list of distributed recovery endpoints as dedicated client connections for joining members. For

more details, see [Section 20.5.4.1, “Connections for Distributed Recovery”](#). Notice that such connections offered to a joining member for distributed recovery is *not* the same connections that are used by Group Replication for communication between online members when the XCom communication stack is used for group communications (`group_replication_communication_stack=XCOM`).

To secure distributed recovery connections in the group, ensure that user credentials for the replication user are properly secured, and use SSL for distributed recovery connections if possible.

### 20.6.3.1 Secure User Credentials for Distributed Recovery

State transfer from the binary log requires a replication user with the correct permissions so that Group Replication can establish direct member-to-member replication channels. The same replication user is used for distributed recovery on all the group members. If group members have been set up to support the use of a remote cloning operation as part of distributed recovery, this replication user is also used as the clone user on the donor, and requires the correct permissions for this role. For detailed instructions to set up this user, see [Section 20.2.1.3, “User Credentials For Distributed Recovery”](#).

To secure the user credentials, you can require SSL for connections with the user account, and provide the user credentials when Group Replication is started, rather than storing them in the replica status tables. Also, if you are using caching SHA-2 authentication, you must set up RSA key-pairs on the group members.

#### Important

When using the MySQL communication stack (`group_replication_communication_stack=MYSQL`) AND secure connections between members (`group_replication_ssl_mode` is not set to `DISABLED`), the recovery users must be properly set up, as they are also the users for group communications. Follow the instructions in [Replication User With SSL](#) and [Providing Replication User Credentials Securely](#).

### Replication User With The Caching SHA-2 Authentication Plugin

By default, users created in MySQL 8 use [Section 8.4.1.1, “Caching SHA-2 Pluggable Authentication”](#). If the replication user you configure for distributed recovery uses the caching SHA-2 authentication plugin, and you are *not* using SSL for distributed recovery connections, RSA key-pairs are used for password exchange. For more information on RSA key-pairs, see [Section 8.3.3, “Creating SSL and RSA Certificates and Keys”](#).

In this situation, you can either copy the public key of the `rpl_user` to the joining member, or configure the donors to provide the public key when requested. The more secure approach is to copy the public key of the replication user account to the joining member. Then you need to configure the `group_replication_recovery_public_key_path` system variable on the joining member with the path to the public key for the replication user account.

The less secure approach is to set `group_replication_recovery_get_public_key=ON` on donors so that they provide the public key of the replication user account to joining members. There is no way to verify the identity of a server, therefore only set `group_replication_recovery_get_public_key=ON` when you are sure there is no risk of server identity being compromised, for example by a man-in-the-middle attack.

### Replication User With SSL

A replication user that requires an SSL connection must be created *before* the server joining the group (the joining member) connects to the donor. Typically, this is set up at the time you are provisioning a server to

join the group. To create a replication user for distributed recovery that requires an SSL connection, issue these statements on all servers that are going to participate in the group:

```
mysql> SET SQL_LOG_BIN=0;
mysql> CREATE USER 'rec_ssl_user'@'%' IDENTIFIED BY 'password' REQUIRE SSL;
mysql> GRANT REPLICATION SLAVE ON *.* TO 'rec_ssl_user'@'%';
mysql> GRANT CONNECTION_ADMIN ON *.* TO 'rec_ssl_user'@'%';
mysql> GRANT BACKUP_ADMIN ON *.* TO 'rec_ssl_user'@'%';
mysql> GRANT GROUP_REPLICATION_STREAM ON *.* TO 'rec_ssl_user'@'%';
mysql> FLUSH PRIVILEGES;
mysql> SET SQL_LOG_BIN=1;
```

### Note

The `GROUP_REPLICATION_STREAM` privilege is required when using both the MySQL communication stack (`group_replication_communication_stack=MYSQL`) and secure connections between members (`group_replication_ssl_mode` not set to `DISABLED`). See [Section 20.6.1, “Communication Stack for Connection Security Management”](#).

## Providing Replication User Credentials Securely

To supply the user credentials for the replication user, you can set them permanently as the credentials for the `group_replication_recovery` channel, using a `CHANGE REPLICATION SOURCE TO` statement. Alternatively, you can specify them in the `START GROUP_REPLICATION` statement each time Group Replication is started. User credentials specified in `START GROUP_REPLICATION` take precedence over any user credentials that have been set using a `CHANGE REPLICATION SOURCE TO` statement.

User credentials set using `CHANGE REPLICATION SOURCE TO` are stored in plain text in the replication metadata repositories on the server, but user credentials specified on `START GROUP_REPLICATION` are saved in memory only, and are removed by a `STOP GROUP_REPLICATION` statement or server shutdown. Using `START GROUP_REPLICATION` to specify the user credentials therefore helps to secure the Group Replication servers against unauthorized access. However, this method is not compatible with starting Group Replication automatically, as specified by the `group_replication_start_on_boot` system variable.

If you want to set the user credentials permanently using a `CHANGE REPLICATION SOURCE TO` statement, issue this statement on the member that is going to join the group:

```
mysql> CHANGE REPLICATION SOURCE TO SOURCE_USER='rec_ssl_user',
-> SOURCE_PASSWORD='password'
-> FOR CHANNEL 'group_replication_recovery';
```

To supply the user credentials on `START GROUP_REPLICATION`, issue this statement when starting Group Replication for the first time, or after a server restart:

```
mysql> START GROUP_REPLICATION USER='rec_ssl_user', PASSWORD='password';
```

### Important

If you switch to using `START GROUP_REPLICATION` to specify user credentials on a server that previously supplied the credentials using `CHANGE REPLICATION SOURCE TO`, you must complete the following steps to get the security benefits of this change.

1. Stop Group Replication on the group member using a `STOP GROUP_REPLICATION` statement. Although it is possible to take the following two steps while Group Replication is running, you need to restart Group Replication to implement the changes.

2. Set the value of the `group_replication_start_on_boot` system variable to `OFF` (the default is `ON`).
3. Remove the distributed recovery credentials from the replica status tables by issuing this statement:

```
mysql> CHANGE REPLICATION SOURCE TO SOURCE_USER='', SOURCE_PASSWORD=''
-> FOR CHANNEL 'group_replication_recovery';
```

4. Restart Group Replication on the group member using a `START GROUP_REPLICATION` statement that specifies the distributed recovery user credentials.

Without these steps, the credentials remain stored in the replica status tables, and can also be transferred to other group members during remote cloning operations for distributed recovery. The `group_replication_recovery` channel could then be inadvertently started with the stored credentials, on either the original member or members that were cloned from it. An automatic start of Group Replication on server boot (including after a remote cloning operation) would use the stored user credentials, and they would also be used if an operator did not specify the distributed recovery credentials as part of `START GROUP_REPLICATION`.

### 20.6.3.2 Secure Socket Layer (SSL) Connections for Distributed Recovery

#### Important

When using the MySQL communication stack (`group_replication_communication_stack=MYSQL`) AND secure connections between members (`group_replication_ssl_mode` is not set to `DISABLED`), the security settings discussed in this section are applied not just to distributed recovery connections, but to group communications between members in general. See [Section 20.6.1, “Communication Stack for Connection Security Management”](#).

Whether the distributed recovery connection is made using the standard SQL client connection or a distributed recovery endpoint, to configure the connection securely, you can use Group Replication's dedicated distributed recovery SSL options. These options correspond to the server SSL options that are used for group communication connections, but they are only applied for distributed recovery connections. By default, distributed recovery connections do not use SSL, even if you activated SSL for group communication connections, and the server SSL options are not applied for distributed recovery connections. You must configure these connections separately.

If a remote cloning operation is used as part of distributed recovery, Group Replication automatically configures the clone plugin's SSL options to match your settings for the distributed recovery SSL options. (For details of how the clone plugin uses SSL, see [Configuring an Encrypted Connection for Cloning](#).)

The distributed recovery SSL options are as follows:

- `group_replication_recovery_use_ssl`: Set to `ON` to make Group Replication use SSL for distributed recovery connections, including remote cloning operations and state transfer from a donor's binary log. If the server you connect to does not use the default configuration for this (see [Section 8.3.1, “Configuring MySQL to Use Encrypted Connections”](#)), use the other distributed recovery SSL options to determine which certificates and cipher suites to use.
- `group_replication_recovery_ssl_ca`: The path name of the Certificate Authority (CA) file to use for distributed recovery connections. Group Replication automatically configures the clone SSL option `clone_ssl_ca` to match this.

`group_replication_recovery_ssl_capath`: The path name of a directory that contains trusted SSL certificate authority (CA) certificate files.

- `group_replication_recovery_ssl_cert`: The path name of the SSL public key certificate file to use for distributed recovery connections. Group Replication automatically configures the clone SSL option `clone_ssl_cert` to match this.
- `group_replication_recovery_ssl_key`: The path name of the SSL private key file to use for distributed recovery connections. Group Replication automatically configures the clone SSL option `clone_ssl_cert` to match this.
- `group_replication_recovery_ssl_verify_server_cert`: Makes the distributed recovery connection check the server's Common Name value in the donor sent certificate. Setting this option to `ON` is the equivalent for distributed recovery connections of setting `VERIFY_IDENTITY` for the `group_replication_ssl_mode` option for group communication connections.
- `group_replication_recovery_ssl_crl`: The path name of a file containing certificate revocation lists.
- `group_replication_recovery_ssl_crlpath`: The path name of a directory containing certificate revocation lists.
- `group_replication_recovery_ssl_cipher`: A list of permissible ciphers for connection encryption for the distributed recovery connection. Specify a list of one or more cipher names, separated by colons. For information about which encryption ciphers MySQL supports, see [Section 8.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#).
- `group_replication_recovery_tls_version`: A comma-separated list of one or more permitted TLS protocols for connection encryption when this server instance is the client in the distributed recovery connection, that is, the joining member. The default for this system variable depends on the TLS protocol versions supported in the MySQL Server release. The group members involved in each distributed recovery connection as the client (joining member) and server (donor) negotiate the highest protocol version that they are both set up to support.
- `group_replication_recovery_tls_ciphersuites`: A colon-separated list of one or more permitted ciphersuites when TLSv1.3 is used for connection encryption for the distributed recovery connection, and this server instance is the client in the distributed recovery connection, that is, the joining member. If this system variable is set to `NULL` when TLSv1.3 is used (which is the default if you do not set the system variable), the ciphersuites that are enabled by default are allowed, as listed in [Section 8.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#). If this system variable is set to the empty string, no cipher suites are allowed, and TLSv1.3 is therefore not used.

## 20.6.4 Group Replication IP Address Permissions

When and only when the XCom communication stack is used for establishing group communications (`group_replication_communication_stack=XCOM`), the Group Replication plugin lets you specify an allowlist of hosts from which an incoming Group Communication System connection can be accepted. If you specify an allowlist on a server `s1`, then when server `s2` is establishing a connection to `s1` for the purpose of engaging group communication, `s1` first checks the allowlist before accepting the connection from `s2`. If `s2` is in the allowlist, then `s1` accepts the connection, otherwise `s1` rejects the connection attempt by `s2`. The system variable `group_replication_ip_allowlist` is used to specify the allowlist.

### Note

When the MySQL communication stack is used for establishing group communications (`group_replication_communication_stack=MYSQL`), the setting for `group_replication_ip_allowlist` is ignored. See [Section 20.6.1, “Communication Stack for Connection Security Management”](#).

If you do not specify an allowlist explicitly, the group communication engine (XCom) automatically scans active interfaces on the host, and identifies those with addresses on private subnetworks, together with the subnet mask that is configured for each interface. These addresses, and the `localhost` IP address for IPv4 and IPv6 are used to create an automatic Group Replication allowlist. The automatic allowlist therefore includes any IP addresses that are found for the host in the following ranges after the appropriate subnet mask has been applied:

```
IPv4 (as defined in RFC 1918)
10/8 prefix (10.0.0.0 - 10.255.255.255) - Class A
172.16/12 prefix (172.16.0.0 - 172.31.255.255) - Class B
192.168/16 prefix (192.168.0.0 - 192.168.255.255) - Class C

IPv6 (as defined in RFC 4193 and RFC 5156)
fc00::/7 prefix - unique-local addresses
fe80::/10 prefix - link-local unicast addresses

127.0.0.1 - localhost for IPv4
::1 - localhost for IPv6
```

An entry is added to the error log stating the addresses that have been allowed automatically for the host.

The automatic allowlist of private addresses cannot be used for connections from servers outside the private network, so a server, even if it has interfaces on public IPs, does not by default allow Group Replication connections from external hosts. For Group Replication connections between server instances that are on different machines, you must provide public IP addresses and specify these as an explicit allowlist. If you specify any entries for the allowlist, the private and `localhost` addresses are not added automatically, so if you use any of these, you must specify them explicitly.

To specify an allow list manually, use the `group_replication_ip_allowlist` system variable. You can change the list while Group Replication is running.

The allowlist must contain the IP address or host name that is specified in each member's `group_replication_local_address` system variable. This address is not the same as the MySQL server SQL protocol host and port, and is not specified in the `bind_address` system variable for the server instance. If a host name used as the Group Replication local address for a server instance resolves to both an IPv4 and an IPv6 address, the IPv4 address is preferred for Group Replication connections.

IP addresses specified as distributed recovery endpoints, and the IP address for the member's standard SQL client connection if that is used for distributed recovery (which is the default), do not need to be added to the allowlist. The allowlist is only for the address specified by `group_replication_local_address` for each member. A joining member must have its initial connection to the group permitted by the allowlist in order to retrieve the address or addresses for distributed recovery.

In the allowlist, you can specify any combination of the following:

- IPv4 addresses (for example, `198.51.100.44`)
- IPv4 addresses with CIDR notation (for example, `192.0.2.21/24`)
- IPv6 addresses (for example, `2001:db8:85a3:8d3:1319:8a2e:370:7348`)
- IPv6 addresses with CIDR notation (for example, `2001:db8:85a3:8d3::/64`)
- Host names (for example, `example.org`)
- Host names with CIDR notation (for example, `www.example.com/24`)

Host names can resolve to IPv4 addresses, IPv6 addresses, or both. If a host name resolves to both an IPv4 and an IPv6 address, the IPv4 address is always used for Group Replication connections. You can

use CIDR notation in combination with host names or IP addresses to permit a block of IP addresses with a particular network prefix, but do ensure that all the IP addresses in the specified subnet are under your control.

**Note**

When a connection attempt from an IP address is refused because the address is not in the allowlist, the refusal message always prints the IP address in IPv6 format. IPv4 addresses are preceded by `::ffff:` in this format (an IPv4-mapped IPv6 address). You do not need to use this format to specify IPv4 addresses in the allowlist; use the standard IPv4 format for them.

A comma must separate each entry in the allowlist. For example:

```
mysql> SET GLOBAL group_replication_ip_allowlist="192.0.2.21/24,198.51.100.44,203.0.113.0/24,2001:db8:85a3
```

To join a replication group, a server needs to be permitted on the seed member to which it makes the request to join the group. Typically, this would be the bootstrap member for the replication group, but it can be any of the servers listed by the `group_replication_group_seeds` option in the configuration for the server joining the group. If any of the seed members for the group are listed in the `group_replication_group_seeds` option with an IPv6 address when a joining member has an IPv4 `group_replication_local_address`, or the reverse, you must also set up and permit an alternative address for the joining member for the protocol offered by the seed member (or a host name that resolves to an address for that protocol). This is because when a server joins a replication group, it must make the initial contact with the seed member using the protocol that the seed member advertises in the `group_replication_group_seeds` option, whether that is IPv4 or IPv6. If a joining member does not have a permitted address for the appropriate protocol, its connection attempt is refused. For more information on managing mixed IPv4 and IPv6 replication groups, see [Section 20.5.5, “Support For IPv6 And For Mixed IPv6 And IPv4 Groups”](#).

When a replication group is reconfigured (for example, when a new primary is elected or a member joins or leaves), the group members re-establish connections between themselves. If a group member is only permitted by servers that are no longer part of the replication group after the reconfiguration, it is unable to reconnect to the remaining servers in the replication group that do not permit it. To avoid this scenario entirely, specify the same allowlist for all servers that are members of the replication group.

**Note**

It is possible to configure different allowlists on different group members according to your security requirements, for example, in order to keep different subnets separate. If you need to configure different allowlists to meet your security requirements, ensure that there is sufficient overlap between the allowlists in the replication group to maximize the possibility of servers being able to reconnect in the absence of their original seed member.

For host names, name resolution takes place only when a connection request is made by another server. A host name that cannot be resolved is not considered for allowlist validation, and a warning message is written to the error log. Forward-confirmed reverse DNS (FCrDNS) verification is carried out for resolved host names.

**Warning**

Host names are inherently less secure than IP addresses in an allowlist. FCrDNS verification provides a good level of protection, but can be compromised by certain types of attack. Specify host names in your allowlist only when strictly necessary, and ensure that all components used for name resolution, such as DNS servers,

are maintained under your control. You can also implement name resolution locally using the hosts file, to avoid the use of external components.

## 20.7 Group Replication Performance and Troubleshooting

Group Replication is designed to create fault-tolerant systems with built-in failure detection and automated recovery. If a member server instance leaves voluntarily or stops communicating with the group, the remaining members agree a reconfiguration of the group between themselves, and choose a new primary if needed. Expelled members automatically attempt to rejoin the group, and are brought up to date by distributed recovery. If a group experiences a level of difficulties such that it cannot contact a majority of its members in order to agree on a decision, it identifies itself as having lost quorum and stops processing transactions. Group Replication also has built-in mechanisms and settings to help the group adapt to and manage variations in workload and message size, and stay within the limitations of the underlying system and networking resources.

The default settings for Group Replication's system variables are designed to maximize a group's performance and autonomy. The information in this section is to help you configure a replication group to optimize the automatic handling of any recurring issues that you experience on your particular systems, such as transient network outages or workloads and transactions that exceed a server instance's resources.

If you find that group members are being expelled and rejoining the group more frequently than you would like, it is possible that Group Replication's default failure detection settings are too sensitive for your system. This might be the case on slower networks or machines, networks with a high rate of unexpected transient outages, or during planned network outages. For advice on dealing with that situation by adjusting the settings, see [Section 20.7.7, "Responses to Failure Detection and Network Partitioning"](#).

You should only need to intervene manually in a Group Replication setup if something happens that the group cannot deal with automatically. Some key issues that can require administrator intervention are when a member is in [ERROR](#) status and cannot rejoin the group, or when a network partition causes the group to lose quorum.

- If an otherwise correctly functioning and configured member is unable to join or rejoin the group using distributed recovery, and remains in [ERROR](#) status, [Section 20.5.4.4, "Fault Tolerance for Distributed Recovery"](#), explains the possible issues. One likely cause is that the joining member has extra transactions that are not present on the existing members of the group. For advice on dealing with that situation, see [Section 20.4.1, "GTIDs and Group Replication"](#).
- If a group has lost quorum, this may be due to a network partition that divides the group into two parts, or possibly due to the failure of the majority of the servers. For advice on dealing with that situation, see [Section 20.7.8, "Handling a Network Partition and Loss of Quorum"](#).

### 20.7.1 Fine Tuning the Group Communication Thread

The group communication thread (GCT) runs in a loop while the Group Replication plugin is loaded. The GCT receives messages from the group and from the plugin, handles quorum and failure detection related tasks, sends out some keep alive messages and also handles the incoming and outgoing transactions from/to the server/group. The GCT waits for incoming messages in a queue. When there are no messages, the GCT waits. By configuring this wait to be a little longer (doing an active wait) before actually going to sleep can prove to be beneficial in some cases. This is because the alternative is for the operating system to switch out the GCT from the processor and do a context switch.

To force the GCT to do an active wait, use the [group\\_replication\\_poll\\_spin\\_loops](#) option, which makes the GCT loop, doing nothing relevant for the configured number of loops, before actually polling the queue for the next message.

For example:

```
mysql> SET GLOBAL group_replication_poll_spin_loops= 10000;
```

## 20.7.2 Flow Control

MySQL Group Replication ensures that a transaction commits only after a majority of the members in a group have received it and agreed on the relative order amongst all transactions sent concurrently. This approach works well if the total number of writes to the group does not exceed the write capacity of any member in the group. If it does, and some members have less write throughput than others—particularly less than the writer members—these members may start lagging behind the writers.

When some members lag behind the rest of the group, reads on such members may externalize very old data. Depending on why the member is lagging behind, other members in the group may have to save more or less of the replication context to be able to fulfil potential data transfer requests from the slow member.

The replication protocol provides a mechanism to avoid having too much distance, in terms of transactions applied, between fast and slow members. This is known as the flow control mechanism, which has the following objectives:

1. To keep members close, to minimize buffering and desynchronization between them
2. To adapt quickly to changing conditions like different workloads or more writers in the group
3. To give each member a share of the available write capacity
4. Not to reduce throughput more than strictly necessary to avoid wasting resources

Given the design of Group Replication, the decision whether to throttle, or not, may be made taking into account two work queues, the certification queue, and the binary log applier queue. Whenever the size of one of these queues exceeds the user-defined threshold, the throttling mechanism is triggered.

Flow control depends on two basic mechanisms:

1. Monitoring of members to collect statistics on throughput and queue sizes of all group members to make educated guesses concerning the maximum write pressure to which each member should be subjected
2. Throttling of members that are trying to write beyond their allotted shares of the available capacity at each moment in time

### Note

The Group Replication Flow Control Statistics Component, available as part of MySQL Enterprise Edition, supports status variables providing information on Group Replication flow control execution. See [Section 7.5.6.2, “Group Replication Flow Control Statistics Component”](#), for more information.

### 20.7.2.1 Probes and Statistics

The monitoring mechanism works by having each member deploying a set of probes to collect information about its work queues and throughput. It then propagates that information to the group periodically to share that data with the other members.

Such probes are scattered throughout the plugin stack and allow one to establish metrics, such as:

- the certifier queue size;
- the replication applier queue size;
- the total number of transactions certified;
- the total number of remote transactions applied in the member;
- the total number of local transactions.

Once a member receives a message with statistics from another member, it calculates additional metrics regarding how many transactions were certified, applied and locally executed in the last monitoring period.

Monitoring data is shared with others in the group periodically. The monitoring period must be high enough to allow the other members to decide on the current write requests, but low enough that it has minimal impact on group bandwidth. The information is shared every second, and this period is sufficient to address both concerns.

### 20.7.2.2 Group Replication Throttling

Based on the metrics gathered across all servers in the group, a throttling mechanism kicks in and decides whether to limit the rate a member is able to execute/commit new transactions.

Therefore, metrics acquired from all members are the basis for calculating the capacity of each member: if a member has a large queue (for certification or the applier thread), then the capacity to execute new transactions should be close to ones certified or applied in the last period.

The lowest capacity of all the members in the group determines the real capacity of the group, while the number of local transactions determines how many members are writing to it, and, consequently, how many members should that available capacity be shared with.

This means that every member has an established write quota based on the available capacity, in other words a number of transactions it can safely issue for the next period. The writer-quota is enforced by the throttling mechanism if the queue size of the certifier or the binary log applier exceeds a user-defined threshold.

The quota is reduced by the number of transactions that were delayed in the last period, and then also further reduced by 10% to allow the queue that triggered the problem to reduce its size. In order to avoid large jumps in throughput once the queue size goes beyond the threshold, the throughput is only allowed to grow by the same 10% per period after that.

The current throttling mechanism does not penalize transactions below quota, but delays finishing those transactions that exceed it until the end of the monitoring period. As a consequence, if the quota is very small for the write requests issued some transactions may have latencies close to the monitoring period.

### 20.7.3 Single Consensus Leader

By default, the group communication engine for Group Replication (XCom, a Paxos variant) operates using every member of the replication group as a leader. The group communication engine can use a single leader to drive consensus when the group is in single-primary mode. Operating with a single consensus leader improves performance and resilience in single-primary mode, particularly when some of the group's secondary members are currently unreachable.

To use a single consensus leader, the group must be configured as follows:

- The group must be in single-primary mode.

- The `group_replication_paxos_single_leader` system variable must be set to `ON`. With the default setting `OFF`, the behavior is disabled. You must carry out a full reboot of the replication group (bootstrap) for Group Replication to pick up a change to this setting.
- The Group Replication communication protocol version must be set to 8.0.27 or later. Use the `group_replication_get_communication_protocol()` function to view the group's communication protocol version. If a lower version is in use, the group cannot use this behavior. You can use the `group_replication_set_communication_protocol()` function to set the group's communication protocol to a higher version if all group members support it. MySQL InnoDB Cluster manages the communication protocol version automatically. For more information, see [Section 20.5.1.4, “Setting a Group's Communication Protocol Version”](#).

When this configuration is in place, Group Replication instructs the group communication engine to use the group's primary as the single leader to drive consensus. When a new primary is elected, Group Replication tells the group communication engine to use it instead. If the primary is currently unhealthy, the group communication engine uses an alternative member as the consensus leader. The Performance Schema table `replication_group_communication_information` shows the current preferred and actual consensus leader, with the preferred leader being Group Replication's choice, and the actual leader being the one selected by the group communication engine.

If the group is in multi-primary mode, has a lower communication protocol version, or the behavior is disabled by the `group_replication_paxos_single_leader` setting, all members are used as leaders to drive consensus. In this situation, the Performance Schema table `replication_group_communication_information` shows all of the members as both the preferred and actual leaders.

The `WRITE_CONSENSUS_SINGLE_LEADER_CAPABLE` column of the Performance Schema `replication_group_communication_information` table shows whether the group supports the use of a single leader, even if `group_replication_paxos_single_leader` is currently set to `OFF` on the queried member. The column value is 1 if the group was started with `group_replication_paxos_single_leader` set to `ON`, and its communication protocol version is MySQL 8.0.27 or above. This information is returned only for group members in `ONLINE` or `RECOVERING` state.

## 20.7.4 Message Compression

For messages sent between online group members, Group Replication enables message compression by default. Whether a specific message is compressed depends on the threshold that you configure using the `group_replication_compression_threshold` system variable. Messages that have a payload larger than the specified number of bytes are compressed.

The default compression threshold is 1000000 bytes. You could use the following statements to increase the compression threshold to 2MB, for example:

```
STOP GROUP_REPLICATION;
SET GLOBAL group_replication_compression_threshold = 2097152;
START GROUP_REPLICATION;
```

If you set `group_replication_compression_threshold` to zero, message compression is disabled.

Group Replication uses the LZ4 compression algorithm to compress messages sent in the group. Note that the maximum supported input size for the LZ4 compression algorithm is 2113929216 bytes. This limit is lower than the maximum possible value for the `group_replication_compression_threshold` system variable, which is matched to the maximum message size accepted by XCom. The LZ4 maximum input size is therefore a practical limit for message compression, and transactions above this size cannot

be committed when message compression is enabled. With the LZ4 compression algorithm, do not set a value greater than 2113929216 bytes for `group_replication_compression_threshold`.

The value of `group_replication_compression_threshold` is not required by Group Replication to be the same on all group members. However, it is advisable to set the same value on all group members in order to avoid unnecessary rollback of transactions, failure of message delivery, or failure of message recovery.

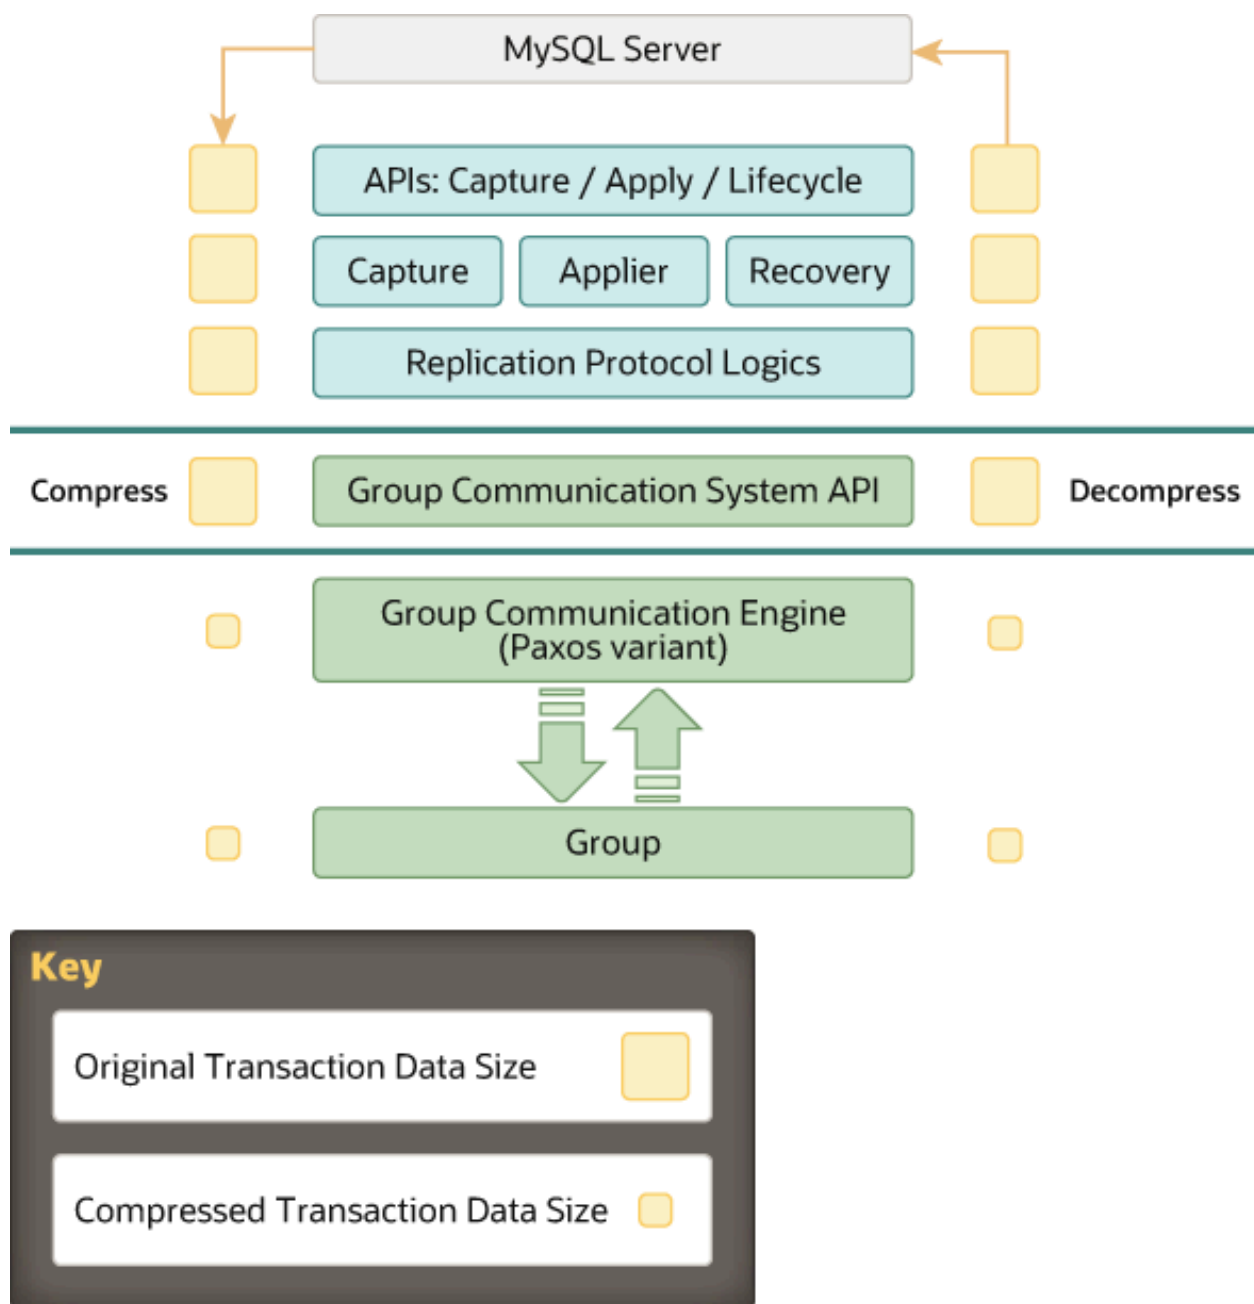

You can also configure compression for messages sent for distributed recovery by the method of state transfer from a donor's binary log. Compression for these messages, which are sent from a donor already in the group to a joining member, is controlled separately using the `group_replication_recovery_compression_algorithms` and `group_replication_recovery_zstd_compression_level` system variables. For more information, see [Section 6.2.8, “Connection Compression Control”](#).

Binary log transaction compression, enabled by the `binlog_transaction_compression` system variable, can also be used to save bandwidth. The transaction payloads remain compressed when they are transferred between group members. If you use binary log transaction compression in combination with Group Replication's message compression, message compression has less opportunity to act on the data, but can still compress headers and those events and transaction payloads that are uncompressed. For more information on binary log transaction compression, see [Section 7.4.4.5, “Binary Log Transaction Compression”](#).

Compression for messages sent in the group happens at the group communication engine level, before the data is handed over to the group communication thread, so it takes place within the context of the `mysql` user session thread. If the message payload size exceeds the threshold set by `group_replication_compression_threshold`, the transaction payload is compressed before being sent out to the group, and decompressed when it is received. Upon receiving a message, the member checks the message envelope to verify whether it is compressed or not. If needed, then the member decompresses the transaction, before delivering it to the upper layer. This process is shown in the following figure.

**Figure 20.13 Compression Support**

When network bandwidth is a bottleneck, message compression can provide up to 30-40% throughput improvement at the group communication level. This is especially important within the context of large groups of servers under load. The TCP peer-to-peer nature of the interconnections between  $N$  participants in the group makes the sender send the same amount of data  $N$  times. Furthermore, binary logs are likely to exhibit a high compression ratio. This makes compression a compelling feature for Group Replication workloads that contain large transactions.

## 20.7.5 Message Fragmentation

When an abnormally large message is sent between Group Replication group members, it can result in some group members being reported as failed and expelled from the group. This is because the single

thread used by Group Replication's group communication engine (XCom, a Paxos variant) is occupied processing the message for too long, so some of the group members might report the receiver as failed. By default, large messages are automatically split into fragments that are sent separately and reassembled by the recipients.

The system variable `group_replication_communication_max_message_size` specifies a maximum message size for Group Replication communications, above which messages are fragmented. The default maximum message size is 10485760 bytes (10 MiB). The greatest permitted value is the same as the maximum value of the `replica_max_allowed_packet` system variable (1 GB). `group_replication_communication_max_message_size` must be less than `replica_max_allowed_packet` because the applier thread cannot handle message fragments larger than the maximum permitted packet size. To switch off fragmentation, specify a zero value for `group_replication_communication_max_message_size`.

As with most other Group Replication system variables, you must restart the Group Replication plugin for the change to take effect. For example:

```
STOP GROUP_REPLICATION;
SET GLOBAL group_replication_communication_max_message_size= 5242880;
START GROUP_REPLICATION;
```

Message delivery for a fragmented message is considered complete when all the fragments of the message have been received and reassembled by all the group members. Fragmented messages include information in their headers that enables a member joining during message transmission to recover the earlier fragments that were sent before it joined. If the joining member fails to recover the fragments, it expels itself from the group.

The Group Replication communication protocol version in use by the group must allow fragmentation. You can obtain the communication protocol in use by a group using `group_replication_get_communication_protocol()`, which returns the oldest MySQL Server version that the group supports. If necessary, use `group_replication_set_communication_protocol()` to set the communication protocol version high enough (8.0.16 or above) to allow fragmentation. For more information, see [Section 20.5.1.4, “Setting a Group's Communication Protocol Version”](#).

If a replication group cannot use fragmentation because some members do not support it, the system variable `group_replication_transaction_size_limit` can be used to limit the maximum size of transactions the group accepts. Transactions above this size are rolled back. You can also use `group_replication_member_expel_timeout` to allow additional time (up to an hour) before a member under suspicion of having failed is expelled from the group.

## 20.7.6 XCom Cache Management

The group communication engine for Group Replication (XCom, a Paxos variant) includes a cache for messages (and their metadata) exchanged between the group members as a part of the consensus protocol. Among other functions, the message cache is used for recovery of missed messages by members that reconnect with the group after a period where they were unable to communicate with the other group members.

A cache size limit can be set for XCom's message cache using the `group_replication_message_cache_size` system variable. If the cache size limit is reached, XCom removes the oldest entries that have been decided and delivered. The same cache size limit should be set on all group members, because an unreachable member that is attempting to reconnect selects any other member at random for recovery of missed messages. The same messages should therefore be available in each member's cache.

Ensure that sufficient memory is available on your system for your chosen cache size limit, considering the size of MySQL Server's other caches and object pools. Note that the limit set using `group_replication_message_cache_size` applies only to the data stored in the cache, and the cache structures require an additional 50 MB of memory.

When choosing the value for `group_replication_message_cache_size`, do so with regard to the expected volume of messages in the period before a member is expelled. The length of this period is controlled by the `group_replication_member_expel_timeout` system variable, which determines the waiting period (up to an hour) that is allowed *in addition to* the initial 5-second detection period for members to return to the group rather than being expelled. The timeout defaults to 5 seconds, so by default a member is not expelled until it has been absent for at least 10 seconds.

### 20.7.6.1 Increasing the cache size

If a member is absent for a period that is not long enough for it to be expelled from the group, it can reconnect and start participating in the group again by retrieving missed transactions from another member's XCom message cache. However, if the transactions that happened during the member's absence have been deleted from the other members' XCom message caches because their maximum size limit was reached, the member cannot reconnect in this way.

Group Replication's Group Communication System (GCS) alerts you, by a warning message, when a message that is likely to be needed for recovery by a member that is currently unreachable is removed from the message cache. This warning message is logged on all the active group members (only once for each unreachable member). Although the group members cannot know for sure what message was the last message seen by the unreachable member, the warning message indicates that the cache size might not be sufficient to support your chosen waiting period before a member is expelled.

In this situation, consider increasing the `group_replication_message_cache_size` limit with reference to the expected volume of messages in the time period specified by the `group_replication_member_expel_timeout` system variable plus the 5-second detection period, so that the cache contains all the missed messages required for members to return successfully. You can also consider increasing the cache size limit temporarily if you expect a member to become unreachable for an unusual period of time.

### 20.7.6.2 Reducing the cache size

The minimum setting for the XCom message cache size in MySQL 9.1 is 128 MB, which enables deployment on a host that has a restricted amount of available memory. Having a very low `group_replication_message_cache_size` setting is not recommended if the host is on an unstable network, because a smaller message cache makes it harder for group members to reconnect after a transient loss of connectivity.

If a reconnecting member cannot retrieve all the messages it needs from the XCom message cache, the member must leave the group and rejoin it, in order to retrieve the missing transactions from another member's binary log using distributed recovery. A member that has left a group makes three auto-rejoin attempts by default, so the process of rejoining the group can still take place without operator intervention. However, rejoining using distributed recovery is a significantly longer and more complex process than retrieving messages from an XCom message cache, so the member takes longer to become available and the performance of the group can be impacted. On a stable network, which minimizes the frequency and duration of transient losses of connectivity for members, the frequency of this occurrence should also be minimized, so the group might be able to tolerate a smaller XCom message cache size without a significant impact on its performance.

If you are considering reducing the cache size limit, you can query the Performance Schema table `memory_summary_global_by_event_name` using the following statement:

```
SELECT * FROM performance_schema.memory_summary_global_by_event_name
WHERE EVENT_NAME LIKE 'memory/group_rpl/GCS_XCom:xcom_cache';
```

This returns memory usage statistics for the message cache, including the current number of cached entries and current size of the cache. If you reduce the cache size limit, XCom removes the oldest entries that have been decided and delivered until the current size is below the limit. XCom might temporarily exceed the cache size limit while this removal process is ongoing.

## 20.7.7 Responses to Failure Detection and Network Partitioning

Group Replication's failure detection mechanism is designed to identify group members that are no longer communicating with the group, and expel them as and when it seems likely that they have failed. Having a failure detection mechanism increases the chance that the group contains a majority of correctly working members, and that requests from clients are therefore processed correctly.

Normally, all group members regularly exchange messages with all other group members. If a group member does not receive any messages from a particular fellow member for 5 seconds, when this detection period ends, it creates a suspicion of the fellow member. When a suspicion times out, the suspected member is assumed to have failed, and is expelled from the group. An expelled member is removed from the membership list seen by the other members, but it does not know that it has been expelled from the group, so it sees itself as online and the other members as unreachable. If the member has not in fact failed (for example, because it was just disconnected due to a temporary network issue) and it is able to resume communication with the other members, it receives a view containing the information that it has been expelled from the group.

The responses of group members, including the failed member itself, to these situations can be configured at a number of points in the process. By default, the following behaviors happen if a member is suspected of having failed:

1. In MySQL 9.1, when a suspicion is created, a waiting period of 5 seconds is added before the suspicion times out and the suspected member is liable for expulsion.
2. If an expelled member resumes communication and realises that it was expelled, it automatically makes three attempts to rejoin the group (with 5 minutes between each attempt); if this auto-rejoin procedure does not work, it then stops trying to rejoin the group.
3. When an expelled member is not trying to rejoin the group, it switches to super-read-only mode and awaits operator attention.

You can use the Group Replication configuration options described in this section to change these behaviors either permanently or temporarily, to suit your system's requirements and your priorities. If you are experiencing unnecessary expulsions caused by slower networks or machines, networks with a high rate of unexpected transient outages, or planned network outages, consider increasing the expel timeout and auto-rejoin attempts. While a member is undergoing any of the default behaviors described previously, although it does not accept writes, reads can still be performed if the member is still communicating with clients, with an increasing likelihood of stale reads over time. If avoiding stale reads is a higher priority for you than avoiding operator intervention, consider reducing the expel timeout and auto-rejoin attempts or setting them to zero.

Members that have not failed might lose contact with part, but not all, of the replication group due to a network partition. For example, in a group of 5 servers (S1, S2, S3, S4, S5), if there is a disconnection between (S1, S2) and (S3, S4, S5) there is a network partition. The first group (S1, S2) is now in a minority because it cannot contact more than half of the group. Any transactions that are processed by the members in the minority group are blocked, because the majority of the group is unreachable, therefore the group cannot achieve quorum. For a detailed description of this scenario, see [Section 20.7.8, “Handling a Network Partition and Loss of Quorum”](#). In this situation, the default behavior is for the members in both the

minority and the majority to remain in the group, continue to accept transactions (although they are blocked on the members in the minority), and wait for operator intervention. This behavior is also configurable.

Note that where group members are at an older MySQL Server release that does not support a relevant setting, or at a release with a different default, they act towards themselves and other group members according to the default behaviors stated above. For example, a member that does not support the `group_replication_member_expel_timeout` system variable expels other members as soon as an expired suspicion is detected, and this expulsion is accepted by other members even if they support the system variable and have a longer timeout set.

### 20.7.7.1 Expel Timeout

You can use the `group_replication_member_expel_timeout` system variable to allow additional time between the creation of a suspicion and the expulsion of the suspect member. A suspicion is created when one server does not receive messages from another server, as explained in [Section 20.1.4.2, “Failure Detection”](#).

There is an initial 5-second detection period before a Group Replication group member creates a suspicion of another member (or of itself). A group member is then expelled when another member's suspicion of it (or its own suspicion of itself) times out. A further short period of time might elapse after that before the expelling mechanism detects and implements the expulsion. `group_replication_member_expel_timeout` specifies the period of time in seconds, called the expel timeout, that a group member waits between creating a suspicion, and expelling the suspected member. Suspect members are listed as `UNREACHABLE` during this waiting period, but are not removed from the group's membership list.

- If a suspect member becomes active again before the suspicion times out at the end of the waiting period, the member applies all the messages that were buffered by the remaining group members in XCom's message cache and enters `ONLINE` state, without operator intervention. In this situation, the member is considered by the group as the same incarnation.
- If a suspect member becomes active only after the suspicion times out and is able to resume communications, it receives a view where it is expelled and at that point realises it was expelled. You can use `group_replication_autorejoin_tries` to make the member try to rejoin the group automatically at this point. This feature is active by default in MySQL 9.1, and the member makes three auto-rejoin attempts. If the auto-rejoin procedure does not succeed or is not attempted, the expelled member then follows the exit action specified by `group_replication_exit_state_action`.

The waiting period before expelling a member only applies to members that have previously been active in the group. Non-members that were never active in the group do not get this waiting period and are removed after the initial detection period because they took too long to join.

If `group_replication_member_expel_timeout` is set to 0, there is no waiting period, and a suspected member is liable for expulsion immediately after the initial 5-second detection period ends. The default is 5, meaning that a suspected member is liable for expulsion 5 seconds after the 5-second detection period has expired. It is not mandatory for all members of a group to have the same setting for `group_replication_member_expel_timeout`, but it is recommended in order to avoid unexpected expulsions. Any member can create a suspicion of any other member, including itself, so the effective expel timeout is that of the member with the lowest setting.

Consider increasing the value of `group_replication_member_expel_timeout` from the default in the following scenarios:

- The network is slow and the default 5 or 10 seconds before expulsion is not long enough for group members to always exchange at least one message.

- The network sometimes has transient outages and you want to avoid unnecessary expulsions and primary member changes at these times.
- The network is not under your direct control and you want to minimize the need for operator intervention.
- A temporary network outage is expected and you do not want some or all of the members to be expelled due to this.
- An individual machine is experiencing a slowdown and you do not want it to be expelled from the group.

You can specify an expel timeout up to a maximum of 3600 seconds (1 hour). It is important to ensure that XCom's message cache is sufficiently large to contain the expected volume of messages in your specified time period, plus the initial 5-second detection period, otherwise members cannot reconnect. You can adjust the cache size limit using the `group_replication_message_cache_size` system variable. For more information, see [Section 20.7.6, “XCom Cache Management”](#).

If any members in a group are currently under suspicion, the group membership cannot be reconfigured (by adding or removing members or electing a new leader). If group membership changes need to be implemented while one or more members are under suspicion, and you want the suspect members to remain in the group, take any actions required to make the members active again, if that is possible. If you cannot make the members active again and you want them to be expelled from the group, you can force the suspicions to time out immediately. Do this by changing the value of `group_replication_member_expel_timeout` on any active members to a value lower than the time that has already elapsed since the suspicions were created. The suspect members then become liable for expulsion immediately.

If a replication group member stops unexpectedly and is immediately restarted (for example, because it was started with `mysqld_safe`), it automatically attempts to rejoin the group if `group_replication_start_on_boot=on` is set. In this situation, it is possible for the restart and rejoin attempt to take place before the member's previous incarnation has been expelled from the group, in which case the member cannot rejoin. Group Replication automatically uses a Group Communication System (GCS) feature to retry the rejoin attempt for the member 10 times, with a 5-second interval between each retry. This should cover most cases and allow enough time for the previous incarnation to be expelled from the group, letting the member rejoin. Note that if the `group_replication_member_expel_timeout` system variable is set to specify a longer waiting period before the member is expelled, the automatic rejoin attempts might still not succeed.

For alternative mitigation strategies to avoid unnecessary expulsions where the `group_replication_member_expel_timeout` system variable is not available, see [Section 20.3.2, “Group Replication Limitations”](#).

### 20.7.7.2 Unreachable Majority Timeout

By default, members that find themselves in a minority due to a network partition do not automatically leave the group. You can use the system variable `group_replication_unreachable_majority_timeout` to set a number of seconds for a member to wait after losing contact with the majority of group members, and then exit the group. Setting a timeout means you do not need to pro-actively monitor for servers that are in a minority group after a network partition, and you can avoid the possibility of creating a split-brain situation (with two versions of the group membership) due to inappropriate intervention.

When the timeout specified by `group_replication_unreachable_majority_timeout` elapses, all pending transactions that have been processed by the member and the others in the minority group are rolled back, and the servers in that group move to the `ERROR` state. You can use the `group_replication_autorejoin_tries` system variable to force the member to try to rejoin the group automatically at this point. This feature is active by default; the member makes three auto-rejoin

attempts. If the auto-rejoin procedure does not succeed or is not attempted, the minority member then follows the exit action specified by `group_replication_exit_state_action`.

Consider the following points when deciding whether or not to set an unreachable majority timeout:

- In a symmetric group, for example a group with two or four servers, if both partitions contain an equal number of servers, both groups consider themselves to be in a minority and enter the `ERROR` state. In this situation, the group has no functional partition.
- While a minority group exists, any transactions processed by the minority group are accepted, but blocked because the minority servers cannot reach quorum, until either `STOP GROUP_REPLICATION` is issued on those servers or the unreachable majority timeout is reached.
- If you do not set an unreachable majority timeout, the servers in the minority group never enter the `ERROR` state automatically, and you must stop them manually.
- Setting an unreachable majority timeout has no effect if it is set on the servers in the minority group after the loss of majority has been detected.

If you do not use the `group_replication_unreachable_majority_timeout` system variable, the process for operator intervention in the event of a network partition is described in [Section 20.7.8, “Handling a Network Partition and Loss of Quorum”](#). The process involves checking which servers are functioning and forcing a new group membership if necessary.

### 20.7.7.3 Auto-Rejoin

The `group_replication_autorejoin_tries` system variable makes a member that has been expelled or reached its unreachable majority timeout try to rejoin the group automatically. The default (3), means that the member automatically makes 3 attempts to rejoin the group, with 5 minutes between each attempt.

When auto-rejoin is not activated, a member accepts its expulsion as soon as it resumes communication, and proceeds to the action specified by the `group_replication_exit_state_action` system variable. After this, manual intervention is needed to bring the member back into the group. Using the auto-rejoin feature is appropriate if you can tolerate the possibility of stale reads and want to minimize the need for manual intervention, especially where transient network issues fairly often result in the expulsion of members.

With auto-rejoin, when the member's expulsion or unreachable majority timeout is reached, it makes an attempt to rejoin (using the current plugin option values), then continues to make further auto-rejoin attempts up to the specified number of tries. After an unsuccessful auto-rejoin attempt, the member waits 5 minutes before the next try. The auto-rejoin attempts and the time between them are called the auto-rejoin procedure. If the specified number of tries is exhausted without the member rejoining or being stopped, the member proceeds to the action specified by the `group_replication_exit_state_action` system variable.

During and between auto-rejoin attempts, a member remains in super read only mode and displays an `ERROR` state on its view of the replication group. During this time, the member does not accept writes. However, reads can still be made on the member, with an increasing likelihood of stale reads over time. If you do want to intervene to take the member offline during the auto-rejoin procedure, the member can be stopped manually at any time by using a `STOP GROUP_REPLICATION` statement or shutting down the server. If you cannot tolerate the possibility of stale reads for any period of time, set the `group_replication_autorejoin_tries` system variable to 0.

You can monitor the auto-rejoin procedure using the Performance Schema. While an auto-rejoin procedure is taking place, the Performance Schema table `events_stages_current`

shows the event “Undergoing auto-rejoin procedure”, with the number of retries that have been attempted so far during this instance of the procedure (in the `WORK_COMPLETED` column). The `events_stages_summary_global_by_event_name` table shows the number of times the server instance has initiated the auto-rejoin procedure (in the `COUNT_STAR` column). The `events_stages_history_long` table shows the time each of these auto-rejoin procedures was completed (in the `TIMER_END` column). While a member is rejoining a replication group, its status can be displayed as `OFFLINE` or `ERROR` before the group completes the compatibility checks and accepts it as a member. When the member is catching up with the group's transactions, its status is `RECOVERING`.

#### 20.7.7.4 Exit Action

The `group_replication_exit_state_action` system variable specifies what Group Replication does when the member leaves the group unintentionally due to an error or problem, and either fails to auto-rejoin or does not try. Note that in the case of an expelled member, the member does not know that it was expelled until it reconnects to the group, so the specified action is only taken if the member manages to reconnect, or if the member raises a suspicion on itself and expels itself.

In order of impact, the exit actions are as follows:

1. If `READ_ONLY` is the exit action, the instance switches MySQL to super read only mode by setting the system variable `super_read_only` to `ON`. When the member is in super read only mode, clients cannot make any updates, even if they have the `CONNECTION_ADMIN` privilege (or the deprecated `SUPER` privilege). However, clients can still read data, and because updates are no longer being made, there is a probability of stale reads which increases over time. With this setting, you therefore need to pro-actively monitor the servers for failures. This exit action is the default; after it is taken, the member's status is shown as `ERROR` in the view of the group.
2. If `OFFLINE_MODE` is the exit action, the instance switches MySQL to offline mode by setting the system variable `offline_mode` to `ON`. When the member is in offline mode, connected client users are disconnected on their next request and connections are no longer accepted, with the exception of client users that have the `CONNECTION_ADMIN` privilege (or the deprecated `SUPER` privilege). Group Replication also sets the system variable `super_read_only` to `ON`, so clients cannot make any updates, even if they have connected with the `CONNECTION_ADMIN` or `SUPER` privilege. This exit action prevents both updates and stale reads (with the exception of reads by client users with the stated privileges), and enables proxy tools such as MySQL Router to recognize that the server is unavailable and redirect client connections. It also leaves the instance running so that an administrator can attempt to resolve the issue without shutting down MySQL. After this exit action is taken, the member's status is displayed as `ERROR` in the view of the group (not `OFFLINE`, which means a member has Group Replication functionality available but does not currently belong to a group).
3. If `ABORT_SERVER` is the exit action, the instance shuts down MySQL. Instructing the member to shut itself down prevents all stale reads and client updates, but it means that the MySQL Server instance is unavailable and must be restarted, even if the issue could have been resolved without that step. After this exit action is taken, the member is removed from the listing of servers in the view of the group.

Bear in mind that operator intervention is required whatever exit action is set, as an ex-member that has exhausted its auto-rejoin attempts (or never had any) and has been expelled from the group is not allowed to rejoin without a restart of Group Replication. The exit action only influences whether or not clients can still read data on the server that was unable to rejoin the group, and whether or not the server stays running.

#### Important

If a failure occurs before the member has successfully joined the group, the exit action specified by `group_replication_exit_state_action` is *not taken*.

This is the case if there is a failure during the local configuration check, or a mismatch between the configuration of the joining member and the configuration of the group. In these situations, the `super_read_only` system variable is left with its original value, and the server does not shut down MySQL. To ensure that the server cannot accept updates when Group Replication did not start, we therefore recommend that `super_read_only=ON` is set in the server's configuration file at startup, which Group Replication changes to `OFF` on primary members after it has been started successfully. This safeguard is particularly important when the server is configured to start Group Replication on server boot (`group_replication_start_on_boot=ON`), but it is also useful when Group Replication is started manually using a `START GROUP_REPLICATION` statement.

If a failure occurs after the member has successfully joined the group, the specified exit action is taken. This is the case in the following situations:

1. *Applier error* - There is an error in the replication applier. This issue is not recoverable.
2. *Distributed recovery not possible* - There is an issue that means Group Replication's distributed recovery process (which uses remote cloning operations and state transfer from the binary log) cannot be completed. Group Replication retries distributed recovery automatically where this makes sense, but stops if there are no more options to complete the process. For details, see [Section 20.5.4.4, “Fault Tolerance for Distributed Recovery”](#).
3. *Group configuration change error* - An error occurred during a group-wide configuration change carried out using a function, as described in [Section 20.5.1, “Configuring an Online Group”](#).
4. *Primary election error* - An error occurred during election of a new primary member for a group in single-primary mode, as described in [Section 20.1.3.1, “Single-Primary Mode”](#).
5. *Unreachable majority timeout* - The member has lost contact with a majority of the group members so is in a minority, and a timeout that was set by the `group_replication_unreachable_majority_timeout` system variable has expired.
6. *Member expelled from group* - A suspicion has been raised on the member, and any timeout set by the `group_replication_member_expel_timeout` system variable has expired, and the member has resumed communication with the group and found that it has been expelled.
7. *Out of auto-rejoin attempts* - The `group_replication_autorejoin_tries` system variable was set to specify a number of auto-rejoin attempts after a loss of majority or expulsion, and the member completed this number of attempts without success.

The following table summarizes the failure scenarios and actions in each case:

**Table 20.3 Exit actions in Group Replication failure situations**

Failure situation	Group Replication started with <code>START GROUP_REPLICATION</code>	Group Replication started with <code>group_replication_start_on_boot=ON</code>
Member fails local configuration check	<code>super_read_only</code> and <code>offline_mode</code> unchanged	<code>super_read_only</code> and <code>offline_mode</code> unchanged
Mismatch between joining member and group configuration	MySQL continues running Set <code>super_read_only=ON</code> at startup to prevent updates	MySQL continues running

Failure situation	Group Replication started with <code>START GROUP_REPLICATION</code>	Group Replication started with <code>group_replication_start_on_boot=ON</code>
		Set <code>super_read_only=ON</code> at startup to prevent updates (Important)
Applier error on member	<code>super_read_only</code> set to ON	<code>super_read_only</code> set to ON
Distributed recovery not possible	OR	OR
Group configuration change error	<code>offline_mode</code> and <code>super_read_only</code> set to ON	<code>offline_mode</code> and <code>super_read_only</code> set to ON
Primary election error	OR	OR
Unreachable majority timeout	MySQL shuts down	MySQL shuts down
Member expelled from group		
Out of auto-rejoin attempts		

## 20.7.8 Handling a Network Partition and Loss of Quorum

The group needs to achieve consensus whenever a change that needs to be replicated happens. This is the case for regular transactions but is also required for group membership changes and some internal messaging that keeps the group consistent. Consensus requires a majority of group members to agree on a given decision. When a majority of group members is lost, the group is unable to progress and blocks because it cannot secure majority or quorum.

Quorum may be lost when there are multiple involuntary failures, causing a majority of servers to be removed abruptly from the group. For example, in a group of 5 servers, if 3 of them become silent at once, the majority is compromised and thus no quorum can be achieved. In fact, the remaining two are not able to tell if the other 3 servers have crashed or whether a network partition has isolated these 2 alone and therefore the group cannot be reconfigured automatically.

On the other hand, if servers exit the group voluntarily, they instruct the group that it should reconfigure itself. In practice, this means that a server that is leaving tells others that it is going away. This means that other members can reconfigure the group properly, the consistency of the membership is maintained and the majority is recalculated. For example, in the above scenario of 5 servers where 3 leave at once, if the 3 leaving servers warn the group that they are leaving, one by one, then the membership is able to adjust itself from 5 to 2, and at the same time, securing quorum while that happens.

### Note

Loss of quorum is by itself a side-effect of bad planning. Plan the group size for the number of expected failures (regardless whether they are consecutive, happen all at once or are sporadic).

For a group in single-primary mode, the primary might have transactions that are not yet present on other members at the time of the network partition. If you are considering excluding the primary from the new group, be aware that such transactions might be lost. A member with extra transactions cannot rejoin the group, and the attempt results in an error with the message `This member has more executed transactions than those present in the group`. Set the `group_replication_unreachable_majority_timeout` system variable for the group members to avoid this situation.

The following sections explain what to do if the system partitions in such a way that no quorum is automatically achieved by the servers in the group.

## Detecting Partitions

The `replication_group_members` performance schema table presents the status of each server in the current view from the perspective of this server. The majority of the time the system does not run into partitioning, and therefore the table shows information that is consistent across all servers in the group. In other words, the status of each server on this table is agreed by all in the current view. However, if there is network partitioning, and quorum is lost, then the table shows the status `UNREACHABLE` for those servers that it cannot contact. This information is exported by the local failure detector built into Group Replication.

Figure 20.14 Losing Quorum

To understand this type of network partition the following section describes a scenario where there are initially 5 servers working together correctly, and the changes that then happen to the group once only 2 servers are online. The scenario is depicted in the figure.

As such, let's assume that there is a group with these 5 servers in it:

- Server s1 with member identifier `199b2df7-4aaf-11e6-bb16-28b2bd168d07`
- Server s2 with member identifier `199bb88e-4aaf-11e6-babe-28b2bd168d07`
- Server s3 with member identifier `1999b9fb-4aaf-11e6-bb54-28b2bd168d07`
- Server s4 with member identifier `19ab72fc-4aaf-11e6-bb51-28b2bd168d07`
- Server s5 with member identifier `19b33846-4aaf-11e6-ba81-28b2bd168d07`

Initially the group is running fine and the servers are happily communicating with each other. You can verify this by logging into s1 and looking at its `replication_group_members` performance schema table. For example:

```
mysql> SELECT MEMBER_ID, MEMBER_STATE, MEMBER_ROLE FROM performance_schema.replication_group_members;
```

MEMBER_ID	MEMBER_STATE	MEMBER_ROLE
1999b9fb-4aaf-11e6-bb54-28b2bd168d07	ONLINE	SECONDARY
199b2df7-4aaf-11e6-bb16-28b2bd168d07	ONLINE	PRIMARY
199bb88e-4aaf-11e6-babe-28b2bd168d07	ONLINE	SECONDARY
19ab72fc-4aaf-11e6-bb51-28b2bd168d07	ONLINE	SECONDARY
19b33846-4aaf-11e6-ba81-28b2bd168d07	ONLINE	SECONDARY

However, moments later there is a catastrophic failure and servers s3, s4 and s5 stop unexpectedly. A few seconds after this, looking again at the `replication_group_members` table on s1 shows that it is still online, but several other members are not. In fact, as seen below they are marked as `UNREACHABLE`. Moreover, the system could not reconfigure itself to change the membership, because the majority has been lost.

```
mysql> SELECT MEMBER_ID, MEMBER_STATE FROM performance_schema.replication_group_members;
```

MEMBER_ID	MEMBER_STATE
1999b9fb-4aaf-11e6-bb54-28b2bd168d07	UNREACHABLE
199b2df7-4aaf-11e6-bb16-28b2bd168d07	ONLINE
199bb88e-4aaf-11e6-babe-28b2bd168d07	ONLINE
19ab72fc-4aaf-11e6-bb51-28b2bd168d07	UNREACHABLE
19b33846-4aaf-11e6-ba81-28b2bd168d07	UNREACHABLE

The table shows that s1 is now in a group that has no means of progressing without external intervention, because a majority of the servers are unreachable. In this particular case, the group membership list needs to be reset to allow the system to proceed, which is explained in this section. Alternatively, you could also choose to stop Group Replication on s1 and s2 (or stop completely s1 and s2), figure out what happened with s3, s4 and s5 and then restart Group Replication (or the servers).

## Unblocking a Partition

Group replication enables you to reset the group membership list by forcing a specific configuration. For instance in the case above, where s1 and s2 are the only servers online, you could choose to force a membership configuration consisting of only s1 and s2. This requires checking some information about s1 and s2 and then using the `group_replication_force_members` variable.

**Figure 20.15 Forcing a New Membership**

Suppose that you are back in the situation where s1 and s2 are the only servers left in the group. Servers s3, s4 and s5 have left the group unexpectedly. To make servers s1 and s2 continue, you want to force a membership configuration that contains only s1 and s2.

**Warning**
