This variable controls the time zone of timestamps in messages written to the error log, and in general query log and slow query log messages written to files. It does not affect the time zone of general query log and slow query log messages written to tables (`mysql.general_log`, `mysql.slow_log`). Rows

retrieved from those tables can be converted from the local system time zone to any desired time zone with `CONVERT_TZ()` or by setting the session `time_zone` system variable.

Permitted `log_timestamps` values are `UTC` (the default) and `SYSTEM` (the local system time zone).

Timestamps are written using ISO 8601 / RFC 3339 format: `YYYY-MM-DDThh:mm:ss.uuuuuu` plus a tail value of `Z` signifying Zulu time (UTC) or `±hh:mm` (an offset from UTC).

- `log_throttle_queries_not_using_indexes`

Command-Line Format	<code>--log-throttle-queries-not-using-indexes=#</code>
System Variable	<code>log_throttle_queries_not_using_indexes</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	4294967295

If `log_queries_not_using_indexes` is enabled, the `log_throttle_queries_not_using_indexes` variable limits the number of such queries per minute that can be written to the slow query log. A value of 0 (the default) means “no limit”. For more information, see [Section 7.4.5, “The Slow Query Log”](#).

- `long_query_time`

Command-Line Format	<code>--long-query-time=#</code>
System Variable	<code>long_query_time</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Numeric
Default Value	10
Minimum Value	0
Maximum Value	31536000
Unit	seconds

If a query takes longer than this many seconds, the server increments the `Slow_queries` status variable. If the slow query log is enabled, the query is logged to the slow query log file. This value is measured in real time, not CPU time, so a query that is under the threshold on a lightly loaded system might be above the threshold on a heavily loaded one. The minimum and default values of `long_query_time` are 0 and 10, respectively. The maximum is 31536000, which is 365 days in

seconds. The value can be specified to a resolution of microseconds. See [Section 7.4.5, “The Slow Query Log”](#).

Smaller values of this variable result in more statements being considered long-running, with the result that more space is required for the slow query log. For very small values (less than one second), the log may grow quite large in a small time. Increasing the number of statements considered long-running may also result in false positives for the “excessive Number of Long Running Processes” alert in MySQL Enterprise Monitor, especially if Group Replication is enabled. For these reasons, very small values should be used in test environments only, or, in production environments, only for a short period.

`mysqldump` performs a full table scan, which means its queries can often exceed a `long_query_time` setting that is useful for regular queries. If you want to exclude most or all of the queries generated by `mysqldump` from the slow query log, you can use `--mysqld-long-query-time` to change the session value of the system variable to a higher value.

- `low_priority_updates`

Command-Line Format	<code>--low-priority-updates[={OFF ON}]</code>
System Variable	<code>low_priority_updates</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

If set to `1`, all `INSERT`, `UPDATE`, `DELETE`, and `LOCK TABLE WRITE` statements wait until there is no pending `SELECT` or `LOCK TABLE READ` on the affected table. The same effect can be obtained using `{INSERT | REPLACE | DELETE | UPDATE} LOW_PRIORITY ...` to lower the priority of only one query. This variable affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`). See [Section 10.11.2, “Table Locking Issues”](#).

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 7.1.9.1, “System Variable Privileges”](#).

- `lower_case_file_system`

System Variable	<code>lower_case_file_system</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Boolean

This variable describes the case sensitivity of file names on the file system where the data directory is located. `OFF` means file names are case-sensitive, `ON` means they are not case-sensitive. This variable is read only because it reflects a file system attribute and setting it would have no effect on the file system.

- `lower_case_table_names`

Command-Line Format	<code>--lower-case-table-names[=#]</code>
System Variable	<code>lower_case_table_names</code>

Scope	Global
Dynamic	No
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value (macOS)	2
Default Value (Unix)	0
Default Value (Windows)	1
Minimum Value	0
Maximum Value	2

If set to 0, table names are stored as specified and comparisons are case-sensitive. If set to 1, table names are stored in lowercase on disk and comparisons are not case-sensitive. If set to 2, table names are stored as given but compared in lowercase. This option also applies to database names and table aliases. For additional details, see [Section 11.2.3, “Identifier Case Sensitivity”](#).

The default value of this variable is platform-dependent (see [lower\\_case\\_file\\_system](#)). On Linux and other Unix-like systems, the default is 0. On Windows the default value is 1. On macOS, the default value is 2. On Linux (and other Unix-like systems), setting the value to 2 is not supported; the server forces the value to 0 instead.

You should *not* set [lower\\_case\\_table\\_names](#) to 0 if you are running MySQL on a system where the data directory resides on a case-insensitive file system (such as on Windows or macOS). It is an unsupported combination that could result in a hang condition when running an `INSERT INTO ... SELECT ... FROM tbl_name` operation with the wrong *tbl\_name* lettercase. With [MyISAM](#), accessing table names using different lettercases could cause index corruption.

An error message is printed and the server exits if you attempt to start the server with `--lower_case_table_names=0` on a case-insensitive file system.

The setting of this variable affects the behavior of replication filtering options with regard to case sensitivity. For more information, see [Section 19.2.5, “How Servers Evaluate Replication Filtering Rules”](#).

It is prohibited to start the server with a [lower\\_case\\_table\\_names](#) setting that is different from the setting used when the server was initialized. The restriction is necessary because collations used by various data dictionary table fields are determined by the setting defined when the server is initialized, and restarting the server with a different setting would introduce inconsistencies with respect to how identifiers are ordered and compared.

It is therefore necessary to configure [lower\\_case\\_table\\_names](#) to the desired setting before initializing the server. In most cases, this requires configuring [lower\\_case\\_table\\_names](#) in a MySQL option file before starting the MySQL server for the first time. For APT installations on Debian and Ubuntu, however, the server is initialized for you, and there is no opportunity to configure the setting in an option file beforehand. You must therefore use the `debconf-set-selections` utility prior to installing MySQL using APT to enable [lower\\_case\\_table\\_names](#). To do so, run this command before installing MySQL using APT:

```
$> sudo debconf-set-selections <<< "mysql-server mysql-server/lowercase-table-names select Enabled"
```

- [mandatory\\_roles](#)

Command-Line Format	<code>--mandatory-roles=value</code>
---------------------	--------------------------------------

System Variable	<code>mandatory_roles</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value	<code>empty string</code>

Roles the server should treat as mandatory. In effect, these roles are automatically granted to every user, although setting `mandatory_roles` does not actually change any user accounts, and the granted roles are not visible in the `mysql.role_edges` system table.

The variable value is a comma-separated list of role names. Example:

```
SET PERSIST mandatory_roles = '`role1`@`%`,`role2`,role3,role4@localhost';
```

Setting the runtime value of `mandatory_roles` requires the `ROLE_ADMIN` privilege, in addition to the `SYSTEM_VARIABLES_ADMIN` privilege (or the deprecated `SUPER` privilege) normally required to set a global system variable runtime value.

Role names consist of a user part and host part in `user_name@host_name` format. The host part, if omitted, defaults to `%`. For additional information, see [Section 8.2.5, “Specifying Role Names”](#).

The `mandatory_roles` value is a string, so user names and host names, if quoted, must be written in a fashion permitted for quoting within quoted strings.

Roles named in the value of `mandatory_roles` cannot be revoked with `REVOKE` or dropped with `DROP ROLE` or `DROP USER`.

To prevent sessions from being made system sessions by default, a role that has the `SYSTEM_USER` privilege cannot be listed in the value of the `mandatory_roles` system variable:

- If `mandatory_roles` is assigned a role at startup that has the `SYSTEM_USER` privilege, the server writes a message to the error log and exits.
- If `mandatory_roles` is assigned a role at runtime that has the `SYSTEM_USER` privilege, an error occurs and the `mandatory_roles` value remains unchanged.

Mandatory roles, like explicitly granted roles, do not take effect until activated (see [Activating Roles](#)). At login time, role activation occurs for all granted roles if the `activate_all_roles_on_login` system variable is enabled; otherwise, or for roles that are set as default roles otherwise. At runtime, `SET ROLE` activates roles.

Roles that do not exist when assigned to `mandatory_roles` but are created later may require special treatment to be considered mandatory. For details, see [Defining Mandatory Roles](#).

`SHOW GRANTS` displays mandatory roles according to the rules described in [Section 15.7.7.22, “SHOW GRANTS Statement”](#).

- `max_allowed_packet`

Command-Line Format	<code>--max-allowed-packet=#</code>
System Variable	<code>max_allowed_packet</code>
Scope	Global, Session

Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	67108864
Minimum Value	1024
Maximum Value	1073741824
Unit	bytes
Block Size	1024

The maximum size of one packet or any generated/intermediate string, or any parameter sent by the `mysql_stmt_send_long_data()` C API function. The default is 64MB.

The packet message buffer is initialized to `net_buffer_length` bytes, but can grow up to `max_allowed_packet` bytes when needed. This value by default is small, to catch large (possibly incorrect) packets.

You must increase this value if you are using large `BLOB` columns or long strings. It should be as big as the largest `BLOB` you want to use. The protocol limit for `max_allowed_packet` is 1GB. The value should be a multiple of 1024; nonmultiples are rounded down to the nearest multiple.

When you change the message buffer size by changing the value of the `max_allowed_packet` variable, you should also change the buffer size on the client side if your client program permits it. The default `max_allowed_packet` value built in to the client library is 1GB, but individual client programs might override this. For example, `mysql` and `mysqldump` have defaults of 16MB and 24MB, respectively. They also enable you to change the client-side value by setting `max_allowed_packet` on the command line or in an option file.

The session value of this variable is read only. The client can receive up to as many bytes as the session value. However, the server does not send to the client more bytes than the current global `max_allowed_packet` value. (The global value could be less than the session value if the global value is changed after the client connects.)

- `max_connect_errors`

Command-Line Format	<code>--max-connect-errors=#</code>
System Variable	<code>max_connect_errors</code>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	100
Minimum Value	1
Maximum Value (64-bit platforms)	18446744073709551615
Maximum Value (32-bit platforms)	4294967295

After `max_connect_errors` successive connection requests from a host are interrupted without a successful connection, the server blocks that host from further connections. If a connection from a host is established successfully within fewer than `max_connect_errors` attempts after a previous

connection was interrupted, the error count for the host is cleared to zero. To unblock blocked hosts, flush the host cache; see [Flushing the Host Cache](#).

- `max_connections`

Command-Line Format	<code>--max-connections=#</code>
System Variable	<code>max_connections</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	151
Minimum Value	1
Maximum Value	100000

The maximum permitted number of simultaneous client connections. The maximum effective value is the lesser of the effective value of `open_files_limit` - 810, and the value actually set for `max_connections`.

For more information, see [Section 7.1.12.1, “Connection Interfaces”](#).

- `max_delayed_threads`

Command-Line Format	<code>--max-delayed-threads=#</code>
Deprecated	Yes
System Variable	<code>max_delayed_threads</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	20
Minimum Value	0
Maximum Value	16384

This system variable is deprecated (because `DELAYED` inserts are not supported) and subject to removal in a future MySQL release.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 7.1.9.1, “System Variable Privileges”](#).

- `max_digest_length`

Command-Line Format	<code>--max-digest-length=#</code>
System Variable	<code>max_digest_length</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No

Type	Integer
Default Value	1024
Minimum Value	0
Maximum Value	1048576
Unit	bytes

The maximum number of bytes of memory reserved per session for computation of normalized statement digests. Once that amount of space is used during digest computation, truncation occurs: no further tokens from a parsed statement are collected or figure into its digest value. Statements that differ only after that many bytes of parsed tokens produce the same normalized statement digest and are considered identical if compared or if aggregated for digest statistics.

The length used for calculating a normalized statement digest is the sum of the length of the normalized statement digest and the length of the statement digest. Since the length of the statement digest is always 64, this is equivalent to `LENGTH ( STATEMENT_DIGEST_TEXT(statement) ) + 64`. This means that, when the value of `max_digest_length` is 1024 (the default), the maximum length for a normalized SQL statement before truncation occurs is in effect 960 bytes.

### Warning

Setting `max_digest_length` to zero disables digest production, which also disables server functionality that requires digests, such as MySQL Enterprise Firewall.

Decreasing the `max_digest_length` value reduces memory use but causes the digest value of more statements to become indistinguishable if they differ only at the end. Increasing the value permits longer statements to be distinguished but increases memory use, particularly for workloads that involve large numbers of simultaneous sessions (the server allocates `max_digest_length` bytes per session).

The parser uses this system variable as a limit on the maximum length of normalized statement digests that it computes. The Performance Schema, if it tracks statement digests, makes a copy of the digest value, using the `performance_schema_max_digest_length` system variable as a limit on the maximum length of digests that it stores. Consequently, if `performance_schema_max_digest_length` is less than `max_digest_length`, digest values stored in the Performance Schema are truncated relative to the original digest values.

For more information about statement digesting, see [Section 29.10, “Performance Schema Statement Digests and Sampling”](#).

- `max_error_count`

Command-Line Format	<code>--max-error-count=#</code>
System Variable	<code>max_error_count</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Integer
Default Value	1024
Minimum Value	0

Maximum Value	65535
---------------	-------

The maximum number of error, warning, and information messages to be stored for display by the [SHOW ERRORS](#) and [SHOW WARNINGS](#) statements. This is the same as the number of condition areas in the diagnostics area, and thus the number of conditions that can be inspected by [GET DIAGNOSTICS](#).

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 7.1.9.1, “System Variable Privileges”](#).

- [max\\_execution\\_time](#)

Command-Line Format	<code>--max-execution-time=#</code>
System Variable	<a href="#">max_execution_time</a>
Scope	Global, Session
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	Yes
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	4294967295
Unit	milliseconds

The execution timeout for [SELECT](#) statements, in milliseconds. If the value is 0, timeouts are not enabled.

[max\\_execution\\_time](#) applies as follows:

- The global [max\\_execution\\_time](#) value provides the default for the session value for new connections. The session value applies to [SELECT](#) executions executed within the session that include no [MAX\\_EXECUTION\\_TIME\(N\)](#) optimizer hint or for which *N* is 0.
- [max\\_execution\\_time](#) applies to read-only [SELECT](#) statements. Statements that are not read only are those that invoke a stored function that modifies data as a side effect.
- [max\\_execution\\_time](#) is ignored for [SELECT](#) statements in stored programs.
- [max\\_heap\\_table\\_size](#)

Command-Line Format	<code>--max-heap-table-size=#</code>
System Variable	<a href="#">max_heap_table_size</a>
Scope	Global, Session
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	Yes
Type	Integer
Default Value	16777216
Minimum Value	16384
Maximum Value (64-bit platforms)	18446744073709550592
Maximum Value (32-bit platforms)	4294966272

Unit	bytes
<a href="#">Block Size</a>	<a href="#">1024</a>

This variable sets the maximum size to which user-created [MEMORY](#) tables are permitted to grow. The value of the variable is used to calculate [MEMORY](#) table [MAX\\_ROWS](#) values.

Setting this variable has no effect on any existing [MEMORY](#) table, unless the table is re-created with a statement such as [CREATE TABLE](#) or altered with [ALTER TABLE](#) or [TRUNCATE TABLE](#). A server restart also sets the maximum size of existing [MEMORY](#) tables to the global [max\\_heap\\_table\\_size](#) value.

This variable is also used in conjunction with [tmp\\_table\\_size](#) to limit the size of internal in-memory tables. See [Section 10.4.4, “Internal Temporary Table Use in MySQL”](#) and [Count\\_hit\\_tmp\\_table\\_size](#).

[max\\_heap\\_table\\_size](#) is not replicated. See [Section 19.5.1.22, “Replication and MEMORY Tables”](#), and [Section 19.5.1.40, “Replication and Variables”](#), for more information.

- [max\\_insert\\_delayed\\_threads](#)

Deprecated	Yes
System Variable	<a href="#">max_insert_delayed_threads</a>
Scope	Global, Session
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	<a href="#">0</a>
Minimum Value	<a href="#">20</a>
Maximum Value	<a href="#">16384</a>

This variable is a synonym for [max\\_delayed\\_threads](#). Like [max\\_delayed\\_threads](#), it is deprecated (because [DELAYED](#) inserts are not supported) and subject to removal in a future MySQL release.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 7.1.9.1, “System Variable Privileges”](#).

- [max\\_join\\_size](#)

Command-Line Format	<a href="#">--max-join-size=#</a>
System Variable	<a href="#">max_join_size</a>
Scope	Global, Session
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	Yes
Type	Integer
Default Value	<a href="#">18446744073709551615</a>
Minimum Value	<a href="#">1</a>

Maximum Value	18446744073709551615
---------------	----------------------

This represents a limit on the maximum number of row accesses in base tables made by a join. If the server's estimate indicates that a greater number of rows than `max_join_size` must be read from the base tables, the statement is rejected with an error.

Setting this variable to a value other than `DEFAULT` resets the value of `sql_big_selects` to 0. If you set the `sql_big_selects` value again, the `max_join_size` variable is ignored.

- `max_length_for_sort_data`

Command-Line Format	<code>--max-length-for-sort-data=#</code>
Deprecated	Yes
System Variable	<code>max_length_for_sort_data</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Integer
Default Value	4096
Minimum Value	4
Maximum Value	8388608
Unit	bytes

This variable is deprecated, and has no effect in MySQL 9.1.

- `max_points_in_geometry`

Command-Line Format	<code>--max-points-in-geometry=#</code>
System Variable	<code>max_points_in_geometry</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Integer
Default Value	65536
Minimum Value	3
Maximum Value	1048576

The maximum value of the `points_per_circle` argument to the `ST_Buffer_Strategy()` function.

- `max_prepared_stmt_count`

Command-Line Format	<code>--max-prepared-stmt-count=#</code>
System Variable	<code>max_prepared_stmt_count</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No

Type	Integer
Default Value	16382
Minimum Value	0
Maximum Value	4194304

This variable limits the total number of prepared statements in the server. It can be used in environments where there is the potential for denial-of-service attacks based on running the server out of memory by preparing huge numbers of statements. If the value is set lower than the current number of prepared statements, existing statements are not affected and can be used, but no new statements can be prepared until the current number drops below the limit. Setting the value to 0 disables prepared statements.

- `max_seeks_for_key`

Command-Line Format	<code>--max-seeks-for-key=#</code>
System Variable	<code>max_seeks_for_key</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Integer
Default Value (Windows)	4294967295
Default Value (Other, 64-bit platforms)	18446744073709551615
Default Value (Other, 32-bit platforms)	4294967295
Minimum Value	1
Maximum Value (Windows)	4294967295
Maximum Value (Other, 64-bit platforms)	18446744073709551615
Maximum Value (Other, 32-bit platforms)	4294967295

Limit the assumed maximum number of seeks when looking up rows based on a key. The MySQL optimizer assumes that no more than this number of key seeks are required when searching for matching rows in a table by scanning an index, regardless of the actual cardinality of the index (see [Section 15.7.7.23, “SHOW INDEX Statement”](#)). By setting this to a low value (say, 100), you can force MySQL to prefer indexes instead of table scans.

- `max_sort_length`

Command-Line Format	<code>--max-sort-length=#</code>
System Variable	<code>max_sort_length</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Integer
Default Value	1024
Minimum Value	4
Maximum Value	8388608

Unit	bytes
------	-------

The number of bytes to use when sorting string values which use `PAD SPACE` collations. The server uses only the first `max_sort_length` bytes of any such value and ignores the rest. Consequently, such values that differ only after the first `max_sort_length` bytes compare as equal for `GROUP BY`, `ORDER BY`, and `DISTINCT` operations. (This behavior differs from previous versions of MySQL, where this setting was applied to all values used in comparisons.)

Increasing the value of `max_sort_length` may require increasing the value of `sort_buffer_size` as well. For details, see [Section 10.2.1.16, “ORDER BY Optimization”](#)

- `max_sp_recursion_depth`

Command-Line Format	<code>--max-sp-recursion-depth[=#]</code>
System Variable	<code>max_sp_recursion_depth</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	255

The number of times that any given stored procedure may be called recursively. The default value for this option is 0, which completely disables recursion in stored procedures. The maximum value is 255.

Stored procedure recursion increases the demand on thread stack space. If you increase the value of `max_sp_recursion_depth`, it may be necessary to increase thread stack size by increasing the value of `thread_stack` at server startup.

- `max_user_connections`

Command-Line Format	<code>--max-user-connections=#</code>
System Variable	<code>max_user_connections</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0

Maximum Value	4294967295
---------------	------------

The maximum number of simultaneous connections permitted to any given MySQL user account. A value of 0 (the default) means “no limit.”

This variable has a global value that can be set at server startup or runtime. It also has a read-only session value that indicates the effective simultaneous-connection limit that applies to the account associated with the current session. The session value is initialized as follows:

- If the user account has a nonzero `MAX_USER_CONNECTIONS` resource limit, the session `max_user_connections` value is set to that limit.
- Otherwise, the session `max_user_connections` value is set to the global value.

Account resource limits are specified using the `CREATE USER` or `ALTER USER` statement. See [Section 8.2.21, “Setting Account Resource Limits”](#).

- `max_write_lock_count`

Command-Line Format	<code>--max-write-lock-count=#</code>
System Variable	<code>max_write_lock_count</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value (Windows)	4294967295
Default Value (Other, 64-bit platforms)	18446744073709551615
Default Value (Other, 32-bit platforms)	4294967295
Minimum Value	1
Maximum Value (Windows)	4294967295
Maximum Value (Other, 64-bit platforms)	18446744073709551615
Maximum Value (Other, 32-bit platforms)	4294967295

After this many write locks, permit some pending read lock requests to be processed in between. Write lock requests have higher priority than read lock requests. However, if `max_write_lock_count` is set to some low value (say, 10), read lock requests may be preferred over pending write lock requests if the read lock requests have already been passed over in favor of 10 write lock requests. Normally this behavior does not occur because `max_write_lock_count` by default has a very large value.

- `mecab_rc_file`

Command-Line Format	<code>--mecab-rc-file=file_name</code>
System Variable	<code>mecab_rc_file</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No

Type	File name
------	-----------

The `mecab_rc_file` option is used when setting up the MeCab full-text parser.

The `mecab_rc_file` option defines the path to the `mecabrc` configuration file, which is the configuration file for MeCab. The option is read-only and can only be set at startup. The `mecabrc` configuration file is required to initialize MeCab.

For information about the MeCab full-text parser, see [Section 14.9.9, “MeCab Full-Text Parser Plugin”](#).

For information about options that can be specified in the MeCab `mecabrc` configuration file, refer to the [MeCab Documentation](#) on the [Google Developers](#) site.

- `min_examined_row_limit`

Command-Line Format	<code>--min-examined-row-limit=#</code>
System Variable	<code>min_examined_row_limit</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value (64-bit platforms)	18446744073709551615
Maximum Value (32-bit platforms)	4294967295

Queries that examine fewer than this number of rows are not logged to the slow query log.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 7.1.9.1, “System Variable Privileges”](#).

- `myisam_data_pointer_size`

Command-Line Format	<code>--myisam-data-pointer-size=#</code>
System Variable	<code>myisam_data_pointer_size</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	6
Minimum Value	2
Maximum Value	7
Unit	bytes

The default pointer size in bytes, to be used by `CREATE TABLE` for `MyISAM` tables when no `MAX_ROWS` option is specified. This variable cannot be less than 2 or larger than 7. The default value is 6. See [Section B.3.2.10, “The table is full”](#).

- `myisam_max_sort_file_size`

Command-Line Format	<code>--myisam-max-sort-file-size=#</code>
System Variable	<code>myisam_max_sort_file_size</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value (Windows)	2146435072
Default Value (Other, 64-bit platforms)	9223372036853727232
Default Value (Other, 32-bit platforms)	2147483648
Minimum Value	0
Maximum Value (Windows)	2146435072
Maximum Value (Other, 64-bit platforms)	9223372036853727232
Maximum Value (Other, 32-bit platforms)	2147483648
Unit	bytes

The maximum size of the temporary file that MySQL is permitted to use while re-creating a [MyISAM](#) index (during [REPAIR TABLE](#), [ALTER TABLE](#), or [LOAD DATA](#)). If the file size would be larger than this value, the index is created using the key cache instead, which is slower. The value is given in bytes.

If [MyISAM](#) index files exceed this size and disk space is available, increasing the value may help performance. The space must be available in the file system containing the directory where the original index file is located.

- `myisam_mmap_size`

Command-Line Format	<code>--myisam-mmap-size=#</code>
System Variable	<code>myisam_mmap_size</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value (64-bit platforms)	18446744073709551615
Default Value (32-bit platforms)	4294967295
Minimum Value	7
Maximum Value (64-bit platforms)	18446744073709551615
Maximum Value (32-bit platforms)	4294967295
Unit	bytes

The maximum amount of memory to use for memory mapping compressed [MyISAM](#) files. If many compressed [MyISAM](#) tables are used, the value can be decreased to reduce the likelihood of memory-swapping problems.

- `myisam_recover_options`

Command-Line Format	<code>--myisam-recover-options[=list]</code>
System Variable	<code>myisam_recover_options</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	<code>OFF</code>
Valid Values	<code>OFF</code>  <code>DEFAULT</code>  <code>BACKUP</code>  <code>FORCE</code>  <code>QUICK</code>

Set the `MyISAM` storage engine recovery mode. The variable value is any combination of the values of `OFF`, `DEFAULT`, `BACKUP`, `FORCE`, or `QUICK`. If you specify multiple values, separate them by commas. Specifying the variable with no value at server startup is the same as specifying `DEFAULT`, and specifying with an explicit value of `" "` disables recovery (same as a value of `OFF`). If recovery is enabled, each time `mysqld` opens a `MyISAM` table, it checks whether the table is marked as crashed or was not closed properly. (The last option works only if you are running with external locking disabled.) If this is the case, `mysqld` runs a check on the table. If the table was corrupted, `mysqld` attempts to repair it.

The following options affect how the repair works.

Option	Description
<code>OFF</code>	No recovery.
<code>DEFAULT</code>	Recovery without backup, forcing, or quick checking.
<code>BACKUP</code>	If the data file was changed during recovery, save a backup of the <code>tbl_name.MYD</code> file as <code>tbl_name-datetime.BAK</code> .
<code>FORCE</code>	Run recovery even if we would lose more than one row from the <code>.MYD</code> file.
<code>QUICK</code>	Do not check the rows in the table if there are not any delete blocks.

Before the server automatically repairs a table, it writes a note about the repair to the error log. If you want to be able to recover from most problems without user intervention, you should use the options `BACKUP`, `FORCE`. This forces a repair of a table even if some rows would be deleted, but it keeps the old data file as a backup so that you can later examine what happened.

See [Section 18.2.1, “MyISAM Startup Options”](#).

- `myisam_sort_buffer_size`

Command-Line Format	<code>--myisam-sort-buffer-size=#</code>
System Variable	<code>myisam_sort_buffer_size</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	8388608
Minimum Value	4096
Maximum Value (64-bit platforms)	18446744073709551615
Maximum Value (32-bit platforms)	4294967295
Unit	bytes

The size of the buffer that is allocated when sorting **MyISAM** indexes during a `REPAIR TABLE` or when creating indexes with `CREATE INDEX` or `ALTER TABLE`.

- `myisam_stats_method`

Command-Line Format	<code>--myisam-stats-method=name</code>
System Variable	<code>myisam_stats_method</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Enumeration
Default Value	<code>nulls_unequal</code>
Valid Values	<code>nulls_unequal</code>  <code>nulls_equal</code>  <code>nulls_ignored</code>

How the server treats **NULL** values when collecting statistics about the distribution of index values for **MyISAM** tables. This variable has three possible values, `nulls_equal`, `nulls_unequal`, and `nulls_ignored`. For `nulls_equal`, all **NULL** index values are considered equal and form a single value group that has a size equal to the number of **NULL** values. For `nulls_unequal`, **NULL** values are considered unequal, and each **NULL** forms a distinct value group of size 1. For `nulls_ignored`, **NULL** values are ignored.

The method that is used for generating table statistics influences how the optimizer chooses indexes for query execution, as described in [Section 10.3.8, “InnoDB and MyISAM Index Statistics Collection”](#).

- `myisam_use_mmap`

Command-Line Format	<code>--myisam-use-mmap[={OFF ON}]</code>
System Variable	<code>myisam_use_mmap</code>
Scope	Global

Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Boolean
Default Value	<a href="#">OFF</a>

Use memory mapping for reading and writing [MyISAM](#) tables.

- [named\\_pipe](#)

Command-Line Format	<code>--named-pipe[={OFF ON}]</code>
System Variable	<a href="#">named_pipe</a>
Scope	Global
Dynamic	No
<a href="#">SET_VAR</a> Hint Applies	No
Platform Specific	Windows
Type	Boolean
Default Value	<a href="#">OFF</a>

(Windows only.) Indicates whether the server supports connections over named pipes.

- [named\\_pipe\\_full\\_access\\_group](#)

Command-Line Format	<code>--named-pipe-full-access-group=value</code>
System Variable	<a href="#">named_pipe_full_access_group</a>
Scope	Global
Dynamic	No
<a href="#">SET_VAR</a> Hint Applies	No
Platform Specific	Windows
Type	String
Default Value	<a href="#">empty string</a>
Valid Values	<a href="#">empty string</a>  <a href="#">valid Windows local group name</a>  <a href="#">*everyone*</a>

(Windows only.) The access control granted to clients on the named pipe created by the MySQL server is set to the minimum necessary for successful communication when the [named\\_pipe](#) system variable is enabled to support named-pipe connections. Some MySQL client software can open named pipe connections without any additional configuration; however, other client software may still require full access to open a named pipe connection.

This variable sets the name of a Windows local group whose members are granted sufficient access by the MySQL server to use named-pipe clients. The default value is an empty string, which means that no Windows user is granted full access to the named pipe.

A new Windows local group name (for example, [mysql\\_access\\_client\\_users](#)) can be created in Windows and then used to replace the default value when access is absolutely necessary. In this case,

limit the membership of the group to as few users as possible, removing users from the group when their client software is upgraded. A non-member of the group who attempts to open a connection to MySQL with the affected named-pipe client is denied access until a Windows administrator adds the user to the group. Newly added users must log out and log in again to join the group (required by Windows).

Setting the value to `'*everyone*'` provides a language-independent way of referring to the Everyone group on Windows. The Everyone group is not secure by default.

- `net_buffer_length`

Command-Line Format	<code>--net-buffer-length=#</code>
System Variable	<code>net_buffer_length</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	16384
Minimum Value	1024
Maximum Value	1048576
Unit	bytes
Block Size	1024

Each client thread is associated with a connection buffer and result buffer. Both begin with a size given by `net_buffer_length` but are dynamically enlarged up to `max_allowed_packet` bytes as needed. The result buffer shrinks to `net_buffer_length` after each SQL statement.

This variable should not normally be changed, but if you have very little memory, you can set it to the expected length of statements sent by clients. If statements exceed this length, the connection buffer is automatically enlarged. The maximum value to which `net_buffer_length` can be set is 1MB.

The session value of this variable is read only.

- `net_read_timeout`

Command-Line Format	<code>--net-read-timeout=#</code>
System Variable	<code>net_read_timeout</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	30
Minimum Value	1
Maximum Value	31536000
Unit	seconds

The number of seconds to wait for more data from a connection before aborting the read. When the server is reading from the client, `net_read_timeout` is the timeout value controlling when to abort.

When the server is writing to the client, `net_write_timeout` is the timeout value controlling when to abort. See also `replica_net_timeout`.

- `net_retry_count`

Command-Line Format	<code>--net-retry-count=#</code>
System Variable	<code>net_retry_count</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	10
Minimum Value	1
Maximum Value (64-bit platforms)	18446744073709551615
Maximum Value (32-bit platforms)	4294967295

If a read or write on a communication port is interrupted, retry this many times before giving up. This value should be set quite high on FreeBSD because internal interrupts are sent to all threads.

- `net_write_timeout`

Command-Line Format	<code>--net-write-timeout=#</code>
System Variable	<code>net_write_timeout</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	60
Minimum Value	1
Maximum Value	31536000
Unit	seconds

The number of seconds to wait for a block to be written to a connection before aborting the write. See also `net_read_timeout`.

- `ngram_token_size`

Command-Line Format	<code>--ngram-token-size=#</code>
System Variable	<code>ngram_token_size</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	2
Minimum Value	1

Maximum Value	10
---------------	----

Defines the n-gram token size for the n-gram full-text parser. The `ngram_token_size` option is read-only and can only be modified at startup. The default value is 2 (bigram). The maximum value is 10.

For more information about how to configure this variable, see [Section 14.9.8, “ngram Full-Text Parser”](#).

- `offline_mode`

Command-Line Format	<code>--offline-mode[={OFF ON}]</code>
System Variable	<code>offline_mode</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

In offline mode, the MySQL instance disconnects client users unless they have relevant privileges, and does not allow them to initiate new connections. Clients that are refused access receive an error. The precise error and error message are determined as follows:

1. The server attempts to obtain the value of an attribute named `reason` attached to `offline_mode`; this is equivalent to the result of a query similar to this one:

```
SELECT ATTR_VALUE INTO @sreason
FROM performance_schema.global_variable_attributes
WHERE VARIABLE_NAME='offline_mode' AND ATTR_NAME='reason';
```

2. If `@sreason` is not `NULL`, the server tries to obtain the time the `offline_mode` system variable was last set; this is equivalent to the following query:

```
SELECT SET_TIME INTO @stime
FROM performance.schema_variables_info
WHERE VARIABLE_NAME='offline_mode';
```

- If `@stime` is not `NULL`, the server raises `ER_SERVER_OFFLINE_MODE_REASON`, and prints the following error message:

```
The server is currently in offline mode since @stime, reason: @sreason
```

- If `@stime` is `NULL`, the server raises `ER_SERVER_OFFLINE_MODE` and prints the message `The server is currently in offline mode.`
3. If `@sreason` is empty, the server obtains the time `offline_mode` was last set and the name of the user that set it; this is equivalent to the query shown here:

```
SELECT SET_TIME, SET_USER INTO @stime, @suser
FROM performance.schema_variables_info
```

```
WHERE VARIABLE_NAME='offline_mode';
```

- If neither `@stime` nor `@suser` is `NULL`, the server raises `ER_SERVER_OFFLINE_MODE_USER` and prints the error message shown here:

```
The server is currently in offline mode since @stime, set by user @suser
```

- Should either or both of `@suser` and `@stime` be `NULL`, the server raises `ER_SERVER_OFFLINE_MODE` and prints the text shown previously for this error.

For more information about the Performance Schema tables used here, see [Section 29.12.14.1, “Performance Schema global\\_variable\\_attributes Table”](#), and [Section 29.12.14.3, “Performance Schema variables\\_info Table”](#).

To put a server in offline mode, change the value of the `offline_mode` system variable from `OFF` to `ON`. To resume normal operations, change `offline_mode` from `ON` to `OFF`. To control offline mode, an administrator account must have the `SYSTEM_VARIABLES_ADMIN` privilege and the `CONNECTION_ADMIN` privilege (or the deprecated `SUPER` privilege, which covers both these privileges). `CONNECTION_ADMIN` is required, to prevent accidental lockout.

Offline mode has these characteristics:

- Connected client users who do not have the `CONNECTION_ADMIN` privilege (or the deprecated `SUPER` privilege) are disconnected on the next request, with an appropriate error. Disconnection includes terminating running statements and releasing locks. Such clients also cannot initiate new connections, and receive an appropriate error.
- Connected client users who have the `CONNECTION_ADMIN` or `SUPER` privilege are not disconnected, and can initiate new connections to manage the server.
- If the user that puts a server in offline mode does not have the `SYSTEM_USER` privilege, connected client users who have the `SYSTEM_USER` privilege are also not disconnected. However, these users cannot initiate new connections to the server while it is in offline mode, unless they have the `CONNECTION_ADMIN` or `SUPER` privilege as well. It is only their existing connection that cannot be terminated, because the `SYSTEM_USER` privilege is required to kill a session or statement that is executing with the `SYSTEM_USER` privilege.
- Replication threads are permitted to keep applying data to the server.
- `old_alter_table`

Command-Line Format	<code>--old-alter-table[={OFF ON}]</code>
System Variable	<code>old_alter_table</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

When this variable is enabled, the server does not use the optimized method of processing an `ALTER TABLE` operation. It reverts to using a temporary table, copying over the data, and then renaming the

temporary table to the original, as used by MySQL 5.0 and earlier. For more information on the operation of `ALTER TABLE`, see [Section 15.1.9, “ALTER TABLE Statement”](#).

`ALTER TABLE ... DROP PARTITION` with `old_alter_table=ON` rebuilds the partitioned table and attempts to move data from the dropped partition to another partition with a compatible `PARTITION ... VALUES` definition. Data that cannot be moved to another partition is deleted. In earlier releases, `ALTER TABLE ... DROP PARTITION` with `old_alter_table=ON` deletes data stored in the partition and drops the partition.

- `open_files_limit`

Command-Line Format	<code>--open-files-limit=#</code>
System Variable	<code>open_files_limit</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	5000, with possible adjustment
Minimum Value	0
Maximum Value	platform dependent

The number of file descriptors available to `mysqld` from the operating system:

- At startup, `mysqld` reserves descriptors with `setrlimit()`, using the value requested at by setting this variable directly or by using the `--open-files-limit` option to `mysqld_safe`. If `mysqld` produces the error `Too many open files`, try increasing the `open_files_limit` value. Internally, the maximum value for this variable is the maximum unsigned integer value, but the actual maximum is platform dependent.
- At runtime, the value of `open_files_limit` indicates the number of file descriptors actually permitted to `mysqld` by the operating system, which might differ from the value requested at startup. If the number of file descriptors requested during startup cannot be allocated, `mysqld` writes a warning to the error log.

The effective `open_files_limit` value is based on the value specified at system startup (if any) and the values of `max_connections` and `table_open_cache`, using these formulas:

- $10 + \text{max\_connections} + (\text{table\_open\_cache} * 2)$ . Using the defaults for these variables yields 8161.

On Windows only, 2048 (the value of the C Run-Time Library file descriptor maximum) is added to this number. This totals 10209, again using the default values for the indicated system variables.

- `max_connections * 5`

- The operating system limit.

The server attempts to obtain the number of file descriptors using the maximum of those values, capped to the maximum unsigned integer value. If that many descriptors cannot be obtained, the server attempts to obtain as many as the system permits.

The effective value is 0 on systems where MySQL cannot change the number of open files.

On Unix, the value cannot be set greater than the value displayed by the `ulimit -n` command. On Linux systems using `systemd`, the value cannot be set greater than `LimitNOFILE` (this is `DefaultLimitNOFILE`, if `LimitNOFILE` is not set); otherwise, on Linux, the value of `open_files_limit` cannot exceed `ulimit -n`.

- `optimizer_prune_level`

Command-Line Format	<code>--optimizer-prune-level=#</code>
System Variable	<code>optimizer_prune_level</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Integer
Default Value	1
Minimum Value	0
Maximum Value	1

Controls the heuristics applied during query optimization to prune less-promising partial plans from the optimizer search space. A value of 0 disables heuristics so that the optimizer performs an exhaustive search. A value of 1 causes the optimizer to prune plans based on the number of rows retrieved by intermediate plans.

- `optimizer_search_depth`

Command-Line Format	<code>--optimizer-search-depth=#</code>
System Variable	<code>optimizer_search_depth</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Integer
Default Value	62
Minimum Value	0
Maximum Value	62

The maximum depth of search performed by the query optimizer. Values larger than the number of relations in a query result in better query plans, but take longer to generate an execution plan for a query. Values smaller than the number of relations in a query return an execution plan quicker, but the resulting plan may be far from being optimal. If set to 0, the system automatically picks a reasonable value.

- `optimizer_switch`

Command-Line Format	<code>--optimizer-switch=value</code>
System Variable	<code>optimizer_switch</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Set
Valid Values	<code>batched_key_access={on off}</code> <code>block_nested_loop={on off}</code> <code>condition_fanout_filter={on off}</code> <code>derived_condition_pushdown={on off}</code> <code>derived_merge={on off}</code> <code>duplicateweedout={on off}</code> <code>engine_condition_pushdown={on off}</code> <code>firstmatch={on off}</code> <code>hash_join={on off}</code> <code>index_condition_pushdown={on off}</code> <code>index_merge={on off}</code> <code>index_merge_intersection={on off}</code> <code>index_merge_sort_union={on off}</code> <code>index_merge_union={on off}</code> <code>loosescan={on off}</code> <code>materialization={on off}</code> <code>mrr={on off}</code> <code>mrr_cost_based={on off}</code> <code>prefer_ordering_index={on off}</code> <code>semi join={on off}</code> <code>skip_scan={on off}</code> <code>subquery_materialization_cost_based={on off}</code> <code>subquery_to_derived={on off}</code>

<pre>use_index_extensions={on off}  use_invisible_indexes={on off}</pre>
--------------------------------------------------------------------------

The `optimizer_switch` system variable enables control over optimizer behavior. The value of this variable is a set of flags, each of which has a value of `on` or `off` to indicate whether the corresponding optimizer behavior is enabled or disabled. This variable has global and session values and can be changed at runtime. The global default can be set at server startup.

To see the current set of optimizer flags, select the variable value:

```
mysql> SELECT @@optimizer_switch\G
***** 1. row *****
@@optimizer_switch: index_merge=on,index_merge_union=on,
 index_merge_sort_union=on,index_merge_intersection=on,
 engine_condition_pushdown=on,index_condition_pushdown=on,
 mrr=on,mrr_cost_based=on,block_nested_loop=on,
 batched_key_access=off,materialization=on,semijoin=on,
 loosescan=on,firstmatch=on,duplicateweedout=on,
 subquery_materialization_cost_based=on,
 use_index_extensions=on,condition_fanout_filter=on,
 derived_merge=on,use_invisible_indexes=off,skip_scan=on,
 hash_join=on,subquery_to_derived=off,
 prefer_ordering_index=on,hypergraph_optimizer=off,
 derived_condition_pushdown=on,hash_set_operations=on

1 row in set (0.00 sec)
```

For more information about the syntax of this variable and the optimizer behaviors that it controls, see [Section 10.9.2, “Switchable Optimizations”](#).

- `optimizer_trace`

Command-Line Format	<code>--optimizer-trace=value</code>
System Variable	<code>optimizer_trace</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String

This variable controls optimizer tracing. For details, see [Section 10.15, “Tracing the Optimizer”](#).

- `optimizer_trace_features`

Command-Line Format	<code>--optimizer-trace-features=value</code>
System Variable	<code>optimizer_trace_features</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String

This variable enables or disables selected optimizer tracing features. For details, see [Section 10.15, “Tracing the Optimizer”](#).

- `optimizer_trace_limit`

Command-Line Format	<code>--optimizer-trace-limit=#</code>
System Variable	<code>optimizer_trace_limit</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	1
Minimum Value	0
Maximum Value	2147483647

The maximum number of optimizer traces to display. For details, see [Section 10.15, “Tracing the Optimizer”](#).

- `optimizer_trace_max_mem_size`

Command-Line Format	<code>--optimizer-trace-max-mem-size=#</code>
System Variable	<code>optimizer_trace_max_mem_size</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Integer
Default Value	1048576
Minimum Value	0
Maximum Value	4294967295
Unit	bytes

The maximum cumulative size of stored optimizer traces. For details, see [Section 10.15, “Tracing the Optimizer”](#).

- `optimizer_trace_offset`

Command-Line Format	<code>--optimizer-trace-offset=#</code>
System Variable	<code>optimizer_trace_offset</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	-1
Minimum Value	-2147483647
Maximum Value	2147483647

The offset of optimizer traces to display. For details, see [Section 10.15, “Tracing the Optimizer”](#).

- `performance_schema_xxx`

Performance Schema system variables are listed in [Section 29.15, “Performance Schema System Variables”](#). These variables may be used to configure Performance Schema operation.

- `parser_max_mem_size`

Command-Line Format	<code>--parser-max-mem-size=#</code>
System Variable	<code>parser_max_mem_size</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value (64-bit platforms)	18446744073709551615
Default Value (32-bit platforms)	4294967295
Minimum Value	10000000
Maximum Value (64-bit platforms)	18446744073709551615
Maximum Value (32-bit platforms)	4294967295
Unit	bytes

The maximum amount of memory available to the parser. The default value places no limit on memory available. The value can be reduced to protect against out-of-memory situations caused by parsing long or complex SQL statements.

- `partial_revokes`

Command-Line Format	<code>--partial-revokes[={OFF ON}]</code>
System Variable	<code>partial_revokes</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code> (if partial revokes do not exist) <code>ON</code> (if partial revokes exist)

Enabling this variable makes it possible to revoke privileges partially. Specifically, for users who have privileges at the global level, `partial_revokes` enables privileges for specific schemas to be revoked while leaving the privileges in place for other schemas. For example, a user who has the global `UPDATE` privilege can be restricted from exercising this privilege on the `mysql` system schema. (Or, stated another way, the user is enabled to exercise the `UPDATE` privilege on all schemas except the `mysql` schema.) In this sense, the user's global `UPDATE` privilege is partially revoked.

Once enabled, `partial_revokes` cannot be disabled if any account has privilege restrictions. If any such account exists, disabling `partial_revokes` fails:

- For attempts to disable `partial_revokes` at startup, the server logs an error message and enables `partial_revokes`.

- For attempts to disable `partial_revokes` at runtime, an error occurs and the `partial_revokes` value remains unchanged.

To disable `partial_revokes` in this case, first modify each account that has partially revoked privileges, either by re-granting the privileges or by removing the account.

#### Note

In privilege assignments, enabling `partial_revokes` causes MySQL to interpret occurrences of unescaped `_` and `%` SQL wildcard characters in schema names as literal characters, just as if they had been escaped as `\_` and `\%`. Because this changes how MySQL interprets privileges, it may be advisable to avoid unescaped wildcard characters in privilege assignments for installations where `partial_revokes` may be enabled.

In addition, use of `_` and `%` as wildcard characters in grants is deprecated, and you should expect support for them to be removed in a future version of MySQL.

For more information, including instructions for removing partial revokes, see [Section 8.2.12, “Privilege Restriction Using Partial Revokes”](#).

- `password_history`

Command-Line Format	<code>--password-history=#</code>
System Variable	<code>password_history</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	4294967295

This variable defines the global policy for controlling reuse of previous passwords based on required minimum number of password changes. For an account password used previously, this variable indicates the number of subsequent account password changes that must occur before the password can be reused. If the value is 0 (the default), there is no reuse restriction based on number of password changes.

Changes to this variable apply immediately to all accounts defined with the `PASSWORD HISTORY DEFAULT` option.

The global number-of-changes password reuse policy can be overridden as desired for individual accounts using the `PASSWORD HISTORY` option of the `CREATE USER` and `ALTER USER` statements. See [Section 8.2.15, “Password Management”](#).

- `password_require_current`

Command-Line Format	<code>--password-require-current[={OFF ON}]</code>
System Variable	<code>password_require_current</code>
Scope	Global

Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Boolean
Default Value	<a href="#">OFF</a>

This variable defines the global policy for controlling whether attempts to change an account password must specify the current password to be replaced.

Changes to this variable apply immediately to all accounts defined with the [PASSWORD REQUIRE CURRENT DEFAULT](#) option.

The global verification-required policy can be overridden as desired for individual accounts using the [PASSWORD REQUIRE](#) option of the [CREATE USER](#) and [ALTER USER](#) statements. See [Section 8.2.15, “Password Management”](#).

- [password\\_reuse\\_interval](#)

Command-Line Format	<a href="#">--password-reuse-interval=#</a>
System Variable	<a href="#">password_reuse_interval</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	4294967295
Unit	days

This variable defines the global policy for controlling reuse of previous passwords based on time elapsed. For an account password used previously, this variable indicates the number of days that must pass before the password can be reused. If the value is 0 (the default), there is no reuse restriction based on time elapsed.

Changes to this variable apply immediately to all accounts defined with the [PASSWORD REUSE INTERVAL DEFAULT](#) option.

The global time-elapsed password reuse policy can be overridden as desired for individual accounts using the [PASSWORD REUSE INTERVAL](#) option of the [CREATE USER](#) and [ALTER USER](#) statements. See [Section 8.2.15, “Password Management”](#).

- [persisted\\_globals\\_load](#)

Command-Line Format	<a href="#">--persisted-globals-load[={OFF ON}]</a>
System Variable	<a href="#">persisted_globals_load</a>
Scope	Global
Dynamic	No
<a href="#">SET_VAR</a> Hint Applies	No
Type	Boolean

Default Value	ON
---------------	----

Whether to load persisted configuration settings from the `mysqld-auto.cnf` file in the data directory. The server normally processes this file at startup after all other option files (see [Section 6.2.2.2, “Using Option Files”](#)). Disabling `persisted_globals_load` causes the server startup sequence to skip `mysqld-auto.cnf`.

To modify the contents of `mysqld-auto.cnf`, use the `SET PERSIST`, `SET PERSIST_ONLY`, and `RESET PERSIST` statements. See [Section 7.1.9.3, “Persisted System Variables”](#).

- `persist_only_admin_x509_subject`

Command-Line Format	<code>--persist-only-admin-x509-subject=string</code>
System Variable	<code>persist_only_admin_x509_subject</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value	empty string

`SET PERSIST` and `SET PERSIST_ONLY` enable system variables to be persisted to the `mysqld-auto.cnf` option file in the data directory (see [Section 15.7.6.1, “SET Syntax for Variable Assignment”](#)). Persisting system variables enables runtime configuration changes that affect subsequent server restarts, which is convenient for remote administration not requiring direct access to MySQL server host option files. However, some system variables are nonpersistible or can be persisted only under certain restrictive conditions.

The `persist_only_admin_x509_subject` system variable specifies the SSL certificate X.509 Subject value that users must have to be able to persist system variables that are persist-restricted. The default value is the empty string, which disables the Subject check so that persist-restricted system variables cannot be persisted by any user.

If `persist_only_admin_x509_subject` is nonempty, users who connect to the server using an encrypted connection and supply an SSL certificate with the designated Subject value then can use `SET PERSIST_ONLY` to persist persist-restricted system variables. For information about persist-restricted system variables and instructions for configuring MySQL to enable `persist_only_admin_x509_subject`, see [Section 7.1.9.4, “Nonpersistible and Persist-Restricted System Variables”](#).

- `persist_sensitive_variables_in_plaintext`

Command-Line Format	<code>--persist_sensitive_variables_in_plaintext[={OFF ON}]</code>
System Variable	<code>persist_sensitive_variables_in_plaintext</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Boolean

Default Value	ON
---------------	----

`persist_sensitive_variables_in_plaintext` controls whether the server is permitted to store the values of sensitive system variables in an unencrypted format, if keyring component support is not available at the time when `SET PERSIST` is used to set the value of the system variable. It also controls whether or not the server can start if the encrypted values cannot be decrypted. Note that keyring plugins do not support secure storage of sensitive system variables; a keyring component (see [Section 8.4.4, “The MySQL Keyring”](#)) must be enabled on the MySQL Server instance to support secure storage.

The default setting, `ON`, encrypts the values if keyring component support is available, and persists them unencrypted (with a warning) if it is not. The next time any persisted system variable is set, if keyring support is available at that time, the server encrypts the values of any unencrypted sensitive system variables. The `ON` setting also allows the server to start if encrypted system variable values cannot be decrypted, in which case a warning is issued and the default values for the system variables are used. In that situation, their values cannot be changed until they can be decrypted.

The most secure setting, `OFF`, means sensitive system variable values cannot be persisted if keyring component support is unavailable. The `OFF` setting also means the server does not start if encrypted system variable values cannot be decrypted.

For more information, see [Persisting Sensitive System Variables](#).

- `pid_file`

Command-Line Format	<code>--pid-file=file_name</code>
System Variable	<code>pid_file</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	File name

The path name of the file in which the server writes its process ID. The server creates the file in the data directory unless an absolute path name is given to specify a different directory. If you specify this variable, you must specify a value. If you do not specify this variable, MySQL uses a default value of `host_name.pid`, where `host_name` is the name of the host machine.

The process ID file is used by other programs such as `mysqld_safe` to determine the server's process ID. On Windows, this variable also affects the default error log file name. See [Section 7.4.2, “The Error Log”](#).

- `plugin_dir`

Command-Line Format	<code>--plugin-dir=dir_name</code>
System Variable	<code>plugin_dir</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Directory name

Default Value	<code>BASEDIR/lib/plugin</code>
---------------	---------------------------------

The path name of the plugin directory.

If the plugin directory is writable by the server, it may be possible for a user to write executable code to a file in the directory using `SELECT ... INTO DUMPFILE`. This can be prevented by making `plugin_dir` read only to the server or by setting `secure_file_priv` to a directory where `SELECT` writes can be made safely.

- `port`

Command-Line Format	<code>--port=port_num</code>
System Variable	<code>port</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	3306
Minimum Value	0
Maximum Value	65535

The number of the port on which the server listens for TCP/IP connections. This variable can be set with the `--port` option.

- `preload_buffer_size`

Command-Line Format	<code>--preload-buffer-size=#</code>
System Variable	<code>preload_buffer_size</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	32768
Minimum Value	1024
Maximum Value	1073741824
Unit	bytes

The size of the buffer that is allocated when preloading indexes.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 7.1.9.1, “System Variable Privileges”](#).

- `print_identified_with_as_hex`

Command-Line Format	<code>--print-identified-with-as-hex[={OFF ON}]</code>
System Variable	<code>print_identified_with_as_hex</code>

Scope	Global, Session
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Password hash values displayed in the `IDENTIFIED WITH` clause of output from `SHOW CREATE USER` may contain unprintable characters that have adverse effects on terminal displays and in other environments. Enabling `print_identified_with_as_hex` causes `SHOW CREATE USER` to display such hash values as hexadecimal strings rather than as regular string literals. Hash values that do not contain unprintable characters still display as regular string literals, even with this variable enabled.

- `profiling`

If set to 0 or `OFF` (the default), statement profiling is disabled. If set to 1 or `ON`, statement profiling is enabled and the `SHOW PROFILE` and `SHOW PROFILES` statements provide access to profiling information. See [Section 15.7.7.32, “SHOW PROFILES Statement”](#).

This variable is deprecated; expect it to be removed in a future MySQL release.

- `profiling_history_size`

The number of statements for which to maintain profiling information if `profiling` is enabled. The default value is 15. The maximum value is 100. Setting the value to 0 effectively disables profiling. See [Section 15.7.7.32, “SHOW PROFILES Statement”](#).

This variable is deprecated; expect it to be removed in a future MySQL release.

- `protocol_compression_algorithms`

Command-Line Format	<code>--protocol-compression-algorithms=value</code>
System Variable	<code>protocol_compression_algorithms</code>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Set
Default Value	<code>zlib,zstd,uncompressed</code>
Valid Values	<code>zlib</code>  <code>zstd</code>

	<code>uncompressed</code>
--	---------------------------

The compression algorithms that the server permits for incoming connections. These include connections by client programs and by servers participating in source/replica replication or Group Replication. Compression does not apply to connections for `FEDERATED` tables.

`protocol_compression_algorithms` does not control connection compression for X Protocol. See [Section 22.5.5, “Connection Compression with X Plugin”](#) for information on how this operates.

The variable value is a list of one or more comma-separated compression algorithm names, in any order, chosen from the following items (not case-sensitive):

- `zlib`: Permit connections that use the `zlib` compression algorithm.
- `zstd`: Permit connections that use the `zstd` compression algorithm.
- `uncompressed`: Permit uncompressed connections. If this algorithm name is not included in the `protocol_compression_algorithms` value, the server does not permit uncompressed connections. It permits only compressed connections that use whichever other algorithms are specified in the value, and there is no fallback to uncompressed connections.

The default value of `zlib`, `zstd`, `uncompressed` indicates that the server permits all compression algorithms.

For more information, see [Section 6.2.8, “Connection Compression Control”](#).

- `protocol_version`

System Variable	<code>protocol_version</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	10
Minimum Value	0
Maximum Value	4294967295

The version of the client/server protocol used by the MySQL server.

- `proxy_user`

System Variable	<code>proxy_user</code>
Scope	Session
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	String

If the current client is a proxy for another user, this variable is the proxy user account name. Otherwise, this variable is `NULL`. See [Section 8.2.19, “Proxy Users”](#).

- `pseudo_replica_mode`

System Variable	<code>pseudo_replica_mode</code>
Scope	Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean

`pseudo_replica_mode` is for internal server use. It assists with the correct handling of transactions that originated on older or newer servers than the server currently processing them. `mysqlbinlog` sets the value of `pseudo_replica_mode` to true before executing any SQL statements.

Setting the session value of `pseudo_replica_mode` is a restricted operation. The session user must have either the `REPLICATION_APPLIER` privilege (see [Section 19.3.3, “Replication Privilege Checks”](#)), or privileges sufficient to set restricted session variables (see [Section 7.1.9.1, “System Variable Privileges”](#)). However, note that the variable is not intended for users to set; it is set automatically by the replication infrastructure.

`pseudo_replica_mode` has the following effects on the handling of prepared XA transactions, which can be attached to or detached from the handling session (by default, the session that issues `XA START`):

- If true, and the handling session has executed an internal-use `BINLOG` statement, XA transactions are automatically detached from the session as soon as the first part of the transaction up to `XA PREPARE` finishes, so they can be committed or rolled back by any session that has the `XA_RECOVER_ADMIN` privilege.
- If false, XA transactions remain attached to the handling session as long as that session is alive, during which time no other session can commit the transaction. The prepared transaction is only detached if the session disconnects or the server restarts.

`pseudo_replica_mode` has the following effects on the `original_commit_timestamp` replication delay timestamp and the `original_server_version` system variable:

- If true, transactions that do not explicitly set `original_commit_timestamp` or `original_server_version` are assumed to originate on another, unknown server, so the value 0, meaning unknown, is assigned to both the timestamp and the system variable.
- If false, transactions that do not explicitly set `original_commit_timestamp` or `original_server_version` are assumed to originate on the current server, so the current timestamp and the current server's version are assigned to the timestamp and the system variable.

`pseudo_replica_mode` has the following effects on the handling of a statement that sets one or more unsupported (removed or unknown) SQL modes:

- If true, the server ignores the unsupported mode and raises a warning.
- If false, the server rejects the statement with `ER_UNSUPPORTED_SQL_MODE`.
- `pseudo_slave_mode`

Deprecated	Yes
System Variable	<code>pseudo_slave_mode</code>
Scope	Session

Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Boolean

Deprecated alias for [pseudo\\_replica\\_mode](#).

- [pseudo\\_thread\\_id](#)

System Variable	<a href="#">pseudo_thread_id</a>
Scope	Session
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	<a href="#">2147483647</a>
Minimum Value	0
Maximum Value	<a href="#">2147483647</a>

This variable is for internal server use.

#### Warning

Changing the session value of the [pseudo\\_thread\\_id](#) system variable changes the value returned by the [CONNECTION\\_ID\(\)](#) function.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 7.1.9.1, “System Variable Privileges”](#).

- [query\\_alloc\\_block\\_size](#)

Command-Line Format	<a href="#">--query-alloc-block-size=#</a>
System Variable	<a href="#">query_alloc_block_size</a>
Scope	Global, Session
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	<a href="#">8192</a>
Minimum Value	<a href="#">1024</a>
Maximum Value	<a href="#">4294966272</a>
Unit	bytes
<a href="#">Block Size</a>	<a href="#">1024</a>

The allocation size in bytes of memory blocks that are allocated for objects created during statement parsing and execution. If you have problems with memory fragmentation, it might help to increase this parameter.

The block size for the byte number is 1024. A value that is not an exact multiple of the block size is rounded down to the next lower multiple of the block size by MySQL Server before storing the value for

the system variable. The parser allows values up to the maximum unsigned integer value for the platform (4294967295 or  $2^{32}-1$  for a 32-bit system, 18446744073709551615 or  $2^{64}-1$  for a 64-bit system) but the actual maximum is a block size lower.

- `query_prealloc_size`

Command-Line Format	<code>--query-prealloc-size=#</code>
Deprecated	Yes
System Variable	<code>query_prealloc_size</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	8192
Minimum Value	8192
Maximum Value (64-bit platforms)	18446744073709550592
Maximum Value (32-bit platforms)	4294966272
Unit	bytes
Block Size	1024

`query_prealloc_size` is deprecated, and setting it has no effect; you should expect its removal in a future release of MySQL.

- `rand_seed1`

System Variable	<code>rand_seed1</code>
Scope	Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	N/A
Minimum Value	0
Maximum Value	4294967295

The `rand_seed1` and `rand_seed2` variables exist as session variables only, and can be set but not read. The variables—but not their values—are shown in the output of `SHOW VARIABLES`.

The purpose of these variables is to support replication of the `RAND( )` function. For statements that invoke `RAND( )`, the source passes two values to the replica, where they are used to seed the random number generator. The replica uses these values to set the session variables `rand_seed1` and `rand_seed2` so that `RAND( )` on the replica generates the same value as on the source.

- `rand_seed2`

See the description for `rand_seed1`.

- `range_alloc_block_size`

Command-Line Format	<code>--range-alloc-block-size=#</code>
System Variable	<code>range_alloc_block_size</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Integer
Default Value	4096
Minimum Value	4096
Maximum Value (64-bit platforms)	18446744073709550592
Maximum Value	4294966272
Unit	bytes
Block Size	1024

The size in bytes of blocks that are allocated when doing range optimization.

The block size for the byte number is 1024. A value that is not an exact multiple of the block size is rounded down to the next lower multiple of the block size by MySQL Server before storing the value for the system variable. The parser allows values up to the maximum unsigned integer value for the platform (4294967295 or  $2^{32}-1$  for a 32-bit system, 18446744073709551615 or  $2^{64}-1$  for a 64-bit system) but the actual maximum is a block size lower.

- `range_optimizer_max_mem_size`

Command-Line Format	<code>--range-optimizer-max-mem-size=#</code>
System Variable	<code>range_optimizer_max_mem_size</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Integer
Default Value	8388608
Minimum Value	0
Maximum Value	18446744073709551615
Unit	bytes

The limit on memory consumption for the range optimizer. A value of 0 means “no limit.” If an execution plan considered by the optimizer uses the range access method but the optimizer estimates that the amount of memory needed for this method would exceed the limit, it abandons the plan and considers other plans. For more information, see [Limiting Memory Use for Range Optimization](#).

- `rbr_exec_mode`

System Variable	<code>rbr_exec_mode</code>
Scope	Session
Dynamic	Yes

<a href="#">SET_VAR</a> Hint Applies	No
Type	Enumeration
Default Value	<a href="#">STRICT</a>
Valid Values	<a href="#">STRICT</a> <a href="#">IDEMPOTENT</a>

For internal use by [mysqlbinlog](#). This variable switches the server between [IDEMPOTENT](#) mode and [STRICT](#) mode. [IDEMPOTENT](#) mode causes suppression of duplicate-key and no-key-found errors in [BINLOG](#) statements generated by [mysqlbinlog](#). This mode is useful when replaying a row-based binary log on a server that causes conflicts with existing data. [mysqlbinlog](#) sets this mode when you specify the `--idempotent` option by writing the following to the output:

```
SET SESSION RBR_EXEC_MODE=IDEMPOTENT;
```

- [read\\_buffer\\_size](#)

Command-Line Format	<code>--read-buffer-size=#</code>
System Variable	<a href="#">read_buffer_size</a>
Scope	Global, Session
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	Yes
Type	Integer
Default Value	<a href="#">131072</a>
Minimum Value	<a href="#">8192</a>
Maximum Value	<a href="#">2147479552</a>
Unit	bytes
<a href="#">Block Size</a>	<a href="#">4096</a>

Each thread that does a sequential scan for a [MyISAM](#) table allocates a buffer of this size (in bytes) for each table it scans. If you do many sequential scans, you might want to increase this value, which defaults to 131072. The value of this variable should be a multiple of 4KB. If it is set to a value that is not a multiple of 4KB, its value is rounded down to the nearest multiple of 4KB.

This option is also used in the following context for all other storage engines with the exception of [InnoDB](#):

- For caching the indexes in a temporary file (not a temporary table), when sorting rows for [ORDER BY](#).
- For bulk insert into partitions.

- For caching results of nested queries.

`read_buffer_size` is also used in one other storage engine-specific way: to determine the memory block size for `MEMORY` tables.

`select_into_buffer_size` is used for the I/O cache buffer for `SELECT INTO DUMPFILE` and `SELECT INTO OUTFILE` statements. (`read_buffer_size` is used for the I/O cache buffer size in all other cases.)

For more information about memory use during different operations, see [Section 10.12.3.1, “How MySQL Uses Memory”](#).

- `read_only`

Command-Line Format	<code>--read-only[={OFF ON} ]</code>
System Variable	<code>read_only</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

If the `read_only` system variable is enabled, the server permits no client updates except from users who have the `CONNECTION_ADMIN` privilege (or the deprecated `SUPER` privilege). This variable is disabled by default.

The server also supports a `super_read_only` system variable (disabled by default), which has these effects:

- If `super_read_only` is enabled, the server prohibits client updates, even from users who have the `CONNECTION_ADMIN` or `SUPER` privilege.
- Setting `super_read_only` to `ON` implicitly forces `read_only` to `ON`.
- Setting `read_only` to `OFF` implicitly forces `super_read_only` to `OFF`.

When `read_only` is enabled and when `super_read_only` is enabled, the server still permits these operations:

- Updates performed by replication threads, if the server is a replica. In replication setups, it can be useful to enable `read_only` on replica servers to ensure that replicas accept updates only from the source server and not from clients.
- Writes to the system table `mysql.gtid_executed`, which stores GTIDs for executed transactions that are not present in the current binary log file.
- Use of `ANALYZE TABLE` or `OPTIMIZE TABLE` statements. The purpose of read-only mode is to prevent changes to table structure or contents. Analysis and optimization do not qualify as such changes. This means, for example, that consistency checks on read-only replicas can be performed with `mysqlcheck --all-databases --analyze`.
- Use of `FLUSH STATUS` statements, which are always written to the binary log.

- Operations on `TEMPORARY` tables.
- Inserts into the log tables (`mysql.general_log` and `mysql.slow_log`); see [Section 7.4.1, “Selecting General Query Log and Slow Query Log Output Destinations”](#).
- Updates to Performance Schema tables, such as `UPDATE` or `TRUNCATE TABLE` operations.

Changes to `read_only` on a replication source server are not replicated to replica servers. The value can be set on a replica independent of the setting on the source.

The following conditions apply to attempts to enable `read_only` (including implicit attempts resulting from enabling `super_read_only`):

- The attempt fails and an error occurs if you have any explicit locks (acquired with `LOCK TABLES`) or have a pending transaction.
  - The attempt blocks while other clients have any ongoing statement, active `LOCK TABLES WRITE`, or ongoing commit, until the locks are released and the statements and transactions end. While the attempt to enable `read_only` is pending, requests by other clients for table locks or to begin transactions also block until `read_only` has been set.
  - The attempt blocks if there are active transactions that hold metadata locks, until those transactions end.
  - `read_only` can be enabled while you hold a global read lock (acquired with `FLUSH TABLES WITH READ LOCK`) because that does not involve table locks.
- `read_rnd_buffer_size`

Command-Line Format	<code>--read-rnd-buffer-size=#</code>
System Variable	<code>read_rnd_buffer_size</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Integer
Default Value	262144
Minimum Value	1
Maximum Value	2147483647
Unit	bytes

This variable is used for reads from `MyISAM` tables, and, for any storage engine, for Multi-Range Read optimization.

When reading rows from a `MyISAM` table in sorted order following a key-sorting operation, the rows are read through this buffer to avoid disk seeks. See [Section 10.2.1.16, “ORDER BY Optimization”](#). Setting the variable to a large value can improve `ORDER BY` performance by a lot. However, this is a buffer

allocated for each client, so you should not set the global variable to a large value. Instead, change the session variable only from within those clients that need to run large queries.

For more information about memory use during different operations, see [Section 10.12.3.1, “How MySQL Uses Memory”](#). For information about Multi-Range Read optimization, see [Section 10.2.1.11, “Multi-Range Read Optimization”](#).

- `regexp_stack_limit`

Command-Line Format	<code>--regexp-stack-limit=#</code>
System Variable	<code>regexp_stack_limit</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	8000000
Minimum Value	0
Maximum Value	2147483647
Unit	bytes

The maximum available memory in bytes for the internal stack used for regular expression matching operations performed by `REGEXP_LIKE()` and similar functions (see [Section 14.8.2, “Regular Expressions”](#)).

- `regexp_time_limit`

Command-Line Format	<code>--regexp-time-limit=#</code>
System Variable	<code>regexp_time_limit</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	32
Minimum Value	0
Maximum Value	2147483647

The time limit for regular expression matching operations performed by `REGEXP_LIKE()` and similar functions (see [Section 14.8.2, “Regular Expressions”](#)). This limit is expressed as the maximum permitted number of steps performed by the match engine, and thus affects execution time only indirectly. Typically, it is on the order of milliseconds.

- `require_row_format`

System Variable	<code>require_row_format</code>
Scope	Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No

Type	Boolean
Default Value	OFF

This variable is for internal server use by replication and `mysqlbinlog`. It restricts DML events executed in the session to events encoded in row-based binary logging format only, and temporary tables cannot be created. Queries that do not respect the restrictions fail.

Setting the session value of this system variable to `ON` requires no privileges. Setting the session value of this system variable to `OFF` is a restricted operation, and the session user must have privileges sufficient to set restricted session variables. See [Section 7.1.9.1, “System Variable Privileges”](#).

- `require_secure_transport`

Command-Line Format	<code>--require-secure-transport[={OFF ON}]</code>
System Variable	<code>require_secure_transport</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Whether client connections to the server are required to use some form of secure transport. When this variable is enabled, the server permits only TCP/IP connections encrypted using TLS/SSL, or connections that use a socket file (on Unix) or shared memory (on Windows). The server rejects nonsecure connection attempts, which fail with an `ER_SECURE_TRANSPORT_REQUIRED` error.

This capability supplements per-account SSL requirements, which take precedence. For example, if an account is defined with `REQUIRE SSL`, enabling `require_secure_transport` does not make it possible to use the account to connect using a Unix socket file.

It is possible for a server to have no secure transports available. For example, a server on Windows supports no secure transports if started without specifying any SSL certificate or key files and with the `shared_memory` system variable disabled. Under these conditions, attempts to enable `require_secure_transport` at startup cause the server to write a message to the error log and exit. Attempts to enable the variable at runtime fail with an `ER_NO_SECURE_TRANSPORTS_CONFIGURED` error.

See also [Configuring Encrypted Connections as Mandatory](#).

- `restrict_fk_on_non_standard_key`

Command-Line Format	<code>--restrict-fk-on-non-standard-key</code>
Deprecated	Yes
System Variable	<code>restrict_fk_on_non_standard_key</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean

Default Value	ON
---------------	----

This variable, when [ON](#) (the default), prevents the use of non-unique keys or partial keys as foreign keys. To allow such keys to be used as foreign keys in the current session, use [SET @@session.restrict\\_fk\\_on\\_non\\_standard\\_key=OFF](#); to allow them to be used globally, set the global variable or start the server with [--skip-restrict-fk-on-non-standard-key](#).

Using non-unique or partial keys as foreign keys in a [CREATE TABLE](#) or [ALTER TABLE](#) statement is deprecated, and you should expect support for it to be removed in a future version of MySQL. When [restrict\\_fk\\_on\\_non\\_standard\\_key](#) is [ON](#), attempts to do so are rejected with [ER\\_FK\\_NO\\_INDEX\\_PARENT](#); when it is [OFF](#), this usage is permitted but still raises [ER\\_WARN\\_DEPRECATED\\_NON\\_STANDARD\\_KEY](#) as a warning.

[restrict\\_fk\\_on\\_non\\_standard\\_key](#) is deprecated, and subject to removal in a future version of MySQL. Setting it raises a deprecation warning.

**Implication for MySQL Replication.** When a foreign key is created on a nonstandard key on the primary because [restrict\\_fk\\_on\\_non\\_standard\\_key](#) is [OFF](#), the statement succeeds on the replica regardless of any setting on the replica for this variable.

- [resultset\\_metadata](#)

System Variable	<a href="#">resultset_metadata</a>
Scope	Session
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Enumeration
Default Value	<a href="#">FULL</a>
Valid Values	<a href="#">FULL</a> <a href="#">NONE</a>

For connections for which metadata transfer is optional, the client sets the [resultset\\_metadata](#) system variable to control whether the server returns result set metadata. Permitted values are [FULL](#) (return all metadata; this is the default) and [NONE](#) (return no metadata).

For connections that are not metadata-optional, setting [resultset\\_metadata](#) to [NONE](#) produces an error.

For details about managing result set metadata transfer, see [Optional Result Set Metadata](#).

- [secondary\\_engine\\_cost\\_threshold](#)

System Variable	<a href="#">secondary_engine_cost_threshold</a>
Scope	Session
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	Yes
Type	Numeric
Default Value	<a href="#">100000.000000</a>
Minimum Value	<a href="#">0</a>

Maximum Value	DBL_MAX (maximum double value)
---------------	--------------------------------

The optimizer cost threshold for query offload to a secondary engine.

For use with HeatWave. See [HeatWave User Guide](#).

- `schema_definition_cache`

Command-Line Format	<code>--schema-definition-cache=#</code>
System Variable	<code>schema_definition_cache</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	256
Minimum Value	256
Maximum Value	524288

Defines a limit for the number of schema definition objects, both used and unused, that can be kept in the dictionary object cache.

Unused schema definition objects are only kept in the dictionary object cache when the number in use is less than the capacity defined by `schema_definition_cache`.

A setting of 0 means that schema definition objects are only kept in the dictionary object cache while they are in use.

For more information, see [Section 16.4, “Dictionary Object Cache”](#).

- `secure_file_priv`

Command-Line Format	<code>--secure-file-priv=dir_name</code>
System Variable	<code>secure_file_priv</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	String
Default Value	<code>platform specific</code>
Valid Values	<code>empty string</code> <code>dirname</code>

	NULL
--	------

This variable is used to limit the effect of data import and export operations, such as those performed by the `LOAD DATA` and `SELECT ... INTO OUTFILE` statements and the `LOAD_FILE()` function. These operations are permitted only to users who have the `FILE` privilege.

`secure_file_priv` may be set as follows:

- If empty, the variable has no effect. This is not a secure setting.
- If set to the name of a directory, the server limits import and export operations to work only with files in that directory. The directory must exist; the server does not create it.
- If set to `NULL`, the server disables import and export operations.

The default value is platform specific and depends on the value of the `INSTALL_LAYOUT` CMake option, as shown in the following table. To specify the default `secure_file_priv` value explicitly if you are building from source, use the `INSTALL_SECURE_FILE_PRIVDIR` CMake option.

INSTALL_LAYOUT Value	Default <code>secure_file_priv</code> Value
STANDALONE	empty
DEB, RPM, SVR4	/var/lib/mysql-files
Otherwise	mysql-files under the CMAKE_INSTALL_PREFIX value

The server checks the value of `secure_file_priv` at startup and writes a warning to the error log if the value is insecure. A non-`NULL` value is considered insecure if it is empty, or the value is the data directory or a subdirectory of it, or a directory that is accessible by all users. If `secure_file_priv` is set to a nonexistent path, the server writes an error message to the error log and exits.

- `select_into_buffer_size`

Command-Line Format	<code>--select-into-buffer-size=#</code>
System Variable	<code>select_into_buffer_size</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	Yes
Type	Integer
Default Value	131072
Minimum Value	8192
Maximum Value	2147479552
Unit	bytes
Block Size	4096

When using `SELECT INTO OUTFILE` or `SELECT INTO DUMPFILE` to dump data into one or more files for backup creation, data migration, or other purposes, writes can often be buffered and then trigger a large burst of write I/O activity to the disk or other storage device and stall other queries that are more sensitive to latency. You can use this variable to control the size of the buffer used to write data to the

storage device to determine when buffer synchronization should occur, and thus to prevent write stalls of the kind just described from occurring.

`select_into_buffer_size` overrides any value set for `read_buffer_size`. (`select_into_buffer_size` and `read_buffer_size` have the same default, maximum, and minimum values.) You can also use `select_into_disk_sync_delay` to set a timeout to be observed afterwards, each time synchronization takes place.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 7.1.9.1, “System Variable Privileges”](#).

- `select_into_disk_sync`

Command-Line Format	<code>--select-into-disk-sync={ON OFF}</code>
System Variable	<code>select_into_disk_sync</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Boolean
Default Value	<code>OFF</code>
Valid Values	<code>OFF</code> <code>ON</code>

When set on `ON`, enables buffer synchronization of writes to an output file by a long-running `SELECT INTO OUTFILE` or `SELECT INTO DUMPFILE` statement using `select_into_buffer_size`.

- `select_into_disk_sync_delay`

Command-Line Format	<code>--select-into-disk-sync-delay=#</code>
System Variable	<code>select_into_disk_sync_delay</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	31536000
Unit	milliseconds

When buffer synchronization of writes to an output file by a long-running `SELECT INTO OUTFILE` or `SELECT INTO DUMPFILE` statement is enabled by `select_into_disk_sync`, this variable sets an optional delay (in milliseconds) following synchronization. 0 (the default) means no delay.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 7.1.9.1, “System Variable Privileges”](#).

- `session_track_gtids`

Command-Line Format	<code>--session-track-gtids=value</code>
System Variable	<code>session_track_gtids</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Enumeration
Default Value	<code>OFF</code>
Valid Values	<code>OFF</code>  <code>OWN_GTID</code>  <code>ALL_GTIDS</code>

Controls whether the server returns GTIDs to the client, enabling the client to use them to track the server state. Depending on the variable value, at the end of executing each transaction, the server's GTIDs are captured and returned to the client as part of the acknowledgement. The possible values for `session_track_gtids` are as follows:

- `OFF`: The server does not return GTIDs to the client. This is the default.
- `OWN_GTID`: The server returns the GTIDs for all transactions that were successfully committed by this client in its current session since the last acknowledgement. Typically, this is the single GTID for the last transaction committed, but if a single client request resulted in multiple transactions, the server returns a GTID set containing all the relevant GTIDs.
- `ALL_GTIDS`: The server returns the global value of its `gtid_executed` system variable, which it reads at a point after the transaction is successfully committed. As well as the GTID for the transaction just committed, this GTID set includes all transactions committed on the server by any client, and can include transactions committed after the point when the transaction currently being acknowledged was committed.

`session_track_gtids` cannot be set within transactional context.

For more information about session state tracking, see [Section 7.1.18, “Server Tracking of Client Session State”](#).

- `session_track_schema`

Command-Line Format	<code>--session-track-schema[={OFF ON} ]</code>
System Variable	<code>session_track_schema</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean

Default Value	ON
---------------	----

Controls whether the server tracks when the default schema (database) is set within the current session and notifies the client to make the schema name available.

If the schema name tracker is enabled, name notification occurs each time the default schema is set, even if the new schema name is the same as the old.

For more information about session state tracking, see [Section 7.1.18, “Server Tracking of Client Session State”](#).

- `session_track_state_change`

Command-Line Format	<code>--session-track-state-change[={OFF ON}]</code>
System Variable	<code>session_track_state_change</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	OFF

Controls whether the server tracks changes to the state of the current session and notifies the client when state changes occur. Changes can be reported for these attributes of client session state:

- The default schema (database).
- Session-specific values for system variables.
- User-defined variables.
- Temporary tables.
- Prepared statements.

If the session state tracker is enabled, notification occurs for each change that involves tracked session attributes, even if the new attribute values are the same as the old. For example, setting a user-defined variable to its current value results in a notification.

The `session_track_state_change` variable controls only notification of when changes occur, not what the changes are. For example, state-change notifications occur when the default schema is set or tracked session system variables are assigned, but the notification does not include the schema name or variable values. To receive notification of the schema name or session system variable values, use the `session_track_schema` or `session_track_system_variables` system variable, respectively.

#### Note

Assigning a value to `session_track_state_change` itself is not considered a state change and is not reported as such. However, if its name listed in the value

of `session_track_system_variables`, any assignments to it do result in notification of the new value.

For more information about session state tracking, see [Section 7.1.18, “Server Tracking of Client Session State”](#).

- `session_track_system_variables`

Command-Line Format	<code>--session-track-system-variables=#</code>
System Variable	<code>session_track_system_variables</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value	<code>time_zone, autocommit, character_set_client, character_set_results, character_set_connection</code>

Controls whether the server tracks assignments to session system variables and notifies the client of the name and value of each assigned variable. The variable value is a comma-separated list of variables for which to track assignments. By default, notification is enabled for `time_zone`, `autocommit`, `character_set_client`, `character_set_results`, and `character_set_connection`. (The latter three variables are those affected by `SET NAMES`.)

To enable display of the Statement ID for each statement processed, use the `statement_id` variable. For example:

```
mysql> SET @@SESSION.session_track_system_variables='statement_id'
mysql> SELECT 1;
+----+
| 1 |
+----+
| 1 |
+----+
1 row in set (0.0006 sec)
Statement ID: 603835
```

The special value `*` (asterisk) causes the server to track assignments to all session variables. If given, this value must be specified by itself without specific system variable names. This value also enables display of the Statement ID for each successful statement processed.

To disable notification of session variable assignments, set `session_track_system_variables` to the empty string.

If session system variable tracking is enabled, notification occurs for all assignments to tracked session variables, even if the new values are the same as the old.

For more information about session state tracking, see [Section 7.1.18, “Server Tracking of Client Session State”](#).

- `session_track_transaction_info`

Command-Line Format	<code>--session-track-transaction-info=value</code>
System Variable	<code>session_track_transaction_info</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Enumeration
Default Value	<code>OFF</code>
Valid Values	<code>OFF</code>  <code>STATE</code>  <code>CHARACTERISTICS</code>

Controls whether the server tracks the state and characteristics of transactions within the current session and notifies the client to make this information available. These `session_track_transaction_info` values are permitted:

- `OFF`: Disable transaction state tracking. This is the default.
- `STATE`: Enable transaction state tracking without characteristics tracking. State tracking enables the client to determine whether a transaction is in progress and whether it could be moved to a different session without being rolled back.
- `CHARACTERISTICS`: Enable transaction state tracking, including characteristics tracking. Characteristics tracking enables the client to determine how to restart a transaction in another session so that it has the same characteristics as in the original session. The following characteristics are relevant for this purpose:

```
ISOLATION LEVEL
READ ONLY
READ WRITE
WITH CONSISTENT SNAPSHOT
```

For a client to safely relocate a transaction to another session, it must track not only transaction state but also transaction characteristics. In addition, the client must track the `transaction_isolation` and `transaction_read_only` system variables to correctly determine the session defaults. (To track these variables, list them in the value of the `session_track_system_variables` system variable.)

For more information about session state tracking, see [Section 7.1.18, “Server Tracking of Client Session State”](#).

- `set_operations_buffer_size`

Command-Line Format	<code>--set-operations-buffer-size=#</code>
System Variable	<code>set_operations_buffer_size</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No

Type	Integer
Default Value	256K
Minimum Value	16K
Maximum Value	1 GB

Sets the buffer size for [INTERSECT](#) and [EXCEPT](#) operations that use hash tables when the [hash\\_set\\_operations](#) optimizer switch is [ON](#). In general, increasing the size of this buffer improves performance of these operations when the hashing optimization is enabled.

- [sha256\\_password\\_auto\\_generate\\_rsa\\_keys](#)

Command-Line Format	<code>--sha256-password-auto-generate-rsa-keys[={OFF ON}]</code>
Deprecated	Yes
System Variable	<a href="#">sha256_password_auto_generate_rsa_keys</a>
Scope	Global
Dynamic	No
<a href="#">SET_VAR</a> Hint Applies	No
Type	Boolean
Default Value	<a href="#">ON</a>

The server uses this variable to determine whether to autogenerate RSA private/public key-pair files in the data directory if they do not already exist.

At startup, the server automatically generates RSA private/public key-pair files in the data directory if all of these conditions are true: The [sha256\\_password\\_auto\\_generate\\_rsa\\_keys](#) or [caching\\_sha2\\_password\\_auto\\_generate\\_rsa\\_keys](#) system variable is enabled; no RSA options are specified; the RSA files are missing from the data directory. These key-pair files enable secure password exchange using RSA over unencrypted connections for accounts authenticated by the [sha256\\_password](#) (deprecated) or [caching\\_sha2\\_password](#) plugin; see [Section 8.4.1.2, “SHA-256 Pluggable Authentication”](#), and [Section 8.4.1.1, “Caching SHA-2 Pluggable Authentication”](#).

For more information about RSA file autogeneration, including file names and characteristics, see [Section 8.3.3.1, “Creating SSL and RSA Certificates and Keys using MySQL”](#)

The [auto\\_generate\\_certs](#) system variable is related but controls autogeneration of SSL certificate and key files needed for secure connections using SSL.

- [sha256\\_password\\_private\\_key\\_path](#)

Command-Line Format	<code>--sha256-password-private-key-path=file_name</code>
Deprecated	Yes
System Variable	<a href="#">sha256_password_private_key_path</a>
Scope	Global
Dynamic	No
<a href="#">SET_VAR</a> Hint Applies	No
Type	File name

Default Value	<code>private_key.pem</code>
---------------	------------------------------

The value of this variable is the path name of the RSA private key file for the `sha256_password` (deprecated) authentication plugin. If the file is named as a relative path, it is interpreted relative to the server data directory. The file must be in PEM format.

### Important

Because this file stores a private key, its access mode should be restricted so that only the MySQL server can read it.

For information about `sha256_password`, see [Section 8.4.1.2, “SHA-256 Pluggable Authentication”](#).

- `sha256_password_proxy_users`

Command-Line Format	<code>--sha256-password-proxy-users[={OFF ON}]</code>
Deprecated	Yes
System Variable	<code>sha256_password_proxy_users</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

This variable controls whether the `sha256_password` (deprecated) built-in authentication plugin supports proxy users. It has no effect unless the `check_proxy_users` system variable is enabled. For information about user proxying, see [Section 8.2.19, “Proxy Users”](#).

- `sha256_password_public_key_path`

Command-Line Format	<code>--sha256-password-public-key-path=file_name</code>
Deprecated	Yes
System Variable	<code>sha256_password_public_key_path</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	File name
Default Value	<code>public_key.pem</code>

The value of this variable is the path name of the RSA public key file for the `sha256_password` (deprecated) authentication plugin. If the file is named as a relative path, it is interpreted relative to the server data directory. The file must be in PEM format. Because this file stores a public key, copies can be freely distributed to client users. (Clients that explicitly specify a public key when connecting to the server using RSA password encryption must use the same public key as that used by the server.)

For information about `sha256_password` (deprecated), including information about how clients specify the RSA public key, see [Section 8.4.1.2, “SHA-256 Pluggable Authentication”](#).

- `shared_memory`

Command-Line Format	<code>--shared-memory[={OFF ON}]</code>
System Variable	<code>shared_memory</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Platform Specific	Windows
Type	Boolean
Default Value	<code>OFF</code>

(Windows only.) Whether the server permits shared-memory connections.

- `shared_memory_base_name`

Command-Line Format	<code>--shared-memory-base-name=name</code>
System Variable	<code>shared_memory_base_name</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Platform Specific	Windows
Type	String
Default Value	<code>MYSQL</code>

(Windows only.) The name of shared memory to use for shared-memory connections. This is useful when running multiple MySQL instances on a single physical machine. The default name is `MYSQL`. The name is case-sensitive.

This variable applies only if the server is started with the `shared_memory` system variable enabled to support shared-memory connections.

- `show_create_table_skip_secondary_engine`

Command-Line Format	<code>--show-create-table-skip-secondary-engine[={OFF ON}]</code>
System Variable	<code>show_create_table_skip_secondary_engine</code>
Scope	Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Boolean

Default Value	OFF
---------------	-----

Enabling `show_create_table_skip_secondary_engine` causes the `SECONDARY ENGINE` clause to be excluded from `SHOW CREATE TABLE` output, and from `CREATE TABLE` statements dumped by the `mysqldump` utility.

`mysqldump` provides the `--show-create-skip-secondary-engine` option. When specified, it enables the `show_create_table_skip_secondary_engine` system variable for the duration of the dump operation.

For use with HeatWave. See [HeatWave User Guide](#).

- `show_create_table_verbosity`

Command-Line Format	<code>--show-create-table-verbosity[={OFF ON}]</code>
System Variable	<code>show_create_table_verbosity</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	OFF

`SHOW CREATE TABLE` normally does not show the `ROW_FORMAT` table option if the row format is the default format. Enabling this variable causes `SHOW CREATE TABLE` to display `ROW_FORMAT` regardless of whether it is the default format.

- `show_gipk_in_create_table_and_information_schema`

Command-Line Format	<code>--show-gipk-in-create-table-and-information-schema[={OFF ON}]</code>
System Variable	<code>show_gipk_in_create_table_and_information_schema</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	ON

Whether generated invisible primary keys are visible in the output of `SHOW` statements and in Information Schema tables. When this variable is set to `OFF`, such keys are not shown.

This variable is not replicated.

For more information, see [Section 15.1.20.11, “Generated Invisible Primary Keys”](#).

- `skip_external_locking`

Command-Line Format	<code>--skip-external-locking[={OFF ON}]</code>
System Variable	<code>skip_external_locking</code>

Scope	Global
Dynamic	No
<a href="#">SET_VAR</a> Hint Applies	No
Type	Boolean
Default Value	ON

This is `OFF` if `mysqld` uses external locking (system locking), `ON` if external locking is disabled. This affects only `MyISAM` table access.

This variable is set by the `--external-locking` or `--skip-external-locking` option. External locking is disabled by default.

External locking affects only `MyISAM` table access. For more information, including conditions under which it can and cannot be used, see [Section 10.11.5, “External Locking”](#).

- `skip_name_resolve`

Command-Line Format	<code>--skip-name-resolve[={OFF ON}]</code>
System Variable	<code>skip_name_resolve</code>
Scope	Global
Dynamic	No
<a href="#">SET_VAR</a> Hint Applies	No
Type	Boolean
Default Value	OFF

Whether to resolve host names when checking client connections. If this variable is `OFF`, `mysqld` resolves host names when checking client connections. If it is `ON`, `mysqld` uses only IP numbers; in this case, all `Host` column values in the grant tables must be IP addresses. See [Section 7.1.12.3, “DNS Lookups and the Host Cache”](#).

Depending on the network configuration of your system and the `Host` values for your accounts, clients may need to connect using an explicit `--host` option, such as `--host=127.0.0.1` or `--host>:::1`.

An attempt to connect to the host `127.0.0.1` normally resolves to the `localhost` account. However, this fails if the server is run with `skip_name_resolve` enabled. If you plan to do that, make sure an account exists that can accept a connection. For example, to be able to connect as `root` using `--host=127.0.0.1` or `--host>:::1`, create these accounts:

```
CREATE USER 'root'@'127.0.0.1' IDENTIFIED BY 'root-password';
CREATE USER 'root'@':::1' IDENTIFIED BY 'root-password';
```

- `skip_networking`

Command-Line Format	<code>--skip-networking[={OFF ON}]</code>
System Variable	<code>skip_networking</code>
Scope	Global
Dynamic	No
<a href="#">SET_VAR</a> Hint Applies	No
Type	Boolean

Default Value	OFF
---------------	-----

This variable controls whether the server permits TCP/IP connections. By default, it is disabled (permit TCP connections). If enabled, the server permits only local (non-TCP/IP) connections and all interaction with `mysqld` must be made using named pipes or shared memory (on Windows) or Unix socket files (on Unix). This option is highly recommended for systems where only local clients are permitted. See [Section 7.1.12.3, “DNS Lookups and the Host Cache”](#).

Because starting the server with `--skip-grant-tables` disables authentication checks, the server also disables remote connections in that case by enabling `skip_networking`.

- `skip_show_database`

Command-Line Format	<code>--skip-show-database</code>
System Variable	<code>skip_show_database</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

This prevents people from using the `SHOW DATABASES` statement if they do not have the `SHOW DATABASES` privilege. This can improve security if you have concerns about users being able to see databases belonging to other users. Its effect depends on the `SHOW DATABASES` privilege: If the variable value is `ON`, the `SHOW DATABASES` statement is permitted only to users who have the `SHOW DATABASES` privilege, and the statement displays all database names. If the value is `OFF`, `SHOW DATABASES` is permitted to all users, but displays the names of only those databases for which the user has the `SHOW DATABASES` or other privilege.

#### Caution

Because any static global privilege is considered a privilege for all databases, any static global privilege enables a user to see all database names with `SHOW DATABASES` or by examining the `SCHEMATA` table of `INFORMATION_SCHEMA`, except databases that have been restricted at the database level by partial revokes.

- `slow_launch_time`

Command-Line Format	<code>--slow-launch-time=#</code>
System Variable	<code>slow_launch_time</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	2
Minimum Value	0
Maximum Value	31536000
Unit	seconds

If creating a thread takes longer than this many seconds, the server increments the `Slow_launch_threads` status variable.

- `slow_query_log`

Command-Line Format	<code>--slow-query-log[={OFF ON}]</code>
System Variable	<code>slow_query_log</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Whether the slow query log is enabled. The value can be 0 (or `OFF`) to disable the log or 1 (or `ON`) to enable the log. The destination for log output is controlled by the `log_output` system variable; if that value is `NONE`, no log entries are written even if the log is enabled.

“Slow” is determined by the value of the `long_query_time` variable. See [Section 7.4.5, “The Slow Query Log”](#).

- `slow_query_log_file`

Command-Line Format	<code>--slow-query-log-file=file_name</code>
System Variable	<code>slow_query_log_file</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	File name
Default Value	<code>host_name-slow.log</code>

The name of the slow query log file. The default value is `host_name-slow.log`, but the initial value can be changed with the `--slow-query-log-file` option.

- `socket`

Command-Line Format	<code>--socket={file_name pipe_name}</code>
System Variable	<code>socket</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value (Windows)	<code>MySQL</code>
Default Value (Other)	<code>/tmp/mysql.sock</code>

On Unix platforms, this variable is the name of the socket file that is used for local client connections. The default is `/tmp/mysql.sock`. (For some distribution formats, the directory might be different, such as `/var/lib/mysql` for RPMs.)

On Windows, this variable is the name of the named pipe that is used for local client connections. The default value is `MySQL` (not case-sensitive).

- `sort_buffer_size`

Command-Line Format	<code>--sort-buffer-size=#</code>
System Variable	<code>sort_buffer_size</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Integer
Default Value	262144
Minimum Value	32768
Maximum Value (Windows)	4294967295
Maximum Value (Other, 64-bit platforms)	18446744073709551615
Maximum Value (Other, 32-bit platforms)	4294967295
Unit	bytes

Each session that must perform a sort allocates a buffer of this size. `sort_buffer_size` is not specific to any storage engine and applies in a general manner for optimization. At minimum the `sort_buffer_size` value must be large enough to accommodate fifteen tuples in the sort buffer. Also, increasing the value of `max_sort_length` may require increasing the value of `sort_buffer_size`. For more information, see [Section 10.2.1.16, “ORDER BY Optimization”](#)

If you see many `Sort_merge_passes` per second in `SHOW GLOBAL STATUS` output, you can consider increasing the `sort_buffer_size` value to speed up `ORDER BY` or `GROUP BY` operations that cannot be improved with query optimization or improved indexing.

The optimizer tries to work out how much space is needed but can allocate more, up to the limit. Setting it larger than required globally slows down most queries that perform sorts. It is best to increase it as a session setting, and only for the sessions that need a larger size. On Linux, there are thresholds of 256KB and 2MB where larger values may significantly slow down memory allocation, so you should consider staying below one of those values. Experiment to find the best value for your workload. See [Section B.3.3.5, “Where MySQL Stores Temporary Files”](#).

The maximum permissible setting for `sort_buffer_size` is 4GB-1. Larger values are permitted for 64-bit platforms (except 64-bit Windows, for which large values are truncated to 4GB-1 with a warning).

- `sql_auto_is_null`

System Variable	<code>sql_auto_is_null</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Boolean

Default Value	OFF
---------------	-----

If this variable is enabled, then after a statement that successfully inserts an automatically generated `AUTO_INCREMENT` value, you can find that value by issuing a statement of the following form:

```
SELECT * FROM tbl_name WHERE auto_col IS NULL
```

If the statement returns a row, the value returned is the same as if you invoked the `LAST_INSERT_ID()` function. For details, including the return value after a multiple-row insert, see [Section 14.15, “Information Functions”](#). If no `AUTO_INCREMENT` value was successfully inserted, the `SELECT` statement returns no row.

The behavior of retrieving an `AUTO_INCREMENT` value by using an `IS NULL` comparison is used by some ODBC programs, such as Access. See [Obtaining Auto-Increment Values](#). This behavior can be disabled by setting `sql_auto_is_null` to `OFF`.

The default value of `sql_auto_is_null` is `OFF`.

- `sql_big_selects`

System Variable	<code>sql_big_selects</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Boolean
Default Value	ON

If set to `OFF`, MySQL aborts `SELECT` statements that are likely to take a very long time to execute (that is, statements for which the optimizer estimates that the number of examined rows exceeds the value of `max_join_size`). This is useful when an inadvisable `WHERE` statement has been issued. The default value for a new connection is `ON`, which permits all `SELECT` statements.

If you set the `max_join_size` system variable to a value other than `DEFAULT`, `sql_big_selects` is set to `OFF`.

- `sql_buffer_result`

System Variable	<code>sql_buffer_result</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Boolean
Default Value	OFF

If enabled, `sql_buffer_result` forces results from `SELECT` statements to be put into temporary tables. This helps MySQL free the table locks early and can be beneficial in cases where it takes a long time to send results to the client. The default value is `OFF`.

- `sql_generate_invisible_primary_key`

Command-Line Format	<code>--sql-generate-invisible-primary-key[={OFF ON}]</code>
System Variable	<code>sql_generate_invisible_primary_key</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Whether this server adds a generated invisible primary key to any `InnoDB` table that is created without one.

This variable is not replicated. In addition, even if set on the replica, it is ignored by replication applier threads; this means that, by default, a replica does not generate a primary key for any replicated table which, on the source, was created without one. You can cause the replica to generate invisible primary keys for such tables by setting `REQUIRE_TABLE_PRIMARY_KEY_CHECK = GENERATE` as part of a `CHANGE REPLICATION SOURCE TO` statement, optionally specifying a replication channel.

For more information and examples, see [Section 15.1.20.11, “Generated Invisible Primary Keys”](#).

- `sql_log_off`

System Variable	<code>sql_log_off</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>
Valid Values	<code>OFF</code> (enable logging) <code>ON</code> (disable logging)

This variable controls whether logging to the general query log is disabled for the current session (assuming that the general query log itself is enabled). The default value is `OFF` (that is, enable logging). To disable or enable general query logging for the current session, set the session `sql_log_off` variable to `ON` or `OFF`.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 7.1.9.1, “System Variable Privileges”](#).

- `sql_mode`

Command-Line Format	<code>--sql-mode=name</code>
System Variable	<code>sql_mode</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes

Type	Set
Default Value	ONLY_FULL_GROUP_BY STRICT_TRANS_TABLES NO_ZERO_IN_DATE NO_ZERO_DATE ERROR_FOR_DIVISION_BY_ZERO NO_ENGINE_SUBSTITUTION
Valid Values	ALLOW_INVALID_DATES  ANSI_QUOTES  ERROR_FOR_DIVISION_BY_ZERO  HIGH_NOT_PRECEDENCE  IGNORE_SPACE  NO_AUTO_VALUE_ON_ZERO  NO_BACKSLASH_ESCAPES  NO_DIR_IN_CREATE  NO_ENGINE_SUBSTITUTION  NO_UNSIGNED_SUBTRACTION  NO_ZERO_DATE  NO_ZERO_IN_DATE  ONLY_FULL_GROUP_BY  PAD_CHAR_TO_FULL_LENGTH  PIPES_AS_CONCAT  REAL_AS_FLOAT  STRICT_ALL_TABLES  STRICT_TRANS_TABLES  TIME_TRUNCATE_FRACTIONAL

The current server SQL mode, which can be set dynamically. For details, see [Section 7.1.11, “Server SQL Modes”](#).

#### Note

MySQL installation programs may configure the SQL mode during the installation process.

If the SQL mode differs from the default or from what you expect, check for a setting in an option file that the server reads at startup.

- `sql_notes`

System Variable	<code>sql_notes</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>ON</code>

If enabled (the default), diagnostics of `Note` level increment `warning_count` and the server records them. If disabled, `Note` diagnostics do not increment `warning_count` and the server does not record them. `mysqldump` includes output to disable this variable so that reloading the dump file does not produce warnings for events that do not affect the integrity of the reload operation.

- `sql_quote_show_create`

System Variable	<code>sql_quote_show_create</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>ON</code>

If enabled (the default), the server quotes identifiers for `SHOW CREATE TABLE` and `SHOW CREATE DATABASE` statements. If disabled, quoting is disabled. This option is enabled by default so that replication works for identifiers that require quoting. See [Section 15.7.7.11, “SHOW CREATE TABLE Statement”](#), and [Section 15.7.7.7, “SHOW CREATE DATABASE Statement”](#).

- `sql_require_primary_key`

Command-Line Format	<code>--sql-require-primary-key[={OFF ON}]</code>
System Variable	<code>sql_require_primary_key</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Boolean
Default Value	<code>OFF</code>

Whether statements that create new tables or alter the structure of existing tables enforce the requirement that tables have a primary key.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See [Section 7.1.9.1, “System Variable Privileges”](#).

Enabling this variable helps avoid performance problems in row-based replication that can occur when tables have no primary key. Suppose that a table has no primary key and an update or delete modifies multiple rows. On the replication source server, this operation can be performed using a single table

scan but, when replicated using row-based replication, results in a table scan for each row to be modified on the replica. With a primary key, these table scans do not occur.

`sql_require_primary_key` applies to both base tables and `TEMPORARY` tables, and changes to its value are replicated to replica servers. The table must use MySQL storage engines that can participate in replication.

When enabled, `sql_require_primary_key` has these effects:

- Attempts to create a new table with no primary key fail with an error. This includes `CREATE TABLE ... LIKE`. It also includes `CREATE TABLE ... SELECT`, unless the `CREATE TABLE` part includes a primary key definition.
- Attempts to drop the primary key from an existing table fail with an error, with the exception that dropping the primary key and adding a primary key in the same `ALTER TABLE` statement is permitted.

Dropping the primary key fails even if the table also contains a `UNIQUE NOT NULL` index.

- Attempts to import a table with no primary key fail with an error.

The `REQUIRE_TABLE_PRIMARY_KEY_CHECK` option of the `CHANGE REPLICATION SOURCE TO` statement enables a replica to select its own policy for primary key checks. When the option is set to `ON` for a replication channel, the replica always uses the value `ON` for the `sql_require_primary_key` system variable in replication operations, requiring a primary key. When the option is set to `OFF`, the replica always uses the value `OFF` for the `sql_require_primary_key` system variable in replication operations, so that a primary key is never required, even if the source required one. When the `REQUIRE_TABLE_PRIMARY_KEY_CHECK` option is set to `STREAM`, which is the default, the replica uses whatever value is replicated from the source for each transaction. With the `STREAM` setting for the `REQUIRE_TABLE_PRIMARY_KEY_CHECK` option, if privilege checks are in use for the replication channel, the `PRIVILEGE_CHECKS_USER` account needs privileges sufficient to set restricted session variables, so that it can set the session value for the `sql_require_primary_key` system variable. With the `ON` or `OFF` settings, the account does not need these privileges. For more information, see [Section 19.3.3, “Replication Privilege Checks”](#).

- `sql_safe_updates`

System Variable	<code>sql_safe_updates</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Boolean
Default Value	<code>OFF</code>

If this variable is enabled, `UPDATE` and `DELETE` statements that do not use a key in the `WHERE` clause or a `LIMIT` clause produce an error. This makes it possible to catch `UPDATE` and `DELETE` statements where keys are not used properly and that would probably change or delete a large number of rows. The default value is `OFF`.

For the `mysql` client, `sql_safe_updates` can be enabled by using the `--safe-updates` option. For more information, see [Using Safe-Updates Mode \(--safe-updates\)](#).

- `sql_select_limit`

System Variable	<code>sql_select_limit</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Integer
Default Value	18446744073709551615
Minimum Value	0
Maximum Value	18446744073709551615

The maximum number of rows to return from `SELECT` statements. For more information, see [Using Safe-Updates Mode \(--safe-updates\)](#).

The default value for a new connection is the maximum number of rows that the server permits per table. Typical default values are  $(2^{32})-1$  or  $(2^{64})-1$ . If you have changed the limit, the default value can be restored by assigning a value of `DEFAULT`.

If a `SELECT` has a `LIMIT` clause, the `LIMIT` takes precedence over the value of `sql_select_limit`.

- `sql_warnings`

System Variable	<code>sql_warnings</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

This variable controls whether single-row `INSERT` statements produce an information string if warnings occur. The default is `OFF`. Set the value to `ON` to produce an information string.

- `ssl_ca`

Command-Line Format	<code>--ssl-ca=file_name</code>
System Variable	<code>ssl_ca</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	File name
Default Value	<code>NULL</code>

The path name of the Certificate Authority (CA) certificate file in PEM format. The file contains a list of trusted SSL Certificate Authorities.

This variable can be modified at runtime to affect the TLS context the server uses for new connections established after the execution of `ALTER INSTANCE RELOAD TLS` or after a restart if the variable value was persisted. See [Server-Side Runtime Configuration and Monitoring for Encrypted Connections](#).

- `ssl_capath`

Command-Line Format	<code>--ssl-capath=dir_name</code>
System Variable	<code>ssl_capath</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Directory name
Default Value	<code>NULL</code>

The path name of the directory that contains trusted SSL Certificate Authority (CA) certificate files in PEM format. You must run OpenSSL `rehash` on the directory specified by this option prior to using it. On Linux systems, you can invoke `rehash` like this:

```
$> openssl rehash path/to/directory
```

On Windows platforms, you can use the `c_rehash` script in a command prompt, like this:

```
\> c_rehash path/to/directory
```

See [openssl-rehash](#) for complete syntax and other information.

This variable is can be modified at runtime to affect the TLS context the server uses for new connections established after the execution of `ALTER INSTANCE RELOAD TLS` or after a restart if the variable value was persisted. See [Server-Side Runtime Configuration and Monitoring for Encrypted Connections](#).

- `ssl_cert`

Command-Line Format	<code>--ssl-cert=file_name</code>
System Variable	<code>ssl_cert</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	File name
Default Value	<code>NULL</code>

The path name of the server SSL public key certificate file in PEM format.

If the server is started with `ssl_cert` set to a certificate that uses any restricted cipher or cipher category, the server starts with support for encrypted connections disabled. For information about cipher restrictions, see [Connection Cipher Configuration](#).

This variable can be modified at runtime to affect the TLS context the server uses for new connections established after the execution of `ALTER INSTANCE RELOAD TLS` or after a restart if the variable value was persisted. See [Server-Side Runtime Configuration and Monitoring for Encrypted Connections](#).

- `ssl_cipher`

Command-Line Format	<code>--ssl-cipher=name</code>
System Variable	<code>ssl_cipher</code>

Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	String
Default Value	<a href="#">NULL</a>

The list of permissible encryption ciphers for connections that use TLSv1.2. If no cipher in the list is supported, encrypted connections that use this TLS protocol do not work.

The list may include any of the following values:

- [ECDHE-ECDSA-AES128-GCM-SHA256](#)
- [ECDHE-ECDSA-AES256-GCM-SHA384](#)
- [ECDHE-RSA-AES128-GCM-SHA256](#)
- [ECDHE-RSA-AES256-GCM-SHA384](#)
- [ECDHE-ECDSA-CHACHA20-POLY1305](#)
- [ECDHE-RSA-CHACHA20-POLY1305](#)
- [ECDHE-ECDSA-AES256-CCM](#)
- [ECDHE-ECDSA-AES128-CCM](#)
- [DHE-RSA-AES128-GCM-SHA256](#)
- [DHE-RSA-AES256-GCM-SHA384](#)
- [DHE-RSA-AES256-CCM](#)
- [DHE-RSA-AES128-CCM](#)
- [DHE-RSA-CHACHA20-POLY1305](#)

Trying to include any values in the cipher list that are not shown here when setting this variable raises an error ([ER\\_BLOCKED\\_CIPHER](#)).

For greatest portability, the cipher list should be a list of one or more cipher names, separated by colons. The following example shows two cipher names separated by a colon:

```
[mysqld]
ssl_cipher="DHE-RSA-AES128-GCM-SHA256:AES128-SHA"
```

OpenSSL supports the syntax for specifying ciphers described in the OpenSSL documentation at <https://www.openssl.org/docs/manmaster/man1/ciphers.html>.

For information about which encryption ciphers MySQL supports, see [Section 8.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#).

This variable can be modified at runtime to affect the TLS context the server uses for new connections established after the execution of [ALTER INSTANCE RELOAD TLS](#) or after a restart if the variable value was persisted. See [Server-Side Runtime Configuration and Monitoring for Encrypted Connections](#).

- `ssl_crl`

Command-Line Format	<code>--ssl-crl=file_name</code>
System Variable	<code>ssl_crl</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	File name
Default Value	<code>NULL</code>

The path name of the file containing certificate revocation lists in PEM format.

This variable can be modified at runtime to affect the TLS context the server uses for new connections established after the execution of `ALTER INSTANCE RELOAD TLS` or after a restart if the variable value was persisted. See [Server-Side Runtime Configuration and Monitoring for Encrypted Connections](#).

- `ssl_crlpath`

Command-Line Format	<code>--ssl-crlpath=dir_name</code>
System Variable	<code>ssl_crlpath</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Directory name
Default Value	<code>NULL</code>

The path of the directory that contains certificate revocation-list files in PEM format.

This variable can be modified at runtime to affect the TLS context the server uses for new connections established after the execution of `ALTER INSTANCE RELOAD TLS` or after a restart if the variable value was persisted. See [Server-Side Runtime Configuration and Monitoring for Encrypted Connections](#).

- `ssl_fips_mode`

Command-Line Format	<code>--ssl-fips-mode={OFF ON STRICT}</code>
Deprecated	Yes
System Variable	<code>ssl_fips_mode</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Enumeration
Default Value	<code>OFF</code>
Valid Values	<code>OFF</code> (or 0) <code>ON</code> (or 1)

	<code>STRICT</code> (or 2)
--	----------------------------

Controls whether to enable FIPS mode on the server side. The `ssl_fips_mode` system variable differs from other `ssl_xxx` system variables in that it is not used to control whether the server permits encrypted connections, but rather to affect which cryptographic operations are permitted. See [Section 8.8, “FIPS Support”](#).

These `ssl_fips_mode` values are permitted:

- `OFF` (or 0): Disable FIPS mode.
- `ON` (or 1): Enable FIPS mode.
- `STRICT` (or 2): Enable “strict” FIPS mode.

#### Note

If the OpenSSL FIPS Object Module is not available, the only permitted value for `ssl_fips_mode` is `OFF`. In this case, setting `ssl_fips_mode` to `ON` or `STRICT` at startup causes the server to produce an error message and exit.

This option is deprecated and made read-only. Expect it to be removed in a future version of MySQL.

- `ssl_key`

Command-Line Format	<code>--ssl-key=file_name</code>
System Variable	<code>ssl_key</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	File name
Default Value	<code>NULL</code>

The path name of the server SSL private key file in PEM format. For better security, use a certificate with an RSA key size of at least 2048 bits.

If the key file is protected by a passphrase, the server prompts the user for the passphrase. The password must be given interactively; it cannot be stored in a file. If the passphrase is incorrect, the program continues as if it could not read the key.

This variable can be modified at runtime to affect the TLS context the server uses for new connections established after the execution of `ALTER INSTANCE RELOAD TLS` or after a restart if the variable value was persisted. See [Server-Side Runtime Configuration and Monitoring for Encrypted Connections](#).

- `ssl_session_cache_mode`

Command-Line Format	<code>--ssl_session_cache_mode={ON OFF}</code>
System Variable	<code>ssl_session_cache_mode</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No

Type	Boolean
Default Value	ON
Valid Values	ON OFF

Controls whether to enable the session cache in memory on the server side and session-ticket generation by the server. The default mode is `ON` (enable session cache mode). A change to the `ssl_session_cache_mode` system variable has an effect only after the `ALTER INSTANCE RELOAD TLS` statement has been executed, or after a restart if the variable value was persisted.

These `ssl_session_cache_mode` values are permitted:

- `ON`: Enable session cache mode.
- `OFF`: Disable session cache mode.

The server does not advertise its support for session resumption if the value of this system variable is `OFF`. When running on OpenSSL 1.0.x the session tickets are always generated, but the tickets are not usable when `ssl_session_cache_mode` is enabled.

The current value in effect for `ssl_session_cache_mode` can be observed with the `Ssl_session_cache_mode` status variable.

- `ssl_session_cache_timeout`

Command-Line Format	<code>--ssl_session_cache_timeout</code>
System Variable	<code>ssl_session_cache_timeout</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	300
Minimum Value	0
Maximum Value	84600
Unit	seconds

Sets a period of time during which prior session reuse is permitted when establishing a new encrypted connection to the server, provided the `ssl_session_cache_mode` system variable is enabled and prior session data is available. If the session timeout expires, a session can no longer be reused.

The default value is 300 seconds and the maximum value is 84600 (or one day in seconds). A change to the `ssl_session_cache_timeout` system variable has an effect only after the `ALTER INSTANCE RELOAD TLS` statement has been executed, or after a restart if the variable value was persisted. The current value in effect for `ssl_session_cache_timeout` can be observed with the `Ssl_session_cache_timeout` status variable.

- `statement_id`

System Variable	<code>statement_id</code>
-----------------	---------------------------

Scope	Session
Dynamic	No
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer

Each statement executed in the current session is assigned a sequence number. This can be used together with the [session\\_track\\_system\\_variables](#) system variable to identify this statement in Performance Schema tables such as the [events\\_statements\\_history](#) table.

- [stored\\_program\\_cache](#)

Command-Line Format	<code>--stored-program-cache=#</code>
System Variable	<a href="#">stored_program_cache</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	256
Minimum Value	16
Maximum Value	524288

Sets a soft upper limit for the number of cached stored routines per connection. The value of this variable is specified in terms of the number of stored routines held in each of the two caches maintained by the MySQL Server for, respectively, stored procedures and stored functions.

Whenever a stored routine is executed this cache size is checked before the first or top-level statement in the routine is parsed; if the number of routines of the same type (stored procedures or stored functions according to which is being executed) exceeds the limit specified by this variable, the corresponding cache is flushed and memory previously allocated for cached objects is freed. This allows the cache to be flushed safely, even when there are dependencies between stored routines.

The stored procedure and stored function caches exist in parallel with the stored program definition cache partition of the [dictionary object cache](#). The stored procedure and stored function caches are per connection, while the stored program definition cache is shared. The existence of objects in the stored procedure and stored function caches have no dependence on the existence of objects in the stored program definition cache, and vice versa. For more information, see [Section 16.4, "Dictionary Object Cache"](#).

- [stored\\_program\\_definition\\_cache](#)

Command-Line Format	<code>--stored-program-definition-cache=#</code>
System Variable	<a href="#">stored_program_definition_cache</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	256

Minimum Value	256
Maximum Value	524288

Defines a limit for the number of stored program definition objects, both used and unused, that can be kept in the dictionary object cache.

Unused stored program definition objects are only kept in the dictionary object cache when the number in use is less than the capacity defined by `stored_program_definition_cache`.

A setting of 0 means that stored program definition objects are only kept in the dictionary object cache while they are in use.

The stored program definition cache partition exists in parallel with the stored procedure and stored function caches that are configured using the `stored_program_cache` option.

The `stored_program_cache` option sets a soft upper limit for the number of cached stored procedures or functions per connection, and the limit is checked each time a connection executes a stored procedure or function. The stored program definition cache partition, on the other hand, is a shared cache that stores stored program definition objects for other purposes. The existence of objects in the stored program definition cache partition has no dependence on the existence of objects in the stored procedure cache or stored function cache, and vice versa.

For related information, see [Section 16.4, “Dictionary Object Cache”](#).

- `super_read_only`

Command-Line Format	<code>--super-read-only[={OFF ON}]</code>
System Variable	<code>super_read_only</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

If the `read_only` system variable is enabled, the server permits no client updates except from users who have the `CONNECTION_ADMIN` privilege (or the deprecated `SUPER` privilege). If the `super_read_only` system variable is also enabled, the server prohibits client updates even from users who have `CONNECTION_ADMIN` or `SUPER`. See the description of the `read_only` system variable for a description of read-only mode and information about how `read_only` and `super_read_only` interact.

Client updates prevented when `super_read_only` is enabled include operations that do not necessarily appear to be updates, such as `CREATE FUNCTION` (to install a loadable function), `INSTALL PLUGIN`, and `INSTALL COMPONENT`. These operations are prohibited because they involve changes to tables in the `mysql` system schema.

Similarly, if the Event Scheduler is enabled, enabling the `super_read_only` system variable prevents it from updating event “last executed” timestamps in the `events` data dictionary table. This causes the Event Scheduler to stop the next time it tries to execute a scheduled event, after writing a message to the server error log. (In this situation the `event_scheduler` system variable does not change from `ON` to `OFF`. An implication is that this variable rejects the DBA *intent* that the Event Scheduler be enabled or disabled, where its actual status of started or stopped may be distinct.). If `super_read_only` is

subsequently disabled after being enabled, the server automatically restarts the Event Scheduler as needed.

Changes to `super_read_only` on a replication source server are not replicated to replica servers. The value can be set on a replica independent of the setting on the source.

- `syseventlog.facility`

Command-Line Format	<code>--syseventlog.facility=value</code>
System Variable	<code>syseventlog.facility</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value	<code>daemon</code>

The facility for error log output written to `syslog` (what type of program is sending the message). This variable is unavailable unless the `log_sink_syseventlog` error log component is installed. See [Section 7.4.2.8, “Error Logging to the System Log”](#).

The permitted values can vary per operating system; consult your system `syslog` documentation.

This variable does not exist on Windows.

- `syseventlog.include_pid`

Command-Line Format	<code>--syseventlog.include-pid[={OFF ON}]</code>
System Variable	<code>syseventlog.include_pid</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>ON</code>

Whether to include the server process ID in each line of error log output written to `syslog`. This variable is unavailable unless the `log_sink_syseventlog` error log component is installed. See [Section 7.4.2.8, “Error Logging to the System Log”](#).

This variable does not exist on Windows.

- `syseventlog.tag`

Command-Line Format	<code>--syseventlog.tag=tag</code>
System Variable	<code>syseventlog.tag</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String

Default Value	empty string
---------------	--------------

The tag to be added to the server identifier in error log output written to `syslog` or the Windows Event Log. This variable is unavailable unless the `log_sink_syseventlog` error log component is installed. See [Section 7.4.2.8, “Error Logging to the System Log”](#).

By default, no tag is set, so the server identifier is simply `MySQL` on Windows, and `mysqld` on other platforms. If a tag value of `tag` is specified, it is appended to the server identifier with a leading hyphen, resulting in a `syslog` identifier of `mysqld-tag` (or `MySQL-tag` on Windows).

On Windows, to use a tag that does not already exist, the server must be run from an account with Administrator privileges, to permit creation of a registry entry for the tag. Elevated privileges are not required if the tag already exists.

- `system_time_zone`

System Variable	<code>system_time_zone</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	String

The server system time zone. When the server begins executing, it inherits a time zone setting from the machine defaults, possibly modified by the environment of the account used for running the server or the startup script. The value is used to set `system_time_zone`. To explicitly specify the system time zone, set the `TZ` environment variable or use the `--timezone` option of the `mysqld_safe` script.

In addition to startup time initialization, if the server host time zone changes (for example, due to daylight saving time), `system_time_zone` reflects that change, which has these implications for applications:

- Queries that reference `system_time_zone` will get one value before a daylight saving change and a different value after the change.
- For queries that begin executing before a daylight saving change and end after the change, the `system_time_zone` remains constant within the query because the value is usually cached at the beginning of execution.

The `system_time_zone` variable differs from the `time_zone` variable. Although they might have the same value, the latter variable is used to initialize the time zone for each client that connects. See [Section 7.1.15, “MySQL Server Time Zone Support”](#).

- `table_definition_cache`

Command-Line Format	<code>--table-definition-cache=#</code>
System Variable	<code>table_definition_cache</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	<code>-1</code> (signifies autosizing; do not assign this literal value)

Minimum Value	400
Maximum Value	524288

The number of table definitions that can be stored in the table definition cache. If you use a large number of tables, you can create a large table definition cache to speed up opening of tables. The table definition cache takes less space and does not use file descriptors, unlike the normal table cache. The minimum value is 400. The default value is based on the following formula, capped to a limit of 2000:

```
MIN(400 + table_open_cache / 2, 2000)
```

For [InnoDB](#), the [table\\_definition\\_cache](#) setting acts as a soft limit for the number of table instances in the dictionary object cache and the number file-per-table tablespaces that can be open at one time.

If the number of table instances in the dictionary object cache exceeds the [table\\_definition\\_cache](#) limit, an LRU mechanism begins marking table instances for eviction and eventually removes them from the dictionary object cache. The number of open tables with cached metadata can be higher than the [table\\_definition\\_cache](#) limit due to table instances with foreign key relationships, which are not placed on the LRU list.

The number of file-per-table tablespaces that can be open at one time is limited by both the [table\\_definition\\_cache](#) and [innodb\\_open\\_files](#) settings. If both variables are set, the highest setting is used. If neither variable is set, the [table\\_definition\\_cache](#) setting, which has a higher default value, is used. If the number of open tablespaces exceeds the limit defined by [table\\_definition\\_cache](#) or [innodb\\_open\\_files](#), an LRU mechanism searches the LRU list for tablespace files that are fully flushed and not currently being extended. This process is performed each time a new tablespace is opened. Only inactive tablespaces are closed.

The table definition cache exists in parallel with the table definition cache partition of the [dictionary object cache](#). Both caches store table definitions but serve different parts of the MySQL server. Objects in one cache have no dependence on the existence of objects in the other. For more information, see [Section 16.4, “Dictionary Object Cache”](#).

- [table\\_encryption\\_privilege\\_check](#)

Command-Line Format	<code>--table-encryption-privilege-check[={OFF ON}]</code>
System Variable	<a href="#">table_encryption_privilege_check</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Boolean
Default Value	<a href="#">OFF</a>

Controls the [TABLE\\_ENCRYPTION\\_ADMIN](#) privilege check that occurs when creating or altering a schema or general tablespace with encryption that differs from the [default\\_table\\_encryption](#)

setting, or when creating or altering a table with an encryption setting that differs from the default schema encryption. The check is disabled by default.

Setting `table_encryption_privilege_check` at runtime requires the `SUPER` privilege.

`table_encryption_privilege_check` supports `SET PERSIST` and `SET PERSIST_ONLY` syntax. See [Section 7.1.9.3, “Persisted System Variables”](#).

For more information, see [Defining an Encryption Default for Schemas and General Tablespaces](#).

- `table_open_cache`

Command-Line Format	<code>--table-open-cache=#</code>
System Variable	<code>table_open_cache</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	4000
Minimum Value	1
Maximum Value	524288

The number of open tables for all threads. Increasing this value increases the number of file descriptors that `mysqld` requires. The effective value of this variable is the greater of the effective value of `open_files_limit - 10 - the effective value of max_connections / 2`, and 400; that is

```
MAX(
 (open_files_limit - 10 - max_connections) / 2,
 400
)
```

You can check whether you need to increase the table cache by checking the `Opened_tables` status variable. If the value of `Opened_tables` is large and you do not use `FLUSH TABLES` often (which just forces all tables to be closed and reopened), then you should increase the value of the `table_open_cache` variable. For more information about the table cache, see [Section 10.4.3.1, “How MySQL Opens and Closes Tables”](#).

- `table_open_cache_instances`

Command-Line Format	<code>--table-open-cache-instances=#</code>
System Variable	<code>table_open_cache_instances</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	16
Minimum Value	1

Maximum Value	64
---------------	----

The number of open tables cache instances. To improve scalability by reducing contention among sessions, the open tables cache can be partitioned into several smaller cache instances of size `table_open_cache / table_open_cache_instances`. A session needs to lock only one instance to access it for DML statements. This segments cache access among instances, permitting higher performance for operations that use the cache when there are many sessions accessing tables. (DDL statements still require a lock on the entire cache, but such statements are much less frequent than DML statements.)

A value of 8 or 16 is recommended on systems that routinely use 16 or more cores. However, if you have many large triggers on your tables that cause a high memory load, the default setting for `table_open_cache_instances` might lead to excessive memory usage. In that situation, it can be helpful to set `table_open_cache_instances` to 1 in order to restrict memory usage.

- `table_open_cache_triggers`

Command-Line Format	<code>--table-open-cache-triggers=value</code>
System Variable	<code>table_open_cache_triggers</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	524288
Minimum Value	1
Maximum Value	524288

The total maximum number of cached open tables having fully loaded triggers. This includes both used and unused tables having fully loaded triggers.

`table_open_cache_triggers` is similar to `table_open_cache`, but controls an eviction mechanism specifically for tables with fully loaded triggers. The default value for `table_open_cache_triggers` is the same as the maximum; setting the value less than this activates the eviction logic specific to tables with fully loaded triggers. Leaving `table_open_cache_triggers` at the default means no tables are evicted from cache based on whether they have any fully loaded triggers, which is the same behavior as in versions of MySQL previous to 9.1.

The maximum number of cached tables having triggers, per cache instance, is determined by `table_open_cache_triggers / table_open_cache_instances`. When these system variables are allowed to retain their default values, this value is 32768.

- `tablespace_definition_cache`

Command-Line Format	<code>--tablespace-definition-cache=#</code>
System Variable	<code>tablespace_definition_cache</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer

Default Value	256
Minimum Value	256
Maximum Value	524288

Defines a limit for the number of tablespace definition objects, both used and unused, that can be kept in the dictionary object cache.

Unused tablespace definition objects are only kept in the dictionary object cache when the number in use is less than the capacity defined by `tablespace_definition_cache`.

A setting of 0 means that tablespace definition objects are only kept in the dictionary object cache while they are in use.

For more information, see [Section 16.4, “Dictionary Object Cache”](#).

- `temptable_max_mmap`

Command-Line Format	<code>--temptable-max-mmap=#</code>
System Variable	<code>temptable_max_mmap</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	$2^{64}-1$
Unit	bytes

Defines the maximum amount of memory (in bytes) the TempTable storage engine is permitted to allocate from memory-mapped temporary files before it starts storing data to InnoDB internal temporary tables on disk. A setting of 0 (default) disables allocation of memory from memory-mapped temporary files. For more information, see [Section 10.4.4, “Internal Temporary Table Use in MySQL”](#).

Before MySQL 8.4, this option was set to 1 GiB instead of 0.

- `temptable_max_ram`

Command-Line Format	<code>--temptable-max-ram=#</code>
System Variable	<code>temptable_max_ram</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	3% of total memory: min 1 GB, max 4 GB
Minimum Value	2097152
Maximum Value	$2^{64}-1$

Unit	bytes
------	-------

Defines the maximum amount of memory that can be occupied by the `TempTable` storage engine before it starts storing data on disk. The default value is 3% of total memory available on the server, with a minimum and maximum default range of 1-4 GiB. For more information, see [Section 10.4.4, “Internal Temporary Table Use in MySQL”](#).

The `TempTable_count_hit_max_ram` status variable counts the number of times that the `TempTable` engine reached the `temptable_max_ram` limit.

Before MySQL 8.4, the default value was always 1 GiB.

- `temptable_use_mmap`

Command-Line Format	<code>--temptable-use-mmap[={OFF ON}]</code>
Deprecated	Yes
System Variable	<code>temptable_use_mmap</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Defines whether the `TempTable` storage engine allocates space for internal in-memory temporary tables as memory-mapped temporary files when the amount of memory occupied by the `TempTable` storage engine exceeds the limit defined by the `temptable_max_ram` variable. When `temptable_use_mmap` is disabled (default), the `TempTable` storage engine uses `InnoDB` on-disk internal temporary tables instead. For more information, see [Section 10.4.4, “Internal Temporary Table Use in MySQL”](#).

- `thread_cache_size`

Command-Line Format	<code>--thread-cache-size=#</code>
System Variable	<code>thread_cache_size</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	<code>-1</code> (signifies autosizing; do not assign this literal value)
Minimum Value	<code>0</code>
Maximum Value	<code>16384</code>

How many threads the server should cache for reuse. When a client disconnects, the client's threads are put in the cache if there are fewer than `thread_cache_size` threads there. Requests for threads are satisfied by reusing threads taken from the cache if possible, and only when the cache is empty is a new thread created. This variable can be increased to improve performance if you have a lot of new connections. Normally, this does not provide a notable performance improvement if you have a good thread implementation. However, if your server sees hundreds of connections per second you should normally set `thread_cache_size` high enough so that most new connections use cached threads. By

examining the difference between the `Connections` and `Threads_created` status variables, you can see how efficient the thread cache is. For details, see [Section 7.1.10, “Server Status Variables”](#).

The default value is based on the following formula, capped to a limit of 100:

```
8 + (max_connections / 100)
```

- `thread_handling`

Command-Line Format	<code>--thread-handling=name</code>
System Variable	<code>thread_handling</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Enumeration
Default Value	<code>one-thread-per-connection</code>
Valid Values	<code>no-threads</code>  <code>one-thread-per-connection</code>  <code>loaded-dynamically</code>

The thread-handling model used by the server for connection threads. The permissible values are `no-threads` (the server uses a single thread to handle one connection), `one-thread-per-connection` (the server uses one thread to handle each client connection), and `loaded-dynamically` (set by the thread pool plugin when it initializes). `no-threads` is useful for debugging under Linux; see [Section 7.9, “Debugging MySQL”](#).

- `thread_pool_algorithm`

Command-Line Format	<code>--thread-pool-algorithm=#</code>
System Variable	<code>thread_pool_algorithm</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	1

This variable controls which algorithm the thread pool plugin uses:

- `0`: Use a conservative low-concurrency algorithm.
- `1`: Use an aggressive high-concurrency algorithm which performs better with optimal thread counts, but performance may be degraded if the number of connections reaches extremely high values.

This variable is available only if the thread pool plugin is enabled. See [Section 7.6.3, “MySQL Enterprise Thread Pool”](#).

- `thread_pool_dedicated_listeners`

Command-Line Format	<code>--thread-pool-dedicated-listeners</code>
System Variable	<code>thread_pool_dedicated_listeners</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Dedicates a listener thread in each thread group to listen for incoming statements from connections assigned to the group.

- `OFF`: (Default) Disables dedicated listener threads.
- `ON`: Dedicates a listener thread in each thread group to listen for incoming statements from connections assigned to the group. Dedicated listener threads do not execute queries.

Enabling `thread_pool_dedicated_listeners` is only useful when a transaction limit is defined by `thread_pool_max_transactions_limit`. Otherwise, `thread_pool_dedicated_listeners` should not be enabled.

HeatWave Service uses this variable, which is available only with MySQL Enterprise Edition, and not supported in MySQL 9.1.

- `thread_pool_high_priority_connection`

Command-Line Format	<code>--thread-pool-high-priority-connection=#</code>
System Variable	<code>thread_pool_high_priority_connection</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	<code>0</code>
Minimum Value	<code>0</code>
Maximum Value	<code>1</code>

This variable affects queuing of new statements prior to execution. If the value is 0 (false, the default), statement queuing uses both the low-priority and high-priority queues. If the value is 1 (true), queued statements always go to the high-priority queue.

This variable is available only if the thread pool plugin is enabled. See [Section 7.6.3, “MySQL Enterprise Thread Pool”](#).

- `thread_pool_longrun_trx_limit`

Command-Line Format	<code>--thread-pool-longrun-trx-limit=#</code>
System Variable	<code>thread_pool_longrun_trx_limit</code>

Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	2000
Minimum Value	10
Maximum Value	60*60*24
Unit	ms

When [thread\\_pool\\_max\\_transactions\\_limit](#) is in use, there is a maximum number of transactions that can be active in each thread group. If entire number available is being used by long-running transactions, any additional transaction assigned to the group blocks until one of the long-running transactions is completed, which users can perceive as an inexplicable hang.

To mitigate this issue, the limit for a given thread group is suspended if all of the threads using up the transaction maximum have been executing longer than the interval (in milliseconds) specified by [thread\\_pool\\_longrun\\_trx\\_limit](#). When the number of long-running transactions decreases, [thread\\_pool\\_max\\_transactions\\_limit](#) can be (and is) enabled again. In order for this to happen, the number of ongoing transactions must be less than [thread\\_pool\\_max\\_transactions\\_limit](#) / 2 for the interval defined as shown:

```
MIN(MAX(thread_pool_longrun_trx_limit * 15, 5000), 30000)
```

This variable is available only if the thread pool plugin is enabled. See [Section 7.6.3, “MySQL Enterprise Thread Pool”](#).

- [thread\\_pool\\_max\\_active\\_query\\_threads](#)

Command-Line Format	<code>--thread-pool-max-active-query-threads</code>
System Variable	<a href="#">thread_pool_max_active_query_threads</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	512

The maximum permissible number of active (running) query threads per group. If the value is 0, the thread pool plugin uses up to as many threads as are available.

This variable is available only if the thread pool plugin is enabled. See [Section 7.6.3, “MySQL Enterprise Thread Pool”](#).

- [thread\\_pool\\_max\\_transactions\\_limit](#)

Command-Line Format	<code>--thread-pool-max-transactions-limit</code>
System Variable	<a href="#">thread_pool_max_transactions_limit</a>

Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	1000000

The maximum number of transactions permitted by the thread pool plugin. Defining a transaction limit binds a thread to a transaction until it commits, which helps stabilize throughput during high concurrency.

The default value of 0 means that there is no transaction limit. The variable is dynamic but cannot be changed from 0 to a higher value at runtime and vice versa. A non-zero value at startup permits dynamic configuration at runtime. The [CONNECTION\\_ADMIN](#) privilege is required to configure [thread\\_pool\\_max\\_transactions\\_limit](#) at runtime.

When you define a transaction limit, enabling [thread\\_pool\\_dedicated\\_listeners](#) creates a dedicated listener thread in each thread group. The additional dedicated listener thread consumes more resources and affects thread pool performance. [thread\\_pool\\_dedicated\\_listeners](#) should therefore be used cautiously.

When the limit defined by [thread\\_pool\\_max\\_transactions\\_limit](#) has been reached, new connections or transactions on existing connections may appear to hang until one or more existing transactions are completed. It should be possible in many cases to mitigate this issue by setting [thread\\_pool\\_longrun\\_trx\\_limit](#) so that the transaction maximum can be relaxed when the number of ongoing transactions matches it for a given length of time. If existing connections continue to be blocked or long-running even after attempting this, a privileged connection may be required to access the server to increase the limit, remove the limit, or kill running transactions. See [Privileged Connections](#).

HeatWave Service uses this variable, which is available only with MySQL Enterprise Edition, and not supported in MySQL 9.1.

- [thread\\_pool\\_max\\_unused\\_threads](#)

Command-Line Format	<a href="#">--thread-pool-max-unused-threads=#</a>
System Variable	<a href="#">thread_pool_max_unused_threads</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	4096

The maximum permitted number of unused threads in the thread pool. This variable makes it possible to limit the amount of memory used by sleeping threads.

A value of 0 (the default) means no limit on the number of sleeping threads. A value of *N* where *N* is greater than 0 means 1 consumer thread and *N*–1 reserve threads. In this case, if a thread is ready to

sleep but the number of sleeping threads is already at the maximum, the thread exits rather than going to sleep.

A sleeping thread is either sleeping as a consumer thread or a reserve thread. The thread pool permits one thread to be the consumer thread when sleeping. If a thread goes to sleep and there is no existing consumer thread, it sleeps as a consumer thread. When a thread must be woken up, a consumer thread is selected if there is one. A reserve thread is selected only when there is no consumer thread to wake up.

This variable is available only if the thread pool plugin is enabled. See [Section 7.6.3, “MySQL Enterprise Thread Pool”](#).

- `thread_pool_prio_kickup_timer`

Command-Line Format	<code>--thread-pool-prio-kickup-timer=#</code>
System Variable	<code>thread_pool_prio_kickup_timer</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	1000
Minimum Value	0
Maximum Value	4294967294
Unit	milliseconds

This variable affects statements waiting for execution in the low-priority queue. The value is the number of milliseconds before a waiting statement is moved to the high-priority queue. The default is 1000 (1 second).

This variable is available only if the thread pool plugin is enabled. See [Section 7.6.3, “MySQL Enterprise Thread Pool”](#).

- `thread_pool_query_threads_per_group`

Command-Line Format	<code>--thread-pool-query-threads-per-group</code>
System Variable	<code>thread_pool_query_threads_per_group</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	1
Minimum Value	1

Maximum Value	4096
---------------	------

The maximum number of query threads permitted in a thread group. The maximum value is 4096, but if `thread_pool_max_transactions_limit` is set, `thread_pool_query_threads_per_group` must not exceed that value.

The default value of 1 means there is one active query thread in each thread group, which works well for many loads. When you are using the high concurrency thread pool algorithm (`thread_pool_algorithm = 1`), consider increasing the value if you experience slower response times due to long-running transactions.

The `CONNECTION_ADMIN` privilege is required to configure `thread_pool_query_threads_per_group` at runtime.

If you decrease the value of `thread_pool_query_threads_per_group` at runtime, threads that are currently running user queries are allowed to complete, then moved to the reserve pool or terminated. If you increment the value at runtime and the thread group needs more threads, these are taken from the reserve pool if possible, otherwise they are created.

HeatWave Service uses this variable, which is available only with MySQL Enterprise Edition, and not supported in MySQL 9.1.

- `thread_pool_size`

Command-Line Format	<code>--thread-pool-size=#</code>
System Variable	<code>thread_pool_size</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	16
Minimum Value	1
Maximum Value	512

The number of thread groups in the thread pool. This is the most important parameter controlling thread pool performance. It affects how many statements can execute simultaneously. If a value outside the range of permissible values is specified, the thread pool plugin does not load and the server writes a message to the error log.

This variable is available only if the thread pool plugin is enabled. See [Section 7.6.3, “MySQL Enterprise Thread Pool”](#).

- `thread_pool_stall_limit`

Command-Line Format	<code>--thread-pool-stall-limit=#</code>
System Variable	<code>thread_pool_stall_limit</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer

Default Value	6
Minimum Value	4
Maximum Value	600
Unit	milliseconds * 10

This variable affects executing statements. The value is the amount of time a statement has to finish after starting to execute before it becomes defined as stalled, at which point the thread pool permits the thread group to begin executing another statement. The value is measured in 10 millisecond units, so the default of 6 means 60ms. Short wait values permit threads to start more quickly. Short values are also better for avoiding deadlock situations. Long wait values are useful for workloads that include long-running statements, to avoid starting too many new statements while the current ones execute.

This variable is available only if the thread pool plugin is enabled. See [Section 7.6.3, “MySQL Enterprise Thread Pool”](#).

- `thread_pool_transaction_delay`

Command-Line Format	<code>--thread-pool-transaction-delay</code>
System Variable	<code>thread_pool_transaction_delay</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	300000

The delay period before executing a new transaction, in milliseconds. The maximum value is 300000 (5 minutes).

A transaction delay can be used in cases where parallel transactions affect the performance of other operations due to resource contention. For example, if parallel transactions affect index creation or an online buffer pool resizing operation, you can configure a transaction delay to reduce resource contention while those operations are running.

Worker threads sleep for the number of milliseconds specified by `thread_pool_transaction_delay` before executing a new transaction.

The `thread_pool_transaction_delay` setting does not affect queries issued from a privileged connection (a connection assigned to the `Admin` thread group). These queries are not subject to a configured transaction delay.

- `thread_stack`

Command-Line Format	<code>--thread-stack=#</code>
System Variable	<code>thread_stack</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No

Type	Integer
Default Value	1048576
Minimum Value	131072
Maximum Value (64-bit platforms)	18446744073709550592
Maximum Value (32-bit platforms)	4294966272
Unit	bytes
Block Size	1024

The stack size for each thread. The default is large enough for normal operation. If the thread stack size is too small, it limits the complexity of the SQL statements that the server can handle, the recursion depth of stored procedures, and other memory-consuming actions.

- `time_zone`

System Variable	<code>time_zone</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	String
Default Value	<code>SYSTEM</code>
Minimum Value	<code>-13:59</code>
Maximum Value	<code>+14:00</code>

The current time zone. This variable is used to initialize the time zone for each client that connects. By default, the initial value of this is '`SYSTEM`' (which means, “use the value of `system_time_zone`”). The value can be specified explicitly at server startup with the `--default-time-zone` option. See [Section 7.1.15, “MySQL Server Time Zone Support”](#).

#### Note

If set to `SYSTEM`, every MySQL function call that requires a time zone calculation makes a system library call to determine the current system time zone. This call may be protected by a global mutex, resulting in contention.

- `timestamp`

System Variable	<code>timestamp</code>
Scope	Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Numeric
Default Value	<code>UNIX_TIMESTAMP ( )</code>
Minimum Value	1

Maximum Value	2147483647
---------------	------------

Set the time for this client. This is used to get the original timestamp if you use the binary log to restore rows. `timestamp_value` should be a Unix epoch timestamp (a value like that returned by `UNIX_TIMESTAMP()`), not a value in `'YYYY-MM-DD hh:mm:ss'` format) or `DEFAULT`.

Setting `timestamp` to a constant value causes it to retain that value until it is changed again. Setting `timestamp` to `DEFAULT` causes its value to be the current date and time as of the time it is accessed.

`timestamp` is a `DOUBLE` rather than `BIGINT` because its value includes a microseconds part. The maximum value corresponds to `'2038-01-19 03:14:07'` UTC, the same as for the `TIMESTAMP` data type.

`SET timestamp` affects the value returned by `NOW()` but not by `SYSDATE()`. This means that timestamp settings in the binary log have no effect on invocations of `SYSDATE()`. The server can be started with the `--sysdate-is-now` option to cause `SYSDATE()` to be a synonym for `NOW()`, in which case `SET timestamp` affects both functions.

- `tls_certificates_enforced_validation`

Command-Line Format	<code>--tls-certificates-enforced-validation[={OFF ON}]</code>
System Variable	<code>tls_certificates_enforced_validation</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

During startup, the server ensures that the location of each required SSL certificate file is present in the default data directory if the file locations are not given on the command line. However, the server does not validate the certificate files and, as a result, it is able to start with an invalid certificate. The `tls_certificates_enforced_validation` system variable controls whether certificate validation is enforced at startup. Discovery of an invalid certificate halts the startup execution when validation enforcement is enabled. By default, certificate validation enforcement is disabled (`OFF`).

Validation enforcement can be enabled by specifying the `--tls-certificates-enforced-validation` option on the command line with or without the `ON` value. With validation enforcement enabled, certificates are also validated at the time of reloading them through the `ALTER INSTANCE RELOAD TLS` statement. This system variable cannot be persisted across reboots. For more information, see [Configuring Certificate Validation Enforcement](#).

- `tls_ciphersuites`

Command-Line Format	<code>--tls-ciphersuites=ciphersuite_list</code>
System Variable	<code>tls_ciphersuites</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String

Default Value	<code>NULL</code>
---------------	-------------------

Which ciphersuites the server permits for encrypted connections that use TLSv1.3. The value is a list of zero or more colon-separated ciphersuite names from among those listed here:

- `TLS_AES_128_GCM_SHA256`
- `TLS_AES_256_GCM_SHA384`
- `TLS_CHACHA20_POLY1305_SHA256`
- `TLS_AES_128_CCM_SHA256`

Trying to include any values in the cipher list that are not shown here when setting this variable raises an error (`ER_BLOCKED_CIPHER`).

The ciphersuites that can be named for this variable depend on the SSL library used to compile MySQL. If this variable is not set, its default value is `NULL`, which means that the server permits the default set of ciphersuites. If the variable is set to the empty string, no ciphersuites are enabled and encrypted connections cannot be established. For more information, see [Section 8.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#).

- `tls_version`

Command-Line Format	<code>--tls-version=protocol_list</code>
System Variable	<code>tls_version</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value	<code>TLSv1.2,TLSv1.3</code>

Which protocols the server permits for encrypted connections. The value is a list of one or more comma-separated protocol names, which are not case-sensitive. The protocols that can be named for this variable depend on the SSL library used to compile MySQL. Permitted protocols should be chosen such as not to leave “holes” in the list. For details, see [Section 8.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#).

This variable can be modified at runtime to affect the TLS context the server uses for new connections. See [Server-Side Runtime Configuration and Monitoring for Encrypted Connections](#).

#### Important

- MySQL 9.1 does not support the TLSv1 and TLSv1.1 connection protocols. See [Removal of Support for the TLSv1 and TLSv1.1 Protocols](#) for more information.
- Support for the TLSv1.3 protocol is available in MySQL 9.1, provided that MySQL Server was compiled using OpenSSL 1.1.1 or higher. The server checks the version of OpenSSL at startup, and if it is lower than 1.1.1, TLSv1.3

is removed from the default value for the system variable. In that case, the default is `TLSv1.2`.

Setting this variable to an empty string disables encrypted connections.

- `tmp_table_size`

Command-Line Format	<code>--tmp-table-size=#</code>
System Variable	<code>tmp_table_size</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Integer
Default Value	<code>16777216</code>
Minimum Value	<code>1024</code>
Maximum Value	<code>18446744073709551615</code>
Unit	bytes

Defines the maximum size of internal in-memory temporary tables created by the `MEMORY` and `TempTable` storage engines. If an internal in-memory temporary table exceeds this size, it is automatically converted to an on-disk internal temporary table.

The `tmp_table_size` variable does not apply to user-created `MEMORY` tables. User-created `TempTable` tables are not supported.

When using the `MEMORY` storage engine for internal in-memory temporary tables, the actual size limit is the smaller of `tmp_table_size` and `max_heap_table_size`. The `max_heap_table_size` setting does not apply to `TempTable` tables.

Increase the value of `tmp_table_size` (and `max_heap_table_size` if necessary when using the `MEMORY` storage engine for internal in-memory temporary tables) if you do many advanced `GROUP BY` queries and you have lots of memory.

The `Count_hit_tmp_table_size` status variable counts the number of [internal temporary tables](#) that were converted from in-memory to on-disk due to reaching size limits for either the `TempTable` or `MEMORY` storage engine.

You can compare the number of internal on-disk temporary tables created to the total number of internal temporary tables created by comparing `Created_tmp_disk_tables` and `Created_tmp_tables` values.

See also [Section 10.4.4, “Internal Temporary Table Use in MySQL”](#).

- `tmpdir`

Command-Line Format	<code>--tmpdir=dir_name</code>
System Variable	<code>tmpdir</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No

Type	Directory name
------	----------------

The path of the directory to use for creating temporary files. It might be useful if your default `/tmp` directory resides on a partition that is too small to hold temporary tables. This variable can be set to a list of several paths that are used in round-robin fashion. Paths should be separated by colon characters (:) on Unix and semicolon characters (;) on Windows.

`tmpdir` can be a non-permanent location, such as a directory on a memory-based file system or a directory that is cleared when the server host restarts. If the MySQL server is acting as a replica, and you are using a non-permanent location for `tmpdir`, consider setting a different temporary directory for the replica using the `replica_load_tmpdir` variable. For a replica, the temporary files used to replicate `LOAD DATA` statements are stored in this directory, so with a permanent location they can survive machine restarts, although replication can now continue after a restart if the temporary files have been removed.

For more information about the storage location of temporary files, see [Section B.3.3.5, “Where MySQL Stores Temporary Files”](#).

- `transaction_alloc_block_size`

Command-Line Format	<code>--transaction-alloc-block-size=#</code>
System Variable	<code>transaction_alloc_block_size</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	8192
Minimum Value	1024
Maximum Value	131072
Unit	bytes
Block Size	1024

The amount in bytes by which to increase a per-transaction memory pool which needs memory. See the description of `transaction_prealloc_size`.

- `transaction_isolation`

Command-Line Format	<code>--transaction-isolation=name</code>
System Variable	<code>transaction_isolation</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Enumeration
Default Value	<code>REPEATABLE-READ</code>
Valid Values	<code>READ-UNCOMMITTED</code> <code>READ-COMMITTED</code>

	REPEATABLE-READ
	SERIALIZABLE

The transaction isolation level. The default is `REPEATABLE-READ`.

The transaction isolation level has three scopes: global, session, and next transaction. This three-scope implementation leads to some nonstandard isolation-level assignment semantics, as described later.

To set the global transaction isolation level at startup, use the `--transaction-isolation` server option.

At runtime, the isolation level can be set directly using the `SET` statement to assign a value to the `transaction_isolation` system variable, or indirectly using the `SET TRANSACTION` statement. If you set `transaction_isolation` directly to an isolation level name that contains a space, the name should be enclosed within quotation marks, with the space replaced by a dash. For example, use this `SET` statement to set the global value:

```
SET GLOBAL transaction_isolation = 'READ-COMMITTED';
```

Setting the global `transaction_isolation` value sets the isolation level for all subsequent sessions. Existing sessions are unaffected.

To set the session or next-level `transaction_isolation` value, use the `SET` statement. For most session system variables, these statements are equivalent ways to set the value:

```
SET @@SESSION.var_name = value;
SET SESSION var_name = value;
SET var_name = value;
SET @@var_name = value;
```

As mentioned previously, the transaction isolation level has a next-transaction scope, in addition to the global and session scopes. To enable the next-transaction scope to be set, `SET` syntax for assigning session system variable values has nonstandard semantics for `transaction_isolation`:

- To set the session isolation level, use any of these syntaxes:

```
SET @@SESSION.transaction_isolation = value;
SET SESSION transaction_isolation = value;
```

```
SET transaction_isolation = value;
```

For each of those syntaxes, these semantics apply:

- Sets the isolation level for all subsequent transactions performed within the session.
- Permitted within transactions, but does not affect the current ongoing transaction.
- If executed between transactions, overrides any preceding statement that sets the next-transaction isolation level.
- Corresponds to `SET SESSION TRANSACTION ISOLATION LEVEL` (with the `SESSION` keyword).
- To set the next-transaction isolation level, use this syntax:

```
SET @@transaction_isolation = value;
```

For that syntax, these semantics apply:

- Sets the isolation level only for the next single transaction performed within the session.
- Subsequent transactions revert to the session isolation level.
- Not permitted within transactions.
- Corresponds to `SET TRANSACTION ISOLATION LEVEL` (without the `SESSION` keyword).

For more information about `SET TRANSACTION` and its relationship to the `transaction_isolation` system variable, see [Section 15.3.7, “SET TRANSACTION Statement”](#).

- `transaction_prealloc_size`

Command-Line Format	<code>--transaction-prealloc-size=#</code>
Deprecated	Yes
System Variable	<code>transaction_prealloc_size</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	4096
Minimum Value	1024
Maximum Value	131072
Unit	bytes
Block Size	1024

There is a per-transaction memory pool from which various transaction-related allocations take memory. The initial size of the pool in bytes is `transaction_prealloc_size`. For every allocation that cannot be satisfied from the pool because it has insufficient memory available, the pool is increased by `transaction_alloc_block_size` bytes. When the transaction ends, the pool is truncated to

`transaction_prealloc_size` bytes. By making `transaction_prealloc_size` sufficiently large to contain all statements within a single transaction, you can avoid many `malloc()` calls.

`transaction_prealloc_size` is deprecated, and setting this variable no longer has any effect. Expect `transaction_prealloc_size` to be removed in a future release of MySQL.

- `transaction_read_only`

Command-Line Format	<code>--transaction-read-only[={OFF ON}]</code>
System Variable	<code>transaction_read_only</code>
Scope	Global, Session
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

The transaction access mode. The value can be `OFF` (read/write; the default) or `ON` (read only).

The transaction access mode has three scopes: global, session, and next transaction. This three-scope implementation leads to some nonstandard access-mode assignment semantics, as described later.

To set the global transaction access mode at startup, use the `--transaction-read-only` server option.

At runtime, the access mode can be set directly using the `SET` statement to assign a value to the `transaction_read_only` system variable, or indirectly using the `SET TRANSACTION` statement. For example, use this `SET` statement to set the global value:

```
SET GLOBAL transaction_read_only = ON;
```

Setting the global `transaction_read_only` value sets the access mode for all subsequent sessions. Existing sessions are unaffected.

To set the session or next-level `transaction_read_only` value, use the `SET` statement. For most session system variables, these statements are equivalent ways to set the value:

```
SET @@SESSION.var_name = value;
SET SESSION var_name = value;
SET var_name = value;
SET @@var_name = value;
```

As mentioned previously, the transaction access mode has a next-transaction scope, in addition to the global and session scopes. To enable the next-transaction scope to be set, `SET` syntax for assigning session system variable values has nonstandard semantics for `transaction_read_only`,

- To set the session access mode, use any of these syntaxes:

```
SET @@SESSION.transaction_read_only = value;
SET SESSION transaction_read_only = value;
```

```
SET transaction_read_only = value;
```

For each of those syntaxes, these semantics apply:

- Sets the access mode for all subsequent transactions performed within the session.
- Permitted within transactions, but does not affect the current ongoing transaction.
- If executed between transactions, overrides any preceding statement that sets the next-transaction access mode.
- Corresponds to `SET SESSION TRANSACTION {READ WRITE | READ ONLY}` (with the `SESSION` keyword).
- To set the next-transaction access mode, use this syntax:

```
SET @@transaction_read_only = value;
```

For that syntax, these semantics apply:

- Sets the access mode only for the next single transaction performed within the session.
- Subsequent transactions revert to the session access mode.
- Not permitted within transactions.
- Corresponds to `SET TRANSACTION {READ WRITE | READ ONLY}` (without the `SESSION` keyword).

For more information about `SET TRANSACTION` and its relationship to the `transaction_read_only` system variable, see [Section 15.3.7, “SET TRANSACTION Statement”](#).

- `unique_checks`

System Variable	<code>unique_checks</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Boolean
Default Value	<code>ON</code>

If set to 1 (the default), uniqueness checks for secondary indexes in `InnoDB` tables are performed. If set to 0, storage engines are permitted to assume that duplicate keys are not present in input data. If you know for certain that your data does not contain uniqueness violations, you can set this to 0 to speed up large table imports to `InnoDB`.

Setting this variable to 0 does not *require* storage engines to ignore duplicate keys. An engine is still permitted to check for them and issue duplicate-key errors if it detects them.

- `updatable_views_with_limit`

Command-Line Format	<code>--updatable-views-with-limit[={OFF ON} ]</code>
System Variable	<code>updatable_views_with_limit</code>

Scope	Global, Session
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	Yes
Type	Boolean
Default Value	1

This variable controls whether updates to a view can be made when the view does not contain all columns of the primary key defined in the underlying table, if the update statement contains a [LIMIT](#) clause. (Such updates often are generated by GUI tools.) An update is an [UPDATE](#) or [DELETE](#) statement. Primary key here means a [PRIMARY KEY](#), or a [UNIQUE](#) index in which no column can contain [NULL](#).

The variable can have two values:

- 1 or [YES](#): Issue a warning only (not an error message). This is the default value.
- 0 or [NO](#): Prohibit the update.
- [use\\_secondary\\_engine](#)

System Variable	<a href="#">use_secondary_engine</a>
Scope	Session
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	Yes
Type	Enumeration
Default Value	<a href="#">ON</a>
Valid Values	<a href="#">OFF</a>  <a href="#">ON</a>  <a href="#">FORCED</a>

For future use.

Whether to execute queries using a secondary engine.

For use with HeatWave. See [HeatWave User Guide](#).

- [validate\\_password.xxx](#)

The [validate\\_password](#) component implements a set of system variables having names of the form [validate\\_password.xxx](#). These variables affect password testing by that component; see [Section 8.4.3.2, “Password Validation Options and Variables”](#).

- [version](#)

The version number for the server. The value might also include a suffix indicating server build or configuration information. [-debug](#) indicates that the server was built with debugging support enabled.

- [version\\_comment](#)

System Variable	<a href="#">version_comment</a>
Scope	Global

Dynamic	No
<a href="#">SET_VAR</a> Hint Applies	No
Type	String

The [CMake](#) configuration program has a [COMPILATION\\_COMMENT\\_SERVER](#) option that permits a comment to be specified when building MySQL. This variable contains the value of that comment.

- [version\\_compile\\_machine](#)

System Variable	<a href="#">version_compile_machine</a>
Scope	Global
Dynamic	No
<a href="#">SET_VAR</a> Hint Applies	No
Type	String

The type of the server binary.

- [version\\_compile\\_os](#)

System Variable	<a href="#">version_compile_os</a>
Scope	Global
Dynamic	No
<a href="#">SET_VAR</a> Hint Applies	No
Type	String

The type of operating system on which MySQL was built.

- [version\\_compile\\_zlib](#)

System Variable	<a href="#">version_compile_zlib</a>
Scope	Global
Dynamic	No
<a href="#">SET_VAR</a> Hint Applies	No
Type	String

The version of the compiled-in [zlib](#) library.

- [wait\\_timeout](#)

Command-Line Format	<a href="#">--wait-timeout=#</a>
System Variable	<a href="#">wait_timeout</a>
Scope	Global, Session
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	<a href="#">28800</a>

Minimum Value	1
Maximum Value (Windows)	2147483
Maximum Value (Other)	31536000
Unit	seconds

The number of seconds the server waits for activity on a noninteractive connection before closing it.

On thread startup, the session `wait_timeout` value is initialized from the global `wait_timeout` value or from the global `interactive_timeout` value, depending on the type of client (as defined by the `CLIENT_INTERACTIVE` connect option to `mysql_real_connect()`). See also `interactive_timeout`.

- `warning_count`

The number of errors, warnings, and notes that resulted from the last statement that generated messages. This variable is read only. See [Section 15.7.7.41, “SHOW WARNINGS Statement”](#).

- `windowing_use_high_precision`

Command-Line Format	<code>--windowing-use-high-precision[={OFF ON}]</code>
System Variable	<code>windowing_use_high_precision</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	Yes
Type	Boolean
Default Value	<code>ON</code>

Whether to compute window operations without loss of precision. See [Section 10.2.1.21, “Window Function Optimization”](#).

- `xa_detach_on_prepare`

Command-Line Format	<code>--xa-detach-on-prepare[={OFF ON}]</code>
System Variable	<code>xa_detach_on_prepare</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>ON</code>

When set to `ON` (enabled), all XA transactions are detached (disconnected) from the connection (session) as part of `XA PREPARE`. This means that the XA transaction can be committed or rolled back

by another connection, even if the originating connection has not terminated, and this connection can start new transactions.

Temporary tables cannot be used inside detached XA transactions.

When this is `OFF` (disabled), an XA transaction is strictly associated with the same connection until the session disconnects. It is recommended that you allow it to be enabled (the default behavior) for replication.

For more information, see [Section 15.3.8.2, “XA Transaction States”](#).

## 7.1.9 Using System Variables

The MySQL server maintains many system variables that configure its operation. [Section 7.1.8, “Server System Variables”](#), describes the meaning of these variables. Each system variable has a default value. System variables can be set at server startup using options on the command line or in an option file. Most of them can be changed dynamically while the server is running by means of the `SET` statement, which enables you to modify operation of the server without having to stop and restart it. You can also use system variable values in expressions.

Many system variables are built in. System variables may also be installed by server plugins or components:

- System variables implemented by a server plugin are exposed when the plugin is installed and have names that begin with the plugin name. For example, the `audit_log` plugin implements a system variable named `audit_log_policy`.
- System variables implemented by a component are exposed when the component is installed and have names that begin with a component-specific prefix. For example, the `log_filter_dragnet` error log filter component implements a system variable named `log_error_filter_rules`, the full name of which is `dragnet.log_error_filter_rules`. To refer to this variable, use the full name.

There are two scopes in which system variables exist. Global variables affect the overall operation of the server. Session variables affect its operation for individual client connections. A given system variable can have both a global and a session value. Global and session system variables are related as follows:

- When the server starts, it initializes each global variable to its default value. These defaults can be changed by options specified on the command line or in an option file. (See [Section 6.2.2, “Specifying Program Options”](#).)
- The server also maintains a set of session variables for each client that connects. The client's session variables are initialized at connect time using the current values of the corresponding global variables. For example, a client's SQL mode is controlled by the session `sql_mode` value, which is initialized when the client connects to the value of the global `sql_mode` value.

For some system variables, the session value is not initialized from the corresponding global value; if so, that is indicated in the variable description.

System variable values can be set globally at server startup by using options on the command line or in an option file. At startup, the syntax for system variables is the same as for command options, so within variable names, dashes and underscores may be used interchangeably. For example, `--general_log=ON` and `--general-log=ON` are equivalent.

When you use a startup option to set a variable that takes a numeric value, the value can be given with a suffix of `K`, `M`, `G`, `T`, `P`, or `E` (either uppercase or lowercase) to indicate a multiplier of  $1024$ ,  $1024^2$ ,  $1024^3$ ,  $1024^4$ ,  $1024^5$ , or  $1024^6$ ; that is, units of kilobytes, megabytes, gigabytes, terabytes, petabytes, or ettabytes,

respectively. Thus, the following command starts the server with a sort buffer size of 256 kilobytes and a maximum packet size of one gigabyte:

```
mysqld --sort-buffer-size=256K --max-allowed-packet=1G
```

Within an option file, those variables are set like this:

```
[mysqld]
sort_buffer_size=256K
max_allowed_packet=1G
```

The lettercase of suffix letters does not matter; `256K` and `256k` are equivalent, as are `1G` and `1g`.

To restrict the maximum value to which a system variable can be set at runtime with the `SET` statement, specify this maximum by using an option of the form `--maximum-var_name=value` at server startup. For example, to prevent the value of `sort_buffer_size` from being increased to more than 32MB at runtime, use the option `--maximum-sort-buffer-size=32M`.

Many system variables are dynamic and can be changed at runtime by using the `SET` statement. For a list, see [Section 7.1.9.2, “Dynamic System Variables”](#). To change a system variable with `SET`, refer to it by name, optionally preceded by a modifier. At runtime, system variable names must be written using underscores, not dashes. The following examples briefly illustrate this syntax:

- Set a global system variable:

```
SET GLOBAL max_connections = 1000;
SET @@GLOBAL.max_connections = 1000;
```

- Persist a global system variable to the `mysqld-auto.cnf` file (and set the runtime value):

```
SET PERSIST max_connections = 1000;
SET @@PERSIST.max_connections = 1000;
```

- Persist a global system variable to the `mysqld-auto.cnf` file (without setting the runtime value):

```
SET PERSIST_ONLY back_log = 1000;
SET @@PERSIST_ONLY.back_log = 1000;
```

- Set a session system variable:

```
SET SESSION sql_mode = 'TRADITIONAL';
SET @@SESSION.sql_mode = 'TRADITIONAL';
SET @@sql_mode = 'TRADITIONAL';
```

For complete details about `SET` syntax, see [Section 15.7.6.1, “SET Syntax for Variable Assignment”](#). For a description of the privilege requirements for setting and persisting system variables, see [Section 7.1.9.1, “System Variable Privileges”](#)

Suffixes for specifying a value multiplier can be used when setting a variable at server startup, but not to set the value with `SET` at runtime. On the other hand, with `SET` you can assign a variable's value using an expression, which is not true when you set a variable at server startup. For example, the first of the following lines is legal at server startup, but the second is not:

```
$> mysql --max_allowed_packet=16M
$> mysql --max_allowed_packet=16*1024*1024
```

Conversely, the second of the following lines is legal at runtime, but the first is not:

```
mysql> SET GLOBAL max_allowed_packet=16M;
mysql> SET GLOBAL max_allowed_packet=16*1024*1024;
```

To display system variable names and values, use the `SHOW VARIABLES` statement:

```
mysql> SHOW VARIABLES;
```

Variable_name	Value
activate_all_roles_on_login	OFF
admin_address	
admin_port	33062
admin_ssl_ca	
admin_ssl_capath	
admin_ssl_cert	
admin_ssl_cipher	
admin_ssl_crl	
admin_ssl_crlpath	
admin_ssl_key	
admin_tls_ciphersuites	
admin_tls_version	TLSv1.2,TLSv1.3
authentication_policy	*,,
auto_generate_certs	ON
auto_increment_increment	1
auto_increment_offset	1
autocommit	ON
automatic_sp_privileges	ON
...	
version	8.4.0
version_comment	Source distribution
version_compile_machine	x86_64
version_compile_os	Linux
version_compile_zlib	1.2.13
wait_timeout	28800
warning_count	0
windowing_use_high_precision	ON
xa_detach_on_prepare	ON

With a `LIKE` clause, the statement displays only those variables that match the pattern. To obtain a specific variable name, use a `LIKE` clause as shown:

```
SHOW VARIABLES LIKE 'max_join_size';
SHOW SESSION VARIABLES LIKE 'max_join_size';
```

To get a list of variables whose name match a pattern, use the `%` wildcard character in a `LIKE` clause:

```
SHOW VARIABLES LIKE '%size%';
SHOW GLOBAL VARIABLES LIKE '%size%';
```

Wildcard characters can be used in any position within the pattern to be matched. Strictly speaking, because `_` is a wildcard that matches any single character, you should escape it as `\_` to match it literally. In practice, this is rarely necessary.

For `SHOW VARIABLES`, if you specify neither `GLOBAL` nor `SESSION`, MySQL returns `SESSION` values.

The reason for requiring the `GLOBAL` keyword when setting `GLOBAL`-only variables but not when retrieving them is to prevent problems in the future:

- Were a `SESSION` variable to be removed that has the same name as a `GLOBAL` variable, a client with privileges sufficient to modify global variables might accidentally change the `GLOBAL` variable rather than just the `SESSION` variable for its own session.
- Were a `SESSION` variable to be added with the same name as a `GLOBAL` variable, a client that intends to change the `GLOBAL` variable might find only its own `SESSION` variable changed.

### 7.1.9.1 System Variable Privileges

A system variable can have a global value that affects server operation as a whole, a session value that affects only the current session, or both:

- For dynamic system variables, the `SET` statement can be used to change their global or session runtime value (or both), to affect operation of the current server instance. (For information about dynamic variables, see [Section 7.1.9.2, “Dynamic System Variables”](#).)
- For certain global system variables, `SET` can be used to persist their value to the `mysqld-auto.cnf` file in the data directory, to affect server operation for subsequent startups. (For information about persisting system variables and the `mysqld-auto.cnf` file, see [Section 7.1.9.3, “Persisted System Variables”](#).)
- For persisted global system variables, `RESET PERSIST` can be used to remove their value from `mysqld-auto.cnf`, to affect server operation for subsequent startups.

This section describes the privileges required for operations that assign values to system variables at runtime. This includes operations that affect runtime values, and operations that persist values.

To set a global system variable, use a `SET` statement with the appropriate keyword. These privileges apply:

- To set a global system variable runtime value, use the `SET GLOBAL` statement, which requires the `SYSTEM_VARIABLES_ADMIN` privilege (or the deprecated `SUPER` privilege).
- To persist a global system variable to the `mysqld-auto.cnf` file (and set the runtime value), use the `SET PERSIST` statement, which requires the `SYSTEM_VARIABLES_ADMIN` or `SUPER` privilege.
- To persist a global system variable to the `mysqld-auto.cnf` file (without setting the runtime value), use the `SET PERSIST_ONLY` statement, which requires the `SYSTEM_VARIABLES_ADMIN` and `PERSIST_RO_VARIABLES_ADMIN` privileges. `SET PERSIST_ONLY` can be used for both dynamic and read-only system variables, but is particularly useful for persisting read-only variables, for which `SET PERSIST` cannot be used.
- Some global system variables are persist-restricted (see [Section 7.1.9.4, “Nonpersistible and Persist-Restricted System Variables”](#)). To persist these variables, use the `SET PERSIST_ONLY` statement, which requires the privileges described previously. In addition, you must connect to the server using an encrypted connection and supply an SSL certificate with the Subject value specified by the `persist_only_admin_x509_subject` system variable.

To remove a persisted global system variable from the `mysqld-auto.cnf` file, use the `RESET PERSIST` statement. These privileges apply:

- For dynamic system variables, `RESET PERSIST` requires the `SYSTEM_VARIABLES_ADMIN` or `SUPER` privilege.
- For read-only system variables, `RESET PERSIST` requires the `SYSTEM_VARIABLES_ADMIN` and `PERSIST_RO_VARIABLES_ADMIN` privileges.
- For persist-restricted variables, `RESET PERSIST` does not require an encrypted connection to the server made using a particular SSL certificate.

If a global system variable has any exceptions to the preceding privilege requirements, the variable description indicates those exceptions. Examples include `default_table_encryption` and `mandatory_roles`, which require additional privileges. These additional privileges apply to operations that set the global runtime value, but not operations that persist the value.

To set a session system variable runtime value, use the `SET SESSION` statement. In contrast to setting global runtime values, setting session runtime values normally requires no special privileges and can be

done by any user to affect the current session. For some system variables, setting the session value may have effects outside the current session and thus is a restricted operation that can be done only by users who have a special privilege:

- The privilege required is `SESSION_VARIABLES_ADMIN`.

#### Note

Any user who has `SYSTEM_VARIABLES_ADMIN` or `SUPER` effectively has `SESSION_VARIABLES_ADMIN` by implication and need not be granted `SESSION_VARIABLES_ADMIN` explicitly.

If a session system variable is restricted, the variable description indicates that restriction. Examples include `binlog_format` and `sql_log_bin`. Setting the session value of these variables affects binary logging for the current session, but may also have wider implications for the integrity of server replication and backups.

`SESSION_VARIABLES_ADMIN` enables administrators to minimize the privilege footprint of users who may previously have been granted `SYSTEM_VARIABLES_ADMIN` or `SUPER` for the purpose of enabling them to modify restricted session system variables. Suppose that an administrator has created the following role to confer the ability to set restricted session system variables:

```
CREATE ROLE set_session_sysvars;
GRANT SYSTEM_VARIABLES_ADMIN ON *.* TO set_session_sysvars;
```

Any user granted the `set_session_sysvars` role (and who has that role active) is able to set restricted session system variables. However, that user is also able to set global system variables, which may be undesirable.

By modifying the role to have `SESSION_VARIABLES_ADMIN` instead of `SYSTEM_VARIABLES_ADMIN`, the role privileges can be reduced to the ability to set restricted session system variables and nothing else. To modify the role, use these statements:

```
GRANT SESSION_VARIABLES_ADMIN ON *.* TO set_session_sysvars;
REVOKE SYSTEM_VARIABLES_ADMIN ON *.* FROM set_session_sysvars;
```

Modifying the role has an immediate effect: Any account granted the `set_session_sysvars` role no longer has `SYSTEM_VARIABLES_ADMIN` and is not able to set global system variables without being granted that ability explicitly. A similar `GRANT/REVOKE` sequence can be applied to any account that was granted `SYSTEM_VARIABLES_ADMIN` directly rather than by means of a role.

### 7.1.9.2 Dynamic System Variables

Many server system variables are dynamic and can be set at runtime. See [Section 15.7.6.1, “SET Syntax for Variable Assignment”](#). For a description of the privilege requirements for setting system variables, see [Section 7.1.9.1, “System Variable Privileges”](#)

The following table lists all dynamic system variables applicable within `mysqld`.

The table lists each variable's data type and scope. The last column indicates whether the scope for each variable is Global, Session, or both. Please see the corresponding item descriptions for details on setting and using the variables. Where appropriate, direct links to further information about the items are provided.

Variables that have a type of “string” take a string value. Variables that have a type of “numeric” take a numeric value. Variables that have a type of “boolean” can be set to 0, 1, `ON` or `OFF`. Variables that are marked as “enumeration” normally should be set to one of the available values for the variable, but can also be set to the number that corresponds to the desired enumeration value. For enumerated system

variables, the first enumeration value corresponds to 0. This differs from the `ENUM` data type used for table columns, for which the first enumeration value corresponds to 1.

**Table 7.5 Dynamic System Variable Summary**

Variable Name	Variable Type	Variable Scope
<code>activate_all_roles_on_login</code>	Boolean	Global
<code>admin_ssl_ca</code>	File name	Global
<code>admin_ssl_caphash</code>	Directory name	Global
<code>admin_ssl_cert</code>	File name	Global
<code>admin_ssl_cipher</code>	String	Global
<code>admin_ssl_crl</code>	File name	Global

### 7.1.9.3 Persisted System Variables

The MySQL server maintains system variables that configure its operation. A system variable can have a global value that affects server operation as a whole, a session value that affects the current session, or both. Many system variables are dynamic and can be changed at runtime using the [SET](#) statement to affect operation of the current server instance. [SET](#) can also be used to persist certain global system variables to the `mysqld-auto.cnf` file in the data directory, to affect server operation for subsequent startups. [RESET PERSIST](#) removes persisted settings from `mysqld-auto.cnf`.

The following discussion describes aspects of persisting system variables:

- [Overview of Persisted System Variables](#)
- [Syntax for Persisting System Variables](#)
- [Obtaining Information About Persisted System Variables](#)
- [Format and Server Handling of the `mysqld-auto.cnf` File](#)
- [Persisting Sensitive System Variables](#)

#### Overview of Persisted System Variables

The capability of persisting global system variables at runtime enables server configuration that persists across server startups. Although many system variables can be set at startup from a `my.cnf` option file, or at runtime using the [SET](#) statement, those methods of configuring the server either require login access to the server host, or do not provide the capability of persistently configuring the server at runtime or remotely:

- Modifying an option file requires direct access to that file, which requires login access to the MySQL server host. This is not always convenient.

- Modifying system variables with `SET GLOBAL` is a runtime capability that can be done from clients run locally or from remote hosts, but the changes affect only the currently running server instance. The settings are not persistent and do not carry over to subsequent server startups.

To augment administrative capabilities for server configuration beyond what is achievable by editing option files or using `SET GLOBAL`, MySQL provides variants of `SET` syntax that persist system variable settings to a file named `mysqld-auto.cnf` file in the data directory. Examples:

```
SET PERSIST max_connections = 1000;
SET @@PERSIST.max_connections = 1000;

SET PERSIST_ONLY back_log = 100;
SET @@PERSIST_ONLY.back_log = 100;
```

MySQL also provides a `RESET PERSIST` statement for removing persisted system variables from `mysqld-auto.cnf`.

Server configuration performed by persisting system variables has these characteristics:

- Persisted settings are made at runtime.
- Persisted settings are permanent. They apply across server restarts.
- Persisted settings can be made from local clients or clients who connect from a remote host. This provides the convenience of remotely configuring multiple MySQL servers from a central client host.
- To persist system variables, you need not have login access to the MySQL server host or file system access to option files. Ability to persist settings is controlled using the MySQL privilege system. See [Section 7.1.9.1, “System Variable Privileges”](#).
- An administrator with sufficient privileges can reconfigure a server by persisting system variables, then cause the server to use the changed settings immediately by executing a `RESTART` statement.
- Persisted settings provide immediate feedback about errors. An error in a manually entered setting might not be discovered until much later. `SET` statements that persist system variables avoid the possibility of malformed settings because settings with syntax errors do not succeed and do not change server configuration.

## Syntax for Persisting System Variables

These `SET` syntax options are available for persisting system variables:

- To persist a global system variable to the `mysqld-auto.cnf` option file in the data directory, precede the variable name by the `PERSIST` keyword or the `@@PERSIST.` qualifier:

```
SET PERSIST max_connections = 1000;
SET @@PERSIST.max_connections = 1000;
```

Like `SET GLOBAL`, `SET PERSIST` sets the global variable runtime value, but also writes the variable setting to the `mysqld-auto.cnf` file (replacing any existing variable setting if there is one).

- To persist a global system variable to the `mysqld-auto.cnf` file without setting the global variable runtime value, precede the variable name by the `PERSIST_ONLY` keyword or the `@@PERSIST_ONLY.` qualifier:

```
SET PERSIST_ONLY back_log = 1000;
SET @@PERSIST_ONLY.back_log = 1000;
```

Like `PERSIST`, `PERSIST_ONLY` writes the variable setting to `mysqld-auto.cnf`. However, unlike `PERSIST`, `PERSIST_ONLY` does not modify the global variable runtime value. This makes

`PERSIST_ONLY` suitable for configuring read-only system variables that can be set only at server startup.

For more information about `SET`, see [Section 15.7.6.1, “SET Syntax for Variable Assignment”](#).

These `RESET PERSIST` syntax options are available for removing persisted system variables:

- To remove all persisted variables from `mysqld-auto.cnf`, use `RESET PERSIST` without naming any system variable:

```
RESET PERSIST;
```

- To remove a specific persisted variable from `mysqld-auto.cnf`, name it in the statement:

```
RESET PERSIST system_var_name;
```

This includes plugin system variables, even if the plugin is not currently installed. If the variable is not present in the file, an error occurs.

- To remove a specific persisted variable from `mysqld-auto.cnf`, but produce a warning rather than an error if the variable is not present in the file, add an `IF EXISTS` clause to the previous syntax:

```
RESET PERSIST IF EXISTS system_var_name;
```

For more information about `RESET PERSIST`, see [Section 15.7.8.7, “RESET PERSIST Statement”](#).

Using `SET` to persist a global system variable to a value of `DEFAULT` or to its literal default value assigns the variable its default value and adds a setting for the variable to `mysqld-auto.cnf`. To remove the variable from the file, use `RESET PERSIST`.

Some system variables cannot be persisted. See [Section 7.1.9.4, “Nonpersistible and Persist-Restricted System Variables”](#).

A system variable implemented by a plugin can be persisted if the plugin is installed when the `SET` statement is executed. Assignment of the persisted plugin variable takes effect for subsequent server restarts if the plugin is still installed. If the plugin is no longer installed, the plugin variable does not exist when the server reads the `mysqld-auto.cnf` file. In this case, the server writes a warning to the error log and continues:

```
currently unknown variable 'var_name'
was read from the persisted config file
```

## Obtaining Information About Persisted System Variables

The Performance Schema `persisted_variables` table provides an SQL interface to the `mysqld-auto.cnf` file, enabling its contents to be inspected at runtime using `SELECT` statements. See [Section 29.12.14.2, “Performance Schema `persisted\_variables` Table”](#).

The Performance Schema `variables_info` table contains information showing when and by which user each system variable was most recently set. See [Section 29.12.14.3, “Performance Schema `variables\_info` Table”](#).

`RESET PERSIST` affects the contents of the `persisted_variables` table because the table contents correspond to the contents of the `mysqld-auto.cnf` file. On the other hand, because `RESET PERSIST` does not change variable values, it has no effect on the contents of the `variables_info` table until the server is restarted.

## Format and Server Handling of the `mysqld-auto.cnf` File

The `mysqld-auto.cnf` file uses a `JSON` format like this (reformatted slightly for readability):

```
{
 "Version": 1,
 "mysql_server": {
 "max_connections": {
 "Value": "152",
 "Metadata": {
 "Timestamp": 1519921341372531,
 "User": "root",
 "Host": "localhost"
 }
 },
 "transaction_isolation": {
 "Value": "READ-COMMITTED",
 "Metadata": {
 "Timestamp": 1519921553880520,
 "User": "root",
 "Host": "localhost"
 }
 },
 "mysql_server_static_options": {
 "innodb_api_enable_md1": {
 "Value": "0",
 "Metadata": {
 "Timestamp": 1519922873467872,
 "User": "root",
 "Host": "localhost"
 }
 },
 "log_replica_updates": {
 "Value": "1",
 "Metadata": {
 "Timestamp": 1519925628441588,
 "User": "root",
 "Host": "localhost"
 }
 }
 }
 }
}
```

At startup, the server processes the `mysqld-auto.cnf` file after all other option files (see [Section 6.2.2.2, “Using Option Files”](#)). The server handles the file contents as follows:

- If the `persisted_globals_load` system variable is disabled, the server ignores the `mysqld-auto.cnf` file.
- The `"mysql_server_static_options"` section contains read-only variables persisted using `SET PERSIST_ONLY`. The section may also (despite its name) contain certain dynamic variables that are not read only. All variables present inside this section are appended to the command line and processed with other command-line options.
- All remaining persisted variables are set by executing the equivalent of a `SET GLOBAL` statement later, just before the server starts listening for client connections. These settings therefore do not take effect until late in the startup process, which might be unsuitable for certain system variables. It may be preferable to set such variables in `my.cnf` rather than in `mysqld-auto.cnf`.

Management of the `mysqld-auto.cnf` file should be left to the server. Manipulation of the file should be performed only using `SET` and `RESET PERSIST` statements, not manually:

- Removal of the file results in a loss of all persisted settings at the next server startup. (This is permissible if your intent is to reconfigure the server without these settings.) To remove all settings in the file without removing the file itself, use this statement:

```
RESET PERSIST;
```

- Manual changes to the file may result in a parse error at server startup. In this case, the server reports an error and exits. If this issue occurs, start the server with the `persisted_globals_load` system variable disabled or with the `--no-defaults` option. Alternatively, remove the `mysqld-auto.cnf` file. However, as noted previously, removing this file results in a loss of all persisted settings.

## Persisting Sensitive System Variables

MySQL 9.1 has the capability to store persisted system variable values containing sensitive data such as private keys or passwords securely, and to restrict viewing of the values. No MySQL Server system variables are currently marked as sensitive, but this capability allows system variables containing sensitive data to be persisted securely in the future. A `mysqld-auto.cnf` option file created by MySQL 9.1 cannot be read by older releases of MySQL Server.

### Note

A keyring component must be enabled on the MySQL Server instance to support secure storage for persisted system variable values, rather than a keyring plugin, which do not support the function. See [Section 8.4.4, “The MySQL Keyring”](#).

In the `mysqld-auto.cnf` option file, the names and values of sensitive system variables are stored in an encrypted format, along with a generated file key to decrypt them. The generated file key is in turn encrypted using a master key (`persisted_variables_key`) that is stored in a keyring. When the server starts up, the persisted sensitive system variables are decrypted and used. By default, if encrypted values are present in the option file but cannot be successfully decrypted at startup, their default settings are used. The optional most secure setting makes the server halt startup if the encrypted values cannot be decrypted.

The system variable `persist_sensitive_variables_in_plaintext` controls whether the server is permitted to store the values of sensitive system variables in an unencrypted format, if keyring component support is not available at the time when `SET PERSIST` is used to set the value. It also controls whether or not the server can start if the encrypted values cannot be decrypted.

- The default setting, `ON`, encrypts the values if keyring component support is available, and persists them unencrypted (with a warning) if it is not. The next time any persisted system variable is set, if keyring support is available at that time, the server encrypts the values of any unencrypted sensitive system variables. The `ON` setting also allows the server to start if encrypted system variable values cannot be decrypted, in which case a warning is issued and the default values for the system variables are used. In that situation, their values cannot be changed until they can be decrypted.
- The most secure setting, `OFF`, means sensitive system variable values cannot be persisted if keyring component support is unavailable. The `OFF` setting also means the server does not start if encrypted system variable values cannot be decrypted.

The privilege `SENSITIVE_VARIABLES_OBSERVER` allows a holder to view the values of sensitive system variables in the Performance Schema tables `global_variables`, `session_variables`, `variables_by_thread`, and `persisted_variables`, to issue `SELECT` statements to return their values, and to track changes to them in session trackers for connections. Users without this privilege cannot view or track those system variable values.

If a `SET` statement is issued for a sensitive system variable, the query is rewritten to replace the value with “<redacted>” before it is logged to the general log and audit log. This takes place even if secure storage through a keyring component is not available on the server instance.

### 7.1.9.4 Nonpersistible and Persist-Restricted System Variables

`SET PERSIST` and `SET PERSIST_ONLY` enable global system variables to be persisted to the `mysqld-auto.cnf` option file in the data directory (see [Section 15.7.6.1, “SET Syntax for Variable Assignment”](#)).

However, not all system variables can be persisted, or can be persisted only under certain restrictive conditions. Here are some reasons why a system variable might be nonpersistible or persist-restricted:

- Session system variables cannot be persisted. Session variables cannot be set at server startup, so there is no reason to persist them.
- A global system variable might involve sensitive data such that it should be settable only by a user with direct access to the server host.
- A global system variable might be read only (that is, set only by the server). In this case, it cannot be set by users at all, whether at server startup or at runtime.
- A global system variable might be intended only for internal use.

Nonpersistible system variables cannot be persisted under any circumstances. Persist-restricted system variables can be persisted with `SET PERSIST_ONLY`, but only by users for which the following conditions are satisfied:

- The `persist_only_admin_x509_subject` system variable is set to an SSL certificate X.509 Subject value.
- The user connects to the server using an encrypted connection and supplies an SSL certificate with the designated Subject value.
- The user has sufficient privileges to use `SET PERSIST_ONLY` (see [Section 7.1.9.1, “System Variable Privileges”](#)).

For example, `protocol_version` is read only and set only by the server, so it cannot be persisted under any circumstances. On the other hand, `bind_address` is persist-restricted, so it can be set by users who satisfy the preceding conditions.

The following system variables are nonpersistible. This list may change with ongoing development.

```
audit_log_current_session
audit_log_filter_id
caching_sha2_password_digest_rounds
character_set_system
core_file
have_statement_timeout
have_symlink
hostname
innodb_version
keyring_hashicorp_auth_path
keyring_hashicorp_ca_path
keyring_hashicorp_caching
keyring_hashicorp_commit_auth_path
keyring_hashicorp_commit_ca_path
keyring_hashicorp_commit_caching
keyring_hashicorp_commit_role_id
keyring_hashicorp_commit_server_url
keyring_hashicorp_commit_store_path
keyring_hashicorp_role_id
keyring_hashicorp_secret_id
keyring_hashicorp_server_url
keyring_hashicorp_store_path
large_files_support
large_page_size
license
locked_in_memory
log_bin
log_bin_basename
log_bin_index
```

```
lower_case_file_system
ndb_version
ndb_version_string
persist_only_admin_x509_subject
persisted_globals_load
protocol_version
relay_log_basename
relay_log_index
server_uuid
skip_external_locking
system_time_zone
version_comment
version_compile_machine
version_compile_os
version_compile_zlib
```

Persist-restricted system variables are those that are read only and can be set on the command line or in an option file, other than `persist_only_admin_x509_subject` and `persisted_globals_load`. This list may change with ongoing development.

```
audit_log_file

ssl_capath
ssl_cert
ssl_crl
```

```
ssl_crlpath
ssl_key
tmpdir
version_tokens_session_number
```

To configure the server to enable persisting persist-restricted system variables, use this procedure:

1. Ensure that MySQL is configured to support encrypted connections. See [Section 8.3.1, “Configuring MySQL to Use Encrypted Connections”](#).
2. Designate an SSL certificate X.509 Subject value that signifies the ability to persist persist-restricted system variables, and generate a certificate that has that Subject. See [Section 8.3.3, “Creating SSL and RSA Certificates and Keys”](#).
3. Start the server with `persist_only_admin_x509_subject` set to the designated Subject value. For example, put these lines in your server `my.cnf` file:

```
[mysqld]
persist_only_admin_x509_subject="subject-value"
```

The format of the Subject value is the same as used for `CREATE USER ... REQUIRE SUBJECT`. See [Section 15.7.1.3, “CREATE USER Statement”](#).

You must perform this step directly on the MySQL server host because `persist_only_admin_x509_subject` itself cannot be persisted at runtime.

4. Restart the server.
5. Distribute the SSL certificate that has the designated Subject value to users who are to be permitted to persist persist-restricted system variables.

Suppose that `myclient-cert.pem` is the SSL certificate to be used by clients who can persist persist-restricted system variables. Display the certificate contents using the `openssl` command:

```
$> openssl x509 -text -in myclient-cert.pem
Certificate:
 Data:
 Version: 3 (0x2)
 Serial Number: 2 (0x2)
 Signature Algorithm: md5WithRSAEncryption
 Issuer: C=US, ST=IL, L=Chicago, O=MyOrg, OU=CA, CN=MyCN
 Validity
 Not Before: Oct 18 17:03:03 2018 GMT
 Not After : Oct 15 17:03:03 2028 GMT
 Subject: C=US, ST=IL, L=Chicago, O=MyOrg, OU=client, CN=MyCN
 ...
```

The `openssl` output shows that the certificate Subject value is:

```
C=US, ST=IL, L=Chicago, O=MyOrg, OU=client, CN=MyCN
```

To specify the Subject for MySQL, use this format:

```
/C=US/ST=IL/L=Chicago/O=MyOrg/OU=client/CN=MyCN
```

Configure the server `my.cnf` file with the Subject value:

```
[mysqld]
persist_only_admin_x509_subject="/C=US/ST=IL/L=Chicago/O=MyOrg/OU=client/CN=MyCN"
```

Restart the server so that the new configuration takes effect.

Distribute the SSL certificate (and any other associated SSL files) to the appropriate users. Such a user then connects to the server with the certificate and any other SSL options required to establish an encrypted connection.

To use X.509, clients must specify the `--ssl-key` and `--ssl-cert` options to connect. It is recommended but not required that `--ssl-ca` also be specified so that the public certificate provided by the server can be verified. For example:

```
$> mysql --ssl-key=myclient-key.pem --ssl-cert=myclient-cert.pem --ssl-ca=mycacert.pem
```

Assuming that the user has sufficient privileges to use `SET PERSIST_ONLY`, persist-restricted system variables can be persisted like this:

```
mysql> SET PERSIST_ONLY socket = '/tmp/mysql.sock';
Query OK, 0 rows affected (0.00 sec)
```

If the server is not configured to enable persisting persist-restricted system variables, or the user does not satisfy the required conditions for that capability, an error occurs:

```
mysql> SET PERSIST_ONLY socket = '/tmp/mysql.sock';
ERROR 1238 (HY000): Variable 'socket' is a non persistent read only variable
```

### 7.1.9.5 Structured System Variables

A structured variable differs from a regular system variable in two respects:

- Its value is a structure with components that specify server parameters considered to be closely related.
- There might be several instances of a given type of structured variable. Each one has a different name and refers to a different resource maintained by the server.

MySQL supports one structured variable type, which specifies parameters governing the operation of key caches. A key cache structured variable has these components:

- `key_buffer_size`
- `key_cache_block_size`
- `key_cache_division_limit`
- `key_cache_age_threshold`

This section describes the syntax for referring to structured variables. Key cache variables are used for syntax examples, but specific details about how key caches operate are found elsewhere, in [Section 10.10.2, “The MyISAM Key Cache”](#).

To refer to a component of a structured variable instance, you can use a compound name in `instance_name.component_name` format. Examples:

```
hot_cache.key_buffer_size
hot_cache.key_cache_block_size
cold_cache.key_cache_block_size
```

For each structured system variable, an instance with the name of `default` is always predefined. If you refer to a component of a structured variable without any instance name, the `default` instance is used. Thus, `default.key_buffer_size` and `key_buffer_size` both refer to the same system variable.

Structured variable instances and components follow these naming rules:

- For a given type of structured variable, each instance must have a name that is unique *within* variables of that type. However, instance names need not be unique *across* structured variable types. For

example, each structured variable has an instance named `default`, so `default` is not unique across variable types.

- The names of the components of each structured variable type must be unique across all system variable names. If this were not true (that is, if two different types of structured variables could share component member names), it would not be clear which default structured variable to use for references to member names that are not qualified by an instance name.
- If a structured variable instance name is not legal as an unquoted identifier, refer to it as a quoted identifier using backticks. For example, `hot-cache` is not legal, but ``hot-cache`` is.
- `global`, `session`, and `local` are not legal instance names. This avoids a conflict with notation such as `@@GLOBAL.var_name` for referring to nonstructured system variables.

Currently, the first two rules have no possibility of being violated because the only structured variable type is the one for key caches. These rules may assume greater significance if some other type of structured variable is created in the future.

With one exception, you can refer to structured variable components using compound names in any context where simple variable names can occur. For example, you can assign a value to a structured variable using a command-line option:

```
$> mysqld --hot_cache.key_buffer_size=64K
```

In an option file, use this syntax:

```
[mysqld]
hot_cache.key_buffer_size=64K
```

If you start the server with this option, it creates a key cache named `hot_cache` with a size of 64KB in addition to the default key cache that has a default size of 8MB.

Suppose that you start the server as follows:

```
$> mysqld --key_buffer_size=256K \
 --extra_cache.key_buffer_size=128K \
 --extra_cache.key_cache_block_size=2048
```

In this case, the server sets the size of the default key cache to 256KB. (You could also have written `--default.key_buffer_size=256K`.) In addition, the server creates a second key cache named `extra_cache` that has a size of 128KB, with the size of block buffers for caching table index blocks set to 2048 bytes.

The following example starts the server with three different key caches having sizes in a 3:1:1 ratio:

```
$> mysqld --key_buffer_size=6M \
 --hot_cache.key_buffer_size=2M \
 --cold_cache.key_buffer_size=2M
```

Structured variable values may be set and retrieved at runtime as well. For example, to set a key cache named `hot_cache` to a size of 10MB, use either of these statements:

```
mysql> SET GLOBAL hot_cache.key_buffer_size = 10*1024*1024;
mysql> SET @@GLOBAL.hot_cache.key_buffer_size = 10*1024*1024;
```

To retrieve the cache size, do this:

```
mysql> SELECT @@GLOBAL.hot_cache.key_buffer_size;
```

However, the following statement does not work. The variable is not interpreted as a compound name, but as a simple string for a `LIKE` pattern-matching operation:

```
mysql> SHOW GLOBAL VARIABLES LIKE 'hot_cache.key_buffer_size';
```

This is the exception to being able to use structured variable names anywhere a simple variable name may occur.

## 7.1.10 Server Status Variables

The MySQL server maintains many status variables that provide information about its operation. You can view these variables and their values by using the `SHOW [GLOBAL | SESSION] STATUS` statement (see [Section 15.7.7.36, “SHOW STATUS Statement”](#)). The optional `GLOBAL` keyword aggregates the values over all connections, and `SESSION` shows the values for the current connection.

```
mysql> SHOW GLOBAL STATUS;
```

Variable_name	Value
Aborted_clients	0
Aborted_connects	0
Bytes_received	155372598
Bytes_sent	1176560426
...	
Connections	30023
Created_tmp_disk_tables	0
Created_tmp_files	3
Created_tmp_tables	2
...	
Threads_created	217
Threads_running	88
Uptime	1389872

Many status variables are reset to 0 by the `FLUSH STATUS` statement.

This section provides a description of each status variable. For a status variable summary, see [Section 7.1.6, “Server Status Variable Reference”](#). For information about status variables specific to NDB Cluster, see [NDB Cluster Status Variables](#).

The status variables have the following meanings.

- `Aborted_clients`

The number of connections that were aborted because the client died without closing the connection properly. See [Section B.3.2.9, “Communication Errors and Aborted Connections”](#).

- `Aborted_connects`

The number of failed attempts to connect to the MySQL server. See [Section B.3.2.9, “Communication Errors and Aborted Connections”](#).

For additional connection-related information, check the `Connection_errors_xxx` status variables and the `host_cache` table.

- `Authentication_ldap_sasl_supported_methods`

The `authentication_ldap_sasl` plugin that implements SASL LDAP authentication supports multiple authentication methods, but depending on host system configuration, they might not all be available. The `Authentication_ldap_sasl_supported_methods` variable provides discoverability for the supported methods. Its value is a string consisting of supported method names separated by spaces. Example: `"SCRAM-SHA 1 SCRAM-SHA-256 GSSAPI"`

- `Binlog_cache_disk_use`

The number of transactions that used the temporary binary log cache but that exceeded the value of `binlog_cache_size` and used a temporary file to store statements from the transaction.

The number of nontransactional statements that caused the binary log transaction cache to be written to disk is tracked separately in the `Binlog_stmt_cache_disk_use` status variable.

- `Acl_cache_items_count`

The number of cached privilege objects. Each object is the privilege combination of a user and its active roles.

- `Binlog_cache_use`

The number of transactions that used the binary log cache.

- `Binlog_stmt_cache_disk_use`

The number of nontransaction statements that used the binary log statement cache but that exceeded the value of `binlog_stmt_cache_size` and used a temporary file to store those statements.

- `Binlog_stmt_cache_use`

The number of nontransactional statements that used the binary log statement cache.

- `Bytes_received`

The number of bytes received from all clients.

- `Bytes_sent`

The number of bytes sent to all clients.

- `Caching_sha2_password_rsa_public_key`

The public key used by the `caching_sha2_password` authentication plugin for RSA key pair-based password exchange. The value is nonempty only if the server successfully initializes the private and public keys in the files named by the `caching_sha2_password_private_key_path` and `caching_sha2_password_public_key_path` system variables. The value of `Caching_sha2_password_rsa_public_key` comes from the latter file.

- `Com_xxx`

The `Com_xxx` statement counter variables indicate the number of times each `xxx` statement has been executed. There is one status variable for each type of statement. For example, `Com_delete` and `Com_update` count `DELETE` and `UPDATE` statements, respectively. `Com_delete_multi` and `Com_update_multi` are similar but apply to `DELETE` and `UPDATE` statements that use multiple-table syntax.

All `Com_stmt_xxx` variables are increased even if a prepared statement argument is unknown or an error occurred during execution. In other words, their values correspond to the number of requests issued, not to the number of requests successfully completed. For example, because status variables are initialized for each server startup and do not persist across restarts, the `Com_restart` and `Com_shutdown` variables that track `RESTART` and `SHUTDOWN` statements normally have a value of zero, but can be nonzero if `RESTART` or `SHUTDOWN` statements were executed but failed.

The `Com_stmt_xxx` status variables are as follows:

- `Com_stmt_prepare`
- `Com_stmt_execute`
- `Com_stmt_fetch`
- `Com_stmt_send_long_data`
- `Com_stmt_reset`
- `Com_stmt_close`

Those variables stand for prepared statement commands. Their names refer to the `COM_xxx` command set used in the network layer. In other words, their values increase whenever prepared statement API calls such as `mysql_stmt_prepare()`, `mysql_stmt_execute()`, and so forth are executed. However, `Com_stmt_prepare`, `Com_stmt_execute` and `Com_stmt_close` also increase for `PREPARE`, `EXECUTE`, or `DEALLOCATE PREPARE`, respectively. Additionally, the values of the older statement counter variables `Com_prepare_sql`, `Com_execute_sql`, and `Com_dealloc_sql` increase for the `PREPARE`, `EXECUTE`, and `DEALLOCATE PREPARE` statements. `Com_stmt_fetch` stands for the total number of network round-trips issued when fetching from cursors.

`Com_stmt_reprepare` indicates the number of times statements were automatically reprepared by the server, for example, after metadata changes to tables or views referred to by the statement. A reprepare operation increments `Com_stmt_reprepare`, and also `Com_stmt_prepare`.

`Com_explain_other` indicates the number of `EXPLAIN FOR CONNECTION` statements executed. See [Section 10.8.4, “Obtaining Execution Plan Information for a Named Connection”](#).

`Com_change_repl_filter` indicates the number of `CHANGE REPLICATION FILTER` statements executed.

- `Compression`

Whether the client connection uses compression in the client/server protocol.

This status variable is deprecated; expect it to be removed in a future version of MySQL. See [Configuring Legacy Connection Compression](#).

- `Compression_algorithm`

The name of the compression algorithm in use for the current connection to the server. The value can be any algorithm permitted in the value of the `protocol_compression_algorithms` system variable. For example, the value is `uncompressed` if the connection does not use compression, or `zlib` if the connection uses the `zlib` algorithm.

For more information, see [Section 6.2.8, “Connection Compression Control”](#).

- `Compression_level`

The compression level in use for the current connection to the server. The value is 6 for `zlib` connections (the default `zlib` algorithm compression level), 1 to 22 for `zstd` connections, and 0 for `uncompressed` connections.

For more information, see [Section 6.2.8, “Connection Compression Control”](#).

- [Connection\\_errors\\_xxx](#)

These variables provide information about errors that occur during the client connection process. They are global only and represent error counts aggregated across connections from all hosts. These variables track errors not accounted for by the host cache (see [Section 7.1.12.3, “DNS Lookups and the Host Cache”](#)), such as errors that are not associated with TCP connections, occur very early in the connection process (even before an IP address is known), or are not specific to any particular IP address (such as out-of-memory conditions).

- [Connection\\_errors\\_accept](#)

The number of errors that occurred during calls to [accept\(\)](#) on the listening port.

- [Connection\\_errors\\_internal](#)

The number of connections refused due to internal errors in the server, such as failure to start a new thread or an out-of-memory condition.

- [Connection\\_errors\\_max\\_connections](#)

The number of connections refused because the server [max\\_connections](#) limit was reached.

- [Connection\\_errors\\_peer\\_address](#)

The number of errors that occurred while searching for connecting client IP addresses.

- [Connection\\_errors\\_select](#)

The number of errors that occurred during calls to [select\(\)](#) or [poll\(\)](#) on the listening port. (Failure of this operation does not necessarily mean a client connection was rejected.)

- [Connection\\_errors\\_tcpwrap](#)

The number of connections refused by the [libwrap](#) library.

- [Connections](#)

The number of connection attempts (successful or not) to the MySQL server.

- [Count\\_hit\\_query\\_past\\_global\\_connection\\_memory\\_status\\_limit](#)

The number of times that queries using any connection have caused total memory consumption to exceed [global\\_connection\\_memory\\_status\\_limit](#). This is incremented when a query brings the total memory consumption from less than [global\\_connection\\_memory\\_status\\_limit](#) to greater than this amount; when a query is executed but total memory consumption already exceeds this limit, the status variable is not incremented.

- [Count\\_hit\\_query\\_past\\_connection\\_memory\\_status\\_limit](#)

The number of times that queries using the current connection have caused total memory consumption to exceed [connection\\_memory\\_limit](#). This is incremented, for a query executed within the connection, when such a query brings the total memory consumption from less than [connection\\_memory\\_limit](#) to greater than this amount; when a query is executed but total memory consumption already exceeds this limit, the status variable is not incremented.

- `Count_hit_tmp_table_size`

The number of [internal temporary tables](#) that were converted from in-memory to on-disk because either the `TempTable` engine reached the `tmp_table_size` limit or the `MEMORY` engine reached the smaller value of `tmp_table_size` and `max_heap_table_size`.

- `Created_tmp_disk_tables`

The number of internal on-disk temporary tables created by the server while executing statements.

You can compare the number of internal on-disk temporary tables created to the total number of internal temporary tables created by comparing `Created_tmp_disk_tables` and `Created_tmp_tables` values.

**Note**

Due to a known limitation, `Created_tmp_disk_tables` does not count on-disk temporary tables created in memory-mapped files. By default, the `TempTable` storage engine overflow mechanism creates internal temporary tables in memory-mapped files. This behavior is controlled by the `temptable_use_mmap` variable.

See also [Section 10.4.4, “Internal Temporary Table Use in MySQL”](#).

- `Created_tmp_files`

How many temporary files `mysqld` has created.

- `Created_tmp_tables`

The number of internal temporary tables created by the server while executing statements.

You can compare the number of internal on-disk temporary tables created to the total number of internal temporary tables created by comparing `Created_tmp_disk_tables` and `Created_tmp_tables` values.

See also [Section 10.4.4, “Internal Temporary Table Use in MySQL”](#).

Each invocation of the `SHOW STATUS` statement uses an internal temporary table and increments the global `Created_tmp_tables` value.

- `Current_tls_ca`

The active `ssl_ca` value in the SSL context that the server uses for new connections. This context value may differ from the current `ssl_ca` system variable value if the system variable has been changed but `ALTER INSTANCE RELOAD TLS` has not subsequently been executed to reconfigure the SSL context from the context-related system variable values and update the corresponding status variables. (This potential difference in values applies to each corresponding pair of context-related system and status variables. See [Server-Side Runtime Configuration and Monitoring for Encrypted Connections](#).)

The `Current_tls_XXX` status variable values are also available through the Performance Schema `tls_channel_status` table. See [Section 29.12.22.10, “The `tls\_channel\_status` Table”](#).

- `Current_tls_capath`

The active `ssl_capath` value in the TLS context that the server uses for new connections. For notes about the relationship between this status variable and its corresponding system variable, see the description of `Current_tls_ca`.

- [Current\\_tls\\_cert](#)

The active [ssl\\_cert](#) value in the TLS context that the server uses for new connections. For notes about the relationship between this status variable and its corresponding system variable, see the description of [Current\\_tls\\_ca](#).

- [Current\\_tls\\_cipher](#)

The active [ssl\\_cipher](#) value in the TLS context that the server uses for new connections. For notes about the relationship between this status variable and its corresponding system variable, see the description of [Current\\_tls\\_ca](#).

- [Current\\_tls\\_ciphersuites](#)

The active [tls\\_ciphersuites](#) value in the TLS context that the server uses for new connections. For notes about the relationship between this status variable and its corresponding system variable, see the description of [Current\\_tls\\_ca](#).

- [Current\\_tls\\_crl](#)

The active [ssl\\_crl](#) value in the TLS context that the server uses for new connections. For notes about the relationship between this status variable and its corresponding system variable, see the description of [Current\\_tls\\_ca](#).

**Note**

When you reload the TLS context, OpenSSL reloads the file containing the CRL (certificate revocation list) as part of the process. If the CRL file is large, the server allocates a large chunk of memory (ten times the file size), which is doubled while the new instance is being loaded and the old one has not yet been released. The process resident memory is not immediately reduced after a large allocation is freed, so if you issue the [ALTER INSTANCE RELOAD TLS](#) statement repeatedly with a large CRL file, the process resident memory usage may grow as a result of this.

- [Current\\_tls\\_crlpath](#)

The active [ssl\\_crlpath](#) value in the TLS context that the server uses for new connections. For notes about the relationship between this status variable and its corresponding system variable, see the description of [Current\\_tls\\_ca](#).

- [Current\\_tls\\_key](#)

The active [ssl\\_key](#) value in the TLS context that the server uses for new connections. For notes about the relationship between this status variable and its corresponding system variable, see the description of [Current\\_tls\\_ca](#).

- [Current\\_tls\\_version](#)

The active [tls\\_version](#) value in the TLS context that the server uses for new connections. For notes about the relationship between this status variable and its corresponding system variable, see the description of [Current\\_tls\\_ca](#).

- [Delayed\\_errors](#)

This status variable is deprecated (because [DELAYED](#) inserts are not supported); expect it to be removed in a future release.

- `Delayed_insert_threads`

This status variable is deprecated (because `DELAYED` inserts are not supported); expect it to be removed in a future release.

- `Delayed_writes`

This status variable is deprecated (because `DELAYED` inserts are not supported); expect it to be removed in a future release.

- `Deprecated_use_i_s_processlist_count`

How many times the `information_schema.processlist` table has been accessed since the last restart.

- `Deprecated_use_i_s_processlist_last_timestamp`

A timestamp indicating the last time the `information_schema.processlist` table has been accessed since the last restart. Shows microseconds since the Unix Epoch.

- `dragnet.Status`

The result of the most recent assignment to the `dragnet.log_error_filter_rules` system variable, empty if no such assignment has occurred.

- `Error_log_buffered_bytes`

The number of bytes currently used in the Performance Schema `error_log` table. It is possible for the value to decrease, for example, if a new event cannot fit until discarding an old event, but the new event is smaller than the old one.

- `Error_log_buffered_events`

The number of events currently present in the Performance Schema `error_log` table. As with `Error_log_buffered_bytes`, it is possible for the value to decrease.

- `Error_log_expired_events`

The number of events discarded from the Performance Schema `error_log` table to make room for new events.

- `Error_log_latest_write`

The time of the last write to the Performance Schema `error_log` table.

- `Flush_commands`

The number of times the server flushes tables, whether because a user executed a `FLUSH TABLES` statement or due to internal server operation. It is also incremented by receipt of a `COM_REFRESH` packet. This is in contrast to `Com_flush`, which indicates how many `FLUSH` statements have been executed, whether `FLUSH TABLES`, `FLUSH LOGS`, and so forth.

- `Global_connection_memory`

The memory used by all user connections to the server. Memory used by system threads or by the MySQL root account is included in the total, but such threads or users are not subject to disconnection due to memory usage. This memory is not calculated unless `global_connection_memory_tracking` is enabled (disabled by default). The Performance Schema must also be enabled.

You can control (indirectly) the frequency with which this variable is updated by setting `connection_memory_chunk_size`.

- `Handler_commit`

The number of internal `COMMIT` statements.

- `Handler_delete`

The number of times that rows have been deleted from tables.

- `Handler_external_lock`

The server increments this variable for each call to its `external_lock()` function, which generally occurs at the beginning and end of access to a table instance. There might be differences among storage engines. This variable can be used, for example, to discover for a statement that accesses a partitioned table how many partitions were pruned before locking occurred: Check how much the counter increased for the statement, subtract 2 (2 calls for the table itself), then divide by 2 to get the number of partitions locked.

- `Handler_mrr_init`

The number of times the server uses a storage engine's own Multi-Range Read implementation for table access.

- `Handler_prepare`

A counter for the prepare phase of two-phase commit operations.

- `Handler_read_first`

The number of times the first entry in an index was read. If this value is high, it suggests that the server is doing a lot of full index scans (for example, `SELECT coll FROM foo`, assuming that `coll` is indexed).

- `Handler_read_key`

The number of requests to read a row based on a key. If this value is high, it is a good indication that your tables are properly indexed for your queries.

- `Handler_read_last`

The number of requests to read the last key in an index. With `ORDER BY`, the server issues a first-key request followed by several next-key requests, whereas with `ORDER BY DESC`, the server issues a last-key request followed by several previous-key requests.

- `Handler_read_next`

The number of requests to read the next row in key order. This value is incremented if you are querying an index column with a range constraint or if you are doing an index scan.

- `Handler_read_prev`

The number of requests to read the previous row in key order. This read method is mainly used to optimize `ORDER BY ... DESC`.

- `Handler_read_rnd`

The number of requests to read a row based on a fixed position. This value is high if you are doing a lot of queries that require sorting of the result. You probably have a lot of queries that require MySQL to scan entire tables or you have joins that do not use keys properly.

- [Handler\\_read\\_rnd\\_next](#)

The number of requests to read the next row in the data file. This value is high if you are doing a lot of table scans. Generally this suggests that your tables are not properly indexed or that your queries are not written to take advantage of the indexes you have.

- [Handler\\_rollback](#)

The number of requests for a storage engine to perform a rollback operation.

- [Handler\\_savepoint](#)

The number of requests for a storage engine to place a savepoint.

- [Handler\\_savepoint\\_rollback](#)

The number of requests for a storage engine to roll back to a savepoint.

- [Handler\\_update](#)

The number of requests to update a row in a table.

- [Handler\\_write](#)

The number of requests to insert a row in a table.

- [Innodb\\_buffer\\_pool\\_dump\\_status](#)

The progress of an operation to record the [pages](#) held in the [InnoDB buffer pool](#), triggered by the setting of [innodb\\_buffer\\_pool\\_dump\\_at\\_shutdown](#) or [innodb\\_buffer\\_pool\\_dump\\_now](#).

For related information and examples, see [Section 17.8.3.6, “Saving and Restoring the Buffer Pool State”](#).

- [Innodb\\_buffer\\_pool\\_load\\_status](#)

The progress of an operation to [warm up](#) the [InnoDB buffer pool](#) by reading in a set of [pages](#) corresponding to an earlier point in time, triggered by the setting of [innodb\\_buffer\\_pool\\_load\\_at\\_startup](#) or [innodb\\_buffer\\_pool\\_load\\_now](#). If the operation introduces too much overhead, you can cancel it by setting [innodb\\_buffer\\_pool\\_load\\_abort](#).

For related information and examples, see [Section 17.8.3.6, “Saving and Restoring the Buffer Pool State”](#).

- [Innodb\\_buffer\\_pool\\_bytes\\_data](#)

The total number of bytes in the [InnoDB buffer pool](#) containing data. The number includes both [dirty](#) and clean pages. For more accurate memory usage calculations than with [Innodb\\_buffer\\_pool\\_pages\\_data](#), when [compressed](#) tables cause the buffer pool to hold pages of different sizes.

- `Innodb_buffer_pool_pages_data`

The number of [pages](#) in the [InnoDB buffer pool](#) containing data. The number includes both [dirty](#) and clean pages. When using [compressed tables](#), the reported `Innodb_buffer_pool_pages_data` value may be larger than `Innodb_buffer_pool_pages_total` (Bug #59550).

- `Innodb_buffer_pool_bytes_dirty`

The total current number of bytes held in [dirty pages](#) in the [InnoDB buffer pool](#). For more accurate memory usage calculations than with `Innodb_buffer_pool_pages_dirty`, when [compressed](#) tables cause the buffer pool to hold pages of different sizes.

- `Innodb_buffer_pool_pages_dirty`

The current number of [dirty pages](#) in the [InnoDB buffer pool](#).

- `Innodb_buffer_pool_pages_flushed`

The number of requests to [flush pages](#) from the [InnoDB buffer pool](#).

- `Innodb_buffer_pool_pages_free`

The number of free [pages](#) in the [InnoDB buffer pool](#).

- `Innodb_buffer_pool_pages_latched`

The number of latched [pages](#) in the [InnoDB buffer pool](#). These are pages currently being read or written, or that cannot be [flushed](#) or removed for some other reason. Calculation of this variable is expensive, so it is available only when the `UNIV_DEBUG` system is defined at server build time.

- `Innodb_buffer_pool_pages_misc`

The number of [pages](#) in the [InnoDB buffer pool](#) that are busy because they have been allocated for administrative overhead, such as [row locks](#) or the [adaptive hash index](#). This value can also be calculated as `Innodb_buffer_pool_pages_total - Innodb_buffer_pool_pages_free - Innodb_buffer_pool_pages_data`. When using [compressed tables](#), `Innodb_buffer_pool_pages_misc` may report an out-of-bounds value (Bug #59550).

- `Innodb_buffer_pool_pages_total`

The total size of the [InnoDB buffer pool](#), in [pages](#). When using [compressed tables](#), the reported `Innodb_buffer_pool_pages_data` value may be larger than `Innodb_buffer_pool_pages_total` (Bug #59550)

- `Innodb_buffer_pool_read_ahead`

The number of [pages](#) read into the [InnoDB buffer pool](#) by the [read-ahead](#) background thread.

- `Innodb_buffer_pool_read_ahead_evicted`

The number of [pages](#) read into the [InnoDB buffer pool](#) by the [read-ahead](#) background thread that were subsequently [evicted](#) without having been accessed by queries.

- `Innodb_buffer_pool_read_ahead_rnd`

The number of “random” read-aheads initiated by [InnoDB](#). This happens when a query scans a large portion of a table but in random order.

- `Innodb_buffer_pool_read_requests`

The number of logical read requests.

- `Innodb_buffer_pool_reads`

The number of logical reads that InnoDB could not satisfy from the [buffer pool](#), and had to read directly from disk.

- `Innodb_buffer_pool_resize_status`

The status of an operation to resize the InnoDB [buffer pool](#) dynamically, triggered by setting the `innodb_buffer_pool_size` parameter dynamically. The `innodb_buffer_pool_size` parameter is dynamic, which allows you to resize the buffer pool without restarting the server. See [Configuring InnoDB Buffer Pool Size Online](#) for related information.

- `Innodb_buffer_pool_resize_status_code`

Reports status codes for tracking online buffer pool resizing operations. Each status code represents a stage in a resizing operation. Status codes include:

- 0: No Resize operation in progress
- 1: Starting Resize
- 2: Disabling AHI (Adaptive Hash Index)
- 3: Withdrawing Blocks
- 4: Acquiring Global Lock
- 5: Resizing Pool
- 6: Resizing Hash
- 7: Resizing Failed

You can use this status variable in conjunction with `Innodb_buffer_pool_resize_status_progress` to track the progress of each stage of a resizing operation. The `Innodb_buffer_pool_resize_status_progress` variable reports a percentage value indicating the progress of the current stage.

For more information, see [Monitoring Online Buffer Pool Resizing Progress](#).

- `Innodb_buffer_pool_resize_status_progress`

Reports a percentage value indicating the progress of the current stage of an online buffer pool resizing operation. This variable is used in conjunction with `Innodb_buffer_pool_resize_status_code`, which reports a status code indicating the current stage of an online buffer pool resizing operation.

The percentage value is updated after each buffer pool instance is processed. As the status code (reported by `Innodb_buffer_pool_resize_status_code`) changes from one status to another, the percentage value is reset to 0.

For related information, see [Monitoring Online Buffer Pool Resizing Progress](#).

- `Innodb_buffer_pool_wait_free`

Normally, writes to the [InnoDB buffer pool](#) happen in the background. When [InnoDB](#) needs to read or create a [page](#) and no clean pages are available, [InnoDB](#) flushes some [dirty pages](#) first and waits for that operation to finish. This counter counts instances of these waits. If `innodb_buffer_pool_size` has been set properly, this value should be small.

- `Innodb_buffer_pool_write_requests`

The number of writes done to the [InnoDB buffer pool](#).

- `Innodb_data_fsyncs`

The number of `fsync()` operations so far. The frequency of `fsync()` calls is influenced by the setting of the `innodb_flush_method` configuration option.

Counts the number of `fdatsync()` operations if `innodb_use_fdatasync` is enabled.

- `Innodb_data_pending_fsyncs`

The current number of pending `fsync()` operations. The frequency of `fsync()` calls is influenced by the setting of the `innodb_flush_method` configuration option.

- `Innodb_data_pending_reads`

The current number of pending reads.

- `Innodb_data_pending_writes`

The current number of pending writes.

- `Innodb_data_read`

The amount of data read since the server was started (in bytes).

- `Innodb_data_reads`

The total number of data reads (OS file reads).

- `Innodb_data_writes`

The total number of data writes.

- `Innodb_data_written`

The amount of data written so far, in bytes.

- `Innodb_dblwr_pages_written`

The number of [pages](#) that have been written to the [doublewrite buffer](#). See [Section 17.11.1, “InnoDB Disk I/O”](#).

- `Innodb_dblwr_writes`

The number of doublewrite operations that have been performed. See [Section 17.11.1, “InnoDB Disk I/O”](#).

- `Innodb_have_atomic_builtins`

Indicates whether the server was built with [atomic instructions](#).

- `Innodb_log_waits`

The number of times that the [log buffer](#) was too small and a [wait](#) was required for it to be [flushed](#) before continuing.

- `Innodb_log_write_requests`

The number of write requests for the [InnoDB redo log](#).

- `Innodb_log_writes`

The number of physical writes to the [InnoDB redo log](#) file.

- `Innodb_num_open_files`

The number of files [InnoDB](#) currently holds open.

- `Innodb_os_log_fsyncs`

The number of `fsync()` writes done to the [InnoDB redo log](#) files.

- `Innodb_os_log_pending_fsyncs`

The number of pending `fsync()` operations for the [InnoDB redo log](#) files.

- `Innodb_os_log_pending_writes`

The number of pending writes to the [InnoDB redo log](#) files.

- `Innodb_os_log_written`

The number of bytes written to the [InnoDB redo log](#) files.

- `Innodb_page_size`

[InnoDB](#) page size (default 16KB). Many values are counted in pages; the page size enables them to be easily converted to bytes.

- `Innodb_pages_created`

The number of pages created by operations on [InnoDB](#) tables.

- `Innodb_pages_read`

The number of pages read from the [InnoDB](#) buffer pool by operations on [InnoDB](#) tables.

- `Innodb_pages_written`

The number of pages written by operations on [InnoDB](#) tables.

- `Innodb_redo_log_enabled`

Whether redo logging is enabled or disabled. See [Disabling Redo Logging](#).

- `Innodb_redo_log_capacity_resized`

The total redo log capacity for all redo log files, in bytes, after the last completed capacity resize operation. The value includes ordinary and spare redo log files.

If there is no pending resize down operation, `Innodb_redo_log_capacity_resized` should be equal to the `innodb_redo_log_capacity` setting if it's used, or it's  $((\text{innodb\_log\_files\_in\_group} * \text{innodb\_log\_file\_size}))$  if those are used instead. See the `innodb_redo_log_capacity` documentation for further clarification. Resize up operations are instantaneous.

For related information, see [Section 17.6.5, “Redo Log”](#).

- `Innodb_redo_log_checkpoint_lsn`

The redo log checkpoint LSN. For related information, see [Section 17.6.5, “Redo Log”](#).

- `Innodb_redo_log_current_lsn`

The current LSN represents the last written position in the redo log buffer. `InnoDB` writes data to the redo log buffer inside the MySQL process before requesting that the operating system write the data to the current redo log file. For related information, see [Section 17.6.5, “Redo Log”](#).

- `Innodb_redo_log_flushed_to_disk_lsn`

The flushed-to-disk LSN. `InnoDB` first writes data to the redo log and then requests that the operating system flush the data to disk. The flushed-to-disk LSN represents the last position in the redo log that `InnoDB` knows has been flushed to disk. For related information, see [Section 17.6.5, “Redo Log”](#).

- `Innodb_redo_log_logical_size`

A data size value, in bytes, representing the LSN range containing in-use redo log data, spanning from the oldest block required by redo log consumers to the latest written block. For related information, see [Section 17.6.5, “Redo Log”](#).

- `Innodb_redo_log_physical_size`

The amount of disk space in bytes currently consumed by all redo log files on disk, excluding spare redo log files. For related information, see [Section 17.6.5, “Redo Log”](#).

- `Innodb_redo_log_read_only`

Whether the redo log is read-only.

- `Innodb_redo_log_resize_status`

The redo log resize status indicating the current state of the redo log capacity resize mechanism. Possible values include:

- `OK`: There are no issues and no pending redo log capacity resize operations.
- `Resizing down`: A resize down operation is in progress.

A resize up operation is instantaneous and therefore has no pending status.

- `Innodb_redo_log_uuid`

The redo log UUID.

- `Innodb_row_lock_current_waits`

The number of [row locks](#) currently waited for by operations on [InnoDB](#) tables.

- [Innodb\\_row\\_lock\\_time](#)

The total time spent in acquiring [row locks](#) for [InnoDB](#) tables, in milliseconds.

- [Innodb\\_row\\_lock\\_time\\_avg](#)

The average time to acquire a [row lock](#) for [InnoDB](#) tables, in milliseconds.

- [Innodb\\_row\\_lock\\_time\\_max](#)

The maximum time to acquire a [row lock](#) for [InnoDB](#) tables, in milliseconds.

- [Innodb\\_row\\_lock\\_waits](#)

The number of times operations on [InnoDB](#) tables had to wait for a [row lock](#).

- [Innodb\\_rows\\_deleted](#)

The number of rows deleted from [InnoDB](#) tables.

- [Innodb\\_rows\\_inserted](#)

The number of rows inserted into [InnoDB](#) tables.

- [Innodb\\_rows\\_read](#)

The number of rows read from [InnoDB](#) tables.

- [Innodb\\_rows\\_updated](#)

The estimated number of rows updated in [InnoDB](#) tables.

**Note**

This value is not meant to be 100% accurate. For an accurate (but more expensive) result, use [ROW\\_COUNT\(\)](#).

- [Innodb\\_system\\_rows\\_deleted](#)

The number of rows deleted from [InnoDB](#) tables belonging to system-created schemas.

- [Innodb\\_system\\_rows\\_inserted](#)

The number of rows inserted into [InnoDB](#) tables belonging to system-created schemas.

- [Innodb\\_system\\_rows\\_updated](#)

The number of rows updated in [InnoDB](#) tables belonging to system-created schemas.

- [Innodb\\_system\\_rows\\_read](#)

The number of rows read from [InnoDB](#) tables belonging to system-created schemas.

- [Innodb\\_truncated\\_status\\_writes](#)

The number of times output from the [SHOW ENGINE INNODB STATUS](#) statement has been truncated.

- `Innodb_undo_tablespaces_active`

The number of active undo tablespaces. Includes both implicit ([InnoDB](#)-created) and explicit (user-created) undo tablespaces. For information about undo tablespaces, see [Section 17.6.3.4, “Undo Tablespaces”](#).

- `Innodb_undo_tablespaces_explicit`

The number of user-created undo tablespaces. For information about undo tablespaces, see [Section 17.6.3.4, “Undo Tablespaces”](#).

- `Innodb_undo_tablespaces_implicit`

The number of undo tablespaces created by [InnoDB](#). Two default undo tablespaces are created by [InnoDB](#) when the MySQL instance is initialized. For information about undo tablespaces, see [Section 17.6.3.4, “Undo Tablespaces”](#).

- `Innodb_undo_tablespaces_total`

The total number of undo tablespaces. Includes both implicit ([InnoDB](#)-created) and explicit (user-created) undo tablespaces, active and inactive. For information about undo tablespaces, see [Section 17.6.3.4, “Undo Tablespaces”](#).

- `Key_blocks_not_flushed`

The number of key blocks in the [MyISAM](#) key cache that have changed but have not yet been flushed to disk.

- `Key_blocks_unused`

The number of unused blocks in the [MyISAM](#) key cache. You can use this value to determine how much of the key cache is in use; see the discussion of `key_buffer_size` in [Section 7.1.8, “Server System Variables”](#).

- `Key_blocks_used`

The number of used blocks in the [MyISAM](#) key cache. This value is a high-water mark that indicates the maximum number of blocks that have ever been in use at one time.

- `Key_read_requests`

The number of requests to read a key block from the [MyISAM](#) key cache.

- `Key_reads`

The number of physical reads of a key block from disk into the [MyISAM](#) key cache. If `Key_reads` is large, then your `key_buffer_size` value is probably too small. The cache miss rate can be calculated as `Key_reads/Key_read_requests`.

- `Key_write_requests`

The number of requests to write a key block to the [MyISAM](#) key cache.

- `Key_writes`

The number of physical writes of a key block from the [MyISAM](#) key cache to disk.

- `Last_query_cost`

The total cost of the last compiled query as computed by the query optimizer. This is useful for comparing the cost of different query plans for the same query. The default value of 0 means that no query has been compiled yet. The default value is 0. `Last_query_cost` has session scope.

This variable shows the cost of queries that have multiple query blocks, summing the cost estimates of each query block, estimating how many times non-cacheable subqueries are executed, and multiplying the cost of those query blocks by the number of subquery executions.

- `Last_query_partial_plans`

The number of iterations the query optimizer made in execution plan construction for the previous query.

`Last_query_partial_plans` has session scope.

- `Locked_connects`

The number of attempts to connect to locked user accounts. For information about account locking and unlocking, see [Section 8.2.20, “Account Locking”](#).

- `Max_execution_time_exceeded`

The number of `SELECT` statements for which the execution timeout was exceeded.

- `Max_execution_time_set`

The number of `SELECT` statements for which a nonzero execution timeout was set. This includes statements that include a nonzero `MAX_EXECUTION_TIME` optimizer hint, and statements that include no such hint but execute while the timeout indicated by the `max_execution_time` system variable is nonzero.

- `Max_execution_time_set_failed`

The number of `SELECT` statements for which the attempt to set an execution timeout failed.

- `Max_used_connections`

The maximum number of connections that have been in use simultaneously since the server started.

- `Max_used_connections_time`

The time at which `Max_used_connections` reached its current value.

- `Not_flushed_delayed_rows`

This status variable is deprecated (because `DELAYED` inserts are not supported); expect it to be removed in a future release.

- `mecab_charset`

The character set currently used by the MeCab full-text parser plugin. For related information, see [Section 14.9.9, “MeCab Full-Text Parser Plugin”](#).

- `Ongoing_anonymous_transaction_count`

Shows the number of ongoing transactions which have been marked as anonymous. This can be used to ensure that no further transactions are waiting to be processed.

- `Ongoing_automatic_gtid_violating_transaction_count`

This status variable is only available in debug builds. Shows the number of ongoing transactions which use `gtid_next=AUTOMATIC` and that violate GTID consistency.

- `Open_files`

The number of files that are open. This count includes regular files opened by the server. It does not include other types of files such as sockets or pipes. Also, the count does not include files that storage engines open using their own internal functions rather than asking the server level to do so.

- `Open_streams`

The number of streams that are open (used mainly for logging).

- `Open_table_definitions`

The number of cached table definitions.

- `Open_tables`

The number of tables that are open.

- `Opened_files`

The number of files that have been opened with `my_open()` (a `mysys` library function). Parts of the server that open files without using this function do not increment the count.

- `Opened_table_definitions`

The number of table definitions that have been cached.

- `Opened_tables`

The number of tables that have been opened. If `Opened_tables` is big, your `table_open_cache` value is probably too small.

- `Performance_schema_xxx`

Performance Schema status variables are listed in [Section 29.16, “Performance Schema Status Variables”](#). These variables provide information about instrumentation that could not be loaded or created due to memory constraints.

- `Prepared_stmt_count`

The current number of prepared statements. (The maximum number of statements is given by the `max_prepared_stmt_count` system variable.)

- `Queries`

The number of statements executed by the server. This variable includes statements executed within stored programs, unlike the `Questions` variable. It does not count `COM_PING` or `COM_STATISTICS` commands.

The discussion at the beginning of this section indicates how to relate this statement-counting status variable to other such variables.

- [Questions](#)

The number of statements executed by the server. This includes only statements sent to the server by clients and not statements executed within stored programs, unlike the [Queries](#) variable. This variable does not count [COM\\_PING](#), [COM\\_STATISTICS](#), [COM\\_STMT\\_PREPARE](#), [COM\\_STMT\\_CLOSE](#), or [COM\\_STMT\\_RESET](#) commands.

The discussion at the beginning of this section indicates how to relate this statement-counting status variable to other such variables.

- [Replica\\_open\\_temp\\_tables](#)

[Replica\\_open\\_temp\\_tables](#) shows the number of temporary tables that the replication SQL thread currently has open. If the value is greater than zero, it is not safe to shut down the replica; see [Section 19.5.1.32, “Replication and Temporary Tables”](#). This variable reports the total count of open temporary tables for *all* replication channels.

- [Resource\\_group\\_supported](#)

Indicates whether the resource group feature is supported.

On some platforms or MySQL server configurations, resource groups are unavailable or have limitations. In particular, Linux systems might require a manual step for some installation methods. For details, see [Resource Group Restrictions](#).

- [Rpl\\_semi\\_sync\\_master\\_clients](#)

The number of semisynchronous replicas.

Deprecated synonym for [Rpl\\_semi\\_sync\\_source\\_clients](#).

- [Rpl\\_semi\\_sync\\_master\\_net\\_avg\\_wait\\_time](#)

Deprecated synonym for [Rpl\\_semi\\_sync\\_source\\_net\\_avg\\_wait\\_time](#).

- [Rpl\\_semi\\_sync\\_master\\_net\\_wait\\_time](#)

Deprecated synonym for [Rpl\\_semi\\_sync\\_source\\_net\\_wait\\_time](#).

- [Rpl\\_semi\\_sync\\_master\\_net\\_waits](#)

The total number of times the source waited for replica replies.

Deprecated synonym for [Rpl\\_semi\\_sync\\_source\\_net\\_waits](#).

- [Rpl\\_semi\\_sync\\_master\\_no\\_times](#)

Deprecated synonym for [Rpl\\_semi\\_sync\\_source\\_no\\_times](#).

- [Rpl\\_semi\\_sync\\_master\\_no\\_tx](#)

Deprecated synonym for [Rpl\\_semi\\_sync\\_source\\_no\\_tx](#).

- [Rpl\\_semi\\_sync\\_master\\_status](#)

Deprecated synonym for [Rpl\\_semi\\_sync\\_source\\_status](#).

- [Rpl\\_semi\\_sync\\_master\\_timefunc\\_failures](#)

Deprecated synonym for `Rpl_semi_sync_source_timefunc_failures`.

- `Rpl_semi_sync_master_tx_avg_wait_time`

Deprecated synonym for `Rpl_semi_sync_source_tx_avg_wait_time`.

- `Rpl_semi_sync_master_tx_wait_time`

Deprecated synonym for `Rpl_semi_sync_source_tx_wait_time`.

- `Rpl_semi_sync_master_tx_waits`

Deprecated synonym for `Rpl_semi_sync_source_tx_waits`.

- `Rpl_semi_sync_master_wait_pos_backtraverse`

Deprecated synonym for `Rpl_semi_sync_source_wait_pos_backtraverse`.

- `Rpl_semi_sync_master_wait_sessions`

Deprecated synonym for `Rpl_semi_sync_source_wait_sessions`.

- `Rpl_semi_sync_master_yes_tx`

Deprecated synonym for `Rpl_semi_sync_source_yes_tx`.

- `Rpl_semi_sync_source_clients`

The number of semisynchronous replicas.

Available when the `rpl_semi_sync_source` plugin (`semisync_source.so` library) is installed on the source.

- `Rpl_semi_sync_source_net_avg_wait_time`

The average time in microseconds the source waited for a replica reply. This variable is always 0, and is deprecated; expect it to be removed in a future version.

Available when the `rpl_semi_sync_source` plugin (`semisync_source.so` library) is installed on the source.

- `Rpl_semi_sync_source_net_wait_time`

The total time in microseconds the source waited for replica replies. This variable is always 0, and is deprecated; expect it to be removed in a future version.

Available when the `rpl_semi_sync_source` plugin (`semisync_source.so` library) is installed on the source.

- `Rpl_semi_sync_source_net_waits`

The total number of times the source waited for replica replies.

Available when the `rpl_semi_sync_source` plugin (`semisync_source.so` library) is installed on the source.

- `Rpl_semi_sync_source_no_times`

The number of times the source turned off semisynchronous replication.

Available when the `rpl_semi_sync_source` plugin (`semisync_source.so` library) is installed on the source.

- `Rpl_semi_sync_source_no_tx`

The number of commits that were not acknowledged successfully by a replica.

Available when the `rpl_semi_sync_source` plugin (`semisync_source.so` library) is installed on the source.

- `Rpl_semi_sync_source_status`

Whether semisynchronous replication currently is operational on the source. The value is `ON` if the plugin has been enabled and a commit acknowledgment has occurred. It is `OFF` if the plugin is not enabled or the source has fallen back to asynchronous replication due to commit acknowledgment timeout.

Available when the `rpl_semi_sync_source` plugin (`semisync_source.so` library) is installed on the source.

- `Rpl_semi_sync_source_timefunc_failures`

The number of times the source failed when calling time functions such as `gettimeofday()`.

Available when the `rpl_semi_sync_source` plugin (`semisync_source.so` library) is installed on the source.

- `Rpl_semi_sync_source_tx_avg_wait_time`

The average time in microseconds the source waited for each transaction.

Available when the `rpl_semi_sync_source` plugin (`semisync_source.so` library) is installed on the source.

- `Rpl_semi_sync_source_tx_wait_time`

The total time in microseconds the source waited for transactions.

Available when the `rpl_semi_sync_source` plugin (`semisync_source.so` library) is installed on the source.

- `Rpl_semi_sync_source_tx_waits`

The total number of times the source waited for transactions.

Available when the `rpl_semi_sync_source` plugin (`semisync_source.so` library) is installed on the source.

- `Rpl_semi_sync_source_wait_pos_backtraverse`

The total number of times the source waited for an event with binary coordinates lower than events waited for previously. This can occur when the order in which transactions start waiting for a reply is different from the order in which their binary log events are written.

Available when the `rpl_semi_sync_source` plugin (`semisync_source.so` library) is installed on the source.

- `Rpl_semi_sync_source_wait_sessions`

The number of sessions currently waiting for replica replies.

Available when the `rpl_semi_sync_source` plugin (`semisync_source.so` library) is installed on the source.

- `Rpl_semi_sync_source_yes_tx`

The number of commits that were acknowledged successfully by a replica.

Available when the `rpl_semi_sync_source` plugin (`semisync_source.so` library) is installed on the source.

- `Rpl_semi_sync_replica_status`

Shows whether semisynchronous replication is currently operational on the replica. This is `ON` if the plugin has been enabled and the replication I/O (receiver) thread is running, `OFF` otherwise.

Available when the `rpl_semi_sync_source` plugin (`semisync_source.so` library) is installed on the source.

- `Rpl_semi_sync_slave_status`

Deprecated synonym for `Rpl_semi_sync_replica_status`.

- `Rsa_public_key`

The value of this variable is the public key used by the `sha256_password` (deprecated) authentication plugin for RSA key pair-based password exchange. The value is nonempty only if the server successfully initializes the private and public keys in the files named by the `sha256_password_private_key_path` and `sha256_password_public_key_path` system variables. The value of `Rsa_public_key` comes from the latter file.

For information about `sha256_password`, see [Section 8.4.1.2, “SHA-256 Pluggable Authentication”](#).

- `Secondary_engine_execution_count`

The number of queries offloaded to a secondary engine.

For use with HeatWave. See [HeatWave User Guide](#).

- `Select_full_join`

The number of joins that perform table scans because they do not use indexes. If this value is not 0, you should carefully check the indexes of your tables.

- `Select_full_range_join`

The number of joins that used a range search on a reference table.

- `Select_range`

The number of joins that used ranges on the first table. This is normally not a critical issue even if the value is quite large.

- `Select_range_check`

The number of joins without keys that check for key usage after each row. If this is not 0, you should carefully check the indexes of your tables.

- `Select_scan`

The number of joins that did a full scan of the first table.

- `Slave_open_temp_tables`

Deprecated alias for `Replica_open_temp_tables`.

- `Slave_rows_last_search_algorithm_used`

Deprecated alias for `Replica_rows_last_search_algorithm_used`.

- `Slow_launch_threads`

The number of threads that have taken more than `slow_launch_time` seconds to create.

- `Slow_queries`

The number of queries that have taken more than `long_query_time` seconds. This counter increments regardless of whether the slow query log is enabled. For information about that log, see [Section 7.4.5, “The Slow Query Log”](#).

- `Sort_merge_passes`

The number of merge passes that the sort algorithm has had to do. If this value is large, you should consider increasing the value of the `sort_buffer_size` system variable.

- `Sort_range`

The number of sorts that were done using ranges.

- `Sort_rows`

The number of sorted rows.

- `Sort_scan`

The number of sorts that were done by scanning the table.

- `Ssl_accept_renegotiates`

The number of negotiates needed to establish the connection.

- `Ssl_accepts`

The number of accepted SSL connections.

- `Ssl_callback_cache_hits`

The number of callback cache hits.

- `Ssl_cipher`

The current encryption cipher (empty for unencrypted connections).

- `Ssl_cipher_list`

The list of possible SSL ciphers (empty for non-SSL connections). If MySQL supports TLSv1.3, the value includes the possible TLSv1.3 ciphersuites. See [Section 8.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#).

- `Ssl_client_connects`

The number of SSL connection attempts to an SSL-enabled replication source server.

- `Ssl_connect_renegotiates`

The number of negotiates needed to establish the connection to an SSL-enabled replication source server.

- `Ssl_ctx_verify_depth`

The SSL context verification depth (how many certificates in the chain are tested).

- `Ssl_ctx_verify_mode`

The SSL context verification mode.

- `Ssl_default_timeout`

The default SSL timeout.

- `Ssl_finished_accepts`

The number of successful SSL connections to the server.

- `Ssl_finished_connects`

The number of successful replica connections to an SSL-enabled replication source server.

- `Ssl_server_not_after`

The last date for which the SSL certificate is valid. To check SSL certificate expiration information, use this statement:

```
mysql> SHOW STATUS LIKE 'Ssl_server_not%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Ssl_server_not_after | Apr 28 14:16:39 2025 GMT |
| Ssl_server_not_before | May 1 14:16:39 2015 GMT |
+-----+-----+
```

- `Ssl_server_not_before`

The first date for which the SSL certificate is valid.

- `Ssl_session_cache_hits`

The number of SSL session cache hits.

- `Ssl_session_cache_misses`

The number of SSL session cache misses.

- `Ssl_session_cache_mode`

The SSL session cache mode. When the value of the `ssl_session_cache_mode` server variable is `ON`, the value of the `Ssl_session_cache_mode` status variable is `SERVER`.

- `Ssl_session_cache_overflows`

The number of SSL session cache overflows.

- [Ssl\\_session\\_cache\\_size](#)

The SSL session cache size.

- [Ssl\\_session\\_cache\\_timeout](#)

The timeout value in seconds of SSL sessions in the cache.

- [Ssl\\_session\\_cache\\_timeouts](#)

The number of SSL session cache timeouts.

- [Ssl\\_sessions\\_reused](#)

This is equal to 0 if TLS was not used in the current MySQL session, or if a TLS session has not been reused; otherwise it is equal to 1.

[Ssl\\_sessions\\_reused](#) has session scope.

- [Ssl\\_used\\_session\\_cache\\_entries](#)

How many SSL session cache entries were used.

- [Ssl\\_verify\\_depth](#)

The verification depth for replication SSL connections.

- [Ssl\\_verify\\_mode](#)

The verification mode used by the server for a connection that uses SSL. The value is a bitmask; bits are defined in the `openssl/ssl.h` header file:

```
define SSL_VERIFY_NONE 0x00
define SSL_VERIFY_PEER 0x01
define SSL_VERIFY_FAIL_IF_NO_PEER_CERT 0x02
define SSL_VERIFY_CLIENT_ONCE 0x04
```

[SSL\\_VERIFY\\_PEER](#) indicates that the server asks for a client certificate. If the client supplies one, the server performs verification and proceeds only if verification is successful. [SSL\\_VERIFY\\_CLIENT\\_ONCE](#) indicates that a request for the client certificate is performed only in the initial handshake.

- [Ssl\\_version](#)

The SSL protocol version of the connection (for example, TLSv1.2). If the connection is not encrypted, the value is empty.

- [Table\\_locks\\_immediate](#)

The number of times that a request for a table lock could be granted immediately.

- [Table\\_locks\\_waited](#)

The number of times that a request for a table lock could not be granted immediately and a wait was needed. If this is high and you have performance problems, you should first optimize your queries, and then either split your table or tables or use replication.

- [Table\\_open\\_cache\\_hits](#)

The number of hits for open tables cache lookups.

- [Table\\_open\\_cache\\_misses](#)

The number of misses for open tables cache lookups.

- [Table\\_open\\_cache\\_overflows](#)

The number of overflows for the open tables cache. This is the number of times, after a table is opened or closed, a cache instance has an unused entry and the size of the instance is larger than [table\\_open\\_cache](#) / [table\\_open\\_cache\\_instances](#).

- [Table\\_open\\_cache\\_triggers\\_hits](#)

The number of cache hits for open tables with triggers. This number is incremented by 1 when a table with triggers is found by a data modification operation in the list of unused tables which have triggers in the table cache. When such a table is the subject of a read-only operation such as [SELECT](#), the table is handled as if it has no triggers, and [Table\\_open\\_cache\\_hits](#) is incremented instead.

- [Table\\_open\\_cache\\_triggers\\_misses](#)

The number of cache misses for open tables with triggers. This number is incremented by 1 when a table with triggers is not found by a pending data modification operation in the list of unused tables having triggers in the table cache. If the pending operation on the table is read-only, as in the case of a [SELECT](#) statement, the table is treated as if it has no triggers, and [Table\\_open\\_cache\\_misses](#) is incremented instead.

- [Table\\_open\\_cache\\_triggers\\_overflows](#)

The number of cache overflows for open tables with triggers. This number is incremented by 1 when there are more tables with triggers in a given table cache instance than the maximum. That is, this status variable is incremented when [Table\\_open\\_cache\\_triggers\\_hits](#) exceeds maximum number per cache instance of tables with triggers; this maximum is determined by [table\\_open\\_cache\\_triggers](#) / [table\\_open\\_cache\\_instances](#).

#### Note

[Table\\_open\\_cache\\_triggers\\_hits](#) is affected only by data modification operations. Thus, when a read-only operation such as [SELECT](#) accesses a table with triggers, [Table\\_open\\_cache\\_triggers\\_overflows](#) is also unaffected. A read-only operation on a table with triggers increments [Table\\_open\\_cache\\_hits](#); if [Table\\_open\\_cache\\_hits](#) then exceeds the limit determined by [table\\_open\\_cache](#) / [table\\_open\\_cache\\_instances](#), [Table\\_open\\_cache\\_overflows](#) is incremented instead.

- [Tc\\_log\\_max\\_pages\\_used](#)

For the memory-mapped implementation of the log that is used by [mysqld](#) when it acts as the transaction coordinator for recovery of internal XA transactions, this variable indicates the largest number of pages used for the log since the server started. If the product of [Tc\\_log\\_max\\_pages\\_used](#) and [Tc\\_log\\_page\\_size](#) is always significantly less than the log size, the size is larger than necessary and can be reduced. (The size is set by the [--log-tc-size](#) option. This variable is unused: It is unneeded for binary log-based recovery, and the memory-mapped recovery log method is not used unless the number of storage engines that are capable of two-phase commit and that support XA transactions is greater than one. ([InnoDB](#) is the only applicable engine.)

- `Tc_log_page_size`

The page size used for the memory-mapped implementation of the XA recovery log. The default value is determined using `getpagesize()`. This variable is unused for the same reasons as described for `Tc_log_max_pages_used`.

- `Tc_log_page_waits`

For the memory-mapped implementation of the recovery log, this variable increments each time the server was not able to commit a transaction and had to wait for a free page in the log. If this value is large, you might want to increase the log size (with the `--log-tc-size` option). For binary log-based recovery, this variable increments each time the binary log cannot be closed because there are two-phase commits in progress. (The close operation waits until all such transactions are finished.)

- `Telemetry_metrics_supported`

Whether server telemetry metrics is supported.

For more information, see the *Server telemetry metrics service* section in the MySQL Source Code documentation.

- `Telemetry_logs_supported`

Displays whether the server was compiled with Telemetry logs support.

For more information, see the *Server telemetry logs service* section in the MySQL Source Code documentation and [Chapter 35, Telemetry](#).

- `telemetry.live_sessions`

Displays the current number of sessions instrumented with telemetry. This can be useful when unloading the Telemetry component, to monitor how many sessions are blocking the unload operation.

For more information, see the *Server telemetry traces service* section in the MySQL Source Code documentation and [Chapter 35, Telemetry](#).

- `Telemetry_traces_supported`

Whether server telemetry traces is supported.

For more information, see the *Server telemetry traces service* section in the MySQL Source Code documentation.

- `TempTable_count_hit_max_ram`

The number of [internal temporary tables](#) that were converted on-disk because the `TempTable` engine reached the `temptable_max_ram` limit.

- `Threads_cached`

The number of threads in the thread cache.

- `Threads_connected`

The number of currently open connections.

- [Threads\\_created](#)

The number of threads created to handle connections. If [Threads\\_created](#) is big, you may want to increase the [thread\\_cache\\_size](#) value. The cache miss rate can be calculated as [Threads\\_created/Connections](#).

- [Threads\\_running](#)

The number of threads that are not sleeping.

- [Tls\\_library\\_version](#)

The runtime version of the OpenSSL library that is in use for this MySQL instance.

- [Tls\\_sni\\_server\\_name](#)

The Server Name Indication (SNI) that is in use for this session, if specified by the client; otherwise, empty. SNI is an extension to the TLS protocol (OpenSSL must be compiled using TLS extensions for this status variable to function). The MySQL implementation of SNI represents the client-side only.

- [Uptime](#)

The number of seconds that the server has been up.

- [Uptime\\_since\\_flush\\_status](#)

The number of seconds since the most recent [FLUSH STATUS](#) statement.

## 7.1.11 Server SQL Modes

The MySQL server can operate in different SQL modes, and can apply these modes differently for different clients, depending on the value of the [sql\\_mode](#) system variable. DBAs can set the global SQL mode to match site server operating requirements, and each application can set its session SQL mode to its own requirements.

Modes affect the SQL syntax MySQL supports and the data validation checks it performs. This makes it easier to use MySQL in different environments and to use MySQL together with other database servers.

- [Setting the SQL Mode](#)
- [The Most Important SQL Modes](#)
- [Full List of SQL Modes](#)
- [Combination SQL Modes](#)
- [Strict SQL Mode](#)
- [Comparison of the IGNORE Keyword and Strict SQL Mode](#)

For answers to questions often asked about server SQL modes in MySQL, see [Section A.3, “MySQL 9.1 FAQ: Server SQL Mode”](#).

When working with [InnoDB](#) tables, consider also the [innodb\\_strict\\_mode](#) system variable. It enables additional error checks for [InnoDB](#) tables.

## Setting the SQL Mode

The default SQL mode in MySQL 9.1 includes these modes: `ONLY_FULL_GROUP_BY`, `STRICT_TRANS_TABLES`, `NO_ZERO_IN_DATE`, `NO_ZERO_DATE`, `ERROR_FOR_DIVISION_BY_ZERO`, and `NO_ENGINE_SUBSTITUTION`.

To set the SQL mode at server startup, use the `--sql-mode="modes"` option on the command line, or `sql-mode="modes"` in an option file such as `my.cnf` (Unix operating systems) or `my.ini` (Windows). `modes` is a list of different modes separated by commas. To clear the SQL mode explicitly, set it to an empty string using `--sql-mode=""` on the command line, or `sql-mode=""` in an option file.

### Note

MySQL installation programs may configure the SQL mode during the installation process.

If the SQL mode differs from the default or from what you expect, check for a setting in an option file that the server reads at startup.

To change the SQL mode at runtime, set the global or session `sql_mode` system variable using a `SET` statement:

```
SET GLOBAL sql_mode = 'modes';
SET SESSION sql_mode = 'modes';
```

Setting the `GLOBAL` variable requires the `SYSTEM_VARIABLES_ADMIN` privilege (or the deprecated `SUPER` privilege) and affects the operation of all clients that connect from that time on. Setting the `SESSION` variable affects only the current client. Each client can change its session `sql_mode` value at any time.

To determine the current global or session `sql_mode` setting, select its value:

```
SELECT @@GLOBAL.sql_mode;
SELECT @@SESSION.sql_mode;
```

### Important

**SQL mode and user-defined partitioning.** Changing the server SQL mode after creating and inserting data into partitioned tables can cause major changes in the behavior of such tables, and could lead to loss or corruption of data. It is strongly recommended that you never change the SQL mode once you have created tables employing user-defined partitioning.

When replicating partitioned tables, differing SQL modes on the source and replica can also lead to problems. For best results, you should always use the same server SQL mode on the source and replica.

For more information, see [Section 26.6, “Restrictions and Limitations on Partitioning”](#).

## The Most Important SQL Modes

The most important `sql_mode` values are probably these:

- `ANSI`

This mode changes syntax and behavior to conform more closely to standard SQL. It is one of the special [combination modes](#) listed at the end of this section.

- `STRICT_TRANS_TABLES`

If a value could not be inserted as given into a transactional table, abort the statement. For a nontransactional table, abort the statement if the value occurs in a single-row statement or the first row of a multiple-row statement. More details are given later in this section.

- [TRADITIONAL](#)

Make MySQL behave like a “traditional” SQL database system. A simple description of this mode is “give an error instead of a warning” when inserting an incorrect value into a column. It is one of the special [combination modes](#) listed at the end of this section.

**Note**

With [TRADITIONAL](#) mode enabled, an [INSERT](#) or [UPDATE](#) aborts as soon as an error occurs. If you are using a nontransactional storage engine, this may not be what you want because data changes made prior to the error may not be rolled back, resulting in a “partially done” update.

When this manual refers to “strict mode,” it means a mode with either or both [STRICT\\_TRANS\\_TABLES](#) or [STRICT\\_ALL\\_TABLES](#) enabled.

## Full List of SQL Modes

The following list describes all supported SQL modes:

- [ALLOW\\_INVALID\\_DATES](#)

Do not perform full checking of dates. Check only that the month is in the range from 1 to 12 and the day is in the range from 1 to 31. This may be useful for Web applications that obtain year, month, and day in three different fields and store exactly what the user inserted, without date validation. This mode applies to [DATE](#) and [DATETIME](#) columns. It does not apply to [TIMESTAMP](#) columns, which always require a valid date.

With [ALLOW\\_INVALID\\_DATES](#) disabled, the server requires that month and day values be legal, and not merely in the range 1 to 12 and 1 to 31, respectively. With strict mode disabled, invalid dates such as '2004-04-31' are converted to '0000-00-00' and a warning is generated. With strict mode enabled, invalid dates generate an error. To permit such dates, enable [ALLOW\\_INVALID\\_DATES](#).

- [ANSI\\_QUOTES](#)

Treat " as an identifier quote character (like the ` quote character) and not as a string quote character. You can still use ` to quote identifiers with this mode enabled. With [ANSI\\_QUOTES](#) enabled, you cannot use double quotation marks to quote literal strings because they are interpreted as identifiers.

- [ERROR\\_FOR\\_DIVISION\\_BY\\_ZERO](#)

The [ERROR\\_FOR\\_DIVISION\\_BY\\_ZERO](#) mode affects handling of division by zero, which includes [MOD\(N, 0\)](#). For data-change operations ([INSERT](#), [UPDATE](#)), its effect also depends on whether strict SQL mode is enabled.

- If this mode is not enabled, division by zero inserts [NULL](#) and produces no warning.
- If this mode is enabled, division by zero inserts [NULL](#) and produces a warning.
- If this mode and strict mode are enabled, division by zero produces an error, unless [IGNORE](#) is given as well. For [INSERT IGNORE](#) and [UPDATE IGNORE](#), division by zero inserts [NULL](#) and produces a warning.

For `SELECT`, division by zero returns `NULL`. Enabling `ERROR_FOR_DIVISION_BY_ZERO` causes a warning to be produced as well, regardless of whether strict mode is enabled.

`ERROR_FOR_DIVISION_BY_ZERO` is deprecated. `ERROR_FOR_DIVISION_BY_ZERO` is not part of strict mode, but should be used in conjunction with strict mode and is enabled by default. A warning occurs if `ERROR_FOR_DIVISION_BY_ZERO` is enabled without also enabling strict mode or vice versa.

Because `ERROR_FOR_DIVISION_BY_ZERO` is deprecated, you should expect it to be removed in a future MySQL release as a separate mode name and its effect included in the effects of strict SQL mode.

- `HIGH_NOT_PRECEDENCE`

The precedence of the `NOT` operator is such that expressions such as `NOT a BETWEEN b AND c` are parsed as `NOT (a BETWEEN b AND c)`. In some older versions of MySQL, the expression was parsed as `(NOT a) BETWEEN b AND c`. The old higher-precedence behavior can be obtained by enabling the `HIGH_NOT_PRECEDENCE` SQL mode.

```
mysql> SET sql_mode = '';
mysql> SELECT NOT 1 BETWEEN -5 AND 5;
 -> 0
mysql> SET sql_mode = 'HIGH_NOT_PRECEDENCE';
mysql> SELECT NOT 1 BETWEEN -5 AND 5;
 -> 1
```

- `IGNORE_SPACE`

Permit spaces between a function name and the `(` character. This causes built-in function names to be treated as reserved words. As a result, identifiers that are the same as function names must be quoted as described in [Section 11.2, “Schema Object Names”](#). For example, because there is a `COUNT()` function, the use of `count` as a table name in the following statement causes an error:

```
mysql> CREATE TABLE count (i INT);
ERROR 1064 (42000): You have an error in your SQL syntax
```

The table name should be quoted:

```
mysql> CREATE TABLE `count` (i INT);
Query OK, 0 rows affected (0.00 sec)
```

The `IGNORE_SPACE` SQL mode applies to built-in functions, not to loadable functions or stored functions. It is always permissible to have spaces after a loadable function or stored function name, regardless of whether `IGNORE_SPACE` is enabled.

For further discussion of `IGNORE_SPACE`, see [Section 11.2.5, “Function Name Parsing and Resolution”](#).

- `NO_AUTO_VALUE_ON_ZERO`

`NO_AUTO_VALUE_ON_ZERO` affects handling of `AUTO_INCREMENT` columns. Normally, you generate the next sequence number for the column by inserting either `NULL` or `0` into it. `NO_AUTO_VALUE_ON_ZERO` suppresses this behavior for `0` so that only `NULL` generates the next sequence number.

This mode can be useful if `0` has been stored in a table's `AUTO_INCREMENT` column. (Storing `0` is not a recommended practice, by the way.) For example, if you dump the table with `mysqldump` and then reload it, MySQL normally generates new sequence numbers when it encounters the `0` values, resulting in a table with contents different from the one that was dumped. Enabling `NO_AUTO_VALUE_ON_ZERO` before reloading the dump file solves this problem. For this reason, `mysqldump` automatically includes in its output a statement that enables `NO_AUTO_VALUE_ON_ZERO`.

- `NO_BACKSLASH_ESCAPES`

Enabling this mode disables the use of the backslash character (\) as an escape character within strings and identifiers. With this mode enabled, backslash becomes an ordinary character like any other, and the default escape sequence for `LIKE` expressions is changed so that no escape character is used.

- `NO_DIR_IN_CREATE`

When creating a table, ignore all `INDEX DIRECTORY` and `DATA DIRECTORY` directives. This option is useful on replica servers.

- `NO_ENGINE_SUBSTITUTION`

Control automatic substitution of the default storage engine when a statement such as `CREATE TABLE` or `ALTER TABLE` specifies a storage engine that is disabled or not compiled in.

By default, `NO_ENGINE_SUBSTITUTION` is enabled.

Because storage engines can be pluggable at runtime, unavailable engines are treated the same way:

With `NO_ENGINE_SUBSTITUTION` disabled, for `CREATE TABLE` the default engine is used and a warning occurs if the desired engine is unavailable. For `ALTER TABLE`, a warning occurs and the table is not altered.

With `NO_ENGINE_SUBSTITUTION` enabled, an error occurs and the table is not created or altered if the desired engine is unavailable.

- `NO_UNSIGNED_SUBTRACTION`

Subtraction between integer values, where one is of type `UNSIGNED`, produces an unsigned result by default. If the result would otherwise have been negative, an error results:

```
mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT CAST(0 AS UNSIGNED) - 1;
ERROR 1690 (22003): BIGINT UNSIGNED value is out of range in '(cast(0 as unsigned) - 1)'
```

If the `NO_UNSIGNED_SUBTRACTION` SQL mode is enabled, the result is negative:

```
mysql> SET sql_mode = 'NO_UNSIGNED_SUBTRACTION';
mysql> SELECT CAST(0 AS UNSIGNED) - 1;
+-----+
| CAST(0 AS UNSIGNED) - 1 |
+-----+
| -1 |
+-----+
```

If the result of such an operation is used to update an `UNSIGNED` integer column, the result is clipped to the maximum value for the column type, or clipped to 0 if `NO_UNSIGNED_SUBTRACTION` is enabled. With strict SQL mode enabled, an error occurs and the column remains unchanged.

When `NO_UNSIGNED_SUBTRACTION` is enabled, the subtraction result is signed, *even if any operand is unsigned*. For example, compare the type of column `c2` in table `t1` with that of column `c2` in table `t2`:

```
mysql> SET sql_mode='';
mysql> CREATE TABLE test (c1 BIGINT UNSIGNED NOT NULL);
mysql> CREATE TABLE t1 SELECT c1 - 1 AS c2 FROM test;
mysql> DESCRIBE t1;
+-----+-----+-----+-----+-----+-----+
| Table | Non- | NULL | Key |
```

```

+-----+-----+-----+-----+-----+-----+
| Field | Type | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| c2 | bigint(21) unsigned | NO | | 0 | |
+-----+-----+-----+-----+-----+-----+

mysql> SET sql_mode='NO_UNSIGNED_SUBTRACTION';
mysql> CREATE TABLE t2 SELECT c1 - 1 AS c2 FROM test;
mysql> DESCRIBE t2;
+-----+-----+-----+-----+-----+-----+
| Field | Type | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| c2 | bigint(21) | NO | | 0 | |
+-----+-----+-----+-----+-----+-----+

```

This means that `BIGINT UNSIGNED` is not 100% usable in all contexts. See [Section 14.10, “Cast Functions and Operators”](#).

- `NO_ZERO_DATE`

The `NO_ZERO_DATE` mode affects whether the server permits `'0000-00-00'` as a valid date. Its effect also depends on whether strict SQL mode is enabled.

- If this mode is not enabled, `'0000-00-00'` is permitted and inserts produce no warning.
- If this mode is enabled, `'0000-00-00'` is permitted and inserts produce a warning.
- If this mode and strict mode are enabled, `'0000-00-00'` is not permitted and inserts produce an error, unless `IGNORE` is given as well. For `INSERT IGNORE` and `UPDATE IGNORE`, `'0000-00-00'` is permitted and inserts produce a warning.

`NO_ZERO_DATE` is deprecated. `NO_ZERO_DATE` is not part of strict mode, but should be used in conjunction with strict mode and is enabled by default. A warning occurs if `NO_ZERO_DATE` is enabled without also enabling strict mode or vice versa.

Because `NO_ZERO_DATE` is deprecated, you should expect it to be removed in a future MySQL release as a separate mode name and its effect included in the effects of strict SQL mode.

- `NO_ZERO_IN_DATE`

The `NO_ZERO_IN_DATE` mode affects whether the server permits dates in which the year part is nonzero but the month or day part is 0. (This mode affects dates such as `'2010-00-01'` or `'2010-01-00'`, but not `'0000-00-00'`. To control whether the server permits `'0000-00-00'`, use the `NO_ZERO_DATE` mode.) The effect of `NO_ZERO_IN_DATE` also depends on whether strict SQL mode is enabled.

- If this mode is not enabled, dates with zero parts are permitted and inserts produce no warning.
- If this mode is enabled, dates with zero parts are inserted as `'0000-00-00'` and produce a warning.
- If this mode and strict mode are enabled, dates with zero parts are not permitted and inserts produce an error, unless `IGNORE` is given as well. For `INSERT IGNORE` and `UPDATE IGNORE`, dates with zero parts are inserted as `'0000-00-00'` and produce a warning.

`NO_ZERO_IN_DATE` is deprecated. `NO_ZERO_IN_DATE` is not part of strict mode, but should be used in conjunction with strict mode and is enabled by default. A warning occurs if `NO_ZERO_IN_DATE` is enabled without also enabling strict mode or vice versa.

Because `NO_ZERO_IN_DATE` is deprecated, you should expect it to be removed in a future MySQL release as a separate mode name and its effect included in the effects of strict SQL mode.

- `ONLY_FULL_GROUP_BY`

Reject queries for which the select list, `HAVING` condition, or `ORDER BY` list refer to nonaggregated columns that are neither named in the `GROUP BY` clause nor are functionally dependent on (uniquely determined by) `GROUP BY` columns.

A MySQL extension to standard SQL permits references in the `HAVING` clause to aliased expressions in the select list. The `HAVING` clause can refer to aliases regardless of whether `ONLY_FULL_GROUP_BY` is enabled.

For additional discussion and examples, see [Section 14.19.3, “MySQL Handling of GROUP BY”](#).

- `PAD_CHAR_TO_FULL_LENGTH`

By default, trailing spaces are trimmed from `CHAR` column values on retrieval. If `PAD_CHAR_TO_FULL_LENGTH` is enabled, trimming does not occur and retrieved `CHAR` values are padded to their full length. This mode does not apply to `VARCHAR` columns, for which trailing spaces are retained on retrieval.

#### Note

`PAD_CHAR_TO_FULL_LENGTH` is deprecated. Expect it to be removed in a future version of MySQL.

```
mysql> CREATE TABLE t1 (c1 CHAR(10));
Query OK, 0 rows affected (0.37 sec)

mysql> INSERT INTO t1 (c1) VALUES('xy');
Query OK, 1 row affected (0.01 sec)

mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT c1, CHAR_LENGTH(c1) FROM t1;
+-----+-----+
| c1 | CHAR_LENGTH(c1) |
+-----+-----+
| xy | 2 |
+-----+-----+
1 row in set (0.00 sec)

mysql> SET sql_mode = 'PAD_CHAR_TO_FULL_LENGTH';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT c1, CHAR_LENGTH(c1) FROM t1;
+-----+-----+
| c1 | CHAR_LENGTH(c1) |
+-----+-----+
| xy | 10 |
+-----+-----+
1 row in set (0.00 sec)
```

- `PIPES_AS_CONCAT`

Treat `||` as a string concatenation operator (same as `CONCAT( )`) rather than as a synonym for `OR`.

- `REAL_AS_FLOAT`

Treat `REAL` as a synonym for `FLOAT`. By default, MySQL treats `REAL` as a synonym for `DOUBLE`.

- `STRICT_ALL_TABLES`

Enable strict SQL mode for all storage engines. Invalid data values are rejected. For details, see [Strict SQL Mode](#).

- [STRICT\\_TRANS\\_TABLES](#)

Enable strict SQL mode for transactional storage engines, and when possible for nontransactional storage engines. For details, see [Strict SQL Mode](#).

- [TIME\\_TRUNCATE\\_FRACTIONAL](#)

Control whether rounding or truncation occurs when inserting a [TIME](#), [DATE](#), or [TIMESTAMP](#) value with a fractional seconds part into a column having the same type but fewer fractional digits. The default behavior is to use rounding. If this mode is enabled, truncation occurs instead. The following sequence of statements illustrates the difference:

```
CREATE TABLE t (id INT, tval TIME(1));
SET sql_mode='';
INSERT INTO t (id, tval) VALUES(1, 1.55);
SET sql_mode='TIME_TRUNCATE_FRACTIONAL';
INSERT INTO t (id, tval) VALUES(2, 1.55);
```

The resulting table contents look like this, where the first value has been subject to rounding and the second to truncation:

```
mysql> SELECT id, tval FROM t ORDER BY id;
+-----+-----+
| id | tval |
+-----+-----+
| 1 | 00:00:01.6 |
| 2 | 00:00:01.5 |
+-----+-----+
```

See also [Section 13.2.6, “Fractional Seconds in Time Values”](#).

## Combination SQL Modes

The following special modes are provided as shorthand for combinations of mode values from the preceding list.

- [ANSI](#)

Equivalent to [REAL\\_AS\\_FLOAT](#), [PIPES\\_AS\\_CONCAT](#), [ANSI\\_QUOTES](#), [IGNORE\\_SPACE](#), and [ONLY\\_FULL\\_GROUP\\_BY](#).

[ANSI](#) mode also causes the server to return an error for queries where a set function [S](#) with an outer reference [S\(outer\\_ref\)](#) cannot be aggregated in the outer query against which the outer reference has been resolved. This is such a query:

```
SELECT * FROM t1 WHERE t1.a IN (SELECT MAX(t1.b) FROM t2 WHERE ...);
```

Here, [MAX\(t1.b\)](#) cannot be aggregated in the outer query because it appears in the [WHERE](#) clause of that query. Standard SQL requires an error in this situation. If [ANSI](#) mode is not enabled, the server treats [S\(outer\\_ref\)](#) in such queries the same way that it would interpret [S\(const\)](#).

See [Section 1.7, “MySQL Standards Compliance”](#).

- [TRADITIONAL](#)

`TRADITIONAL` is equivalent to `STRICT_TRANS_TABLES`, `STRICT_ALL_TABLES`, `NO_ZERO_IN_DATE`, `NO_ZERO_DATE`, `ERROR_FOR_DIVISION_BY_ZERO`, and `NO_ENGINE_SUBSTITUTION`.

## Strict SQL Mode

Strict mode controls how MySQL handles invalid or missing values in data-change statements such as `INSERT` or `UPDATE`. A value can be invalid for several reasons. For example, it might have the wrong data type for the column, or it might be out of range. A value is missing when a new row to be inserted does not contain a value for a non-`NULL` column that has no explicit `DEFAULT` clause in its definition. (For a `NULL` column, `NULL` is inserted if the value is missing.) Strict mode also affects DDL statements such as `CREATE TABLE`.

If strict mode is not in effect, MySQL inserts adjusted values for invalid or missing values and produces warnings (see [Section 15.7.7.41, “SHOW WARNINGS Statement”](#)). In strict mode, you can produce this behavior by using `INSERT IGNORE` or `UPDATE IGNORE`.

For statements such as `SELECT` that do not change data, invalid values generate a warning in strict mode, not an error.

Strict mode produces an error for attempts to create a key that exceeds the maximum key length. When strict mode is not enabled, this results in a warning and truncation of the key to the maximum key length.

Strict mode does not affect whether foreign key constraints are checked. `foreign_key_checks` can be used for that. (See [Section 7.1.8, “Server System Variables”](#).)

Strict SQL mode is in effect if either `STRICT_ALL_TABLES` or `STRICT_TRANS_TABLES` is enabled, although the effects of these modes differ somewhat:

- For transactional tables, an error occurs for invalid or missing values in a data-change statement when either `STRICT_ALL_TABLES` or `STRICT_TRANS_TABLES` is enabled. The statement is aborted and rolled back.
- For nontransactional tables, the behavior is the same for either mode if the bad value occurs in the first row to be inserted or updated: The statement is aborted and the table remains unchanged. If the statement inserts or modifies multiple rows and the bad value occurs in the second or later row, the result depends on which strict mode is enabled:
  - For `STRICT_ALL_TABLES`, MySQL returns an error and ignores the rest of the rows. However, because the earlier rows have been inserted or updated, the result is a partial update. To avoid this, use single-row statements, which can be aborted without changing the table.
  - For `STRICT_TRANS_TABLES`, MySQL converts an invalid value to the closest valid value for the column and inserts the adjusted value. If a value is missing, MySQL inserts the implicit default value for the column data type. In either case, MySQL generates a warning rather than an error and continues processing the statement. Implicit defaults are described in [Section 13.6, “Data Type Default Values”](#).

Strict mode affects handling of division by zero, zero dates, and zeros in dates as follows:

- Strict mode affects handling of division by zero, which includes `MOD(N, 0)`:

For data-change operations (`INSERT`, `UPDATE`):

- If strict mode is not enabled, division by zero inserts `NULL` and produces no warning.
- If strict mode is enabled, division by zero produces an error, unless `IGNORE` is given as well. For `INSERT IGNORE` and `UPDATE IGNORE`, division by zero inserts `NULL` and produces a warning.

For `SELECT`, division by zero returns `NULL`. Enabling strict mode causes a warning to be produced as well.

- Strict mode affects whether the server permits `'0000-00-00'` as a valid date:
  - If strict mode is not enabled, `'0000-00-00'` is permitted and inserts produce no warning.
  - If strict mode is enabled, `'0000-00-00'` is not permitted and inserts produce an error, unless `IGNORE` is given as well. For `INSERT IGNORE` and `UPDATE IGNORE`, `'0000-00-00'` is permitted and inserts produce a warning.
- Strict mode affects whether the server permits dates in which the year part is nonzero but the month or day part is 0 (dates such as `'2010-00-01'` or `'2010-01-00'`):
  - If strict mode is not enabled, dates with zero parts are permitted and inserts produce no warning.
  - If strict mode is enabled, dates with zero parts are not permitted and inserts produce an error, unless `IGNORE` is given as well. For `INSERT IGNORE` and `UPDATE IGNORE`, dates with zero parts are inserted as `'0000-00-00'` (which is considered valid with `IGNORE`) and produce a warning.

For more information about strict mode with respect to `IGNORE`, see [Comparison of the IGNORE Keyword and Strict SQL Mode](#).

Strict mode affects handling of division by zero, zero dates, and zeros in dates in conjunction with the `ERROR_FOR_DIVISION_BY_ZERO`, `NO_ZERO_DATE`, and `NO_ZERO_IN_DATE` modes.

## Comparison of the IGNORE Keyword and Strict SQL Mode

This section compares the effect on statement execution of the `IGNORE` keyword (which downgrades errors to warnings) and strict SQL mode (which upgrades warnings to errors). It describes which statements they affect, and which errors they apply to.

The following table presents a summary comparison of statement behavior when the default is to produce an error versus a warning. An example of when the default is to produce an error is inserting a `NULL` into a `NOT NULL` column. An example of when the default is to produce a warning is inserting a value of the wrong data type into a column (such as inserting the string `'abc'` into an integer column).

Operational Mode	When Statement Default is Error	When Statement Default is Warning
Without <code>IGNORE</code> or strict SQL mode	Error	Warning
With <code>IGNORE</code>	Warning	Warning (same as without <code>IGNORE</code> or strict SQL mode)
With strict SQL mode	Error (same as without <code>IGNORE</code> or strict SQL mode)	Error
With <code>IGNORE</code> and strict SQL mode	Warning	Warning

One conclusion to draw from the table is that when the `IGNORE` keyword and strict SQL mode are both in effect, `IGNORE` takes precedence. This means that, although `IGNORE` and strict SQL mode can be considered to have opposite effects on error handling, they do not cancel when used together.

- [The Effect of IGNORE on Statement Execution](#)
- [The Effect of Strict SQL Mode on Statement Execution](#)

## The Effect of IGNORE on Statement Execution

Several statements in MySQL support an optional `IGNORE` keyword. This keyword causes the server to downgrade certain types of errors and generate warnings instead. For a multiple-row statement, downgrading an error to a warning may enable a row to be processed. Otherwise, `IGNORE` causes the statement to skip to the next row instead of aborting. (For nonignorable errors, an error occurs regardless of the `IGNORE` keyword.)

Example: If the table `t` has a primary key column `i` containing unique values, attempting to insert the same value of `i` into multiple rows normally produces a duplicate-key error:

```
mysql> CREATE TABLE t (i INT NOT NULL PRIMARY KEY);
mysql> INSERT INTO t (i) VALUES(1),(1);
ERROR 1062 (23000): Duplicate entry '1' for key 't.PRIMARY'
```

With `IGNORE`, the row containing the duplicate key still is not inserted, but a warning occurs instead of an error:

```
mysql> INSERT IGNORE INTO t (i) VALUES(1),(1);
Query OK, 1 row affected, 1 warning (0.01 sec)
Records: 2 Duplicates: 1 Warnings: 1

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Warning | 1062 | Duplicate entry '1' for key 't.PRIMARY' |
+-----+-----+-----+
1 row in set (0.00 sec)
```

Example: If the table `t2` has a `NOT NULL` column `id`, attempting to insert `NULL` produces an error in strict SQL mode:

```
mysql> CREATE TABLE t2 (id INT NOT NULL);
mysql> INSERT INTO t2 (id) VALUES(1),(NULL),(3);
ERROR 1048 (23000): Column 'id' cannot be null
mysql> SELECT * FROM t2;
Empty set (0.00 sec)
```

If the SQL mode is not strict, `IGNORE` causes the `NULL` to be inserted as the column implicit default (0 in this case), which enables the row to be handled without skipping it:

```
mysql> INSERT INTO t2 (id) VALUES(1),(NULL),(3);
mysql> SELECT * FROM t2;
+----+
| id |
+----+
| 1 |
| 0 |
| 3 |
+----+
```

These statements support the `IGNORE` keyword:

- `CREATE TABLE ... SELECT`: `IGNORE` does not apply to the `CREATE TABLE` or `SELECT` parts of the statement but to inserts into the table of rows produced by the `SELECT`. Rows that duplicate an existing row on a unique key value are discarded.
- `DELETE`: `IGNORE` causes MySQL to ignore errors during the process of deleting rows.
- `INSERT`: With `IGNORE`, rows that duplicate an existing row on a unique key value are discarded. Rows set to values that would cause data conversion errors are set to the closest valid values instead.

For partitioned tables where no partition matching a given value is found, `IGNORE` causes the insert operation to fail silently for rows containing the unmatched value.

- `LOAD DATA`, `LOAD XML`: With `IGNORE`, rows that duplicate an existing row on a unique key value are discarded.
- `UPDATE`: With `IGNORE`, rows for which duplicate-key conflicts occur on a unique key value are not updated. Rows updated to values that would cause data conversion errors are updated to the closest valid values instead.

The `IGNORE` keyword applies to the following ignorable errors:

- `ER_BAD_NULL_ERROR`
- `ER_DUP_ENTRY`
- `ER_DUP_ENTRY_WITH_KEY_NAME`
- `ER_DUP_KEY`
- `ER_NO_PARTITION_FOR_GIVEN_VALUE`
- `ER_NO_PARTITION_FOR_GIVEN_VALUE_SILENT`
- `ER_NO_REFERENCED_ROW_2`
- `ER_ROW_DOES_NOT_MATCH_GIVEN_PARTITION_SET`
- `ER_ROW_IS_REFERENCED_2`
- `ER_SUBQUERY_NO_1_ROW`
- `ER_VIEW_CHECK_FAILED`

## The Effect of Strict SQL Mode on Statement Execution

The MySQL server can operate in different SQL modes, and can apply these modes differently for different clients, depending on the value of the `sql_mode` system variable. In “strict” SQL mode, the server upgrades certain warnings to errors.

For example, in non-strict SQL mode, inserting the string `'abc'` into an integer column results in conversion of the value to 0 and a warning:

```
mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t (i) VALUES('abc');
Query OK, 1 row affected, 1 warning (0.01 sec)

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Warning | 1366 | Incorrect integer value: 'abc' for column 'i' at row 1 |
+-----+-----+-----+
1 row in set (0.00 sec)
```

In strict SQL mode, the invalid value is rejected with an error:

```
mysql> SET sql_mode = 'STRICT_ALL_TABLES';
```

```
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t (i) VALUES('abc');
ERROR 1366 (HY000): Incorrect integer value: 'abc' for column 'i' at row 1
```

For more information about possible settings of the `sql_mode` system variable, see [Section 7.1.11](#), “Server SQL Modes”.

Strict SQL mode applies to the following statements under conditions for which some value might be out of range or an invalid row is inserted into or deleted from a table:

- `ALTER TABLE`
- `CREATE TABLE`
- `CREATE TABLE ... SELECT`
- `DELETE` (both single table and multiple table)
- `INSERT`
- `LOAD DATA`
- `LOAD XML`
- `SELECT SLEEP()`
- `UPDATE` (both single table and multiple table)

Within stored programs, individual statements of the types just listed execute in strict SQL mode if the program was defined while strict mode was in effect.

Strict SQL mode applies to the following errors, which represent a class of errors in which an input value is either invalid or missing. A value is invalid if it has the wrong data type for the column or might be out of range. A value is missing if a new row to be inserted does not contain a value for a `NOT NULL` column that has no explicit `DEFAULT` clause in its definition.

```
ER_BAD_NULL_ERROR
ER_CUT_VALUE_GROUP_CONCAT
ER_DATA_TOO_LONG
ER_DATETIME_FUNCTION_OVERFLOW
ER_DIVISION_BY_ZERO
ER_INVALID_ARGUMENT_FOR_LOGARITHM
ER_NO_DEFAULT_FOR_FIELD
ER_NO_DEFAULT_FOR_VIEW_FIELD
ER_TOO_LONG_KEY
ER_TRUNCATED_WRONG_VALUE
ER_TRUNCATED_WRONG_VALUE_FOR_FIELD
ER_WARN_DATA_OUT_OF_RANGE
ER_WARN_NULL_TO_NOTNULL
ER_WARN_TOO_FEW_RECORDS
ER_WRONG_ARGUMENTS
ER_WRONG_VALUE_FOR_TYPE
WARN_DATA_TRUNCATED
```

#### Note

Because continued MySQL development defines new errors, there may be errors not in the preceding list to which strict SQL mode applies.

## 7.1.12 Connection Management

This section describes how MySQL Server manages connections. This includes a description of the available connection interfaces, how the server uses connection handler threads, details about the administrative connection interface, and management of DNS lookups.

### 7.1.12.1 Connection Interfaces

This section describes aspects of how the MySQL server manages client connections.

- [Network Interfaces and Connection Manager Threads](#)
- [Client Connection Thread Management](#)
- [Connection Volume Management](#)

#### Network Interfaces and Connection Manager Threads

The server is capable of listening for client connections on multiple network interfaces. Connection manager threads handle client connection requests on the network interfaces that the server listens to:

- On all platforms, one manager thread handles TCP/IP connection requests.
- On Unix, the same manager thread also handles Unix socket file connection requests.
- On Windows, one manager thread handles shared-memory connection requests, and another handles named-pipe connection requests.
- On all platforms, an additional network interface may be enabled to accept administrative TCP/IP connection requests. This interface can use the manager thread that handles “ordinary” TCP/IP requests, or a separate thread.

The server does not create threads to handle interfaces that it does not listen to. For example, a Windows server that does not have support for named-pipe connections enabled does not create a thread to handle them.

Individual server plugins or components may implement their own connection interface:

- X Plugin enables MySQL Server to communicate with clients using X Protocol. See [Section 22.5, “X Plugin”](#).

#### Client Connection Thread Management

Connection manager threads associate each client connection with a thread dedicated to it that handles authentication and request processing for that connection. Manager threads create a new thread when necessary but try to avoid doing so by consulting the thread cache first to see whether it contains a thread that can be used for the connection. When a connection ends, its thread is returned to the thread cache if the cache is not full.

In this connection thread model, there are as many threads as there are clients currently connected, which has some disadvantages when server workload must scale to handle large numbers of connections. For example, thread creation and disposal becomes expensive. Also, each thread requires server and kernel resources, such as stack space. To accommodate a large number of simultaneous connections, the stack size per thread must be kept small, leading to a situation where it is either too small or the server consumes large amounts of memory. Exhaustion of other resources can occur as well, and scheduling overhead can become significant.

MySQL Enterprise Edition includes a thread pool plugin that provides an alternative thread-handling model designed to reduce overhead and improve performance. It implements a thread pool that increases server

performance by efficiently managing statement execution threads for large numbers of client connections. See [Section 7.6.3, “MySQL Enterprise Thread Pool”](#).

To control and monitor how the server manages threads that handle client connections, several system and status variables are relevant. (See [Section 7.1.8, “Server System Variables”](#), and [Section 7.1.10, “Server Status Variables”](#).)

- The `thread_cache_size` system variable determines the thread cache size. By default, the server autosizes the value at startup, but it can be set explicitly to override this default. A value of 0 disables caching, which causes a thread to be set up for each new connection and disposed of when the connection terminates. To enable *N* inactive connection threads to be cached, set `thread_cache_size` to *N* at server startup or at runtime. A connection thread becomes inactive when the client connection with which it was associated terminates.
- To monitor the number of threads in the cache and how many threads have been created because a thread could not be taken from the cache, check the `Threads_cached` and `Threads_created` status variables.
- When the thread stack is too small, this limits the complexity of the SQL statements the server can handle, the recursion depth of stored procedures, and other memory-consuming actions. To set a stack size of *N* bytes for each thread, start the server with `thread_stack` set to *N*.

## Connection Volume Management

To control the maximum number of clients the server permits to connect simultaneously, set the `max_connections` system variable at server startup or at runtime. It may be necessary to increase `max_connections` if more clients attempt to connect simultaneously than the server is configured to handle (see [Section B.3.2.5, “Too many connections”](#)). If the server refuses a connection because the `max_connections` limit is reached, it increments the `Connection_errors_max_connections` status variable.

`mysqld` actually permits `max_connections` + 1 client connections. The extra connection is reserved for use by accounts that have the `CONNECTION_ADMIN` privilege (or the deprecated `SUPER` privilege). By granting the privilege to administrators and not to normal users (who should not need it), an administrator can connect to the server and use `SHOW PROCESSLIST` to diagnose problems even if the maximum number of unprivileged clients are connected. See [Section 15.7.7.30, “SHOW PROCESSLIST Statement”](#).

The server also permits administrative connections on an administrative network interface, which you can set up using a dedicated IP address and port. See [Section 7.1.12.2, “Administrative Connection Management”](#).

The Group Replication plugin interacts with MySQL Server using internal sessions to perform SQL API operations. Group Replication's internal sessions are handled separately from client connections, so they do not count towards the `max_connections` limit and are not refused if the server has reached this limit.

The maximum number of client connections MySQL supports (that is, the maximum value to which `max_connections` can be set) depends on several factors:

- The quality of the thread library on a given platform.
- The amount of RAM available.
- The amount of RAM is used for each connection.
- The workload from each connection.
- The desired response time.

- The number of file descriptors available.

Linux or Solaris should be able to support at least 500 to 1000 simultaneous connections routinely and as many as 10,000 connections if you have many gigabytes of RAM available and the workload from each is low or the response time target undemanding.

Increasing the `max_connections` value increases the number of file descriptors that `mysqld` requires. If the required number of descriptors are not available, the server reduces the value of `max_connections`. For comments on file descriptor limits, see [Section 10.4.3.1, “How MySQL Opens and Closes Tables”](#).

Increasing the `open_files_limit` system variable may be necessary, which may also require raising the operating system limit on how many file descriptors can be used by MySQL. Consult your operating system documentation to determine whether it is possible to increase the limit and how to do so. See also [Section B.3.2.16, “File Not Found and Similar Errors”](#).

### 7.1.12.2 Administrative Connection Management

As mentioned in [Connection Volume Management](#), to allow for the need to perform administrative operations even when `max_connections` connections are already established on the interfaces used for ordinary connections, the MySQL server permits a single administrative connection to users who have the `CONNECTION_ADMIN` privilege (or the deprecated `SUPER` privilege).

The server also permits dedicating a TCP/IP port for administrative connections, as described in the following sections.

- [Administrative Interface Characteristics](#)
- [Administrative Interface Support for Encrypted Connections](#)

#### Administrative Interface Characteristics

The administrative connection interface has these characteristics:

- The server enables the interface only if the `admin_address` system variable is set at startup to indicate the IP address for it. If `admin_address` is not set, the server maintains no administrative interface.
- The `admin_port` system variable specifies the interface TCP/IP port number (default 33062).
- There is no limit on the number of administrative connections, but connections are permitted only for users who have the `SERVICE_CONNECTION_ADMIN` privilege.
- The `create_admin_listener_thread` system variable enables DBAs to choose at startup whether the administrative interface has its own separate thread. The default is `OFF`; that is, the manager thread for ordinary connections on the main interface also handles connections for the administrative interface.

These lines in the server `my.cnf` file enable the administrative interface on the loopback interface and configure it to use port number 33064 (that is, a port different from the default):

```
[mysqld]
admin_address=127.0.0.1
admin_port=33064
```

MySQL client programs connect to either the main or administrative interface by specifying appropriate connection parameters. If the server running on the local host is using the default TCP/IP port numbers of 3306 and 33062 for the main and administrative interfaces, these commands connect to those interfaces:

```
mysql --protocol=TCP --port=3306
```

```
mysql --protocol=TCP --port=33062
```

## Administrative Interface Support for Encrypted Connections

The administrative interface has its own configuration parameters for encrypted connections. These correspond to the main interface parameters but enable independent configuration of encrypted connections for the administrative interface:

The `admin_tls_XXX` and `admin_ssl_XXX` system variables are like the `tls_XXX` and `ssl_XXX` system variables, but they configure the TLS context for the administrative interface rather than the main interface.

For general information about configuring connection-encryption support, see [Section 8.3.1, “Configuring MySQL to Use Encrypted Connections”](#), and [Section 8.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#). That discussion is written for the main connection interface, but the parameter names are similar for the administrative connection interface. Use that discussion together with the following remarks, which provide information specific to the administrative interface.

TLS configuration for the administrative interface follows these rules:

- The administrative interface supports encrypted connections. For connections on the interface, the applicable TLS context depends on whether any nondefault administrative TLS parameter is configured:
  - If all administrative TLS parameters have their default values, the administrative interface uses the same TLS context as the main interface.
  - If any administrative TLS parameter has a nondefault value, the administrative interface uses the TLS context defined by its own parameters. (This is the case if any `admin_tls_XXX` or `admin_ssl_XXX` system variable is set to a value different from its default.) If a valid TLS context cannot be created from those parameters, the administrative interface falls back to the main interface TLS context.
- It is possible to disable encrypted connections to the administrative interface by setting the `admin_tls_version` system variable to the empty value to indicate that no TLS versions are supported. For example, these lines in the server `my.cnf` file disable encrypted connections on the administrative interface:

```
[mysqld]
admin_tls_version='
```

Examples:

- This configuration in the server `my.cnf` file enables the administrative interface, but does not set any of the TLS parameters specific to that interface:

```
[mysqld]
admin_address=127.0.0.1
```

As a result, the administrative interface supports encrypted connections (because encryption is supported by default when the administrative interface is enabled), and uses the main interface TLS context. When clients connect to the administrative interface, they should use the same certificate and key files as for ordinary connections on the main interface. For example (enter the command on a single line):

```
mysql --protocol=TCP --port=33062
 --ssl-ca=ca.pem
 --ssl-cert=client-cert.pem
 --ssl-key=client-key.pem
```

- This server configuration enables the administrative interface and sets the TLS certificate and key file parameters specific to that interface:

```
[mysqld]
admin_address=127.0.0.1
admin_ssl_ca=admin-ca.pem
admin_ssl_cert=admin-server-cert.pem
admin_ssl_key=admin-server-key.pem
```

As a result, the administrative interface supports encrypted connections using its own TLS context. When clients connect to the administrative interface, they should use certificate and key files specific to that interface. For example (enter the command on a single line):

```
mysql --protocol=TCP --port=33062
 --ssl-ca=admin-ca.pem
 --ssl-cert=admin-client-cert.pem
 --ssl-key=admin-client-key.pem
```

### 7.1.12.3 DNS Lookups and the Host Cache

The MySQL server maintains an in-memory host cache that contains information about clients: IP address, host name, and error information. The Performance Schema `host_cache` table exposes the contents of the host cache so that it can be examined using `SELECT` statements. This may help you diagnose the causes of connection problems. See [Section 29.12.22.3, “The host\\_cache Table”](#).

The following sections discuss how the host cache works, as well as other topics such as how to configure and monitor the cache.

- [Host Cache Operation](#)
- [Configuring the Host Cache](#)
- [Monitoring the Host Cache](#)
- [Flushing the Host Cache](#)
- [Dealing with Blocked Hosts](#)

#### Host Cache Operation

The server uses the host cache only for non-localhost TCP connections. It does not use the cache for TCP connections established using a loopback interface address (for example, `127.0.0.1` or `::1`), or for connections established using a Unix socket file, named pipe, or shared memory.

The server uses the host cache for several purposes:

- By caching the results of IP-to-host name lookups, the server avoids doing a Domain Name System (DNS) lookup for each client connection. Instead, for a given host, it needs to perform a lookup only for the first connection from that host.
- The cache contains information about errors that occur during the client connection process. Some errors are considered “blocking.” If too many of these occur successively from a given host without a successful connection, the server blocks further connections from that host. The `max_connect_errors` system variable determines the permitted number of successive errors before blocking occurs.

For each applicable new client connection, the server uses the client IP address to check whether the client host name is in the host cache. If so, the server refuses or continues to process the connection request depending on whether or not the host is blocked. If the host is not in the cache, the server attempts to resolve the host name. First, it resolves the IP address to a host name and resolves that host name back to an IP address. Then it compares the result to the original IP address to ensure that they are the same.

The server stores information about the result of this operation in the host cache. If the cache is full, the least recently used entry is discarded.

The server performs host name resolution using the `getaddrinfo()` system call.

The server handles entries in the host cache like this:

1. When the first TCP client connection reaches the server from a given IP address, a new cache entry is created to record the client IP, host name, and client lookup validation flag. Initially, the host name is set to `NULL` and the flag is false. This entry is also used for subsequent client TCP connections from the same originating IP.
2. If the validation flag for the client IP entry is false, the server attempts an IP-to-host name-to-IP DNS resolution. If that is successful, the host name is updated with the resolved host name and the validation flag is set to true. If resolution is unsuccessful, the action taken depends on whether the error is permanent or transient. For permanent failures, the host name remains `NULL` and the validation flag is set to true. For transient failures, the host name and validation flag remain unchanged. (In this case, another DNS resolution attempt occurs the next time a client connects from this IP.)
3. If an error occurs while processing an incoming client connection from a given IP address, the server updates the corresponding error counters in the entry for that IP. For a description of the errors recorded, see [Section 29.12.22.3, “The host\\_cache Table”](#).

To unblock blocked hosts, flush the host cache; see [Dealing with Blocked Hosts](#).

It is possible for a blocked host to become unblocked even without flushing the host cache if activity from other hosts occurs:

- If the cache is full when a connection arrives from a client IP not in the cache, the server discards the least recently used cache entry to make room for the new entry.
- If the discarded entry is for a blocked host, that host becomes unblocked.

Some connection errors are not associated with TCP connections, occur very early in the connection process (even before an IP address is known), or are not specific to any particular IP address (such as out-of-memory conditions). For information about these errors, check the `Connection_errors_xxx` status variables (see [Section 7.1.10, “Server Status Variables”](#)).

## Configuring the Host Cache

The host cache is enabled by default. The `host_cache_size` system variable controls its size, as well as the size of the Performance Schema `host_cache` table that exposes the cache contents. The cache size can be set at server startup and changed at runtime. For example, to set the size to 100 at startup, put these lines in the server `my.cnf` file:

```
[mysqld]
host_cache_size=200
```

To change the size to 300 at runtime, do this:

```
SET GLOBAL host_cache_size=300;
```

Setting `host_cache_size` to 0, either at server startup or at runtime, disables the host cache. With the cache disabled, the server performs a DNS lookup every time a client connects.

Changing the cache size at runtime causes an implicit host cache flushing operation that clears the host cache, truncates the `host_cache` table, and unblocks any blocked hosts; see [Flushing the Host Cache](#).

To disable DNS host name lookups, start the server with the `skip_name_resolve` system variable enabled. In this case, the server uses only IP addresses and not host names to match connecting hosts to rows in the MySQL grant tables. Only accounts specified in those tables using IP addresses can be used. (A client may not be able to connect if no account exists that specifies the client IP address.)

If you have a very slow DNS and many hosts, you might be able to improve performance either by enabling `skip_name_resolve` to disable DNS lookups, or by increasing the value of `host_cache_size` to make the host cache larger.

To disallow TCP/IP connections entirely, start the server with the `skip_networking` system variable enabled.

To adjust the permitted number of successive connection errors before host blocking occurs, set the `max_connect_errors` system variable. For example, to set the value at startup put these lines in the server `my.cnf` file:

```
[mysqld]
max_connect_errors=10000
```

To change the value at runtime, do this:

```
SET GLOBAL max_connect_errors=10000;
```

## Monitoring the Host Cache

The Performance Schema `host_cache` table exposes the contents of the host cache. This table can be examined using `SELECT` statements, which may help you diagnose the causes of connection problems. For information about this table, see [Section 29.12.22.3, “The host\\_cache Table”](#).

## Flushing the Host Cache

Flushing the host cache might be advisable or desirable under these conditions:

- Some of your client hosts change IP address.
- The error message `Host 'host_name' is blocked` occurs for connections from legitimate hosts. (See [Dealing with Blocked Hosts](#).)

Flushing the host cache has these effects:

- It clears the in-memory host cache.
- It removes all rows from the Performance Schema `host_cache` table that exposes the cache contents.
- It unblocks any blocked hosts. This enables further connection attempts from those hosts.

To flush the host cache, use any of these methods:

- Change the value of the `host_cache_size` system variable. This requires the `SYSTEM_VARIABLES_ADMIN` privilege (or the deprecated `SUPER` privilege).
- Execute a `TRUNCATE TABLE` statement that truncates the Performance Schema `host_cache` table. This requires the `DROP` privilege for the table.
- Execute a `mysqladmin flush-hosts` command. This requires the `DROP` privilege for the Performance Schema `host_cache` table or the `RELOAD` privilege.

## Dealing with Blocked Hosts

The server uses the host cache to track errors that occur during the client connection process. If the following error occurs, it means that `mysqld` has received many connection requests from the given host that were interrupted in the middle:

```
Host 'host_name' is blocked because of many connection errors.
Unblock with 'mysqladmin flush-hosts'
```

The value of the `max_connect_errors` system variable determines how many successive interrupted connection requests the server permits before blocking a host. After `max_connect_errors` failed requests without a successful connection, the server assumes that something is wrong (for example, that someone is trying to break in), and blocks the host from further connection requests.

To unblock blocked hosts, flush the host cache; see [Flushing the Host Cache](#).

Alternatively, to avoid having the error message occur, set `max_connect_errors` as described in [Configuring the Host Cache](#). The default value of `max_connect_errors` is 100. Increasing `max_connect_errors` to a large value makes it less likely that a host reaches the threshold and becomes blocked. However, if the `Host 'host_name' is blocked` error message occurs, first verify that there is nothing wrong with TCP/IP connections from the blocked hosts. It does no good to increase the value of `max_connect_errors` if there are network problems.

### 7.1.13 IPv6 Support

Support for IPv6 in MySQL includes these capabilities:

- MySQL Server can accept TCP/IP connections from clients connecting over IPv6. For example, this command connects over IPv6 to the MySQL server on the local host:

```
$> mysql -h ::1
```

To use this capability, two things must be true:

- Your system must be configured to support IPv6. See [Section 7.1.13.1, “Verifying System Support for IPv6”](#).
- The default MySQL server configuration permits IPv6 connections in addition to IPv4 connections. To change the default configuration, start the server with the `bind_address` system variable set to an appropriate value. See [Section 7.1.8, “Server System Variables”](#).
- MySQL account names permit IPv6 addresses to enable DBAs to specify privileges for clients that connect to the server over IPv6. See [Section 8.2.4, “Specifying Account Names”](#). IPv6 addresses can be specified in account names in statements such as `CREATE USER`, `GRANT`, and `REVOKE`. For example:

```
mysql> CREATE USER 'bill'@':::1' IDENTIFIED BY 'secret';
mysql> GRANT SELECT ON mydb.* TO 'bill'@':::1';
```

- IPv6 functions enable conversion between string and internal format IPv6 address formats, and checking whether values represent valid IPv6 addresses. For example, `INET6_ATON()` and `INET6_NTOA()` are similar to `INET_ATON()` and `INET_NTOA()`, but handle IPv6 addresses in addition to IPv4 addresses. See [Section 14.24, “Miscellaneous Functions”](#).
- Group Replication group members can use IPv6 addresses for communications within the group. A group can contain a mix of members using IPv6 and members using IPv4. See [Section 20.5.5, “Support For IPv6 And For Mixed IPv6 And IPv4 Groups”](#).

The following sections describe how to set up MySQL so that clients can connect to the server over IPv6.

### 7.1.13.1 Verifying System Support for IPv6

Before MySQL Server can accept IPv6 connections, the operating system on your server host must support IPv6. As a simple test to determine whether that is true, try this command:

```
$> ping6 ::1
16 bytes from ::1, icmp_seq=0 hlim=64 time=0.171 ms
16 bytes from ::1, icmp_seq=1 hlim=64 time=0.077 ms
...
```

To produce a description of your system's network interfaces, invoke `ifconfig -a` and look for IPv6 addresses in the output.

If your host does not support IPv6, consult your system documentation for instructions on enabling it. It might be that you need only reconfigure an existing network interface to add an IPv6 address. Or a more extensive change might be needed, such as rebuilding the kernel with IPv6 options enabled.

These links may be helpful in setting up IPv6 on various platforms:

- [Windows](#)
- [Gentoo Linux](#)
- [Ubuntu Linux](#)
- [Linux \(Generic\)](#)
- [macOS](#)

### 7.1.13.2 Configuring the MySQL Server to Permit IPv6 Connections

The MySQL server listens on one or more network sockets for TCP/IP connections. Each socket is bound to one address, but it is possible for an address to map onto multiple network interfaces.

Set the `bind_address` system variable at server startup to specify the TCP/IP connections that a server instance accepts. You can specify multiple values for this option, including any combination of IPv6 addresses, IPv4 addresses, and host names that resolve to IPv6 or IPv4 addresses. Alternatively, you can specify one of the wildcard address formats that permit listening on multiple network interfaces. A value of `*`, which is the default, or a value of `:::`, permit both IPv4 and IPv6 connections on all server host IPv4 and IPv6 interfaces. For more information, see the `bind_address` description in [Section 7.1.8, "Server System Variables"](#).

### 7.1.13.3 Connecting Using the IPv6 Local Host Address

The following procedure shows how to configure MySQL to permit IPv6 connections by clients that connect to the local server using the `::1` local host address. The instructions given here assume that your system supports IPv6.

1. Start the MySQL server with an appropriate `bind_address` setting to permit it to accept IPv6 connections. For example, put the following lines in the server option file and restart the server:

```
[mysqld]
bind_address = *
```

Specifying `*` (or `:::`) as the value for `bind_address` permits both IPv4 and IPv6 connections on all server host IPv4 and IPv6 interfaces. If you want to bind the server to a specific list of addresses, you can do this by specifying a comma-separated list of values for `bind_address`. This example specifies the local host addresses for both IPv4 and IPv6:

```
[mysqld]
bind_address = 127.0.0.1,::1
```

For more information, see the `bind_address` description in [Section 7.1.8, “Server System Variables”](#).

2. As an administrator, connect to the server and create an account for a local user who can connect from the `::1` local IPv6 host address:

```
mysql> CREATE USER 'ipv6user'@'::1' IDENTIFIED BY 'ipv6pass';
```

For the permitted syntax of IPv6 addresses in account names, see [Section 8.2.4, “Specifying Account Names”](#). In addition to the `CREATE USER` statement, you can issue `GRANT` statements that give specific privileges to the account, although that is not necessary for the remaining steps in this procedure.

3. Invoke the `mysql` client to connect to the server using the new account:

```
$> mysql -h ::1 -u ipv6user -pipv6pass
```

4. Try some simple statements that show connection information:

```
mysql> STATUS
...
Connection: ::1 via TCP/IP
...

mysql> SELECT CURRENT_USER(), @@bind_address;
+-----+-----+
| CURRENT_USER() | @@bind_address |
+-----+-----+
| ipv6user@::1 | :: |
+-----+-----+
```

### 7.1.13.4 Connecting Using IPv6 Nonlocal Host Addresses

The following procedure shows how to configure MySQL to permit IPv6 connections by remote clients. It is similar to the preceding procedure for local clients, but the server and client hosts are distinct and each has its own nonlocal IPv6 address. The example uses these addresses:

```
Server host: 2001:db8:0:f101::1
Client host: 2001:db8:0:f101::2
```

These addresses are chosen from the nonroutable address range recommended by [IANA](#) for documentation purposes and suffice for testing on your local network. To accept IPv6 connections from clients outside the local network, the server host must have a public address. If your network provider assigns you an IPv6 address, you can use that. Otherwise, another way to obtain an address is to use an IPv6 broker; see [Section 7.1.13.5, “Obtaining an IPv6 Address from a Broker”](#).

1. Start the MySQL server with an appropriate `bind_address` setting to permit it to accept IPv6 connections. For example, put the following lines in the server option file and restart the server:

```
[mysqld]
bind_address = *
```

Specifying `*` (or `::`) as the value for `bind_address` permits both IPv4 and IPv6 connections on all server host IPv4 and IPv6 interfaces. If you want to bind the server to a specific list of addresses, you can do this by specifying a comma-separated list of values for `bind_address`. This example specifies an IPv4 address as well as the required server host IPv6 address:

```
[mysqld]
bind_address = 198.51.100.20,2001:db8:0:f101::1
```

For more information, see the `bind_address` description in [Section 7.1.8, “Server System Variables”](#).

2. On the server host (`2001:db8:0:f101::1`), create an account for a user who can connect from the client host (`2001:db8:0:f101::2`):

```
mysql> CREATE USER 'remoteipv6user'@'2001:db8:0:f101::2' IDENTIFIED BY 'remoteipv6pass';
```

3. On the client host (`2001:db8:0:f101::2`), invoke the `mysql` client to connect to the server using the new account:

```
$> mysql -h 2001:db8:0:f101::1 -u remoteipv6user -premoveipv6pass
```

4. Try some simple statements that show connection information:

```
mysql> STATUS
...
Connection: 2001:db8:0:f101::1 via TCP/IP
...

mysql> SELECT CURRENT_USER(), @@bind_address;
+-----+-----+
| CURRENT_USER() | @@bind_address |
+-----+-----+
| remoteipv6user@2001:db8:0:f101::2 | :: |
+-----+-----+
```

### 7.1.13.5 Obtaining an IPv6 Address from a Broker

If you do not have a public IPv6 address that enables your system to communicate over IPv6 outside your local network, you can obtain one from an IPv6 broker. The [Wikipedia IPv6 Tunnel Broker page](#) lists several brokers and their features, such as whether they provide static addresses and the supported routing protocols.

After configuring your server host to use a broker-supplied IPv6 address, start the MySQL server with an appropriate `bind_address` setting to permit the server to accept IPv6 connections. You can specify `*` (or `::`) as the `bind_address` value, or bind the server to the specific IPv6 address provided by the broker. For more information, see the `bind_address` description in [Section 7.1.8, “Server System Variables”](#).

Note that if the broker allocates dynamic addresses, the address provided for your system might change the next time you connect to the broker. If so, any accounts you create that name the original address become invalid. To bind to a specific address but avoid this change-of-address problem, you might be able to arrange with the broker for a static IPv6 address.

The following example shows how to use Freenet6 as the broker and the `gogoc` IPv6 client package on Gentoo Linux.

1. Create an account at Freenet6 by visiting this URL and signing up:

```
http://gogonet.gogo6.com
```

2. After creating the account, go to this URL, sign in, and create a user ID and password for the IPv6 broker:

```
http://gogonet.gogo6.com/page/freenet6-registration
```

3. As `root`, install `gogoc`:

```
$> emerge gogoc
```

4. Edit `/etc/gogoc/gogoc.conf` to set the `userid` and `password` values. For example:

```
userid=gogouser
passwd=gogopass
```

5. Start `gogoc`:

```
$> /etc/init.d/gogoc start
```

To start `gogoc` each time your system boots, execute this command:

```
$> rc-update add gogoc default
```

6. Use `ping6` to try to ping a host:

```
$> ping6 ipv6.google.com
```

7. To see your IPv6 address:

```
$> ifconfig tun
```

## 7.1.14 Network Namespace Support

A network namespace is a logical copy of the network stack from the host system. Network namespaces are useful for setting up containers or virtual environments. Each namespace has its own IP addresses, network interfaces, routing tables, and so forth. The default or global namespace is the one in which the host system physical interfaces exist.

Namespace-specific address spaces can lead to problems when MySQL connections cross namespaces. For example, the network address space for a MySQL instance running in a container or virtual network may differ from the address space of the host machine. This can produce phenomena such as a client connection from an address in one namespace appearing to the MySQL server to be coming from a different address, even for client and server running on the same machine. Suppose that both processes run on a host with IP address `203.0.113.10` but use different namespaces. A connection may produce a result like this:

```
$> mysql --user=admin --host=203.0.113.10 --protocol=tcp

mysql> SELECT USER();
+-----+
| USER() |
+-----+
| admin@198.51.100.2 |
+-----+
```

In this case, the expected `USER()` value is `admin@203.0.113.10`. Such behavior can make it difficult to assign account permissions properly if the address from which a connection originates is not what it appears.

To address this issue, MySQL enables specifying the network namespace to use for TCP/IP connections, so that both endpoints of connections use an agreed-upon common address space.

MySQL supports network namespaces on platforms that implement them. Support within MySQL applies to:

- The MySQL server, `mysqld`.
- X Plugin.
- The `mysql` client and the `mysqlxtest` test suite client. (Other clients are not supported. They must be invoked from within the network namespace of the server to which they are to connect.)

- Regular replication.
- Group Replication, only when using the MySQL communication stack to establish group communication connections.

The following sections describe how to use network namespaces in MySQL:

- [Host System Prerequisites](#)
- [MySQL Configuration](#)
- [Network Namespace Monitoring](#)

## Host System Prerequisites

Prior to using network namespace support in MySQL, these host system prerequisites must be satisfied:

- The host operating system must support network namespaces. (For example, Linux.)
- Any network namespace to be used by MySQL must first be created on the host system.
- Host name resolution must be configured by the system administrator to support network namespaces.

### Note

A known limitation is that, within MySQL, host name resolution does not work for names specified in network namespace-specific host files. For example, if the address for a host name in the `red` namespace is specified in the `/etc/netns/red/hosts` file, binding to the name fails on both the server and client sides. The workaround is to use the IP address rather than the host name.

- The system administrator must enable the `CAP_SYS_ADMIN` operating system privilege for the MySQL binaries that support network namespaces (`mysqld`, `mysql`, `mysqlxtest`).

### Important

Enabling `CAP_SYS_ADMIN` is a security sensitive operation because it enables a process to perform other privileged actions in addition to setting namespaces. For a description of its effects, see <https://man7.org/linux/man-pages/man7/capabilities.7.html>.

Because `CAP_SYS_ADMIN` must be enabled explicitly by the system administrator, MySQL binaries by default do not have network namespace support enabled. The system administrator should evaluate the security implications of running MySQL processes with `CAP_SYS_ADMIN` before enabling it.

The instructions in the following example set up network namespaces named `red` and `blue`. The names you choose may differ, as may the network addresses and interfaces on your host system.

Invoke the commands shown here either as the `root` operating system user or by prefixing each command with `sudo`. For example, to invoke the `ip` or `setcap` command if you are not `root`, use `sudo ip` or `sudo setcap`.

To configure network namespaces, use the `ip` command. For some operations, the `ip` command must execute within a particular namespace (which must already exist). In such cases, begin the command like this:

```
ip netns exec namespace_name
```

For example, this command executes within the *red* namespace to bring up the loopback interface:

```
ip netns exec red ip link set lo up
```

To add namespaces named *red* and *blue*, each with its own virtual Ethernet device used as a link between namespaces and its own loopback interface:

```
ip netns add red
ip link add veth-red type veth peer name vpeer-red
ip link set vpeer-red netns red
ip addr add 192.0.2.1/24 dev veth-red
ip link set veth-red up
ip netns exec red ip addr add 192.0.2.2/24 dev vpeer-red
ip netns exec red ip link set vpeer-red up
ip netns exec red ip link set lo up

ip netns add blue
ip link add veth-blue type veth peer name vpeer-blue
ip link set vpeer-blue netns blue
ip addr add 198.51.100.1/24 dev veth-blue
ip link set veth-blue up
ip netns exec blue ip addr add 198.51.100.2/24 dev vpeer-blue
ip netns exec blue ip link set vpeer-blue up
ip netns exec blue ip link set lo up

if you want to enable inter-subnet routing...
sysctl net.ipv4.ip_forward=1
ip netns exec red ip route add default via 192.0.2.1
ip netns exec blue ip route add default via 198.51.100.1
```

A diagram of the links between namespaces looks like this:

red		global		blue
192.0.2.2	<=>	192.0.2.1		
(vpeer-red)		(veth-red)		
		198.51.100.1	<=>	198.51.100.2
		(veth-blue)		(vpeer-blue)

To check which namespaces and links exist:

```
ip netns list
ip link list
```

To see the routing tables for the global and named namespaces:

```
ip route show
ip netns exec red ip route show
ip netns exec blue ip route show
```

To remove the *red* and *blue* links and namespaces:

```
ip link del veth-red
ip link del veth-blue

ip netns del red
ip netns del blue

sysctl net.ipv4.ip_forward=0
```

So that the MySQL binaries that include network namespace support can actually use namespaces, you must grant them the *CAP\_SYS\_ADMIN* capability. The following *setcap* commands assume that you have

changed location to the directory containing your MySQL binaries (adjust the pathname for your system as necessary):

```
cd /usr/local/mysql/bin
```

To grant `CAP_SYS_ADMIN` capability to the appropriate binaries:

```
setcap cap_sys_admin+ep ./mysqld
setcap cap_sys_admin+ep ./mysql
setcap cap_sys_admin+ep ./mysqlxtest
```

To check `CAP_SYS_ADMIN` capability:

```
$> getcap ./mysqld ./mysql ./mysqlxtest
./mysqld = cap_sys_admin+ep
./mysql = cap_sys_admin+ep
./mysqlxtest = cap_sys_admin+ep
```

To remove `CAP_SYS_ADMIN` capability:

```
setcap -r ./mysqld
setcap -r ./mysql
setcap -r ./mysqlxtest
```

### Important

If you reinstall binaries to which you have previously applied `setcap`, you must use `setcap` again. For example, if you perform an in-place MySQL upgrade, failure to grant the `CAP_SYS_ADMIN` capability again results in namespace-related failures. The server fails with this error for attempts to bind to an address with a named namespace:

```
[ERROR] [MY-013408] [Server] setns() failed with error 'Operation not permitted'
```

A client invoked with the `--network-namespace` option fails like this:

```
ERROR: Network namespace error: Operation not permitted
```

## MySQL Configuration

Assuming that the preceding host system prerequisites have been satisfied, MySQL enables configuring the server-side namespace for the listening (inbound) side of connections and the client-side namespace for the outbound side of connections.

On the server side, the `bind_address`, `admin_address`, and `mysqlx_bind_address` system variables have extended syntax for specifying the network namespace to use for a given IP address or host name on which to listen for incoming connections. To specify a namespace for an address, add a slash and the namespace name. For example, a server `my.cnf` file might contain these lines:

```
[mysqld]
bind_address = 127.0.1.1,192.0.2.2/red,198.51.100.2/blue
admin_address = 102.0.2.2/red
mysqlx_bind_address = 102.0.2.2/red
```

These rules apply:

- A network namespace can be specified for an IP address or a host name.
- A network namespace cannot be specified for a wildcard IP address.

- For a given address, the network namespace is optional. If given, it must be specified as a `/ns` suffix immediately following the address.
- An address with no `/ns` suffix uses the host system global namespace. The global namespace is therefore the default.
- An address with a `/ns` suffix uses the namespace named `ns`.
- The host system must support network namespaces and each named namespace must previously have been set up. Naming a nonexistent namespace produces an error.
- `bind_address` and `mysqlx_bind_address` accept a list of multiple comma-separated addresses, the variable value can specify addresses in the global namespace, in named namespaces, or a mix.

If an error occurs during server startup for attempts to use a namespace, the server does not start. If errors occur for X Plugin during plugin initialization such that it is unable to bind to any address, the plugin fails its initialization sequence and the server does not load it.

On the client side, a network namespace can be specified in these contexts:

- For the `mysql` client and the `mysqlxtest` test suite client, use the `--network-namespace` option. For example:

```
mysql --host=192.0.2.2 --network-namespace=red
```

If the `--network-namespace` option is omitted, the connection uses the default (global) namespace.

- For replication connections from replica servers to source servers, use the `CHANGE REPLICATION SOURCE TO` statement and specify the `NETWORK_NAMESPACE` option. For example:

```
CHANGE REPLICATION SOURCE TO
SOURCE_HOST = '192.0.2.2',
NETWORK_NAMESPACE = 'red';
```

If the `NETWORK_NAMESPACE` option is omitted, replication connections use the default (global) namespace.

The following example sets up a MySQL server that listens for connections in the global, `red`, and `blue` namespaces, and shows how to configure accounts that connect from the `red` and `blue` namespaces. It is assumed that the `red` and `blue` namespaces have already been created as shown in [Host System Prerequisites](#).

1. Configure the server to listen on addresses in multiple namespaces. Put these lines in the server `my.cnf` file and start the server:

```
[mysqld]
bind_address = 127.0.1.1,192.0.2.2/red,198.51.100.2/blue
```

The value tells the server to listen on the loopback address `127.0.0.1` in the global namespace, the address `192.0.2.2` in the `red` namespace, and the address `198.51.100.2` in the `blue` namespace.

2. Connect to the server in the global namespace and create accounts that have permission to connect from an address in the address space of each named namespace:

```
$> mysql -u root -h 127.0.0.1 -p
Enter password: root_password

mysql> CREATE USER 'red_user'@'192.0.2.2'
```

```
IDENTIFIED BY 'red_user_password';
mysql> CREATE USER 'blue_user'@'198.51.100.2'
IDENTIFIED BY 'blue_user_password';
```

3. Verify that you can connect to the server in each named namespace:

```
$> mysql -u red_user -h 192.0.2.2 --network-namespace=red -p
Enter password: red_user_password

mysql> SELECT USER();
+-----+
| USER() |
+-----+
| red_user@192.0.2.2 |
+-----+

$> mysql -u blue_user -h 198.51.100.2 --network-namespace=blue -p
Enter password: blue_user_password

mysql> SELECT USER();
+-----+
| USER() |
+-----+
| blue_user@198.51.100.2 |
+-----+
```

#### Note

You might see different results from `USER()`, which can return a value that includes a host name rather than an IP address if your DNS is configured to be able to resolve the address to the corresponding host name and the server is not run with the `skip_name_resolve` system variable enabled.

You might also try invoking `mysql` without the `--network-namespace` option to see whether the connection attempt succeeds, and, if so, how the `USER()` value is affected.

## Network Namespace Monitoring

For replication monitoring purposes, these information sources have a column that displays the applicable network namespace for connections:

- The Performance Schema `replication_connection_configuration` table. See [Section 29.12.11.12, “The replication\\_connection\\_configuration Table”](#).
- The replica server connection metadata repository. See [Section 19.2.4.2, “Replication Metadata Repositories”](#).
- The `SHOW REPLICA STATUS` statement.

## 7.1.15 MySQL Server Time Zone Support

This section describes the time zone settings maintained by MySQL, how to load the system tables required for named time support, how to stay current with time zone changes, and how to enable leap-second support.

Time zone offsets are also supported for inserted datetime values; see [Section 13.2.2, “The DATE, DATETIME, and TIMESTAMP Types”](#), for more information.

For information about time zone settings in replication setups, see [Section 19.5.1.14, “Replication and System Functions”](#) and [Section 19.5.1.34, “Replication and Time Zones”](#).

- [Time Zone Variables](#)
- [Populating the Time Zone Tables](#)
- [Staying Current with Time Zone Changes](#)
- [Time Zone Leap Second Support](#)

## Time Zone Variables

MySQL Server maintains several time zone settings:

- The server system time zone. When the server starts, it attempts to determine the time zone of the host machine and uses it to set the `system_time_zone` system variable.

To explicitly specify the system time zone for MySQL Server at startup, set the `TZ` environment variable before you start `mysqld`. If you start the server using `mysqld_safe`, its `--timezone` option provides another way to set the system time zone. The permissible values for `TZ` and `--timezone` are system dependent. Consult your operating system documentation to see what values are acceptable.

- The server current time zone. The global `time_zone` system variable indicates the time zone the server currently is operating in. The initial `time_zone` value is `'SYSTEM'`, which indicates that the server time zone is the same as the system time zone.

### Note

If set to `SYSTEM`, every MySQL function call that requires a time zone calculation makes a system library call to determine the current system time zone. This call may be protected by a global mutex, resulting in contention.

The initial global server time zone value can be specified explicitly at startup with the `--default-time-zone` option on the command line, or you can use the following line in an option file:

```
default-time-zone='timezone'
```

If you have the `SYSTEM_VARIABLES_ADMIN` privilege (or the deprecated `SUPER` privilege), you can set the global server time zone value at runtime with this statement:

```
SET GLOBAL time_zone = timezone;
```

- Per-session time zones. Each client that connects has its own session time zone setting, given by the session `time_zone` variable. Initially, the session variable takes its value from the global `time_zone` variable, but the client can change its own time zone with this statement:

```
SET time_zone = timezone;
```

The session time zone setting affects display and storage of time values that are zone-sensitive. This includes the values displayed by functions such as `NOW()` or `CURTIME()`, and values stored in and retrieved from `TIMESTAMP` columns. Values for `TIMESTAMP` columns are converted from the session time zone to UTC for storage, and from UTC to the session time zone for retrieval.

The session time zone setting does not affect values displayed by functions such as `UTC_TIMESTAMP()` or values in `DATE`, `TIME`, or `DATETIME` columns. Nor are values in those data types stored in UTC; the time zone applies for them only when converting from `TIMESTAMP` values. If you want locale-specific arithmetic for `DATE`, `TIME`, or `DATETIME` values, convert them to UTC, perform the arithmetic, and then convert back.

The current global and session time zone values can be retrieved like this:

```
SELECT @@GLOBAL.time_zone, @@SESSION.time_zone;
```

`timezone` values can be given in several formats, none of which are case-sensitive:

- As the value `'SYSTEM'`, indicating that the server time zone is the same as the system time zone.
- As a string indicating an offset from UTC of the form `[H]H:MM`, prefixed with a `+` or `-`, such as `'+10:00'`, `'-6:00'`, or `'+05:30'`. A leading zero can optionally be used for hours values less than 10; MySQL prepends a leading zero when storing and retrieving the value in such cases. MySQL converts `'-00:00'` or `'-0:00'` to `'+00:00'`.

This value must be in the range `'-13:59'` to `'+14:00'`, inclusive.

- As a named time zone, such as `'Europe/Helsinki'`, `'US/Eastern'`, `'MET'`, or `'UTC'`.

#### Note

Named time zones can be used only if the time zone information tables in the `mysql` database have been created and populated. Otherwise, use of a named time zone results in an error:

```
mysql> SET time_zone = 'UTC';
ERROR 1298 (HY000): Unknown or incorrect time zone: 'UTC'
```

## Populating the Time Zone Tables

Several tables in the `mysql` system schema exist to store time zone information (see [Section 7.3, “The mysql System Schema”](#)). The MySQL installation procedure creates the time zone tables, but does not load them. To do so manually, use the following instructions.

#### Note

Loading the time zone information is not necessarily a one-time operation because the information changes occasionally. When such changes occur, applications that use the old rules become out of date and you may find it necessary to reload the time zone tables to keep the information used by your MySQL server current. See [Staying Current with Time Zone Changes](#).

If your system has its own `zoneinfo` database (the set of files describing time zones), use the `mysql_tzinfo_to_sql` program to load the time zone tables. Examples of such systems are Linux, macOS, FreeBSD, and Solaris. One likely location for these files is the `/usr/share/zoneinfo` directory. If your system has no `zoneinfo` database, you can use a downloadable package, as described later in this section.

To load the time zone tables from the command line, pass the `zoneinfo` directory path name to `mysql_tzinfo_to_sql` and send the output into the `mysql` program. For example:

```
mysql_tzinfo_to_sql /usr/share/zoneinfo | mysql -u root -p mysql
```

The `mysql` command shown here assumes that you connect to the server using an account such as `root` that has privileges for modifying tables in the `mysql` system schema. Adjust the connection parameters as required.

`mysql_tzinfo_to_sql` reads your system's time zone files and generates SQL statements from them. `mysql` processes those statements to load the time zone tables.

`mysql_tzinfo_to_sql` also can be used to load a single time zone file or generate leap second information:

- To load a single time zone file `tz_file` that corresponds to a time zone name `tz_name`, invoke `mysql_tzinfo_to_sql` like this:

```
mysql_tzinfo_to_sql tz_file tz_name | mysql -u root -p mysql
```

With this approach, you must execute a separate command to load the time zone file for each named zone that the server needs to know about.

- If your time zone must account for leap seconds, initialize leap second information like this, where `tz_file` is the name of your time zone file:

```
mysql_tzinfo_to_sql --leap tz_file | mysql -u root -p mysql
```

After running `mysql_tzinfo_to_sql`, restart the server so that it does not continue to use any previously cached time zone data.

If your system has no zoneinfo database (for example, Windows), you can use a package containing SQL statements that is available for download at the MySQL Developer Zone:

<https://dev.mysql.com/downloads/timezones.html>

#### Warning

Do *not* use a downloadable time zone package if your system has a zoneinfo database. Use the `mysql_tzinfo_to_sql` utility instead. Otherwise, you may cause a difference in datetime handling between MySQL and other applications on your system.

To use an SQL-statement time zone package that you have downloaded, unpack it, then load the unpacked file contents into the time zone tables:

```
mysql -u root -p mysql < file_name
```

Then restart the server.

#### Warning

Do *not* use a downloadable time zone package that contains `MyISAM` tables. That is intended for older MySQL versions. MySQL now uses `InnoDB` for the time zone tables. Trying to replace them with `MyISAM` tables causes problems.

## Staying Current with Time Zone Changes

When time zone rules change, applications that use the old rules become out of date. To stay current, it is necessary to make sure that your system uses current time zone information is used. For MySQL, there are multiple factors to consider in staying current:

- The operating system time affects the value that the MySQL server uses for times if its time zone is set to `SYSTEM`. Make sure that your operating system is using the latest time zone information. For most operating systems, the latest update or service pack prepares your system for the time changes. Check the website for your operating system vendor for an update that addresses the time changes.
- If you replace the system's `/etc/localtime` time zone file with a version that uses rules differing from those in effect at `mysqld` startup, restart `mysqld` so that it uses the updated rules. Otherwise, `mysqld` might not notice when the system changes its time.
- If you use named time zones with MySQL, make sure that the time zone tables in the `mysql` database are up to date:

- If your system has its own zoneinfo database, reload the MySQL time zone tables whenever the zoneinfo database is updated.
- For systems that do not have their own zoneinfo database, check the MySQL Developer Zone for updates. When a new update is available, download it and use it to replace the content of your current time zone tables.

For instructions for both methods, see [Populating the Time Zone Tables](#). `mysqld` caches time zone information that it looks up, so after updating the time zone tables, restart `mysqld` to make sure that it does not continue to serve outdated time zone data.

If you are uncertain whether named time zones are available, for use either as the server's time zone setting or by clients that set their own time zone, check whether your time zone tables are empty. The following query determines whether the table that contains time zone names has any rows:

```
mysql> SELECT COUNT(*) FROM mysql.time_zone_name;
+-----+
| COUNT(*) |
+-----+
| 0 |
+-----+
```

A count of zero indicates that the table is empty. In this case, no applications currently are using named time zones, and you need not update the tables (unless you want to enable named time zone support). A count greater than zero indicates that the table is not empty and that its contents are available to be used for named time zone support. In this case, be sure to reload your time zone tables so that applications that use named time zones can obtain correct query results.

To check whether your MySQL installation is updated properly for a change in Daylight Saving Time rules, use a test like the one following. The example uses values that are appropriate for the 2007 DST 1-hour change that occurs in the United States on March 11 at 2 a.m.

The test uses this query:

```
SELECT
 CONVERT_TZ('2007-03-11 2:00:00','US/Eastern','US/Central') AS time1,
 CONVERT_TZ('2007-03-11 3:00:00','US/Eastern','US/Central') AS time2;
```

The two time values indicate the times at which the DST change occurs, and the use of named time zones requires that the time zone tables be used. The desired result is that both queries return the same result (the input time, converted to the equivalent value in the 'US/Central' time zone).

Before updating the time zone tables, you see an incorrect result like this:

```
+-----+-----+
| time1 | time2 |
+-----+-----+
| 2007-03-11 01:00:00 | 2007-03-11 02:00:00 |
+-----+-----+
```

After updating the tables, you should see the correct result:

```
+-----+-----+
| time1 | time2 |
+-----+-----+
| 2007-03-11 01:00:00 | 2007-03-11 01:00:00 |
+-----+-----+
```

## Time Zone Leap Second Support

Leap second values are returned with a time part that ends with `:59:59`. This means that a function such as `NOW()` can return the same value for two or three consecutive seconds during the leap second. It remains true that literal temporal values having a time part that ends with `:59:60` or `:59:61` are considered invalid.

If it is necessary to search for `TIMESTAMP` values one second before the leap second, anomalous results may be obtained if you use a comparison with `'YYYY-MM-DD hh:mm:ss'` values. The following example demonstrates this. It changes the session time zone to UTC so there is no difference between internal `TIMESTAMP` values (which are in UTC) and displayed values (which have time zone correction applied).

```
mysql> CREATE TABLE t1 (
 a INT,
 ts TIMESTAMP DEFAULT CURRENT_TIMESTAMP,
 PRIMARY KEY (ts)
);
Query OK, 0 rows affected (0.01 sec)

mysql> -- change to UTC
mysql> SET time_zone = '+00:00';
Query OK, 0 rows affected (0.00 sec)

mysql> -- Simulate NOW() = '2008-12-31 23:59:59'
mysql> SET timestamp = 1230767999;
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t1 (a) VALUES (1);
Query OK, 1 row affected (0.00 sec)

mysql> -- Simulate NOW() = '2008-12-31 23:59:60'
mysql> SET timestamp = 1230768000;
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t1 (a) VALUES (2);
Query OK, 1 row affected (0.00 sec)

mysql> -- values differ internally but display the same
mysql> SELECT a, ts, UNIX_TIMESTAMP(ts) FROM t1;
+-----+-----+-----+
| a | ts | UNIX_TIMESTAMP(ts) |
+-----+-----+-----+
| 1 | 2008-12-31 23:59:59 | 1230767999 |
| 2 | 2008-12-31 23:59:59 | 1230768000 |
+-----+-----+-----+
2 rows in set (0.00 sec)

mysql> -- only the non-leap value matches
mysql> SELECT * FROM t1 WHERE ts = '2008-12-31 23:59:59';
+-----+-----+
| a | ts |
+-----+-----+
| 1 | 2008-12-31 23:59:59 |
+-----+-----+
1 row in set (0.00 sec)

mysql> -- the leap value with seconds=60 is invalid
mysql> SELECT * FROM t1 WHERE ts = '2008-12-31 23:59:60';
Empty set, 2 warnings (0.00 sec)
```

To work around this, you can use a comparison based on the UTC value actually stored in the column, which has the leap second correction applied:

```
mysql> -- selecting using UNIX_TIMESTAMP value return leap value
mysql> SELECT * FROM t1 WHERE UNIX_TIMESTAMP(ts) = 1230768000;
+-----+-----+-----+
| a | ts | UNIX_TIMESTAMP(ts) |
+-----+-----+-----+
| 2 | 2008-12-31 23:59:59 | 1230768000 |
+-----+-----+-----+
1 row in set (0.00 sec)
```

```

| a | ts |
+---+-----+
| 2 | 2008-12-31 23:59:59 |
+---+-----+
1 row in set (0.00 sec)

```

## 7.1.16 Resource Groups

MySQL supports creation and management of resource groups, and permits assigning threads running within the server to particular groups so that threads execute according to the resources available to the group. Group attributes enable control over its resources, to enable or restrict resource consumption by threads in the group. DBAs can modify these attributes as appropriate for different workloads.

Currently, CPU time is a manageable resource, represented by the concept of “virtual CPU” as a term that includes CPU cores, hyperthreads, hardware threads, and so forth. The server determines at startup how many virtual CPUs are available, and database administrators with appropriate privileges can associate these CPUs with resource groups and assign threads to groups.

For example, to manage execution of batch jobs that need not execute with high priority, a DBA can create a [Batch](#) resource group, and adjust its priority up or down depending on how busy the server is. (Perhaps batch jobs assigned to the group should run at lower priority during the day and at higher priority during the night.) The DBA can also adjust the set of CPUs available to the group. Groups can be enabled or disabled to control whether threads are assignable to them.

The following sections describe aspects of resource group use in MySQL:

- [Resource Group Elements](#)
- [Resource Group Attributes](#)
- [Resource Group Management](#)
- [Resource Group Replication](#)
- [Resource Group Restrictions](#)

### Important

On some platforms or MySQL server configurations, resource groups are unavailable or have limitations. In particular, Linux systems might require a manual step for some installation methods. For details, see [Resource Group Restrictions](#).

## Resource Group Elements

These capabilities provide the SQL interface for resource group management in MySQL:

- SQL statements enable creating, altering, and dropping resource groups, and enable assigning threads to resource groups. An optimizer hint enables assigning individual statements to resource groups.
- Resource group privileges provide control over which users can perform resource group operations.
- The Information Schema [RESOURCE\\_GROUPS](#) table exposes information about resource group definitions and the Performance Schema [threads](#) table shows the resource group assignment for each thread.
- Status variables provide execution counts for each management SQL statement.

## Resource Group Attributes

Resource groups have attributes that define the group. All attributes can be set at group creation time. Some attributes are fixed at creation time; others can be modified any time thereafter.

These attributes are defined at resource group creation time and cannot be modified:

- Each group has a name. Resource group names are identifiers like table and column names, and need not be quoted in SQL statements unless they contain special characters or are reserved words. Group names are not case-sensitive and may be up to 64 characters long.
- Each group has a type, which is either `SYSTEM` or `USER`. The resource group type affects the range of priority values assignable to the group, as described later. This attribute together with the differences in permitted priorities enables system threads to be identified so as to protect them from contention for CPU resources against user threads.

System and user threads correspond to background and foreground threads as listed in the Performance Schema `threads` table.

These attributes are defined at resource group creation time and can be modified any time thereafter:

- The CPU affinity is the set of virtual CPUs the resource group can use. An affinity can be any nonempty subset of the available CPUs. If a group has no affinity, it can use all available CPUs.
- The thread priority is the execution priority for threads assigned to the resource group. Priority values range from -20 (highest priority) to 19 (lowest priority). The default priority is 0, for both system and user groups.

System groups are permitted a higher priority than user groups, ensuring that user threads never have a higher priority than system threads:

- For system resource groups, the permitted priority range is -20 to 0.
- For user resource groups, the permitted priority range is 0 to 19.
- Each group can be enabled or disabled, affording administrators control over thread assignment. Threads can be assigned only to enabled groups.

## Resource Group Management

By default, there is one system group and one user group, named `SYS_default` and `USR_default`, respectively. These default groups cannot be dropped and their attributes cannot be modified. Each default group has no CPU affinity and priority 0.

Newly created system and user threads are assigned to the `SYS_default` and `USR_default` groups, respectively.

For user-defined resource groups, all attributes are assigned at group creation time. After a group has been created, its attributes can be modified, with the exception of the name and type attributes.

To create and manage user-defined resource groups, use these SQL statements:

- `CREATE RESOURCE GROUP` creates a new group. See [Section 15.7.2.2, “CREATE RESOURCE GROUP Statement”](#).
- `ALTER RESOURCE GROUP` modifies an existing group. See [Section 15.7.2.1, “ALTER RESOURCE GROUP Statement”](#).
- `DROP RESOURCE GROUP` drops an existing group. See [Section 15.7.2.3, “DROP RESOURCE GROUP Statement”](#).

Those statements require the `RESOURCE_GROUP_ADMIN` privilege.

To manage resource group assignments, use these capabilities:

- `SET RESOURCE GROUP` assigns threads to a group. See [Section 15.7.2.4, “SET RESOURCE GROUP Statement”](#).
- The `RESOURCE_GROUP` optimizer hint assigns individual statements to a group. See [Section 10.9.3, “Optimizer Hints”](#).

Those operations require the `RESOURCE_GROUP_ADMIN` or `RESOURCE_GROUP_USER` privilege.

Resource group definitions are stored in the `resource_groups` data dictionary table so that groups persist across server restarts. Because `resource_groups` is part of the data dictionary, it is not directly accessible by users. Resource group information is available using the Information Schema `RESOURCE_GROUPS` table, which is implemented as a view on the data dictionary table. See [Section 28.3.26, “The INFORMATION\\_SCHEMA RESOURCE\\_GROUPS Table”](#).

Initially, the `RESOURCE_GROUPS` table has these rows describing the default groups:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.RESOURCE_GROUPS\G
***** 1. row *****
RESOURCE_GROUP_NAME: USR_default
RESOURCE_GROUP_TYPE: USER
RESOURCE_GROUP_ENABLED: 1
VCPU_IDS: 0-3
THREAD_PRIORITY: 0
***** 2. row *****
RESOURCE_GROUP_NAME: SYS_default
RESOURCE_GROUP_TYPE: SYSTEM
RESOURCE_GROUP_ENABLED: 1
VCPU_IDS: 0-3
THREAD_PRIORITY: 0
```

The `THREAD_PRIORITY` values are 0, indicating the default priority. The `VCPU_IDS` values show a range comprising all available CPUs. For the default groups, the displayed value varies depending on the system on which the MySQL server runs.

Earlier discussion mentioned a scenario involving a resource group named `Batch` to manage execution of batch jobs that need not execute with high priority. To create such a group, use a statement similar to this:

```
CREATE RESOURCE GROUP Batch
TYPE = USER
VCPU = 2-3 -- assumes a system with at least 4 CPUs
THREAD_PRIORITY = 10;
```

To verify that the resource group was created as expected, check the `RESOURCE_GROUPS` table:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.RESOURCE_GROUPS
WHERE RESOURCE_GROUP_NAME = 'Batch'\G
***** 1. row *****
RESOURCE_GROUP_NAME: Batch
RESOURCE_GROUP_TYPE: USER
RESOURCE_GROUP_ENABLED: 1
VCPU_IDS: 2-3
THREAD_PRIORITY: 10
```

If the `THREAD_PRIORITY` value is 0 rather than 10, check whether your platform or system configuration limits the resource group capability; see [Resource Group Restrictions](#).

To assign a thread to the `Batch` group, do this:

```
SET RESOURCE GROUP Batch FOR thread_id;
```

Thereafter, statements in the named thread execute with `Batch` group resources.

If a session's own current thread should be in the `Batch` group, execute this statement within the session:

```
SET RESOURCE GROUP Batch;
```

Thereafter, statements in the session execute with `Batch` group resources.

To execute a single statement using the `Batch` group, use the `RESOURCE_GROUP` optimizer hint:

```
INSERT /*+ RESOURCE_GROUP(Batch) */ INTO t2 VALUES(2);
```

Threads assigned to the `Batch` group execute with its resources, which can be modified as desired:

- For times when the system is highly loaded, decrease the number of CPUs assigned to the group, lower its priority, or (as shown) both:

```
ALTER RESOURCE GROUP Batch
 VCPU = 3
 THREAD_PRIORITY = 19;
```

- For times when the system is lightly loaded, increase the number of CPUs assigned to the group, raise its priority, or (as shown) both:

```
ALTER RESOURCE GROUP Batch
 VCPU = 0-3
 THREAD_PRIORITY = 0;
```

## Resource Group Replication

Resource group management is local to the server on which it occurs. Resource group SQL statements and modifications to the `resource_groups` data dictionary table are not written to the binary log and are not replicated.

## Resource Group Restrictions

On some platforms or MySQL server configurations, resource groups are unavailable or have limitations:

- Resource groups are unavailable if the thread pool plugin is installed.
- Resource groups are unavailable on macOS, which provides no API for binding CPUs to a thread.
- On FreeBSD and Solaris, resource group thread priorities are ignored. (Effectively, all threads run at priority 0.) Attempts to change priorities result in a warning:

```
mysql> ALTER RESOURCE GROUP abc THREAD_PRIORITY = 10;
Query OK, 0 rows affected, 1 warning (0.18 sec)
```

```
mysql> SHOW WARNINGS;
```

Level	Code	Message
Warning	4560	Attribute <code>thread_priority</code> is ignored (using default value).

- On Linux, resource groups thread priorities are ignored unless the `CAP_SYS_NICE` capability is set. Granting `CAP_SYS_NICE` capability to a process enables a range of privileges; consult <http://man7.org/linux/man-pages/man7/capabilities.7.html> for the full list. Please be careful when enabling this capability.

On Linux platforms using systemd and kernel support for Ambient Capabilities (Linux 4.3 or newer), the recommended way to enable `CAP_SYS_NICE` capability is to modify the MySQL service file and leave the `mysqld` binary unmodified. To adjust the service file for MySQL, use this procedure:

1. Run the appropriate command for your platform:

- Oracle Linux, Red Hat, and Fedora systems:

```
$> sudo systemctl edit mysqld
```

- SUSE, Ubuntu, and Debian systems:

```
$> sudo systemctl edit mysql
```

2. Using an editor, add the following text to the service file:

```
[Service]
AmbientCapabilities=CAP_SYS_NICE
```

3. Restart the MySQL service.

If you cannot enable the `CAP_SYS_NICE` capability as just described, it can be set manually using the `setcap` command, specifying the path name to the `mysqld` executable (this requires `sudo` access). You can check the capabilities using `getcap`. For example:

```
$> sudo setcap cap_sys_nice+ep /path/to/mysqld
$> getcap /path/to/mysqld
/path/to/mysqld = cap_sys_nice+ep
```

As a safety measure, restrict execution of the `mysqld` binary to the `root` user and users with `mysql` group membership:

```
$> sudo chown root:mysql /path/to/mysqld
$> sudo chmod 0750 /path/to/mysqld
```

#### Important

If manual use of `setcap` is required, it must be performed after each reinstall.

- On Windows, threads run at one of five thread priority levels. The resource group thread priority range of -20 to 19 maps onto those levels as indicated in the following table.

**Table 7.6 Resource Group Thread Priority on Windows**

Priority Range	Windows Priority Level
-20 to -10	<code>THREAD_PRIORITY_HIGHEST</code>
-9 to -1	<code>THREAD_PRIORITY_ABOVE_NORMAL</code>
0	<code>THREAD_PRIORITY_NORMAL</code>
1 to 10	<code>THREAD_PRIORITY_BELOW_NORMAL</code>
11 to 19	<code>THREAD_PRIORITY_LOWEST</code>

## 7.1.17 Server-Side Help Support

MySQL Server supports a `HELP` statement that returns information from the MySQL Reference Manual (see [Section 15.8.3, “HELP Statement”](#)). This information is stored in several tables in the `mysql` schema

(see [Section 7.3, “The mysql System Schema”](#)). Proper operation of the `HELP` statement requires that these help tables be initialized.

For a new installation of MySQL using a binary or source distribution on Unix, help-table content initialization occurs when you initialize the data directory (see [Section 2.9.1, “Initializing the Data Directory”](#)). For an RPM distribution on Linux or binary distribution on Windows, content initialization occurs as part of the MySQL installation process.

For a MySQL upgrade using a binary distribution, help-table content is upgraded automatically by the server. To upgrade it manually, locate the `fill_help_tables.sql` file in the `share` or `share/mysql` directory. Change location into that directory and process the file with the `mysql` client as follows:

```
mysql -u root -p mysql < fill_help_tables.sql
```

The command shown here assumes that you connect to the server using an account such as `root` that has privileges for modifying tables in the `mysql` schema. Adjust the connection parameters as required.

## 7.1.18 Server Tracking of Client Session State

The MySQL server implements several session state trackers. A client can enable these trackers to receive notification of changes to its session state.

- [Uses for Session State Trackers](#)
- [Available Session State Trackers](#)
- [C API Session State Tracker Support](#)
- [Test Suite Session State Tracker Support](#)

### Uses for Session State Trackers

Session state trackers have uses such as these:

- To facilitate session migration.
- To facilitate transaction switching.

The tracker mechanism provides a means for MySQL connectors and client applications to determine whether any session context is available to permit session migration from one server to another. (To change sessions in a load-balanced environment, it is necessary to detect whether there is session state to take into consideration when deciding whether a switch can be made.)

The tracker mechanism permits applications to know when transactions can be moved from one session to another. Transaction state tracking enables this, which is useful for applications that may wish to move transactions from a busy server to one that is less loaded. For example, a load-balancing connector managing a client connection pool could move transactions between available sessions in the pool.

However, session switching cannot be done at arbitrary times. If a session is in the middle of a transaction for which reads or writes have been done, switching to a different session implies a transaction rollback on the original session. A session switch must be done only when a transaction does not yet have any reads or writes performed within it.

Examples of when transactions might reasonably be switched:

- Immediately after `START TRANSACTION`
- After `COMMIT AND CHAIN`

In addition to knowing transaction state, it is useful to know transaction characteristics, so as to use the same characteristics if the transaction is moved to a different session. The following characteristics are relevant for this purpose:

```
READ ONLY
READ WRITE
ISOLATION LEVEL
WITH CONSISTENT SNAPSHOT
```

## Available Session State Trackers

To support the session-tracking activities, notification is available for these types of client session state information:

- Changes to these attributes of client session state:
  - The default schema (database).
  - Session-specific values for system variables.
  - User-defined variables.
  - Temporary tables.
  - Prepared statements.

The `session_track_state_change` system variable controls this tracker.

- Changes to the default schema name. The `session_track_schema` system variable controls this tracker.
- Changes to the session values of system variables. The `session_track_system_variables` system variable controls this tracker. The `SENSITIVE_VARIABLES_OBSERVER` privilege is required to track changes to the values of sensitive system variables.
- Available GTIDs. The `session_track_gtids` system variable controls this tracker.
- Information about transaction state and characteristics. The `session_track_transaction_info` system variable controls this tracker.

For descriptions of the tracker-related system variables, see [Section 7.1.8, “Server System Variables”](#). Those system variables permit control over which change notifications occur, but do not provide a way to access notification information. Notification occurs in the MySQL client/server protocol, which includes tracker information in OK packets so that session state changes can be detected.

## C API Session State Tracker Support

To enable client applications to extract state-change information from OK packets returned by the server, the MySQL C API provides a pair of functions:

- `mysql_session_track_get_first()` fetches the first part of the state-change information received from the server. See [mysql\\_session\\_track\\_get\\_first\(\)](#).
- `mysql_session_track_get_next()` fetches any remaining state-change information received from the server. Following a successful call to `mysql_session_track_get_first()`, call this function repeatedly as long as it returns success. See [mysql\\_session\\_track\\_get\\_next\(\)](#).

## Test Suite Session State Tracker Support

The `mysqltest` program has `disable_session_track_info` and `enable_session_track_info` commands that control whether session tracker notifications occur. You can use these commands to see from the command line what notifications SQL statements produce. Suppose that a file `testscript` contains the following `mysqltest` script:

```
DROP TABLE IF EXISTS test.t1;
CREATE TABLE test.t1 (i INT, f FLOAT);
--enable_session_track_info
SET @@SESSION.session_track_schema=ON;
SET @@SESSION.session_track_system_variables='*';
SET @@SESSION.session_track_state_change=ON;
USE information_schema;
SET NAMES 'utf8mb4';
SET @@SESSION.session_track_transaction_info='CHARACTERISTICS';
SET TRANSACTION ISOLATION LEVEL SERIALIZABLE;
SET TRANSACTION READ WRITE;
START TRANSACTION;
SELECT 1;
INSERT INTO test.t1 () VALUES();
INSERT INTO test.t1 () VALUES(1, RAND());
COMMIT;
```

Run the script as follows to see the information provided by the enabled trackers. For a description of the `Tracker`: information displayed by `mysqltest` for the various trackers, see `mysql_session_track_get_first()`.

```
$> mysqltest < testscript
DROP TABLE IF EXISTS test.t1;
CREATE TABLE test.t1 (i INT, f FLOAT);
SET @@SESSION.session_track_schema=ON;
SET @@SESSION.session_track_system_variables='*';
-- Tracker : SESSION_TRACK_SYSTEM_VARIABLES
-- session_track_system_variables
-- *

SET @@SESSION.session_track_state_change=ON;
-- Tracker : SESSION_TRACK_SYSTEM_VARIABLES
-- session_track_state_change
-- ON

USE information_schema;
-- Tracker : SESSION_TRACK_SCHEMA
-- information_schema

-- Tracker : SESSION_TRACK_STATE_CHANGE
-- 1

SET NAMES 'utf8mb4';
-- Tracker : SESSION_TRACK_SYSTEM_VARIABLES
-- character_set_client
-- utf8mb4
-- character_set_connection
-- utf8mb4
-- character_set_results
-- utf8mb4

-- Tracker : SESSION_TRACK_STATE_CHANGE
-- 1

SET @@SESSION.session_track_transaction_info='CHARACTERISTICS';
-- Tracker : SESSION_TRACK_SYSTEM_VARIABLES
-- session_track_transaction_info
-- CHARACTERISTICS

-- Tracker : SESSION_TRACK_STATE_CHANGE
```

```
-- 1

-- Tracker : SESSION_TRACK_TRANSACTION_CHARACTERISTICS
--

-- Tracker : SESSION_TRACK_TRANSACTION_STATE
-- _____

SET TRANSACTION ISOLATION LEVEL SERIALIZABLE;
-- Tracker : SESSION_TRACK_TRANSACTION_CHARACTERISTICS
-- SET TRANSACTION ISOLATION LEVEL SERIALIZABLE;

SET TRANSACTION READ WRITE;
-- Tracker : SESSION_TRACK_TRANSACTION_CHARACTERISTICS
-- SET TRANSACTION ISOLATION LEVEL SERIALIZABLE; SET TRANSACTION READ WRITE;

START TRANSACTION;
-- Tracker : SESSION_TRACK_TRANSACTION_CHARACTERISTICS
-- SET TRANSACTION ISOLATION LEVEL SERIALIZABLE; START TRANSACTION READ WRITE;

-- Tracker : SESSION_TRACK_TRANSACTION_STATE
-- T_____

SELECT 1;
1
1
-- Tracker : SESSION_TRACK_TRANSACTION_STATE
-- T_____S_

INSERT INTO test.t1 () VALUES();
-- Tracker : SESSION_TRACK_TRANSACTION_STATE
-- T_____W_S_

INSERT INTO test.t1 () VALUES(1, RAND());
-- Tracker : SESSION_TRACK_TRANSACTION_STATE
-- T_____WsS_

COMMIT;
-- Tracker : SESSION_TRACK_TRANSACTION_CHARACTERISTICS
--

-- Tracker : SESSION_TRACK_TRANSACTION_STATE
-- _____

ok
```

Preceding the `START TRANSACTION` statement, two `SET TRANSACTION` statements execute that set the isolation level and access mode characteristics for the next transaction. The `SESSION_TRACK_TRANSACTION_CHARACTERISTICS` value indicates those next-transaction values that have been set.

Following the `COMMIT` statement that ends the transaction, the `SESSION_TRACK_TRANSACTION_CHARACTERISTICS` value is reported as empty. This indicates that the next-transaction characteristics that were set preceding the start of the transaction have been reset, and that the session defaults apply. To track changes to those session defaults, track the session values of the `transaction_isolation` and `transaction_read_only` system variables.

To see information about GTIDs, enable the `SESSION_TRACK_GTIDS` tracker using the `session_track_gtids` system system variable.

## 7.1.19 The Server Shutdown Process

The server shutdown process takes place as follows:

1. The shutdown process is initiated.

This can occur initiated several ways. For example, a user with the `SHUTDOWN` privilege can execute a `mysqladmin shutdown` command. `mysqladmin` can be used on any platform supported by MySQL. Other operating system-specific shutdown initiation methods are possible as well: The server shuts down on Unix when it receives a `SIGTERM` signal. A server running as a service on Windows shuts down when the services manager tells it to.

2. The server creates a shutdown thread if necessary.

Depending on how shutdown was initiated, the server might create a thread to handle the shutdown process. If shutdown was requested by a client, a shutdown thread is created. If shutdown is the result of receiving a `SIGTERM` signal, the signal thread might handle shutdown itself, or it might create a separate thread to do so. If the server tries to create a shutdown thread and cannot (for example, if memory is exhausted), it issues a diagnostic message that appears in the error log:

```
Error: Can't create thread to kill server
```

3. The server stops accepting new connections.

To prevent new activity from being initiated during shutdown, the server stops accepting new client connections by closing the handlers for the network interfaces to which it normally listens for connections: the TCP/IP port, the Unix socket file, the Windows named pipe, and shared memory on Windows.

4. The server terminates current activity.

For each thread associated with a client connection, the server breaks the connection to the client and marks the thread as killed. Threads die when they notice that they are so marked. Threads for idle connections die quickly. Threads that currently are processing statements check their state periodically and take longer to die. For additional information about thread termination, see [Section 15.7.8.4, “KILL Statement”](#), in particular for the instructions about killed `REPAIR TABLE` or `OPTIMIZE TABLE` operations on `MyISAM` tables.

For threads that have an open transaction, the transaction is rolled back. If a thread is updating a nontransactional table, an operation such as a multiple-row `UPDATE` or `INSERT` may leave the table partially updated because the operation can terminate before completion.

If the server is a replication source server, it treats threads associated with currently connected replicas like other client threads. That is, each one is marked as killed and exits when it next checks its state.

If the server is a replica server, it stops the replication I/O and SQL threads, if they are active, before marking client threads as killed. The SQL thread is permitted to finish its current statement (to avoid causing replication problems), and then stops. If the SQL thread is in the middle of a transaction at this point, the server waits until the current replication event group (if any) has finished executing, or until the user issues a `KILL QUERY` or `KILL CONNECTION` statement. See also [Section 15.4.2.5, “STOP REPLICA Statement”](#). Since nontransactional statements cannot be rolled back, in order to guarantee crash-safe replication, only transactional tables should be used.

**Note**

To guarantee crash safety on the replica, you must run the replica with `--relay-log-recovery` enabled.

See also [Section 19.2.4, “Relay Log and Replication Metadata Repositories”](#)).

5. The server shuts down or closes storage engines.

At this stage, the server flushes the table cache and closes all open tables.

Each storage engine performs any actions necessary for tables that it manages. [InnoDB](#) flushes its buffer pool to disk (unless `innodb_fast_shutdown` is 2), writes the current LSN to the tablespace, and terminates its own internal threads. [MyISAM](#) flushes any pending index writes for a table.

6. The server exits.

To provide information to management processes, the server returns one of the exit codes described in the following list. The phrase in parentheses indicates the action taken by `systemd` in response to the code, for platforms on which `systemd` is used to manage the server.

- 0 = successful termination (no restart done)
- 1 = unsuccessful termination (no restart done)
- 2 = unsuccessful termination (restart done)

## 7.2 The MySQL Data Directory

Information managed by the MySQL server is stored under a directory known as the data directory. The following list briefly describes the items typically found in the data directory, with cross references for additional information:

- Data directory subdirectories. Each subdirectory of the data directory is a database directory and corresponds to a database managed by the server. All MySQL installations have certain standard databases:
  - The `mysql` directory corresponds to the `mysql` system schema, which contains information required by the MySQL server as it runs. This database contains data dictionary tables and system tables. See [Section 7.3, “The mysql System Schema”](#).
  - The `performance_schema` directory corresponds to the Performance Schema, which provides information used to inspect the internal execution of the server at runtime. See [Chapter 29, MySQL Performance Schema](#).
  - The `sys` directory corresponds to the `sys` schema, which provides a set of objects to help interpret Performance Schema information more easily. See [Chapter 30, MySQL sys Schema](#).
  - The `ndbinfo` directory corresponds to the `ndbinfo` database that stores information specific to NDB Cluster (present only for installations built to include NDB Cluster). See [Section 25.6.17, “ndbinfo: The NDB Cluster Information Database”](#).

Other subdirectories correspond to databases created by users or applications.

### Note

`INFORMATION_SCHEMA` is a standard database, but its implementation uses no corresponding database directory.

- Log files written by the server. See [Section 7.4, “MySQL Server Logs”](#).
- [InnoDB](#) tablespace and log files. See [Chapter 17, The InnoDB Storage Engine](#).
- Default/autogenerated SSL and RSA certificate and key files. See [Section 8.3.3, “Creating SSL and RSA Certificates and Keys”](#).

- The server process ID file (while the server is running).
- The `mysqld-auto.cnf` file that stores persisted global system variable settings. See [Section 15.7.6.1, “SET Syntax for Variable Assignment”](#).

Some items in the preceding list can be relocated elsewhere by reconfiguring the server. In addition, the `--datadir` option enables the location of the data directory itself to be changed. For a given MySQL installation, check the server configuration to determine whether items have been moved.

## 7.3 The mysql System Schema

The `mysql` schema is the system schema. It contains tables that store information required by the MySQL server as it runs. A broad categorization is that the `mysql` schema contains data dictionary tables that store database object metadata, and system tables used for other operational purposes. The following discussion further subdivides the set of system tables into smaller categories.

- [Data Dictionary Tables](#)
- [Grant System Tables](#)
- [Object Information System Tables](#)
- [Log System Tables](#)
- [Server-Side Help System Tables](#)
- [Time Zone System Tables](#)
- [Replication System Tables](#)
- [Optimizer System Tables](#)
- [Miscellaneous System Tables](#)

The remainder of this section enumerates the tables in each category, with cross references for additional information. Data dictionary tables and system tables use the `InnoDB` storage engine unless otherwise indicated.

`mysql` system tables and data dictionary tables reside in a single `InnoDB` tablespace file named `mysql.ibd` in the MySQL data directory. Previously, these tables were created in individual tablespace files in the `mysql` database directory.

Data-at-rest encryption can be enabled for the `mysql` system schema tablespace. For more information, see [Section 17.13, “InnoDB Data-at-Rest Encryption”](#).

### Data Dictionary Tables

These tables comprise the data dictionary, which contains metadata about database objects. For additional information, see [Chapter 16, MySQL Data Dictionary](#).

- `catalogs`: Catalog information.
- `character_sets`: Information about available character sets.
- `check_constraints`: Information about `CHECK` constraints defined on tables. See [Section 15.1.20.6, “CHECK Constraints”](#).
- `collations`: Information about collations for each character set.

- `column_statistics`: Histogram statistics for column values. See [Section 10.9.6, “Optimizer Statistics”](#).
- `column_type_elements`: Information about types used by columns.
- `columns`: Information about columns in tables.
- `dd_properties`: A table that identifies data dictionary properties, such as its version. The server uses this to determine whether the data dictionary must be upgraded to a newer version.
- `events`: Information about Event Scheduler events. See [Section 27.5, “Using the Event Scheduler”](#). If the server is started with the `--skip-grant-tables` option, the event scheduler is disabled and events registered in the table do not run. See [Section 27.5.2, “Event Scheduler Configuration”](#).
- `foreign_keys`, `foreign_key_column_usage`: Information about foreign keys.
- `index_column_usage`: Information about columns used by indexes.
- `index_partitions`: Information about partitions used by indexes.
- `index_stats`: Used to store dynamic index statistics generated when `ANALYZE TABLE` is executed.
- `indexes`: Information about table indexes.
- `innodb_ddl_log`: Stores DDL logs for crash-safe DDL operations.
- `parameter_type_elements`: Information about stored procedure and function parameters, and about return values for stored functions.
- `parameters`: Information about stored procedures and functions. See [Section 27.2, “Using Stored Routines”](#).
- `resource_groups`: Information about resource groups. See [Section 7.1.16, “Resource Groups”](#).
- `routines`: Information about stored procedures and functions. See [Section 27.2, “Using Stored Routines”](#).
- `schemata`: Information about schemata. In MySQL, a schema is a database, so this table provides information about databases.
- `st_spatial_reference_systems`: Information about available spatial reference systems for spatial data.
- `table_partition_values`: Information about values used by table partitions.
- `table_partitions`: Information about partitions used by tables.
- `table_stats`: Information about dynamic table statistics generated when `ANALYZE TABLE` is executed.
- `tables`: Information about tables in databases.
- `tablespace_files`: Information about files used by tablespaces.
- `tablespaces`: Information about active tablespaces.
- `triggers`: Information about triggers.
- `view_routine_usage`: Information about dependencies between views and stored functions used by them.

- `view_table_usage`: Used to track dependencies between views and their underlying tables.

Data dictionary tables are invisible. They cannot be read with `SELECT`, do not appear in the output of `SHOW TABLES`, are not listed in the `INFORMATION_SCHEMA.TABLES` table, and so forth. However, in most cases there are corresponding `INFORMATION_SCHEMA` tables that can be queried. Conceptually, the `INFORMATION_SCHEMA` provides a view through which MySQL exposes data dictionary metadata. For example, you cannot select from the `mysql.schemata` table directly:

```
mysql> SELECT * FROM mysql.schemata;
ERROR 3554 (HY000): Access to data dictionary table 'mysql.schemata' is rejected.
```

Instead, select that information from the corresponding `INFORMATION_SCHEMA` table:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.SCHEMATA\G
***** 1. row *****
 CATALOG_NAME: def
 SCHEMA_NAME: mysql
DEFAULT_CHARACTER_SET_NAME: utf8mb4
DEFAULT_COLLATION_NAME: utf8mb4_0900_ai_ci
 SQL_PATH: NULL
DEFAULT_ENCRYPTION: NO
***** 2. row *****
 CATALOG_NAME: def
 SCHEMA_NAME: information_schema
DEFAULT_CHARACTER_SET_NAME: utf8mb3
DEFAULT_COLLATION_NAME: utf8mb3_general_ci
 SQL_PATH: NULL
DEFAULT_ENCRYPTION: NO
***** 3. row *****
 CATALOG_NAME: def
 SCHEMA_NAME: performance_schema
DEFAULT_CHARACTER_SET_NAME: utf8mb4
DEFAULT_COLLATION_NAME: utf8mb4_0900_ai_ci
 SQL_PATH: NULL
DEFAULT_ENCRYPTION: NO
...

```

There is no Information Schema table that corresponds exactly to `mysql.indexes`, but `INFORMATION_SCHEMA.STATISTICS` contains much of the same information.

As of yet, there are no `INFORMATION_SCHEMA` tables that correspond exactly to `mysql.foreign_keys`, `mysql.foreign_key_column_usage`. The standard SQL way to obtain foreign key information is by using the `INFORMATION_SCHEMA.REFERENTIAL_CONSTRAINTS` and `KEY_COLUMN_USAGE` tables; these tables are now implemented as views on the `foreign_keys`, `foreign_key_column_usage`, and other data dictionary tables.

## Grant System Tables

These system tables contain grant information about user accounts and the privileges held by them. For additional information about the structure, contents, and purpose of these tables, see [Section 8.2.3, “Grant Tables”](#).

The MySQL 9.1 grant tables are `InnoDB` (transactional) tables. Account-management statements are transactional and either succeed for all named users or roll back and have no effect if any error occurs.

- `user`: User accounts, global privileges, and other nonprivilege columns.
- `global_grants`: Assignments of dynamic global privileges to users; see [Static Versus Dynamic Privileges](#).
- `db`: Database-level privileges.

- `tables_priv`: Table-level privileges.
- `columns_priv`: Column-level privileges.
- `procs_priv`: Stored procedure and function privileges.
- `proxies_priv`: Proxy-user privileges.
- `default_roles`: This table lists default roles to be activated after a user connects and authenticates, or executes `SET ROLE DEFAULT`.
- `role_edges`: This table lists edges for role subgraphs.

A given `user` table row might refer to a user account or a role. The server can distinguish whether a row represents a user account, a role, or both by consulting the `role_edges` table for information about relations between authentication IDs.

- `password_history`: Information about password changes.

## Object Information System Tables

These system tables contain information about components, loadable functions, and server-side plugins:

- `component`: The registry for server components installed using `INSTALL COMPONENT`. Any components listed in this table are installed by a loader service during the server startup sequence. See [Section 7.5.1, “Installing and Uninstalling Components”](#).
- `func`: The registry for loadable functions installed using `CREATE FUNCTION`. During the normal startup sequence, the server loads functions registered in this table. If the server is started with the `--skip-grant-tables` option, functions registered in the table are not loaded and are unavailable. See [Section 7.7.1, “Installing and Uninstalling Loadable Functions”](#).

### Note

Like the `mysql.func` system table, the Performance Schema `user_defined_functions` table lists loadable functions installed using `CREATE FUNCTION`. Unlike the `mysql.func` table, the `user_defined_functions` table also lists functions installed automatically by server components or plugins. This difference makes `user_defined_functions` preferable to `mysql.func` for checking which functions are installed. See [Section 29.12.22.11, “The user\\_defined\\_functions Table”](#).

- `plugin`: The registry for server-side plugins installed using `INSTALL PLUGIN`. During the normal startup sequence, the server loads plugins registered in this table. If the server is started with the `--skip-grant-tables` option, plugins registered in the table are not loaded and are unavailable. See [Section 7.6.1, “Installing and Uninstalling Plugins”](#).

## Log System Tables

The server uses these system tables for logging:

- `general_log`: The general query log table.
- `slow_log`: The slow query log table.

Log tables use the `CSV` storage engine.

For more information, see [Section 7.4, “MySQL Server Logs”](#).

## Server-Side Help System Tables

These system tables contain server-side help information:

- `help_category`: Information about help categories.
- `help_keyword`: Keywords associated with help topics.
- `help_relation`: Mappings between help keywords and topics.
- `help_topic`: Help topic contents.

For more information, see [Section 7.1.17, “Server-Side Help Support”](#).

## Time Zone System Tables

These system tables contain time zone information:

- `time_zone`: Time zone IDs and whether they use leap seconds.
- `time_zone_leap_second`: When leap seconds occur.
- `time_zone_name`: Mappings between time zone IDs and names.
- `time_zone_transition`, `time_zone_transition_type`: Time zone descriptions.

For more information, see [Section 7.1.15, “MySQL Server Time Zone Support”](#).

## Replication System Tables

The server uses these system tables to support replication:

- `gtid_executed`: Table for storing GTID values. See [mysql.gtid\\_executed Table](#).
- `ndb_binlog_index`: Binary log information for NDB Cluster replication. This table is created only if the server is built with `NDBCLUSTER` support. See [Section 25.7.4, “NDB Cluster Replication Schema and Tables”](#).
- `slave_master_info`, `slave_relay_log_info`, `slave_worker_info`: Used to store replication information on replica servers. See [Section 19.2.4, “Relay Log and Replication Metadata Repositories”](#).

All of the tables just listed use the `InnoDB` storage engine.

## Optimizer System Tables

These system tables are for use by the optimizer:

- `innodb_index_stats`, `innodb_table_stats`: Used for `InnoDB` persistent optimizer statistics. See [Section 17.8.10.1, “Configuring Persistent Optimizer Statistics Parameters”](#).
- `server_cost`, `engine_cost`: The optimizer cost model uses tables that contain cost estimate information about operations that occur during query execution. `server_cost` contains optimizer cost estimates for general server operations. `engine_cost` contains estimates for operations specific to particular storage engines. See [Section 10.9.5, “The Optimizer Cost Model”](#).

## Miscellaneous System Tables

Other system tables do not fit the preceding categories:

- `audit_log_filter`, `audit_log_user`: If MySQL Enterprise Audit is installed, these tables provide persistent storage of audit log filter definitions and user accounts. See [Audit Log Tables](#).
- `firewall_group_allowlist`, `firewall_groups`, `firewall_membership`, `firewall_users`, `firewall_whitelist`: If MySQL Enterprise Firewall is installed, these tables provide persistent storage for information used by the firewall. See [Section 8.4.7, “MySQL Enterprise Firewall”](#).
- `servers`: Used by the `FEDERATED` storage engine. See [Section 18.8.2.2, “Creating a FEDERATED Table Using CREATE SERVER”](#).
- `innodb_dynamic_metadata`: Used by the `InnoDB` storage engine to store fast-changing table metadata such as auto-increment counter values and index tree corruption flags. Replaces the data dictionary buffer table that resided in the `InnoDB` system tablespace.

## 7.4 MySQL Server Logs

MySQL Server has several logs that can help you find out what activity is taking place.

Log Type	Information Written to Log
Error log	Problems encountered starting, running, or stopping <code>mysqld</code>
General query log	Established client connections and statements received from clients
Binary log	Statements that change data (also used for replication)
Relay log	Data changes received from a replication source server
Slow query log	Queries that took more than <code>long_query_time</code> seconds to execute
DDL logs	Atomic DDL operations performed by DDL statements

By default, no logs are enabled, except the error log on Windows. For information about DDL log behavior, see [Viewing DDL Logs](#). The following log-specific sections provide information about the server options that enable logging.

By default, the server writes files for all enabled logs in the data directory. You can force the server to close and reopen the log files (or in some cases switch to a new log file) by flushing the logs. Log flushing occurs when you issue a `FLUSH LOGS` statement; execute `mysqladmin` with a `flush-logs` or `refresh` argument; or execute `mysqldump` with a `--flush-logs` option. See [Section 15.7.8.3, “FLUSH Statement”](#), [Section 6.5.2, “mysqladmin — A MySQL Server Administration Program”](#), and [Section 6.5.4, “mysqldump — A Database Backup Program”](#). In addition, the binary log is flushed when its size reaches the value of the `max_binlog_size` system variable.

You can control the general query and slow query logs during runtime. You can enable or disable logging, or change the log file name. You can tell the server to write general query and slow query entries to log tables, log files, or both. For details, see [Section 7.4.1, “Selecting General Query Log and Slow Query Log Output Destinations”](#), [Section 7.4.3, “The General Query Log”](#), and [Section 7.4.5, “The Slow Query Log”](#).

The relay log is used only on replicas, to hold data changes from the replication source server that must also be made on the replica. For discussion of relay log contents and configuration, see [Section 19.2.4.1, “The Relay Log”](#).

For information about log maintenance operations such as expiration of old log files, see [Section 7.4.6, “Server Log Maintenance”](#).

For information about keeping logs secure, see [Section 8.1.2.3, “Passwords and Logging”](#).

## 7.4.1 Selecting General Query Log and Slow Query Log Output Destinations

MySQL Server provides flexible control over the destination of output written to the general query log and the slow query log, if those logs are enabled. Possible destinations for log entries are log files or the `general_log` and `slow_log` tables in the `mysql` system database. File output, table output, or both can be selected.

- [Log Control at Server Startup](#)
- [Log Control at Runtime](#)
- [Log Table Benefits and Characteristics](#)

### Log Control at Server Startup

The `log_output` system variable specifies the destination for log output. Setting this variable does not in itself enable the logs; they must be enabled separately.

- If `log_output` is not specified at startup, the default logging destination is `FILE`.
- If `log_output` is specified at startup, its value is a list one or more comma-separated words chosen from `TABLE` (log to tables), `FILE` (log to files), or `NONE` (do not log to tables or files). `NONE`, if present, takes precedence over any other specifiers.

The `general_log` system variable controls logging to the general query log for the selected log destinations. If specified at server startup, `general_log` takes an optional argument of 1 or 0 to enable or disable the log. To specify a file name other than the default for file logging, set the `general_log_file` variable. Similarly, the `slow_query_log` variable controls logging to the slow query log for the selected destinations and setting `slow_query_log_file` specifies a file name for file logging. If either log is enabled, the server opens the corresponding log file and writes startup messages to it. However, further logging of queries to the file does not occur unless the `FILE` log destination is selected.

Examples:

- To write general query log entries to the log table and the log file, use `--log_output=TABLE,FILE` to select both log destinations and `--general_log` to enable the general query log.
- To write general and slow query log entries only to the log tables, use `--log_output=TABLE` to select tables as the log destination and `--general_log` and `--slow_query_log` to enable both logs.
- To write slow query log entries only to the log file, use `--log_output=FILE` to select files as the log destination and `--slow_query_log` to enable the slow query log. In this case, because the default log destination is `FILE`, you could omit the `log_output` setting.

### Log Control at Runtime

The system variables associated with log tables and files enable runtime control over logging:

- The `log_output` variable indicates the current logging destination. It can be modified at runtime to change the destination.

- The `general_log` and `slow_query_log` variables indicate whether the general query log and slow query log are enabled (`ON`) or disabled (`OFF`). You can set these variables at runtime to control whether the logs are enabled.
- The `general_log_file` and `slow_query_log_file` variables indicate the names of the general query log and slow query log files. You can set these variables at server startup or at runtime to change the names of the log files.
- To disable or enable general query logging for the current session, set the session `sql_log_off` variable to `ON` or `OFF`. (This assumes that the general query log itself is enabled.)

## Log Table Benefits and Characteristics

The use of tables for log output offers the following benefits:

- Log entries have a standard format. To display the current structure of the log tables, use these statements:

```
SHOW CREATE TABLE mysql.general_log;
SHOW CREATE TABLE mysql.slow_log;
```

- Log contents are accessible through SQL statements. This enables the use of queries that select only those log entries that satisfy specific criteria. For example, to select log contents associated with a particular client (which can be useful for identifying problematic queries from that client), it is easier to do this using a log table than a log file.
- Logs are accessible remotely through any client that can connect to the server and issue queries (if the client has the appropriate log table privileges). It is not necessary to log in to the server host and directly access the file system.

The log table implementation has the following characteristics:

- In general, the primary purpose of log tables is to provide an interface for users to observe the runtime execution of the server, not to interfere with its runtime execution.
- `CREATE TABLE`, `ALTER TABLE`, and `DROP TABLE` are valid operations on a log table. For `ALTER TABLE` and `DROP TABLE`, the log table cannot be in use and must be disabled, as described later.
- By default, the log tables use the `CSV` storage engine that writes data in comma-separated values format. For users who have access to the `.CSV` files that contain log table data, the files are easy to import into other programs such as spreadsheets that can process CSV input.

The log tables can be altered to use the `MyISAM` storage engine. You cannot use `ALTER TABLE` to alter a log table that is in use. The log must be disabled first. No engines other than `CSV` or `MyISAM` are legal for the log tables.

**Log Tables and “Too many open files” Errors.** If you select `TABLE` as a log destination and the log tables use the `CSV` storage engine, you may find that disabling and enabling the general query log or slow query log repeatedly at runtime results in a number of open file descriptors for the `.CSV` file, possibly resulting in a “Too many open files” error. To work around this issue, execute `FLUSH TABLES` or ensure that the value of `open_files_limit` is greater than the value of `table_open_cache_instances`.

- To disable logging so that you can alter (or drop) a log table, you can use the following strategy. The example uses the general query log; the procedure for the slow query log is similar but uses the `slow_log` table and `slow_query_log` system variable.

```
SET @old_log_state = @@GLOBAL.general_log;
SET GLOBAL general_log = 'OFF';
```

```
ALTER TABLE mysql.general_log ENGINE = MyISAM;
SET GLOBAL general_log = @old_log_state;
```

- **TRUNCATE TABLE** is a valid operation on a log table. It can be used to expire log entries.
- **RENAME TABLE** is a valid operation on a log table. You can atomically rename a log table (to perform log rotation, for example) using the following strategy:

```
USE mysql;
DROP TABLE IF EXISTS general_log2;
CREATE TABLE general_log2 LIKE general_log;
RENAME TABLE general_log TO general_log_backup, general_log2 TO general_log;
```

- **CHECK TABLE** is a valid operation on a log table.
- **LOCK TABLES** cannot be used on a log table.
- **INSERT**, **DELETE**, and **UPDATE** cannot be used on a log table. These operations are permitted only internally to the server itself.
- **FLUSH TABLES WITH READ LOCK** and the state of the `read_only` system variable have no effect on log tables. The server can always write to the log tables.
- Entries written to the log tables are not written to the binary log and thus are not replicated to replicas.
- To flush the log tables or log files, use **FLUSH TABLES** or **FLUSH LOGS**, respectively.
- Partitioning of log tables is not permitted.
- A `mysqldump` dump includes statements to recreate those tables so that they are not missing after reloading the dump file. Log table contents are not dumped.

## 7.4.2 The Error Log

This section discusses how to configure the MySQL server for logging of diagnostic messages to the error log. For information about selecting the error message character set and language, see [Section 12.6, “Error Message Character Set”](#), and [Section 12.12, “Setting the Error Message Language”](#).

The error log contains a record of `mysqld` startup and shutdown times. It also contains diagnostic messages such as errors, warnings, and notes that occur during server startup and shutdown, and while the server is running. For example, if `mysqld` notices that a table needs to be automatically checked or repaired, it writes a message to the error log.

Depending on error log configuration, error messages may also populate the Performance Schema `error_log` table, to provide an SQL interface to the log and enable its contents to be queried. See [Section 29.12.22.2, “The error\\_log Table”](#).

On some operating systems, the error log contains a stack trace if `mysqld` exits abnormally. The trace can be used to determine where `mysqld` exited. See [Section 7.9, “Debugging MySQL”](#).

If used to start `mysqld`, `mysqld_safe` may write messages to the error log. For example, when `mysqld_safe` notices abnormal `mysqld` exits, it restarts `mysqld` and writes a `mysqld restarted` message to the error log.

The following sections discuss aspects of configuring error logging.

### 7.4.2.1 Error Log Configuration

In MySQL 9.1, error logging uses the MySQL component architecture described at [Section 7.5, “MySQL Components”](#). The error log subsystem consists of components that perform log event filtering and writing,

as well as a system variable that configures which components to load and enable to achieve the desired logging result.

This section discusses how to load and enable components for error logging. For instructions specific to log filters, see [Section 7.4.2.4, “Types of Error Log Filtering”](#). For instructions specific to the JSON and system log sinks, see [Section 7.4.2.7, “Error Logging in JSON Format”](#), and [Section 7.4.2.8, “Error Logging to the System Log”](#). For additional details about all available log components, see [Section 7.5.3, “Error Log Components”](#).

Component-based error logging offers these features:

- Log events that can be filtered by filter components to affect the information available for writing.
- Log events that are output by sink (writer) components. Multiple sink components can be enabled, to write error log output to multiple destinations.
- Built-in filter and sink components that implement the default error log format.
- A loadable sink that enables logging in JSON format.
- A loadable sink that enables logging to the system log.
- System variables that control which log components to load and enable and how each component operates.

Error log configuration is described under the following topics in this section:

- [The Default Error Log Configuration](#)
- [Error Log Configuration Methods](#)
- [Implicit Error Log Configuration](#)
- [Explicit Error Log Configuration](#)
- [Changing the Error Log Configuration Method](#)
- [Troubleshooting Configuration Issues](#)
- [Configuring Multiple Log Sinks](#)
- [Log Sink Performance Schema Support](#)

## The Default Error Log Configuration

The `log_error_services` system variable controls which loadable log components to load, and which log components to enable for error logging. By default, `log_error_services` has the value shown here:

```
mysql> SELECT @@GLOBAL.log_error_services;
+-----+
| @@GLOBAL.log_error_services |
+-----+
| log_filter_internal; log_sink_internal |
+-----+
```

That value indicates that log events first pass through the `log_filter_internal` filter component, then through the `log_sink_internal` sink component, both of which are built-in components. A filter modifies log events seen by components named later in the `log_error_services` value. A sink is a destination for log events. Typically, a sink processes log events into log messages that have a particular format and writes these messages to its associated output, such as a file or the system log.

The combination of `log_filter_internal` and `log_sink_internal` implements the default error log filtering and output behavior. The action of these components is affected by other server options and system variables:

- The output destination is determined by the `--log-error` option (and, on Windows, `--pid-file` and `--console`). These determine whether to write error messages to the console or a file and, if to a file, the error log file name. See [Section 7.4.2.2, “Default Error Log Destination Configuration”](#).
- The `log_error_verbosity` and `log_error_suppression_list` system variables affect which types of log events `log_filter_internal` permits or suppresses. See [Section 7.4.2.5, “Priority-Based Error Log Filtering \(log\\_filter\\_internal\)”](#).

When configuring `log_error_services`, be aware of the following characteristics:

- A list of log components may be delimited by semicolons or commas, optionally followed by spaces. A given setting cannot use both semicolon and comma separators. Component order is significant because the server executes components in the order listed.
- The final component in the `log_error_services` value cannot be a filter. This is an error because any changes it has on events would have no effect on output:

```
mysql> SET GLOBAL log_error_services = 'log_filter_internal';
ERROR 1231 (42000): Variable 'log_error_services' can't be set to the value
of 'log_filter_internal'
```

To correct the problem, include a sink at the end of the value:

```
mysql> SET GLOBAL log_error_services = 'log_filter_internal; log_sink_internal';
```

- The order of components named in `log_error_services` is significant, particularly with respect to the relative order of filters and sinks. Consider this `log_error_services` value:

```
log_filter_internal; log_sink_1; log_sink_2
```

In this case, log events pass to the built-in filter, then to the first sink, then to the second sink. Both sinks receive the filtered log events.

Compare that to this `log_error_services` value:

```
log_sink_1; log_filter_internal; log_sink_2
```

In this case, log events pass to the first sink, then to the built-in filter, then to the second sink. The first sink receives unfiltered events. The second sink receives filtered events. You might configure error logging this way if you want one log that contains messages for all log events, and another log that contains messages only for a subset of log events.

## Error Log Configuration Methods

Error log configuration involves loading and enabling error log components as necessary and performing component-specific configuration.

There are two error log configuration methods, *implicit* and *explicit*. It is recommended that one configuration method is selected and used exclusively. Using both methods can result in warnings at startup. For more information, see [Troubleshooting Configuration Issues](#).

- *Implicit Error Log Configuration*

This configuration method loads and enables the log components defined by the `log_error_services` variable. Loadable components that are not already loaded are loaded implicitly

at startup before the [InnoDB](#) storage engine is fully available. This configuration method has the following advantages:

- Log components are loaded early in the startup sequence, before the [InnoDB](#) storage engine, making logged information available sooner.
- It avoids loss of buffered log information should a failure occur during startup.
- Installing error log components using `INSTALL COMPONENT` is not required, simplifying error log configuration.

To use this method, see [Implicit Error Log Configuration](#).

- *Explicit Error Log Configuration*

#### Note

This configuration method is supported for backward compatibility. The implicit configuration method is recommended.

This configuration method requires loading error log components using `INSTALL COMPONENT` and then configuring `log_error_services` to enable the log components. `INSTALL COMPONENT` adds the component to the `mysql.component` table (an [InnoDB](#) table), and the components to load at startup are read from this table, which is only accessible after [InnoDB](#) is initialized.

Logged information is buffered during the startup sequence while the [InnoDB](#) storage engine is initialized, which is sometimes prolonged by operations such as recovery and data dictionary upgrade that occur during the [InnoDB](#) startup sequence.

To use this method, see [Explicit Error Log Configuration](#).

## Implicit Error Log Configuration

This procedure describes how to load and enable error logging components implicitly using `log_error_services`. For a discussion of error log configuration methods, see [Error Log Configuration Methods](#).

To load and enable error logging components implicitly:

1. List the error log components in the `log_error_services` value.

To load and enable the error log components at server startup, set `log_error_services` in an option file. The following example configures the use of the JSON log sink (`log_sink_json`) in addition to the built-in log filter and sink (`log_filter_internal`, `log_sink_internal`).

```
[mysqld]
log_error_services='log_filter_internal; log_sink_internal; log_sink_json'
```

#### Note

To use the JSON log sink (`log_sink_syseventlog`) instead of the default sink (`log_sink_internal`), you would replace `log_sink_internal` with `log_sink_json`.

To load and enable the component immediately and for subsequent restarts, set `log_error_services` using `SET PERSIST`:

```
SET PERSIST log_error_services = 'log_filter_internal; log_sink_internal; log_sink_json';
```

2. If the error log component exposes any system variables that must be set for component initialization to succeed, assign those variables appropriate values. You can set these variables in an option file or using `SET PERSIST`.

### Important

When implementing an implicit configuration, set `log_error_services` first to load a component and expose its system variables, and then set component system variables afterward. This configuration order is required regardless of whether variable assignment is performed on the command-line, in an option file, or using `SET PERSIST`.

To disable a log component, remove it from the `log_error_services` value. Also remove any associated component variables settings that you have defined.

### Note

Loading a log component implicitly using `log_error_services` has no effect on the `mysql.component` table. It does not add the component to the `mysql.component` table, nor does it remove a component previously installed using `INSTALL COMPONENT` from the `mysql.component` table.

## Explicit Error Log Configuration

This procedure describes how to load and enable error logging components explicitly by loading components using `INSTALL COMPONENT` and then enabling using `log_error_services`. For a discussion of error log configuration methods, see [Error Log Configuration Methods](#).

To load and enable error logging components explicitly:

1. Load the component using `INSTALL COMPONENT` (unless it is built in or already loaded). For example, to load the JSON log sink, issue the following statement:

```
INSTALL COMPONENT 'file://component_log_sink_json';
```

Loading a component using `INSTALL COMPONENT` registers it in the `mysql.component` system table so that the server loads it automatically for subsequent startups, after InnoDB is initialized.

The URN to use when loading a log component with `INSTALL COMPONENT` is the component name prefixed with `file://component_`. For example, for the `log_sink_json` component, the corresponding URN is `file://component_log_sink_json`. For error log component URNs, see [Section 7.5.3, “Error Log Components”](#).

2. If the error log component exposes any system variables that must be set for component initialization to succeed, assign those variables appropriate values. You can set these variables in an option file or using `SET PERSIST`.
3. Enable the component by listing it in the `log_error_services` value.

### Important

When loading log components explicitly using `INSTALL COMPONENT`, do not persist or set `log_error_services` in an option file, which loads log components implicitly at startup. Instead, enable log components at runtime using a `SET GLOBAL` statement.

The following example configures the use of the JSON log sink (`log_sink_json`) in addition to the built-in log filter and sink (`log_filter_internal`, `log_sink_internal`).

```
SET GLOBAL log_error_services = 'log_filter_internal; log_sink_internal; log_sink_json';
```

**Note**

To use the JSON log sink (`log_sink_syseventlog`) instead of the default sink (`log_sink_internal`), you would replace `log_sink_internal` with `log_sink_json`.

To disable a log component, remove it from the `log_error_services` value. Then, if the component is loadable and you also want to unload it, use `UNINSTALL COMPONENT`. Also remove any associated component variables settings that you have defined.

Attempts to use `UNINSTALL COMPONENT` to unload a loadable component that is still named in the `log_error_services` value produce an error.

## Changing the Error Log Configuration Method

If you have previously loaded error log components explicitly using `INSTALL COMPONENT` and want to switch to an implicit configuration, as described in [Implicit Error Log Configuration](#), the following steps are recommended:

1. Set `log_error_services` back to its default configuration.

```
SET GLOBAL log_error_services = 'log_filter_internal,log_sink_internal';
```

2. Use `UNINSTALL COMPONENT` to uninstall any loadable logging components that you installed previously. For example, if you installed the JSON log sink previously, uninstall it as shown:

```
UNINSTALL COMPONENT 'file://component_log_sink_json';
```

3. Remove any component variable settings for the uninstalled component. For example, if component variables were set in an option file, remove the settings from the option file. If component variables were set using `SET PERSIST`, use `RESET PERSIST` to clear the settings.
4. Follow the steps in [Implicit Error Log Configuration](#) to reimplement your configuration.

If you need to revert from an implicit configuration to an explicit configuration, perform the following steps:

1. Set `log_error_services` back to its default configuration to unload implicitly loaded log components.

```
SET GLOBAL log_error_services = 'log_filter_internal,log_sink_internal';
```

2. Remove any component variable settings associated with the uninstalled components. For example, if component variables were set in an option file, remove the settings from the option file. If component variables were set using `SET PERSIST`, use `RESET PERSIST` to clear the settings.
3. Restart the server to uninstall the log components that were implicitly loaded.
4. Follow the steps in [Explicit Error Log Configuration](#) to reimplement your configuration.

## Troubleshooting Configuration Issues

Log components listed in the `log_error_services` value at startup are loaded implicitly early in the MySQL Server startup sequence. If the log component was loaded previously using `INSTALL COMPONENT`, the server attempts to load the component again later in the startup sequence, which produces the warning `Cannot load component from specified URN: 'file://component_component_name'`.

You can check for this warning in the error log or by querying the Performance Schema `error_log` table using the following query:

```
SELECT error_code, data
FROM performance_schema.error_log
WHERE data LIKE "%'file://component_%"
AND error_code="MY-013129" AND data LIKE "%MY-003529%";
```

To prevent this warning, follow the instructions in [Changing the Error Log Configuration Method](#) to adjust your error log configuration. Either an implicit or explicit error log configuration should be used, but not both.

A similar error occurs when attempting to explicitly load a component that was implicitly loaded at startup. For example, if `log_error_services` lists the JSON log sink component, that component is implicitly loaded at startup. Attempting to explicitly load the same component later returns this error:

```
mysql> INSTALL COMPONENT 'file://component_log_sink_json';
ERROR 3529 (HY000): Cannot load component from specified URN: 'file://component_log_sink_json'.
```

## Configuring Multiple Log Sinks

It is possible to configure multiple log sinks, which enables sending output to multiple destinations. To enable the JSON log sink in addition to (rather than instead of) the default sink, set the `log_error_services` value like this:

```
SET GLOBAL log_error_services = 'log_filter_internal; log_sink_internal; log_sink_json';
```

To revert to using only the default sink and unload the system log sink, execute these statements:

```
SET GLOBAL log_error_services = 'log_filter_internal; log_sink_internal;
UNINSTALL COMPONENT 'file://component_log_sink_json';
```

## Log Sink Performance Schema Support

If enabled log components include a sink that provides Performance Schema support, events written to the error log are also written to the Performance Schema `error_log` table. This enables examining error log contents using SQL queries. Currently, the traditional-format `log_sink_internal` and JSON-format `log_sink_json` sinks support this capability. See [Section 29.12.22.2, “The error\\_log Table”](#).

### 7.4.2.2 Default Error Log Destination Configuration

This section describes which server options configure the default error log destination, which can be the console or a named file. It also indicates which log sink components base their own output destination on the default destination.

In this discussion, “console” means `stderr`, the standard error output. This is your terminal or console window unless the standard error output has been redirected to a different destination.

The server interprets options that determine the default error log destination somewhat differently for Windows and Unix systems. Be sure to configure the destination using the information appropriate to your platform. After the server interprets the default error log destination options, it sets the `log_error` system variable to indicate the default destination, which affects where several log sink components write error messages. The following sections address these topics.

- [Default Error Log Destination on Windows](#)
- [Default Error Log Destination on Unix and Unix-Like Systems](#)
- [How the Default Error Log Destination Affects Log Sinks](#)

## Default Error Log Destination on Windows

On Windows, `mysqld` uses the `--log-error`, `--pid-file`, and `--console` options to determine whether the default error log destination is the console or a file, and, if a file, the file name:

- If `--console` is given, the default destination is the console. (`--console` takes precedence over `--log-error` if both are given, and the following items regarding `--log-error` do not apply.)
- If `--log-error` is not given, or is given without naming a file, the default destination is a file named `host_name.err` in the data directory, unless the `--pid-file` option is specified. In that case, the file name is the PID file base name with a suffix of `.err` in the data directory.
- If `--log-error` is given to name a file, the default destination is that file (with an `.err` suffix added if the name has no suffix). The file location is under the data directory unless an absolute path name is given to specify a different location.

If the default error log destination is the console, the server sets the `log_error` system variable to `stderr`. Otherwise, the default destination is a file and the server sets `log_error` to the file name.

## Default Error Log Destination on Unix and Unix-Like Systems

On Unix and Unix-like systems, `mysqld` uses the `--log-error` option to determine whether the default error log destination is the console or a file, and, if a file, the file name:

- If `--log-error` is not given, the default destination is the console.
- If `--log-error` is given without naming a file, the default destination is a file named `host_name.err` in the data directory.
- If `--log-error` is given to name a file, the default destination is that file (with an `.err` suffix added if the name has no suffix). The file location is under the data directory unless an absolute path name is given to specify a different location.
- If `--log-error` is given in an option file in a `[mysqld]`, `[server]`, or `[mysqld_safe]` section, on systems that use `mysqld_safe` to start the server, `mysqld_safe` finds and uses the option, and passes it to `mysqld`.

### Note

It is common for Yum or APT package installations to configure an error log file location under `/var/log` with an option like `log-error=/var/log/mysqld.log` in a server configuration file. Removing the path name from the option causes the `host_name.err` file in the data directory to be used.

If the default error log destination is the console, the server sets the `log_error` system variable to `stderr`. Otherwise, the default destination is a file and the server sets `log_error` to the file name.

## How the Default Error Log Destination Affects Log Sinks

After the server interprets the error log destination configuration options, it sets the `log_error` system variable to indicate the default error log destination. Log sink components may base their own output destination on the `log_error` value, or determine their destination independently of `log_error`.

If `log_error` is `stderr`, the default error log destination is the console, and log sinks that base their output destination on the default destination also write to the console:

- `log_sink_internal`, `log_sink_json`, `log_sink_test`: These sinks write to the console. This is true even for sinks such as `log_sink_json` that can be enabled multiple times; all instances write to the console.

- `log_sink_syseventlog`: This sink writes to the system log, regardless of the `log_error` value.

If `log_error` is not `stderr`, the default error log destination is a file and `log_error` indicates the file name. Log sinks that base their output destination on the default destination base output file naming on that file name. (A sink might use exactly that name, or it might use some variant thereof.) Suppose that the `log_error` value `file_name`. Then log sinks use the name like this:

- `log_sink_internal`, `log_sink_test`: These sinks write to `file_name`.
- `log_sink_json`: Successive instances of this sink named in the `log_error_services` value write to files named `file_name` plus a numbered `.NN.json` suffix: `file_name.00.json`, `file_name.01.json`, and so forth.
- `log_sink_syseventlog`: This sink writes to the system log, regardless of the `log_error` value.

### 7.4.2.3 Error Event Fields

Error events intended for the error log contain a set of fields, each of which consists of a key/value pair. An event field may be classified as core, optional, or user-defined:

- A core field is set up automatically for error events. However, its presence in the event during event processing is not guaranteed because a core field, like any type of field, may be unset by a log filter. If this happens, the field cannot be found by subsequent processing within that filter and by components that execute after the filter (such as log sinks).
- An optional field is normally absent but may be present for certain event types. When present, an optional field provides additional event information as appropriate and available.
- A user-defined field is any field with a name that is not already defined as a core or optional field. A user-defined field does not exist until created by a log filter.

As implied by the preceding description, any given field may be absent during event processing, either because it was not present in the first place, or was discarded by a filter. For log sinks, the effect of field absence is sink specific. For example, a sink might omit the field from the log message, indicate that the field is missing, or substitute a default. When in doubt, test: use a filter that unsets the field, then check what the log sink does with it.

The following sections describe the core and optional error event fields. For individual log filter components, there may be additional filter-specific considerations for these fields, or filters may add user-defined fields not listed here. For details, see the documentation for specific filters.

- [Core Error Event Fields](#)
- [Optional Error Event Fields](#)

### Core Error Event Fields

These error event fields are core fields:

- `time`

The event timestamp, with microsecond precision.

- `msg`

The event message string.

- `prio`

The event priority, to indicate a system, error, warning, or note/information event. This field corresponds to severity in `syslog`. The following table shows the possible priority levels.

Event Type	Numeric Priority
System event	0
Error event	1
Warning event	2
Note/information event	3

The `prio` value is numeric. Related to it, an error event may also include an optional `label` field representing the priority as a string. For example, an event with a `prio` value of 2 may have a `label` value of `'Warning'`.

Filter components may include or drop error events based on priority, except that system events are mandatory and cannot be dropped.

In general, message priorities are determined as follows:

Is the situation or event actionable?

- Yes: Is the situation or event ignorable?
  - Yes: Priority is warning.
  - No: Priority is error.
- No: Is the situation or event mandatory?
  - Yes: Priority is system.
  - No: Priority is note/information.

- `err_code`

The event error code, as a number (for example, `1022`).

- `err_symbol`

The event error symbol, as a string (for example, `'ER_DUP_KEY'`).

- `SQL_state`

The event SQLSTATE value, as a string (for example, `'23000'`).

- `subsystem`

The subsystem in which the event occurred. Possible values are `InnoDB` (the `InnoDB` storage engine), `Repl` (the replication subsystem), `Server` (otherwise).

## Optional Error Event Fields

Optional error event fields fall into the following categories:

- Additional information about the error, such as the error signaled by the operating system or the error label:

- `OS_errno`  
The operating system error number.
- `OS_errmsg`  
The operating system error message.
- `label`  
The label corresponding to the `prio` value, as a string.
- Identification of the client for which the event occurred:
  - `user`  
The client user.
  - `host`  
The client host.
  - `thread`  
The ID of the thread within `mysqld` responsible for producing the error event. This ID indicates which part of the server produced the event, and is consistent with general query log and slow query log messages, which include the connection thread ID.
  - `query_id`  
The query ID.
- Debugging information:
  - `source_file`  
The source file in which the event occurred, without any leading path.
  - `source_line`  
The line within the source file at which the event occurred.
  - `function`  
The function in which the event occurred.
  - `component`  
The component or plugin in which the event occurred.

#### 7.4.2.4 Types of Error Log Filtering

Error log configuration normally includes one log filter component and one or more log sink components. For error log filtering, MySQL offers a choice of components:

- `log_filter_internal`: This filter component provides error log filtering based on log event priority and error code, in combination with the `log_error_verbosity` and

`log_error_suppression_list` system variables. `log_filter_internal` is built in and enabled by default. See [Section 7.4.2.5, “Priority-Based Error Log Filtering \(log\\_filter\\_internal\)”](#).

- `log_filter_dragnet`: This filter component provides error log filtering based on user-supplied rules, in combination with the `dragnet.log_error_filter_rules` system variable. See [Section 7.4.2.6, “Rule-Based Error Log Filtering \(log\\_filter\\_dragnet\)”](#).

### 7.4.2.5 Priority-Based Error Log Filtering (log\_filter\_internal)

The `log_filter_internal` log filter component implements a simple form of log filtering based on error event priority and error code. To affect how `log_filter_internal` permits or suppresses error, warning, and information events intended for the error log, set the `log_error_verbosity` and `log_error_suppression_list` system variables.

`log_filter_internal` is built in and enabled by default. If this filter is disabled, `log_error_verbosity` and `log_error_suppression_list` have no effect, so filtering must be performed using another filter service instead where desired (for example, with individual filter rules when using `log_filter_dragnet`). For information about filter configuration, see [Section 7.4.2.1, “Error Log Configuration”](#).

- [Verbosity Filtering](#)
- [Suppression-List Filtering](#)
- [Verbosity and Suppression-List Interaction](#)

#### Verbosity Filtering

Events intended for the error log have a priority of `ERROR`, `WARNING`, or `INFORMATION`. The `log_error_verbosity` system variable controls verbosity based on which priorities to permit for messages written to the log, as shown in the following table.

log_error_verbosity Value	Permitted Message Priorities
1	<code>ERROR</code>
2	<code>ERROR</code> , <code>WARNING</code>
3	<code>ERROR</code> , <code>WARNING</code> , <code>INFORMATION</code>

If `log_error_verbosity` is 2 or greater, the server logs messages about statements that are unsafe for statement-based logging. If the value is 3, the server logs aborted connections and access-denied errors for new connection attempts. See [Section B.3.2.9, “Communication Errors and Aborted Connections”](#).

If you use replication, a `log_error_verbosity` value of 2 or greater is recommended, to obtain more information about what is happening, such as messages about network failures and reconnections.

If `log_error_verbosity` is 2 or greater on a replica, the replica prints messages to the error log to provide information about its status, such as the binary log and relay log coordinates where it starts its job, when it is switching to another relay log, when it reconnects after a disconnect, and so forth.

There is also a message priority of `SYSTEM` that is not subject to verbosity filtering. System messages about non-error situations are printed to the error log regardless of the `log_error_verbosity` value. These messages include startup and shutdown messages, and some significant changes to settings.

In the MySQL error log, system messages are labeled as “System”. Other log sinks might or might not follow the same convention, and in the resulting logs, system messages might be assigned the label used for the information priority level, such as “Note” or “Information”. If you apply any additional filtering or redirection for logging based on the labeling of messages, system messages do not override your filter, but are handled by it in the same way as other messages.

## Suppression-List Filtering

The `log_error_suppression_list` system variable applies to events intended for the error log and specifies which events to suppress when they occur with a priority of `WARNING` or `INFORMATION`. For example, if a particular type of warning is considered undesirable “noise” in the error log because it occurs frequently but is not of interest, it can be suppressed. `log_error_suppression_list` does not suppress messages with a priority of `ERROR` or `SYSTEM`.

The `log_error_suppression_list` value may be the empty string for no suppression, or a list of one or more comma-separated values indicating the error codes to suppress. Error codes may be specified in symbolic or numeric form. A numeric code may be specified with or without the `MY-` prefix. Leading zeros in the numeric part are not significant. Examples of permitted code formats:

```
ER_SERVER_SHUTDOWN_COMPLETE
MY-000031
000031
MY-31
31
```

For readability and portability, symbolic values are preferable to numeric values.

Although codes to be suppressed can be expressed in symbolic or numeric form, the numeric value of each code must be in a permitted range:

- 1 to 999: Global error codes that are used by the server as well as by clients.
- 10000 and higher: Server error codes intended to be written to the error log (not sent to clients).

In addition, each error code specified must actually be used by MySQL. Attempts to specify a code not within a permitted range or within a permitted range but not used by MySQL produce an error and the `log_error_suppression_list` value remains unchanged.

For information about error code ranges and the error symbols and numbers defined within each range, see [Section B.1, “Error Message Sources and Elements”](#), and [MySQL 9.1 Error Message Reference](#).

The server can generate messages for a given error code at differing priorities, so suppression of a message associated with an error code listed in `log_error_suppression_list` depends on its priority. Suppose that the variable has a value of `'ER_PARSER_TRACE,MY-010001,10002'`. Then `log_error_suppression_list` has these effects on messages for those codes:

- Messages generated with a priority of `WARNING` or `INFORMATION` are suppressed.
- Messages generated with a priority of `ERROR` or `SYSTEM` are not suppressed.

## Verbosity and Suppression-List Interaction

The effect of `log_error_verbosity` combines with that of `log_error_suppression_list`. Consider a server started with these settings:

```
[mysqld]
log_error_verbosity=2 # error and warning messages only
log_error_suppression_list='ER_PARSER_TRACE,MY-010001,10002'
```

In this case, `log_error_verbosity` permits messages with `ERROR` or `WARNING` priority and discards messages with `INFORMATION` priority. Of the nondiscarded messages, `log_error_suppression_list` discards messages with `WARNING` priority and any of the named error codes.

### Note

The `log_error_verbosity` value of 2 shown in the example is also its default value, so the effect of this variable on `INFORMATION` messages is as just described

by default, without an explicit setting. You must set `log_error_verbosity` to 3 if you want `log_error_suppression_list` to affect messages with `INFORMATION` priority.

Consider a server started with this setting:

```
[mysqld]
log_error_verbosity=1 # error messages only
```

In this case, `log_error_verbosity` permits messages with `ERROR` priority and discards messages with `WARNING` or `INFORMATION` priority. Setting `log_error_suppression_list` has no effect because all error codes it might suppress are already discarded due to the `log_error_verbosity` setting.

#### 7.4.2.6 Rule-Based Error Log Filtering (`log_filter_dragnet`)

The `log_filter_dragnet` log filter component enables log filtering based on user-defined rules.

To enable the `log_filter_dragnet` filter, first load the filter component, then modify the `log_error_services` value. The following example enables `log_filter_dragnet` in combination with the built-in log sink:

```
INSTALL COMPONENT 'file://component_log_filter_dragnet';
SET GLOBAL log_error_services = 'log_filter_dragnet; log_sink_internal';
```

To set `log_error_services` to take effect at server startup, use the instructions at [Section 7.4.2.1, “Error Log Configuration”](#). Those instructions apply to other error-logging system variables as well.

With `log_filter_dragnet` enabled, define its filter rules by setting the `dragnet.log_error_filter_rules` system variable. A rule set consists of zero or more rules, where each rule is an `IF` statement terminated by a period (.) character. If the variable value is empty (zero rules), no filtering occurs.

Example 1. This rule set drops information events, and, for other events, removes the `source_line` field:

```
SET GLOBAL dragnet.log_error_filter_rules =
 'IF prio>=INFORMATION THEN drop. IF EXISTS source_line THEN unset source_line.';
```

The effect is similar to the filtering performed by the `log_sink_internal` filter with a setting of `log_error_verbosity=2`.

For readability, you might find it preferable to list the rules on separate lines. For example:

```
SET GLOBAL dragnet.log_error_filter_rules = '
 IF prio>=INFORMATION THEN drop.
 IF EXISTS source_line THEN unset source_line.
 ';
```

Example 2: This rule limits information events to no more than one per 60 seconds:

```
SET GLOBAL dragnet.log_error_filter_rules =
 'IF prio>=INFORMATION THEN throttle 1/60.';
```

Once you have the filtering configuration set up as you desire, consider assigning `dragnet.log_error_filter_rules` using `SET PERSIST` rather than `SET GLOBAL` to make the setting persist across server restarts. Alternatively, add the setting to the server option file.

When using `log_filter_dragnet`, `log_error_suppression_list` is ignored.

To stop using the filtering language, first remove it from the set of error logging components. Usually this means using a different filter component rather than no filter component. For example:

```
SET GLOBAL log_error_services = 'log_filter_internal; log_sink_internal';
```

Again, consider using `SET PERSIST` rather than `SET GLOBAL` to make the setting persist across server restarts.

Then uninstall the filter `log_filter_dragnet` component:

```
UNINSTALL COMPONENT 'file://component_log_filter_dragnet';
```

The following sections describe aspects of `log_filter_dragnet` operation in more detail:

- [Grammar for log\\_filter\\_dragnet Rule Language](#)
- [Actions for log\\_filter\\_dragnet Rules](#)
- [Field References in log\\_filter\\_dragnet Rules](#)

## Grammar for log\_filter\_dragnet Rule Language

The following grammar defines the language for `log_filter_dragnet` filter rules. Each rule is an `IF` statement terminated by a period (.) character. The language is not case-sensitive.

```
rule:
 IF condition THEN action
 [ELSEIF condition THEN action] ...
 [ELSE action]
 .

condition: {
 field comparator value
 | [NOT] EXISTS field
 | condition {AND | OR} condition
}

action: {
 drop
 | throttle {count | count / window_size}
 | set field [:= | =] value
 | unset [field]
}

field: {
 core_field
 | optional_field
 | user_defined_field
}

core_field: {
 time
 | msg
 | prio
 | err_code
 | err_symbol
 | SQL_state
 | subsystem
}

optional_field: {
 OS_errno
 | OS_errmsg
 | label
 | user
 | host
 | thread
 | query_id
 | source_file
 | source_line
}
```

```

 | function
 | component
}

user_defined_field:
 sequence of characters in [a-zA-Z0-9_] class

comparator: {== | != | <> | >= | => | <= | =< | < | >}

value: {
 string_literal
 | integer_literal
 | float_literal
 | error_symbol
 | priority
}

count: integer_literal
window_size: integer_literal

string_literal:
 sequence of characters quoted as '...' or "..."

integer_literal:
 sequence of characters in [0-9] class

float_literal:
 integer_literal[.integer_literal]

error_symbol:
 valid MySQL error symbol such as ER_ACCESS_DENIED_ERROR or ER_STARTUP

priority: {
 ERROR
 | WARNING
 | INFORMATION
}

```

Simple conditions compare a field to a value or test field existence. To construct more complex conditions, use the [AND](#) and [OR](#) operators. Both operators have the same precedence and evaluate left to right.

To escape a character within a string, precede it by a backslash (`\`). A backslash is required to include backslash itself or the string-quoting character, optional for other characters.

For convenience, `log_filter_dragnet` supports symbolic names for comparisons to certain fields. For readability and portability, symbolic values are preferable (where applicable) to numeric values.

- Event priority values 1, 2, and 3 can be specified as [ERROR](#), [WARNING](#), and [INFORMATION](#). Priority symbols are recognized only in comparisons with the `prio` field. These comparisons are equivalent:

```

IF prio == INFORMATION THEN ...
IF prio == 3 THEN ...

```

- Error codes can be specified in numeric form or as the corresponding error symbol. For example, [ER\\_STARTUP](#) is the symbolic name for error [1408](#), so these comparisons are equivalent:

```

IF err_code == ER_STARTUP THEN ...
IF err_code == 1408 THEN ...

```

Error symbols are recognized only in comparisons with the `err_code` field and user-defined fields.

To find the error symbol corresponding to a given error code number, use one of these methods:

- Check the list of server errors at [Server Error Message Reference](#).

- Use the `pererror` command. Given an error number argument, `pererror` displays information about the error, including its symbol.

Suppose that a rule set with error numbers looks like this:

```
IF err_code == 10927 OR err_code == 10914 THEN drop.
IF err_code == 1131 THEN drop.
```

Using `pererror`, determine the error symbols:

```
$> pererror 10927 10914 1131
MySQL error code MY-010927 (ER_ACCESS_DENIED_FOR_USER_ACCOUNT_LOCKED):
Access denied for user '%-.48s'@'%-.64s'. Account is locked.
MySQL error code MY-010914 (ER_ABORTING_USER_CONNECTION):
Aborted connection %u to db: '%-.192s' user: '%-.48s' host:
'%-.64s' (%-.64s).
MySQL error code MY-001131 (ER_PASSWORD_ANONYMOUS_USER):
You are using MySQL as an anonymous user and anonymous users
are not allowed to change passwords
```

Substituting error symbols for numbers, the rule set becomes:

```
IF err_code == ER_ACCESS_DENIED_FOR_USER_ACCOUNT_LOCKED
OR err_code == ER_ABORTING_USER_CONNECTION THEN drop.
IF err_code == ER_PASSWORD_ANONYMOUS_USER THEN drop.
```

Symbolic names can be specified as quoted strings for comparison with string fields, but in such cases the names are strings that have no special meaning and `log_filter_dragnet` does not resolve them to the corresponding numeric value. Also, typos may go undetected, whereas an error occurs immediately on `SET` for attempts to use an unquoted symbol unknown to the server.

## Actions for log\_filter\_dragnet Rules

`log_filter_dragnet` supports these actions in filter rules:

- `drop`: Drop the current log event (do not log it).
- `throttle`: Apply rate limiting to reduce log verbosity for events matching particular conditions. The argument indicates a rate, in the form `count` or `count/window_size`. The `count` value indicates the permitted number of event occurrences to log per time window. The `window_size` value is the time window in seconds; if omitted, the default window is 60 seconds. Both values must be integer literals.

This rule throttles plugin-shutdown messages to 5 occurrences per 60 seconds:

```
IF err_code == ER_PLUGIN_SHUTTING_DOWN_PLUGIN THEN throttle 5.
```

This rule throttles errors and warnings to 1000 occurrences per hour and information messages to 100 occurrences per hour:

```
IF prio <= INFORMATION THEN throttle 1000/3600 ELSE throttle 100/3600.
```

- `set`: Assign a value to a field (and cause the field to exist if it did not already). In subsequent rules, `EXISTS` tests against the field name are true, and the new value can be tested by comparison conditions.
- `unset`: Discard a field. In subsequent rules, `EXISTS` tests against the field name are false, and comparisons of the field against any value are false.

In the special case that the condition refers to exactly one field name, the field name following `unset` is optional and `unset` discards the named field. These rules are equivalent:

```
IF myfield == 2 THEN unset myfield.
IF myfield == 2 THEN unset.
```

## Field References in log\_filter\_dragnet Rules

`log_filter_dragnet` rules support references to core, optional, and user-defined fields in error events.

- [Core Field References](#)
- [Optional Field References](#)
- [User-Defined Field References](#)

### Core Field References

The `log_filter_dragnet` grammar at [Grammar for log\\_filter\\_dragnet Rule Language](#) names the core fields that filter rules recognize. For general descriptions of these fields, see [Section 7.4.2.3, “Error Event Fields”](#), with which you are assumed to be familiar. The following remarks provide additional information only as it pertains specifically to core field references as used within `log_filter_dragnet` rules.

- `prio`

The event priority, to indicate an error, warning, or note/information event. In comparisons, each priority can be specified as a symbolic priority name or an integer literal. Priority symbols are recognized only in comparisons with the `prio` field. These comparisons are equivalent:

```
IF prio == INFORMATION THEN ...
IF prio == 3 THEN ...
```

The following table shows the permitted priority levels.

Event Type	Priority Symbol	Numeric Priority
Error event	<code>ERROR</code>	1
Warning event	<code>WARNING</code>	2
Note/information event	<code>INFORMATION</code>	3

There is also a message priority of `SYSTEM`, but system messages cannot be filtered and are always written to the error log.

Priority values follow the principle that higher priorities have lower values, and vice versa. Priority values begin at 1 for the most severe events (errors) and increase for events with decreasing priority. For example, to discard events with priority lower than warnings, test for priority values higher than `WARNING`:

```
IF prio > WARNING THEN drop.
```

The following examples show the `log_filter_dragnet` rules to achieve an effect similar to each `log_error_verbosity` value permitted by the `log_filter_internal` filter:

- Errors only (`log_error_verbosity=1`):

```
IF prio > ERROR THEN drop.
```

- Errors and warnings (`log_error_verbosity=2`):

```
IF prio > WARNING THEN drop.
```

- Errors, warnings, and notes (`log_error_verbosity=3`):

```
IF prio > INFORMATION THEN drop.
```

This rule can actually be omitted because there are no `prio` values greater than `INFORMATION`, so effectively it drops nothing.

- `err_code`

The numeric event error code. In comparisons, the value to test can be specified as a symbolic error name or an integer literal. Error symbols are recognized only in comparisons with the `err_code` field and user-defined fields. These comparisons are equivalent:

```
IF err_code == ER_ACCESS_DENIED_ERROR THEN ...
IF err_code == 1045 THEN ...
```

- `err_symbol`

The event error symbol, as a string (for example, `'ER_DUP_KEY'`). `err_symbol` values are intended more for identifying particular lines in log output than for use in filter rule comparisons because `log_filter_dragonet` does not resolve comparison values specified as strings to the equivalent numeric error code. (For that to occur, an error must be specified using its unquoted symbol.)

## Optional Field References

The `log_filter_dragonet` grammar at [Grammar for log\\_filter\\_dragonet Rule Language](#) names the optional fields that filter rules recognize. For general descriptions of these fields, see [Section 7.4.2.3, "Error Event Fields"](#), with which you are assumed to be familiar. The following remarks provide additional information only as it pertains specifically to optional field references as used within `log_filter_dragonet` rules.

- `label`

The label corresponding to the `prio` value, as a string. Filter rules can change the label for log sinks that support custom labels. `label` values are intended more for identifying particular lines in log output than for use in filter rule comparisons because `log_filter_dragonet` does not resolve comparison values specified as strings to the equivalent numeric priority.

- `source_file`

The source file in which the event occurred, without any leading path. For example, to test for the `sql/gis/distance.cc` file, write the comparison like this:

```
IF source_file == "distance.cc" THEN ...
```

## User-Defined Field References

Any field name in a `log_filter_dragonet` filter rule not recognized as a core or optional field name is taken to refer to a user-defined field.

### 7.4.2.7 Error Logging in JSON Format

This section describes how to configure error logging using the built-in filter, `log_filter_internal`, and the JSON sink, `log_sink_json`, to take effect immediately and for subsequent server startups. For general information about configuring error logging, see [Section 7.4.2.1, "Error Log Configuration"](#).

To enable the JSON sink, first load the sink component, then modify the `log_error_services` value:

```
INSTALL COMPONENT 'file://component_log_sink_json';
SET PERSIST log_error_services = 'log_filter_internal; log_sink_json';
```

To set `log_error_services` to take effect at server startup, use the instructions at [Section 7.4.2.1, “Error Log Configuration”](#). Those instructions apply to other error-logging system variables as well.

It is permitted to name `log_sink_json` multiple times in the `log_error_services` value. For example, to write unfiltered events with one instance and filtered events with another instance, you could set `log_error_services` like this:

```
SET PERSIST log_error_services = 'log_sink_json; log_filter_internal; log_sink_json';
```

The JSON sink determines its output destination based on the default error log destination, which is given by the `log_error` system variable. If `log_error` names a file, the JSON sink bases output file naming on that file name, plus a numbered `.NN.json` suffix, with `NN` starting at 00. For example, if `log_error` is `file_name`, successive instances of `log_sink_json` named in the `log_error_services` value write to `file_name.00.json`, `file_name.01.json`, and so forth.

If `log_error` is `stderr`, the JSON sink writes to the console. If `log_sink_json` is named multiple times in the `log_error_services` value, they all write to the console, which is likely not useful.

### 7.4.2.8 Error Logging to the System Log

It is possible to have `mysqld` write the error log to the system log (the Event Log on Windows, and `syslog` on Unix and Unix-like systems).

This section describes how to configure error logging using the built-in filter, `log_filter_internal`, and the system log sink, `log_sink_syseventlog`, to take effect immediately and for subsequent server startups. For general information about configuring error logging, see [Section 7.4.2.1, “Error Log Configuration”](#).

To enable the system log sink, first load the sink component, then modify the `log_error_services` value:

```
INSTALL COMPONENT 'file://component_log_sink_syseventlog';
SET PERSIST log_error_services = 'log_filter_internal; log_sink_syseventlog';
```

To set `log_error_services` to take effect at server startup, use the instructions at [Section 7.4.2.1, “Error Log Configuration”](#). Those instructions apply to other error-logging system variables as well.

#### Note

Error logging to the system log may require additional system configuration. Consult the system log documentation for your platform.

On Windows, error messages written to the Event Log within the Application log have these characteristics:

- Entries marked as `Error`, `Warning`, and `Note` are written to the Event Log, but not messages such as information statements from individual storage engines.
- Event Log entries have a source of `MySQL` (or `MySQL-tag` if `syseventlog.tag` is defined as `tag`).

On Unix and Unix-like systems, logging to the system log uses `syslog`. The following system variables affect `syslog` messages:

- `syseventlog.facility`: The default facility for `syslog` messages is `daemon`. Set this variable to specify a different facility.
- `syseventlog.include_pid`: Whether to include the server process ID in each line of `syslog` output.

- `syseventlog.tag`: This variable defines a tag to add to the server identifier (`mysqld`) in `syslog` messages. If defined, the tag is appended to the identifier with a leading hyphen.

MySQL uses the custom label “System” for important system messages about non-error situations, such as startup, shutdown, and some significant changes to settings. In logs that do not support custom labels, including the Event Log on Windows, and `syslog` on Unix and Unix-like systems, system messages are assigned the label used for the information priority level. However, these messages are printed to the log even if the MySQL `log_error_verbosity` setting normally excludes messages at the information level.

When a log sink must fall back to a label of “Information” instead of “System” in this way, and the log event is further processed outside of the MySQL server (for example, filtered or forwarded by a `syslog` configuration), these events may by default be processed by the secondary application as being of “Information” priority rather than “System” priority.

### 7.4.2.9 Error Log Output Format

Each error log sink (writer) component has a characteristic output format it uses to write messages to its destination, but other factors may influence the content of the messages:

- The information available to the log sink. If a log filter component executed prior to execution of the sink component removes a log event field, that field is not available for writing. For information about log filtering, see [Section 7.4.2.4, “Types of Error Log Filtering”](#).
- The information relevant to the log sink. Not every sink writes all fields available in error events.
- System variables may affect log sinks. See [System Variables That Affect Error Log Format](#).

For names and descriptions of the fields in error events, see [Section 7.4.2.3, “Error Event Fields”](#). For all log sinks, the thread ID included in error log messages is that of the thread within `mysqld` responsible for writing the message. This ID indicates which part of the server produced the message, and is consistent with general query log and slow query log messages, which include the connection thread ID.

- [log\\_sink\\_internal Output Format](#)
- [log\\_sink\\_json Output Format](#)
- [log\\_sink\\_syseventlog Output Format](#)
- [Early-Startup Logging Output Format](#)
- [System Variables That Affect Error Log Format](#)

### log\_sink\_internal Output Format

The internal log sink produces traditional error log output. For example:

```
2020-08-06T14:25:02.835618Z 0 [Note] [MY-012487] [InnoDB] DDL log recovery : begin
2020-08-06T14:25:02.936146Z 0 [Warning] [MY-010068] [Server] CA certificate /var/mysql/sslinfo/cacert.pem
2020-08-06T14:25:02.963127Z 0 [Note] [MY-010253] [Server] IPv6 is available.
2020-08-06T14:25:03.109022Z 5 [Note] [MY-010051] [Server] Event Scheduler: scheduler thread started with i
```

Traditional-format messages have these fields:

```
time thread [label] [err_code] [subsystem] msg
```

The `[` and `]` square bracket characters are literal characters in the message format. They do not indicate that fields are optional.

The `label` value corresponds to the string form of the `prio` error event priority field.

## log\_sink\_json Output Format

The JSON-format log sink produces messages as JSON objects that contain key-value pairs. For example:

```
{
 "prio": 3,
 "err_code": 10051,
 "source_line": 561,
 "source_file": "event_scheduler.cc",
 "function": "run",
 "msg": "Event Scheduler: scheduler thread started with id 5",
 "time": "2020-08-06T14:25:03.109022Z",
 "ts": 1596724012005,
 "thread": 5,
 "err_symbol": "ER_SCHEDULER_STARTED",
 "SQL_state": "HY000",
 "subsystem": "Server",
 "buffered": 1596723903109022,
 "label": "Note"
}
```

The message shown is reformatted for readability. Events written to the error log appear one message per line.

The `ts` (timestamp) key is unique to the JSON-format log sink. The value is an integer indicating milliseconds since the epoch ('1970-01-01 00:00:00' UTC).

The `ts` and `buffered` values are Unix timestamp values and can be converted using `FROM_UNIXTIME()` and an appropriate divisor:

```
mysql> SET time_zone = '+00:00';
mysql> SELECT FROM_UNIXTIME(1596724012005/1000.0);
+-----+
| FROM_UNIXTIME(1596724012005/1000.0) |
+-----+
| 2020-08-06 14:26:52.0050 |
+-----+
mysql> SELECT FROM_UNIXTIME(1596723903109022/1000000.0);
+-----+
| FROM_UNIXTIME(1596723903109022/1000000.0) |
+-----+
| 2020-08-06 14:25:03.1090 |
+-----+
```

## log\_sink\_syseventlog Output Format

The system log sink produces output that conforms to the system log format used on the local platform.

## Early-Startup Logging Output Format

The server generates some error log messages before startup options have been processed, and thus before it knows error log settings such as the `log_error_verbosity` and `log_timestamps` system variable values, and before it knows which log components are to be used. The server handles error log messages that are generated early in the startup process as follows:

- The server buffers log events (rather than formatted log messages), which enables it to apply configuration settings to those events retroactively, after the settings are known, with the result that flushed messages use the configured settings, not the defaults. Also, messages are flushed to all configured sinks, not just the default sink.

If a fatal error occurs before log configuration is known and the server must exit, the server formats buffered messages using the logging defaults so they are not lost. If no fatal error occurs but startup is

excessively slow prior to processing startup options, the server periodically formats and flushes buffered messages using the logging defaults so as not to appear unresponsive. Although this behavior uses the defaults, it is preferable to losing messages when exceptional conditions occur.

## System Variables That Affect Error Log Format

The `log_timestamps` system variable controls the time zone of timestamps in messages written to the error log (as well as to general query log and slow query log files). The server applies `log_timestamps` to error events before they reach any log sink; it thus affects error message output from all sinks.

Permitted `log_timestamps` values are `UTC` (the default) and `SYSTEM` (the local system time zone). Timestamps are written using ISO 8601 / RFC 3339 format: `YYYY-MM-DDThh:mm:ss.ffffff` plus a tail value of `Z` signifying Zulu time (UTC) or `±hh:mm` (an offset that indicates the local system time zone adjustment relative to UTC). For example:

```
2020-08-07T15:02:00.832521Z (UTC)

### 7.4.2.10 Error Log File Flushing and Renaming

If you flush the error log using a `FLUSH ERROR LOGS` or `FLUSH LOGS` statement, or a `mysqladmin flush-logs` command, the server closes and reopens any error log file to which it is writing. To rename an error log file, do so manually before flushing. Flushing the logs then opens a new file with the original file name. For example, assuming a log file name of `host_name.err`, use the following commands to rename the file and create a new one:

```
mv host_name.err host_name.err-old
mysqladmin flush-logs error
mv host_name.err-old backup-directory
```

On Windows, use `rename` rather than `mv`.

If the location of the error log file is not writable by the server, the log-flushing operation fails to create a new log file. For example, on Linux, the server might write the error log to the `/var/log/mysql.log` file, where the `/var/log` directory is owned by `root` and is not writable by `mysqld`. For information about handling this case, see [Section 7.4.6, “Server Log Maintenance”](#).

If the server is not writing to a named error log file, no error log file renaming occurs when the error log is flushed.

## 7.4.3 The General Query Log

The general query log is a general record of what `mysqld` is doing. The server writes information to this log when clients connect or disconnect, and it logs each SQL statement received from clients. The general query log can be very useful when you suspect an error in a client and want to know exactly what the client sent to `mysqld`.

Each line that shows when a client connects also includes `using connection_type` to indicate the protocol used to establish the connection. `connection_type` is one of `TCP/IP` (TCP/IP connection established without SSL), `SSL/TLS` (TCP/IP connection established with SSL), `Socket` (Unix socket file connection), `Named Pipe` (Windows named pipe connection), or `Shared Memory` (Windows shared memory connection).

`mysqld` writes statements to the query log in the order that it receives them, which might differ from the order in which they are executed. This logging order is in contrast with that of the binary log, for which statements are written after they are executed but before any locks are released. In addition, the query log may contain statements that only select data while such statements are never written to the binary log.

When using statement-based binary logging on a replication source server, statements received by its replicas are written to the query log of each replica. Statements are written to the query log of the source if a client reads events with the `mysqlbinlog` utility and passes them to the server.

However, when using row-based binary logging, updates are sent as row changes rather than SQL statements, and thus these statements are never written to the query log when `binlog_format` is `ROW`. A given update also might not be written to the query log when this variable is set to `MIXED`, depending on the statement used. See [Section 19.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”](#), for more information.

By default, the general query log is disabled. To specify the initial general query log state explicitly, use `--general_log[={0|1}]`. With no argument or an argument of 1, `--general_log` enables the log. With an argument of 0, this option disables the log. To specify a log file name, use `--general_log_file=file_name`. To specify the log destination, use the `log_output` system variable (as described in [Section 7.4.1, “Selecting General Query Log and Slow Query Log Output Destinations”](#)).

**Note**

If you specify the `TABLE` log destination, see [Log Tables and “Too many open files” Errors](#).

If you specify no name for the general query log file, the default name is `host_name.log`. The server creates the file in the data directory unless an absolute path name is given to specify a different directory.

To disable or enable the general query log or change the log file name at runtime, use the global `general_log` and `general_log_file` system variables. Set `general_log` to 0 (or `OFF`) to disable the log or to 1 (or `ON`) to enable it. Set `general_log_file` to specify the name of the log file. If a log file already is open, it is closed and the new file is opened.

When the general query log is enabled, the server writes output to any destinations specified by the `log_output` system variable. If you enable the log, the server opens the log file and writes startup messages to it. However, further logging of queries to the file does not occur unless the `FILE` log destination is selected. If the destination is `NONE`, the server writes no queries even if the general log is enabled. Setting the log file name has no effect on logging if the log destination value does not contain `FILE`.

Server restarts and log flushing do not cause a new general query log file to be generated (although flushing closes and reopens it). To rename the file and create a new one, use the following commands:

```
$> mv host_name.log host_name-old.log
$> mysqladmin flush-logs general
$> mv host_name-old.log backup-directory
```

On Windows, use `rename` rather than `mv`.

You can also rename the general query log file at runtime by disabling the log:

```
SET GLOBAL general_log = 'OFF';
```

With the log disabled, rename the log file externally (for example, from the command line). Then enable the log again:

```
SET GLOBAL general_log = 'ON';
```

This method works on any platform and does not require a server restart.

To disable or enable general query logging for the current session, set the session `sql_log_off` variable to `ON` or `OFF`. (This assumes that the general query log itself is enabled.)

Passwords in statements written to the general query log are rewritten by the server not to occur literally in plain text. Password rewriting can be suppressed for the general query log by starting the server with the `--log-raw` option. This option may be useful for diagnostic purposes, to see the exact text of statements as received by the server, but for security reasons is not recommended for production use. See also [Section 8.1.2.3, “Passwords and Logging”](#).

An implication of password rewriting is that statements that cannot be parsed (due, for example, to syntax errors) are not written to the general query log because they cannot be known to be password free. Use cases that require logging of all statements including those with errors should use the `--log-raw` option, bearing in mind that this also bypasses password rewriting.

Password rewriting occurs only when plain text passwords are expected. For statements with syntax that expect a password hash value, no rewriting occurs. If a plain text password is supplied erroneously for such syntax, the password is logged as given, without rewriting.

The `log_timestamps` system variable controls the time zone of timestamps in messages written to the general query log file (as well as to the slow query log file and the error log). It does not affect the time zone of general query log and slow query log messages written to log tables, but rows retrieved from those tables can be converted from the local system time zone to any desired time zone with `CONVERT_TZ()` or by setting the session `time_zone` system variable.

## 7.4.4 The Binary Log

The binary log contains “events” that describe database changes such as table creation operations or changes to table data. It also contains events for statements that potentially could have made changes (for example, a `DELETE` which matched no rows), unless row-based logging is used. The binary log also contains information about how long each statement took that updated data. The binary log has two important purposes:

- For replication, the binary log on a replication source server provides a record of the data changes to be sent to replicas. The source sends the information contained in its binary log to its replicas, which reproduce those transactions to make the same data changes that were made on the source. See [Section 19.2, “Replication Implementation”](#).
- Certain data recovery operations require use of the binary log. After a backup has been restored, the events in the binary log that were recorded after the backup was made are re-executed. These events bring databases up to date from the point of the backup. See [Section 9.5, “Point-in-Time \(Incremental\) Recovery”](#).

The binary log is not used for statements such as `SELECT` or `SHOW` that do not modify data. To log all statements (for example, to identify a problem query), use the general query log. See [Section 7.4.3, “The General Query Log”](#).

Running a server with binary logging enabled makes performance slightly slower. However, the benefits of the binary log in enabling you to set up replication and for restore operations generally outweigh this minor performance decrement.

The binary log is resilient to unexpected halts. Only complete events or transactions are logged or read back.

Passwords in statements written to the binary log are rewritten by the server not to occur literally in plain text. See also [Section 8.1.2.3, “Passwords and Logging”](#).

MySQL binary log files and relay log files can be encrypted, helping to protect these files and the potentially sensitive data contained in them from being misused by outside attackers, and also from unauthorized viewing by users of the operating system where they are stored. You enable encryption on

a MySQL server by setting the `binlog_encryption` system variable to `ON`. For more information, see [Section 19.3.2, “Encrypting Binary Log Files and Relay Log Files”](#).

The following discussion describes some of the server options and variables that affect the operation of binary logging. For a complete list, see [Section 19.1.6.4, “Binary Logging Options and Variables”](#).

Binary logging is enabled by default (the `log_bin` system variable is set to `ON`). The exception is if you use `mysqld` to initialize the data directory manually by invoking it with the `--initialize` or `--initialize-insecure` option, when binary logging is disabled by default, but can be enabled by specifying the `--log-bin` option.

To disable binary logging, you can specify the `--skip-log-bin` or `--disable-log-bin` option at startup. If either of these options is specified and `--log-bin` is also specified, the option specified later takes precedence.

The `--log-replica-updates` and `--replica-preserve-commit-order` options require binary logging. If you disable binary logging, either omit these options, or specify `--log-replica-updates=OFF` and `--skip-replica-preserve-commit-order`. MySQL disables these options by default when `--skip-log-bin` or `--disable-log-bin` is specified. If you specify `--log-replica-updates` or `--replica-preserve-commit-order` together with `--skip-log-bin` or `--disable-log-bin`, a warning or error message is issued.

The `--log-bin[=base_name]` option is used to specify the base name for binary log files. If you do not supply the `--log-bin` option, MySQL uses `binlog` as the default base name for the binary log files. For compatibility with earlier releases, if you supply the `--log-bin` option with no string or with an empty string, the base name defaults to `host_name-bin`, using the name of the host machine. It is recommended that you specify a base name, so that if the host name changes, you can easily continue to use the same binary log file names (see [Section B.3.7, “Known Issues in MySQL”](#)). If you supply an extension in the log name (for example, `--log-bin=base_name.extension`), the extension is silently removed and ignored.

`mysqld` appends a numeric extension to the binary log base name to generate binary log file names. The number increases each time the server creates a new log file, thus creating an ordered series of files. The server creates a new file in the series each time any of the following events occurs:

- The server is started or restarted
- The server flushes the logs.
- The size of the current log file reaches `max_binlog_size`.

A binary log file may become larger than `max_binlog_size` if you are using large transactions because a transaction is written to the file in one piece, never split between files.

To keep track of which binary log files have been used, `mysqld` also creates a binary log index file that contains the names of the binary log files. By default, this has the same base name as the binary log file, with the extension `'.index'`. You can change the name of the binary log index file with the `--log-bin-index[=file_name]` option. You should not manually edit this file while `mysqld` is running; doing so would confuse `mysqld`.

The term “binary log file” generally denotes an individual numbered file containing database events. The term “binary log” collectively denotes the set of numbered binary log files plus the index file.

The default location for binary log files and the binary log index file is the data directory. You can use the `--log-bin` option to specify an alternative location, by adding a leading absolute path name to the base name to specify a different directory. When the server reads an entry from the binary log index file, which tracks the binary log files that have been used, it checks whether the entry contains a relative path. If it does, the relative part of the path is replaced with the absolute path set using the `--log-bin` option.

An absolute path recorded in the binary log index file remains unchanged; in such a case, the index file must be edited manually to enable a new path or paths to be used. The binary log file base name and any specified path are available as the `log_bin_basename` system variable.

The server can be started with the default server ID when binary logging is enabled, but an informational message is issued if you do not specify a server ID explicitly using the `server_id` system variable. For servers that are used in a replication topology, you must specify a unique nonzero server ID for each server.

A client that has privileges sufficient to set restricted session system variables (see [Section 7.1.9.1, “System Variable Privileges”](#)) can disable binary logging of its own statements by using a `SET sql_log_bin=OFF` statement.

By default, the server logs the length of the event as well as the event itself and uses this to verify that the event was written correctly. You can also cause the server to write checksums for the events by setting the `binlog_checksum` system variable. When reading back from the binary log, the source uses the event length by default, but can be made to use checksums if available by enabling `source_verify_checksum`. The replication I/O (receiver) thread on the replica also verifies events received from the source. You can cause the replication SQL (applier) thread to use checksums if available when reading from the relay log by enabling `replica_sql_verify_checksum`.

The format of the events recorded in the binary log is dependent on the binary logging format. Three format types are supported: row-based logging, statement-based logging and mixed-base logging. The binary logging format used depends on the MySQL version. For descriptions of the logging formats, see [Section 7.4.4.1, “Binary Logging Formats”](#).

The server evaluates the `--binlog-do-db` and `--binlog-ignore-db` options in the same way as it does the `--replicate-do-db` and `--replicate-ignore-db` options. For information about how this is done, see [Section 19.2.5.1, “Evaluation of Database-Level Replication and Binary Logging Options”](#).

A replica is started with `log_replica_updates` enabled by default, meaning that the replica writes to its own binary log any data modifications that are received from the source. The binary log must be enabled for this setting to work (see [Section 19.1.6.3, “Replica Server Options and Variables”](#)). This setting enables the replica to act as a source to other replicas.

You can delete all binary log files with the `RESET BINARY LOGS AND GTIDS` statement, or a subset of them with `PURGE BINARY LOGS`. See [Section 15.7.8.6, “RESET Statement”](#), and [Section 15.4.1.1, “PURGE BINARY LOGS Statement”](#).

If you are using MySQL Replication, you should not delete old binary log files on the source until you are sure that no replica still needs to use them. For example, if your replicas never run more than three days behind, once a day you can execute `mysqladmin flush-logs binary` on the source and then remove any logs that are more than three days old. You can remove the files manually, but it is preferable to use `PURGE BINARY LOGS`, which also safely updates the binary log index file for you (and which can take a date argument). See [Section 15.4.1.1, “PURGE BINARY LOGS Statement”](#).

You can display the contents of binary log files with the `mysqlbinlog` utility. This can be useful when you want to reprocess statements in the log for a recovery operation. For example, you can update a MySQL server from the binary log as follows:

```
$> mysqlbinlog log_file | mysql -h server_name
```

`mysqlbinlog` also can be used to display the contents of the relay log file on a replica, because they are written using the same format as binary log files. For more information on the `mysqlbinlog` utility and how to use it, see [Section 6.6.9, “mysqlbinlog — Utility for Processing Binary Log Files”](#). For more information about the binary log and recovery operations, see [Section 9.5, “Point-in-Time \(Incremental\) Recovery”](#).

Binary logging is done immediately after a statement or transaction completes but before any locks are released or any commit is done. This ensures that the log is logged in commit order.

Updates to nontransactional tables are stored in the binary log immediately after execution.

Within an uncommitted transaction, all updates (`UPDATE`, `DELETE`, or `INSERT`) that change transactional tables such as InnoDB tables are cached until a `COMMIT` statement is received by the server. At that point, `mysqld` writes the entire transaction to the binary log before the `COMMIT` is executed.

Modifications to nontransactional tables cannot be rolled back. If a transaction that is rolled back includes modifications to nontransactional tables, the entire transaction is logged with a `ROLLBACK` statement at the end to ensure that the modifications to those tables are replicated.

When a thread that handles the transaction starts, it allocates a buffer of `binlog_cache_size` to buffer statements. If a statement is bigger than this, the thread opens a temporary file to store the transaction. The temporary file is deleted when the thread ends. If binary log encryption is active on the server, the temporary file is encrypted.

The `Binlog_cache_use` status variable shows the number of transactions that used this buffer (and possibly a temporary file) for storing statements. The `Binlog_cache_disk_use` status variable shows how many of those transactions actually had to use a temporary file. These two variables can be used for tuning `binlog_cache_size` to a large enough value that avoids the use of temporary files.

The `max_binlog_cache_size` system variable (default 4GB, which is also the maximum) can be used to restrict the total size used to cache a multiple-statement transaction. If a transaction is larger than this many bytes, it fails and rolls back. The minimum value is 4096.

If you are using the binary log and row based logging, concurrent inserts are converted to normal inserts for `CREATE ... SELECT` or `INSERT ... SELECT` statements. This is done to ensure that you can re-create an exact copy of your tables by applying the log during a backup operation. If you are using statement-based logging, the original statement is written to the log.

The binary log format has some known limitations that can affect recovery from backups. See [Section 19.5.1, “Replication Features and Issues”](#).

Binary logging for stored programs is done as described in [Section 27.8, “Stored Program Binary Logging”](#).

Note that the binary log format differs in MySQL 9.1 from previous versions of MySQL, due to enhancements in replication. See [Section 19.5.2, “Replication Compatibility Between MySQL Versions”](#).

If the server is unable to write to the binary log, flush binary log files, or synchronize the binary log to disk, the binary log on the replication source server can become inconsistent and replicas can lose synchronization with the source. The `binlog_error_action` system variable controls the action taken if an error of this type is encountered with the binary log.

- The default setting, `ABORT_SERVER`, makes the server halt binary logging and shut down. At this point, you can identify and correct the cause of the error. On restart, recovery proceeds as in the case of an unexpected server halt (see [Section 19.4.2, “Handling an Unexpected Halt of a Replica”](#)).
- The setting `IGNORE_ERROR` provides backward compatibility with older versions of MySQL. With this setting, the server continues the ongoing transaction and logs the error, then halts binary logging, but continues to perform updates. At this point, you can identify and correct the cause of the error. To resume binary logging, `log_bin` must be enabled again, which requires a server restart. Only use this option if you require backward compatibility, and the binary log is non-essential on this MySQL server instance. For example, you might use the binary log only for intermittent auditing or debugging of the server, and not use it for replication from the server or rely on it for point-in-time restore operations.

By default, the binary log is synchronized to disk at each write (`sync_binlog=1`). If `sync_binlog` was not enabled, and the operating system or machine (not only the MySQL server) crashed, there is a chance that the last statements of the binary log could be lost. To prevent this, enable the `sync_binlog` system variable to synchronize the binary log to disk after every *N* commit groups. See [Section 7.1.8, “Server System Variables”](#). The safest value for `sync_binlog` is 1 (the default), but this is also the slowest.

In earlier MySQL releases, there was a chance of inconsistency between the table content and binary log content if a crash occurred, even with `sync_binlog` set to 1. For example, if you are using `InnoDB` tables and the MySQL server processes a `COMMIT` statement, it writes many prepared transactions to the binary log in sequence, synchronizes the binary log, and then commits the transaction into `InnoDB`. If the server unexpectedly exited between those two operations, the transaction would be rolled back by `InnoDB` at restart but still exist in the binary log. Such an issue was resolved in previous releases by enabling `InnoDB` support for two-phase commit in XA transactions. In MySQL 9.1, `InnoDB` support for two-phase commit in XA transactions is always enabled.

`InnoDB` support for two-phase commit in XA transactions ensures that the binary log and `InnoDB` data files are synchronized. However, the MySQL server should also be configured to synchronize the binary log and the `InnoDB` logs to disk before committing the transaction. The `InnoDB` logs are synchronized by default, and `sync_binlog=1` ensures the binary log is synchronized. The effect of implicit `InnoDB` support for two-phase commit in XA transactions and `sync_binlog=1` is that at restart after a crash, after doing a rollback of transactions, the MySQL server scans the latest binary log file to collect transaction `xid` values and calculate the last valid position in the binary log file. The MySQL server then tells `InnoDB` to complete any prepared transactions that were successfully written to the to the binary log, and truncates the binary log to the last valid position. This ensures that the binary log reflects the exact data of `InnoDB` tables, and therefore the replica remains in synchrony with the source because it does not receive a statement which has been rolled back.

If the MySQL server discovers at crash recovery that the binary log is shorter than it should have been, it lacks at least one successfully committed `InnoDB` transaction. This should not happen if `sync_binlog=1` and the disk/file system do an actual sync when they are requested to (some do not), so the server prints an error message `The binary log file_name is shorter than its expected size`. In this case, this binary log is not correct and replication should be restarted from a fresh snapshot of the source's data.

The session values of the following system variables are written to the binary log and honored by the replica when parsing the binary log:

- `sql_mode` (except that the `NO_DIR_IN_CREATE` mode is not replicated; see [Section 19.5.1.40, “Replication and Variables”](#))
- `foreign_key_checks`
- `unique_checks`
- `character_set_client`
- `collation_connection`
- `collation_database`
- `collation_server`
- `sql_auto_is_null`

#### 7.4.4.1 Binary Logging Formats

The server uses several logging formats to record information in the binary log:

- Replication capabilities in MySQL originally were based on propagation of SQL statements from source to replica. This is called *statement-based logging*. You can cause this format to be used by starting the server with `--binlog-format=STATEMENT`.
- In *row-based logging* (the default), the source writes events to the binary log that indicate how individual table rows are affected. You can cause the server to use row-based logging by starting it with `--binlog-format=ROW`.
- A third option is also available: *mixed logging*. With mixed logging, statement-based logging is used by default, but the logging mode switches automatically to row-based in certain cases as described below. You can cause MySQL to use mixed logging explicitly by starting `mysqld` with the option `--binlog-format=MIXED`.

The logging format can also be set or limited by the storage engine being used. This helps to eliminate issues when replicating certain statements between a source and replica which are using different storage engines.

With statement-based replication, there may be issues with replicating nondeterministic statements. In deciding whether or not a given statement is safe for statement-based replication, MySQL determines whether it can guarantee that the statement can be replicated using statement-based logging. If MySQL cannot make this guarantee, it marks the statement as potentially unreliable and issues the warning, `Statement may not be safe to log in statement format`.

You can avoid these issues by using MySQL's row-based replication instead.

#### 7.4.4.2 Setting The Binary Log Format

You can select the binary logging format explicitly by starting the MySQL server with `--binlog-format=type`. The supported values for `type` are:

- `STATEMENT` causes logging to be statement based.
- `ROW` causes logging to be row based. This is the default.
- `MIXED` causes logging to use mixed format.

Setting the binary logging format does not activate binary logging for the server. The setting only takes effect when binary logging is enabled on the server, which is the case when the `log_bin` system variable is set to `ON`. In MySQL 9.1, binary logging is enabled by default, and is disabled only if you start the server with `--skip-log-bin` or `--disable-log-bin`.

The logging format also can be switched at runtime, although note that there are a number of situations in which you cannot do this, as discussed later in this section. Set the global value of the `binlog_format` system variable to specify the format for clients that connect subsequent to the change:

```
mysql> SET GLOBAL binlog_format = 'STATEMENT';
mysql> SET GLOBAL binlog_format = 'ROW';
mysql> SET GLOBAL binlog_format = 'MIXED';
```

An individual client can control the logging format for its own statements by setting the session value of `binlog_format`:

```
mysql> SET SESSION binlog_format = 'STATEMENT';
mysql> SET SESSION binlog_format = 'ROW';
mysql> SET SESSION binlog_format = 'MIXED';
```

Changing the global `binlog_format` value requires privileges sufficient to set global system variables. Changing the session `binlog_format` value requires privileges sufficient to set restricted session system variables. See [Section 7.1.9.1, “System Variable Privileges”](#).

There are several reasons why a client might want to set binary logging on a per-session basis:

- A session that makes many small changes to the database might want to use row-based logging.
- A session that performs updates that match many rows in the `WHERE` clause might want to use statement-based logging because it is more efficient to log a few statements than many rows.
- Some statements require a lot of execution time on the source, but result in just a few rows being modified. It might therefore be beneficial to replicate them using row-based logging.

There are exceptions when you cannot switch the replication format at runtime:

- The replication format cannot be changed from within a stored function or a trigger.
- If the `NDB` storage engine is enabled.
- If a session has open temporary tables, the replication format cannot be changed for the session (`SET @@SESSION.binlog_format`).
- If any replication channel has open temporary tables, the replication format cannot be changed globally (`SET @@GLOBAL.binlog_format` or `SET @@PERSIST.binlog_format`).
- If any replication channel applier thread is currently running, the replication format cannot be changed globally (`SET @@GLOBAL.binlog_format` or `SET @@PERSIST.binlog_format`).

Trying to switch the replication format in any of these cases (or attempting to set the current replication format) results in an error. You can, however, use `PERSIST_ONLY` (`SET @@PERSIST_ONLY.binlog_format`) to change the replication format at any time, because this action does not modify the runtime global system variable value, and takes effect only after a server restart.

Switching the replication format at runtime is not recommended when any temporary tables exist, because temporary tables are logged only when using statement-based replication, whereas with row-based replication and mixed replication, they are not logged.

Switching the replication format while replication is ongoing can also cause issues. Each MySQL Server can set its own and only its own binary logging format (true whether `binlog_format` is set with global or session scope). This means that changing the logging format on a replication source server does not cause a replica to change its logging format to match. When using `STATEMENT` mode, the `binlog_format` system variable is not replicated. When using `MIXED` or `ROW` logging mode, it is replicated but is ignored by the replica.

A replica is not able to convert binary log entries received in `ROW` logging format to `STATEMENT` format for use in its own binary log. The replica must therefore use `ROW` or `MIXED` format if the source does. Changing the binary logging format on the source from `STATEMENT` to `ROW` or `MIXED` while replication is ongoing to a replica with `STATEMENT` format can cause replication to fail with errors such as `Error executing row event: 'Cannot execute statement: impossible to write to binary log since statement is in row format and BINLOG_FORMAT = STATEMENT.'` Changing the binary logging format on the replica to `STATEMENT` format when the source is still using `MIXED` or `ROW` format also causes the same type of replication failure. To change the format safely, you must stop replication and ensure that the same change is made on both the source and the replica.

If you are using `InnoDB` tables and the transaction isolation level is `READ COMMITTED` or `READ UNCOMMITTED`, only row-based logging can be used. It is *possible* to change the logging format to `STATEMENT`, but doing so at runtime leads very rapidly to errors because `InnoDB` can no longer perform inserts.

With the binary log format set to `ROW`, many changes are written to the binary log using the row-based format. Some changes, however, still use the statement-based format. Examples include all DDL (data definition language) statements such as `CREATE TABLE`, `ALTER TABLE`, or `DROP TABLE`.

When row-based binary logging is used, the `binlog_row_event_max_size` system variable and its corresponding startup option `--binlog-row-event-max-size` set a soft limit on the maximum size of row events. The default value is 8192 bytes, and the value can only be changed at server startup. Where possible, rows stored in the binary log are grouped into events with a size not exceeding the value of this setting. If an event cannot be split, the maximum size can be exceeded.

The `--binlog-row-event-max-size` option is available for servers that are capable of row-based replication. Rows are stored into the binary log in chunks having a size in bytes not exceeding the value of this option. The value must be a multiple of 256. The default value is 8192.

#### Warning

When using *statement-based logging* for replication, it is possible for the data on the source and replica to become different if a statement is designed in such a way that the data modification is *nondeterministic*; that is, it is left up to the query optimizer. In general, this is not a good practice even outside of replication. For a detailed explanation of this issue, see [Section B.3.7, “Known Issues in MySQL”](#).

### 7.4.4.3 Mixed Binary Logging Format

When running in `MIXED` logging format, the server automatically switches from statement-based to row-based logging under the following conditions:

- When a function contains `UUID()`.
- When one or more tables with `AUTO_INCREMENT` columns are updated and a trigger or stored function is invoked. Like all other unsafe statements, this generates a warning if `binlog_format = STATEMENT`.

For more information, see [Section 19.5.1.1, “Replication and AUTO\\_INCREMENT”](#).

- When the body of a view requires row-based replication, the statement creating the view also uses it. For example, this occurs when the statement creating a view uses the `UUID()` function.
- When a call to a loadable function is involved.
- When `FOUND_ROWS()` or `ROW_COUNT()` is used. (Bug #12092, Bug #30244)
- When `USER()`, `CURRENT_USER()`, or `CURRENT_USER` is used. (Bug #28086)
- When one of the tables involved is a log table in the `mysql` database.
- When the `LOAD_FILE()` function is used. (Bug #39701)
- When a statement refers to one or more system variables. (Bug #31168)

**Exception.** The following system variables, when used with session scope (only), do not cause the logging format to switch:

- `auto_increment_increment`
- `auto_increment_offset`
- `character_set_client`
- `character_set_connection`
- `character_set_database`

- `character_set_server`
- `collation_connection`
- `collation_database`
- `collation_server`
- `foreign_key_checks`
- `identity`
- `last_insert_id`
- `lc_time_names`
- `pseudo_thread_id`
- `sql_auto_is_null`
- `time_zone`
- `timestamp`
- `unique_checks`

For information about determining system variable scope, see [Section 7.1.9, “Using System Variables”](#).

For information about how replication treats `sql_mode`, see [Section 19.5.1.40, “Replication and Variables”](#).

In releases prior to MySQL 8.0, when mixed binary logging format was in use, if a statement was logged by row and the session that executed the statement had any temporary tables, all subsequent statements were treated as unsafe and logged in row-based format until all temporary tables in use by that session were dropped. In MySQL 9.1, operations on temporary tables are not logged in mixed binary logging format, and the presence of temporary tables in the session has no impact on the logging mode used for each statement.

**Note**

A warning is generated if you try to execute a statement using statement-based logging that should be written using row-based logging. The warning is shown both in the client (in the output of `SHOW WARNINGS`) and through the `mysqld` error log. A warning is added to the `SHOW WARNINGS` table each time such a statement is executed. However, only the first statement that generated the warning for each client session is written to the error log to prevent flooding the log.

In addition to the decisions above, individual engines can also determine the logging format used when information in a table is updated. The logging capabilities of an individual engine can be defined as follows:

- If an engine supports row-based logging, the engine is said to be *row-logging capable*.
- If an engine supports statement-based logging, the engine is said to be *statement-logging capable*.

A given storage engine can support either or both logging formats. The following table lists the formats supported by each engine.

Storage Engine	Row Logging Supported	Statement Logging Supported
ARCHIVE	Yes	Yes
BLACKHOLE	Yes	Yes
CSV	Yes	Yes
EXAMPLE	Yes	No
FEDERATED	Yes	Yes
HEAP	Yes	Yes
InnoDB	Yes	Yes when the transaction isolation level is <a href="#">REPEATABLE READ</a> or <a href="#">SERIALIZABLE</a> ; No otherwise.
MyISAM	Yes	Yes
MERGE	Yes	Yes
NDB	Yes	No

Whether a statement is to be logged and the logging mode to be used is determined according to the type of statement (safe, unsafe, or binary injected), the binary logging format ([STATEMENT](#), [ROW](#), or [MIXED](#)), and the logging capabilities of the storage engine (statement capable, row capable, both, or neither). (Binary injection refers to logging a change that must be logged using [ROW](#) format.)

Statements may be logged with or without a warning; failed statements are not logged, but generate errors in the log. This is shown in the following decision table. **Type**, **binlog\_format**, **SLC**, and **RLC** columns outline the conditions, and **Error / Warning** and **Logged as** columns represent the corresponding actions. **SLC** stands for “statement-logging capable”, and **RLC** stands for “row-logging capable”.

Type	binlog_format	SLC	RLC	Error / Warning	Logged as
*	*	No	No	<a href="#">Error:</a> <a href="#">Cannot execute statement:</a> Binary logging is impossible since at least one engine is involved that is both row-incapable and statement-incapable.	-
Safe	<a href="#">STATEMENT</a>	Yes	No	-	<a href="#">STATEMENT</a>
Safe	<a href="#">MIXED</a>	Yes	No	-	<a href="#">STATEMENT</a>
Safe	<a href="#">ROW</a>	Yes	No	<a href="#">Error:</a> <a href="#">Cannot execute statement:</a> Binary logging is impossible since <a href="#">BINLOG_FORMAT</a> = <a href="#">ROW</a> and at least one table	-

Type	binlog_format	SLC	RLC	Error / Warning	Logged as
				uses a storage engine that is not capable of row-based logging.	
Unsafe	STATEMENT	Yes	No	Warning: Unsafe statement binlogged in statement format, since BINLOG_FORMAT = STATEMENT	STATEMENT
Unsafe	MIXED	Yes	No	Error: Cannot execute statement: Binary logging of an unsafe statement is impossible when the storage engine is limited to statement-based logging, even if BINLOG_FORMAT = MIXED.	-
Unsafe	ROW	Yes	No	Error: Cannot execute statement: Binary logging is impossible since BINLOG_FORMAT = ROW and at least one table uses a storage engine that is not capable of row-based logging.	-
Row Injection	STATEMENT	Yes	No	Error: Cannot execute row injection: Binary logging is not possible since at least one table uses a storage engine	-

Type	binlog_format	SLC	RLC	Error / Warning	Logged as
				that is not capable of row-based logging.	
Row Injection	MIXED	Yes	No	Error: Cannot execute row injection: Binary logging is not possible since at least one table uses a storage engine that is not capable of row-based logging.	-
Row Injection	ROW	Yes	No	Error: Cannot execute row injection: Binary logging is not possible since at least one table uses a storage engine that is not capable of row-based logging.	-
Safe	STATEMENT	No	Yes	Error: Cannot execute statement: Binary logging is impossible since BINLOG_FORMAT = STATEMENT and at least one table uses a storage engine that is not capable of statement-based logging.	-
Safe	MIXED	No	Yes	-	ROW
Safe	ROW	No	Yes	-	ROW
Unsafe	STATEMENT	No	Yes	Error: Cannot execute statement: Binary logging is impossible since	-

Row Injection	<code>MIXED</code>	Yes	Yes	-	<code>ROW</code>
Row Injection	<code>ROW</code>	Yes	Yes	-	<code>ROW</code>

When a warning is produced by the determination, a standard MySQL warning is produced (and is available using `SHOW WARNINGS`). The information is also written to the `mysqld` error log. Only one error for each error instance per client connection is logged to prevent flooding the log. The log message includes the SQL statement that was attempted.

If a replica has `log_error_verbosity` set to display warnings, the replica prints messages to the error log to provide information about its status, such as the binary log and relay log coordinates where it starts its job, when it is switching to another relay log, when it reconnects after a disconnect, statements that are unsafe for statement-based logging, and so forth.

#### 7.4.4.4 Logging Format for Changes to `mysql` Database Tables

The contents of the grant tables in the `mysql` database can be modified directly (for example, with `INSERT` or `DELETE`) or indirectly (for example, with `GRANT` or `CREATE USER`). Statements that affect `mysql` database tables are written to the binary log using the following rules:

- Data manipulation statements that change data in `mysql` database tables directly are logged according to the setting of the `binlog_format` system variable. This pertains to statements such as `INSERT`, `UPDATE`, `DELETE`, `REPLACE`, `DO`, `LOAD DATA`, `SELECT`, and `TRUNCATE TABLE`.
- Statements that change the `mysql` database indirectly are logged as statements regardless of the value of `binlog_format`. This pertains to statements such as `GRANT`, `REVOKE`, `SET PASSWORD`, `RENAME USER`, `CREATE` (all forms except `CREATE TABLE ... SELECT`), `ALTER` (all forms), and `DROP` (all forms).

`CREATE TABLE ... SELECT` is a combination of data definition and data manipulation. The `CREATE TABLE` part is logged using statement format and the `SELECT` part is logged according to the value of `binlog_format`.

#### 7.4.4.5 Binary Log Transaction Compression

MySQL supports binary log transaction compression; when this is enabled, transaction payloads are compressed using the `zstd` algorithm, and then written to the server's binary log file as a single event (a `Transaction_payload_event`).

Compressed transaction payloads remain in a compressed state while they are sent in the replication stream to replicas, other Group Replication group members, or clients such as `mysqlbinlog`. They are not decompressed by receiver threads, and are written to the relay log still in their compressed state. Binary log transaction compression therefore saves storage space both on the originator of the transaction and on the recipient (and for their backups), and saves network bandwidth when the transactions are sent between server instances.

Compressed transaction payloads are decompressed when the individual events contained in them need to be inspected. For example, the `Transaction_payload_event` is decompressed by an applier thread in order to apply the events it contains on the recipient. Decompression is also carried out during recovery, by `mysqlbinlog` when replaying transactions, and by the `SHOW BINLOG EVENTS` and `SHOW RELAYLOG EVENTS` statements.

You can enable binary log transaction compression on a MySQL server instance using the `binlog_transaction_compression` system variable, which defaults to `OFF`. You can also use the `binlog_transaction_compression_level_zstd` system variable to set the level for the `zstd` algorithm that is used for compression. This value determines the compression effort, from 1 (the lowest effort) to 22 (the highest effort). As the compression level increases, the compression ratio increases, which reduces the storage space and network bandwidth required for the transaction payload. However, the effort required for data compression also increases, taking time and CPU and memory resources on the originating server. Increases in the compression effort do not have a linear relationship to increases in the compression ratio.

Setting `binlog_transaction_compression` or `binlog_transaction_compression_level_zstd` (or both) has no immediate effect but rather applies to all subsequent `START REPLICA` statements.

#### Note

You can enable binary logging of compressed transactions for tables using the `NDB` storage engine at run time using the `ndb_log_transaction_compression` system variable, and control the level of compression using `ndb_log_transaction_compression_level_zstd`. Starting `mysqld` with `--binlog-transaction-compression` on the command line or in a `my.cnf` file causes `ndb_log_transaction_compression` to be enabled automatically and any setting for the `--ndb-log-transaction-compression` option to be ignored; to disable binary log transaction compression for the `NDB` storage engine *only*, set `ndb_log_transaction_compression=OFF` in a client session after starting `mysqld`.

The following types of event are excluded from binary log transaction compression, so are always written uncompressed to the binary log:

- Events relating to the GTID for the transaction (including anonymous GTID events).
- Other types of control event, such as view change events and heartbeat events.
- Incident events and the whole of any transactions that contain them.
- Non-transactional events and the whole of any transactions that contain them. A transaction involving a mix of non-transactional and transactional storage engines does not have its payload compressed.
- Events that are logged using statement-based binary logging. Binary log transaction compression is only applied for the row-based binary logging format.

Binary log encryption can be used on binary log files that contain compressed transactions.

### Behaviors When Binary Log Transaction Compression is Enabled

Transactions with payloads that are compressed can be rolled back like any other transaction, and they can also be filtered out on a replica by the usual filtering options. Binary log transaction compression can be applied to XA transactions.

When binary log transaction compression is enabled, the `max_allowed_packet` and `replica_max_allowed_packet` limits for the server still apply, and are measured on the compressed size of the `Transaction_payload_event`, plus the bytes used for the event header.

#### Important

Compressed transaction payloads are sent as a single packet, rather than each event of the transaction being sent in an individual packet, as is the case when binary log transaction compression is not in use. If your replication topology handles large transactions, be aware that a large transaction which can be replicated successfully when binary log transaction compression is not in use, might stop replication due to its size when binary log transaction compression is in use.

For multithreaded workers, each transaction (including its GTID event and `Transaction_payload_event`) is assigned to a worker thread. The worker thread decompresses the transaction payload and applies the individual events in it one by one. If an error is found applying any event within the `Transaction_payload_event`, the complete transaction is reported to the co-ordinator

as having failed. When `replica_parallel_type` or `replica_parallel_type` is set to `DATABASE`, all the databases affected by the transaction are mapped before the transaction is scheduled. The use of binary log transaction compression with the `DATABASE` policy can reduce parallelism compared to uncompressed transactions, which are mapped and scheduled for each event.

For semisynchronous replication (see [Section 19.4.10, “Semisynchronous Replication”](#)), the replica acknowledges the transaction when the complete `Transaction_payload_event` has been received.

When binary log checksums are enabled (which is the default), the replication source server does not write checksums for individual events in a compressed transaction payload. Instead, a checksum is written for the complete `Transaction_payload_event`, and individual checksums are written for any events that were not compressed, such as events relating to GTIDs.

For the `SHOW BINLOG EVENTS` and `SHOW RELAYLOG EVENTS` statements, the `Transaction_payload_event` is first printed as a single unit, then it is unpacked and each event inside it is printed.

For operations that reference the end position of an event, such as `START REPLICATION` with the `UNTIL` clause, `SOURCE_POS_WAIT()`, and `sql_replica_skip_counter`, you must specify the end position of the compressed transaction payload (the `Transaction_payload_event`). When skipping events using `sql_replica_skip_counter`, a compressed transaction payload is counted as a single counter value, so all the events inside it are skipped as a unit.

## Combining Compressed and Uncompressed Transaction Payloads

MySQL Server releases that support binary log transaction compression can handle a mix of compressed and uncompressed transaction payloads.

- The system variables relating to binary log transaction compression do not need to be set the same on all Group Replication group members, and are not replicated from sources to replicas in a replication topology. You can decide whether or not binary log transaction compression is appropriate for each MySQL Server instance that has a binary log.
- If transaction compression is enabled then disabled on a server, compression is not applied to future transactions originated on that server, but transaction payloads that have been compressed can still be handled and displayed.
- If transaction compression is specified for individual sessions by setting the session value of `binlog_transaction_compression`, the binary log can contain a mix of compressed and uncompressed transaction payloads.

When a source in a replication topology and its replica both have binary log transaction compression enabled, the replica receives compressed transaction payloads and writes them compressed to its relay log. It decompresses the transaction payloads to apply the transactions, and then compresses them again after applying for writing to its binary log. Any downstream replicas receive the compressed transaction payloads.

When a source in a replication topology has binary log transaction compression enabled but its replica does not, the replica receives compressed transaction payloads and writes them compressed to its relay log. It decompresses the transaction payloads to apply the transactions, and then writes them uncompressed to its own binary log, if it has one. Any downstream replicas receive the uncompressed transaction payloads.

When a source in a replication topology does not have binary log transaction compression enabled but its replica does, if the replica has a binary log, it compresses the transaction payloads after applying them, and writes the compressed transaction payloads to its binary log. Any downstream replicas receive the compressed transaction payloads.

When a MySQL server instance has no binary log, it can receive, handle, and display compressed transaction payloads regardless of its value for `binlog_transaction_compression`. Compressed transaction payloads received by such server instances are written in their compressed state to the relay log, so they benefit indirectly from compression that was carried out by other servers in the replication topology.

## Monitoring Binary Log Transaction Compression

You can monitor the effects of binary log transaction compression using the Performance Schema table `binary_log_transaction_compression_stats`. The statistics include the data compression ratio for the monitored period, and you can also view the effect of compression on the last transaction on the server. You can reset the statistics by truncating the table. Statistics for binary logs and relay logs are split out so you can see the impact of compression for each log type. The MySQL server instance must have a binary log to produce these statistics.

The Performance Schema table `events_stages_current` shows when a transaction is in the stage of decompression or compression for its transaction payload, and displays its progress for this stage. Compression is carried out by the worker thread handling the transaction, just before the transaction is committed, provided that there are no events in the finalized capture cache that exclude the transaction from binary log transaction compression (for example, incident events). When decompression is required, it is carried out for one event from the payload at a time.

`mysqlbinlog` with the `--verbose` option includes comments stating the compressed size and the uncompressed size for compressed transaction payloads, and the compression algorithm that was used.

You can enable connection compression at the protocol level for replication connections, using the `SOURCE_COMPRESSION_ALGORITHMS` and `SOURCE_ZSTD_COMPRESSION_LEVEL` options of the `CHANGE REPLICATION SOURCE TO` statement, or the `replica_compressed_protocol` system variable. If you enable binary log transaction compression in a system where connection compression is also enabled, the impact of connection compression is reduced, as there might be little opportunity to further compress the compressed transaction payloads. However, connection compression can still operate on uncompressed events and on message headers. Binary log transaction compression can be enabled in combination with connection compression if you need to save storage space as well as network bandwidth. For more information on connection compression for replication connections, see [Section 6.2.8, “Connection Compression Control”](#).

For Group Replication, compression is enabled by default for messages that exceed the threshold set by the `group_replication_compression_threshold` system variable. You can also configure compression for messages sent for distributed recovery by the method of state transfer from a donor's binary log, using the `group_replication_recovery_compression_algorithms` and `group_replication_recovery_zstd_compression_level` system variables. If you enable binary log transaction compression in a system where these are configured, Group Replication's message compression can still operate on uncompressed events and on message headers, but its impact is reduced. For more information on message compression for Group Replication, see [Section 20.7.4, “Message Compression”](#).

## 7.4.5 The Slow Query Log

The slow query log consists of SQL statements that take more than `long_query_time` seconds to execute and require at least `min_examined_row_limit` rows to be examined. The slow query log can be used to find queries that take a long time to execute and are therefore candidates for optimization. However, examining a long slow query log can be a time-consuming task. To make this easier, you can use the `mysqldumpslow` command to process a slow query log file and summarize its contents. See [Section 6.6.10, “mysqldumpslow — Summarize Slow Query Log Files”](#).

The time to acquire the initial locks is not counted as execution time. `mysqld` writes a statement to the slow query log after it has been executed and after all locks have been released, so log order might differ from execution order.

- [Slow Query Log Parameters](#)
- [Slow Query Log Contents](#)

## Slow Query Log Parameters

The minimum and default values of `long_query_time` are 0 and 10, respectively. The value can be specified to a resolution of microseconds.

By default, administrative statements are not logged, nor are queries that do not use indexes for lookups. This behavior can be changed using `log_slow_admin_statements` and `log_queries_not_using_indexes`, as described later.

By default, the slow query log is disabled. To specify the initial slow query log state explicitly, use `--slow_query_log[={0|1}]`. With no argument or an argument of 1, `--slow_query_log` enables the log. With an argument of 0, this option disables the log. To specify a log file name, use `--slow_query_log_file=file_name`. To specify the log destination, use the `log_output` system variable (as described in [Section 7.4.1, “Selecting General Query Log and Slow Query Log Output Destinations”](#)).

### Note

If you specify the `TABLE` log destination, see [Log Tables and “Too many open files” Errors](#).

If you specify no name for the slow query log file, the default name is `host_name-slow.log`. The server creates the file in the data directory unless an absolute path name is given to specify a different directory.

To disable or enable the slow query log or change the log file name at runtime, use the global `slow_query_log` and `slow_query_log_file` system variables. Set `slow_query_log` to 0 to disable the log or to 1 to enable it. Set `slow_query_log_file` to specify the name of the log file. If a log file already is open, it is closed and the new file is opened.

The server writes less information to the slow query log if you use the `--log-short-format` option.

To include slow administrative statements in the slow query log, enable the `log_slow_admin_statements` system variable. Administrative statements include `ALTER TABLE`, `ANALYZE TABLE`, `CHECK TABLE`, `CREATE INDEX`, `DROP INDEX`, `OPTIMIZE TABLE`, and `REPAIR TABLE`.

To include queries that do not use indexes for row lookups in the statements written to the slow query log, enable the `log_queries_not_using_indexes` system variable. (Even with that variable enabled, the server does not log queries that would not benefit from the presence of an index due to the table having fewer than two rows.)

When queries that do not use an index are logged, the slow query log may grow quickly. It is possible to put a rate limit on these queries by setting the `log_throttle_queries_not_using_indexes` system variable. By default, this variable is 0, which means there is no limit. Positive values impose a per-minute limit on logging of queries that do not use indexes. The first such query opens a 60-second window within which the server logs queries up to the given limit, then suppresses additional queries. If there are suppressed queries when the window ends, the server logs a summary that indicates how many there were and the aggregate time spent in them. The next 60-second window begins when the server logs the next query that does not use indexes.

The server uses the controlling parameters in the following order to determine whether to write a query to the slow query log:

1. The query must either not be an administrative statement, or `log_slow_admin_statements` must be enabled.
2. The query must have taken at least `long_query_time` seconds, or `log_queries_not_using_indexes` must be enabled and the query used no indexes for row lookups.
3. The query must have examined at least `min_examined_row_limit` rows.
4. The query must not be suppressed according to the `log_throttle_queries_not_using_indexes` setting.

The `log_timestamps` system variable controls the time zone of timestamps in messages written to the slow query log file (as well as to the general query log file and the error log). It does not affect the time zone of general query log and slow query log messages written to log tables, but rows retrieved from those tables can be converted from the local system time zone to any desired time zone with `CONVERT_TZ()` or by setting the session `time_zone` system variable.

By default, a replica does not write replicated queries to the slow query log. To change this, enable the `log_slow_replica_statements` system variable. Note that if row-based replication is in use (`binlog_format=ROW`), these system variables have no effect. Queries are only added to the replica's slow query log when they are logged in statement format in the binary log, that is, when `binlog_format=STATEMENT` is set, or when `binlog_format=MIXED` is set and the statement is logged in statement format. Slow queries that are logged in row format when `binlog_format=MIXED` is set, or that are logged when `binlog_format=ROW` is set, are not added to the replica's slow query log, even if `log_slow_replica_statements` is enabled.

## Slow Query Log Contents

When the slow query log is enabled, the server writes output to any destinations specified by the `log_output` system variable. If you enable the log, the server opens the log file and writes startup messages to it. However, further logging of queries to the file does not occur unless the `FILE` log destination is selected. If the destination is `NONE`, the server writes no queries even if the slow query log is enabled. Setting the log file name has no effect on logging if `FILE` is not selected as an output destination.

If the slow query log is enabled and `FILE` is selected as an output destination, each statement written to the log is preceded by a line that begins with a `#` character and has these fields (with all fields on a single line):

- `Query_time: duration`

The statement execution time in seconds.

- `Lock_time: duration`

The time to acquire locks in seconds.

- `Rows_sent: N`

The number of rows sent to the client.

- `Rows_examined:`

The number of rows examined by the server layer (not counting any processing internal to storage engines).

Enabling the `log_slow_extra` system variable causes the server to write the following extra fields to `FILE` output in addition to those just listed (`TABLE` output is unaffected). Some field descriptions refer to status variable names. Consult the status variable descriptions for more information. However, in the slow query log, the counters are per-statement values, not cumulative per-session values.

- `Thread_id: ID`

The statement thread identifier.

- `Errno: error_number`

The statement error number, or 0 if no error occurred.

- `Killed: N`

If the statement was terminated, the error number indicating why, or 0 if the statement terminated normally.

- `Bytes_received: N`

The `Bytes_received` value for the statement.

- `Bytes_sent: N`

The `Bytes_sent` value for the statement.

- `Read_first: N`

The `Handler_read_first` value for the statement.

- `Read_last: N`

The `Handler_read_last` value for the statement.

- `Read_key: N`

The `Handler_read_key` value for the statement.

- `Read_next: N`

The `Handler_read_next` value for the statement.

- `Read_prev: N`

The `Handler_read_prev` value for the statement.

- `Read_rnd: N`

The `Handler_read_rnd` value for the statement.

- `Read_rnd_next: N`

The `Handler_read_rnd_next` value for the statement.

- `Sort_merge_passes: N`

The `Sort_merge_passes` value for the statement.

- `Sort_range_count: N`

The `Sort_range` value for the statement.

- `Sort_rows: N`

The `Sort_rows` value for the statement.

- `Sort_scan_count: N`

The `Sort_scan` value for the statement.

- `Created_tmp_disk_tables: N`

The `Created_tmp_disk_tables` value for the statement.

- `Created_tmp_tables: N`

The `Created_tmp_tables` value for the statement.

- `Start: timestamp`

The statement execution start time.

- `End: timestamp`

The statement execution end time.

A given slow query log file may contain a mix of lines with and without the extra fields added by enabling `log_slow_extra`. Log file analyzers can determine whether a line contains the additional fields by the field count.

Each statement written to the slow query log file is preceded by a `SET` statement that includes a timestamp, which indicates when the slow statement began executing.

Passwords in statements written to the slow query log are rewritten by the server not to occur literally in plain text. See [Section 8.1.2.3, “Passwords and Logging”](#).

Statements that cannot be parsed (due, for example, to syntax errors) are not written to the slow query log.

## 7.4.6 Server Log Maintenance

As described in [Section 7.4, “MySQL Server Logs”](#), MySQL Server can create several different log files to help you see what activity is taking place. However, you must clean up these files regularly to ensure that the logs do not take up too much disk space.

When using MySQL with logging enabled, you may want to back up and remove old log files from time to time and tell MySQL to start logging to new files. See [Section 9.2, “Database Backup Methods”](#).

On a Linux (Red Hat) installation, you can use the `mysql-log-rotate` script for log maintenance. If you installed MySQL from an RPM distribution, this script should have been installed automatically. Be careful with this script if you are using the binary log for replication. You should not remove binary logs until you are certain that their contents have been processed by all replicas.

On other systems, you must install a short script yourself that you start from `cron` (or its equivalent) for handling log files.

Binary log files are automatically removed after the server's binary log expiration period. Removal of the files can take place at startup and when the binary log is flushed. The default binary log expiration period is 30 days. To specify an alternative expiration period, use the `binlog_expire_logs_seconds` system

variable. If you are using replication, you should specify an expiration period that is no lower than the maximum amount of time your replicas might lag behind the source. To remove binary logs on demand, use the `PURGE BINARY LOGS` statement (see [Section 15.4.1.1, “PURGE BINARY LOGS Statement”](#)).

To force MySQL to start using new log files, flush the logs. Log flushing occurs when you execute a `FLUSH LOGS` statement or a `mysqladmin flush-logs`, `mysqladmin refresh`, `mysqldump --flush-logs`, or `mysqldump --source-data` command. See [Section 15.7.8.3, “FLUSH Statement”](#), [Section 6.5.2, “mysqladmin — A MySQL Server Administration Program”](#), and [Section 6.5.4, “mysqldump — A Database Backup Program”](#). In addition, the server flushes the binary log automatically when current binary log file size reaches the value of the `max_binlog_size` system variable.

`FLUSH LOGS` supports optional modifiers to enable selective flushing of individual logs (for example, `FLUSH BINARY LOGS`). See [Section 15.7.8.3, “FLUSH Statement”](#).

A log-flushing operation has the following effects:

- If binary logging is enabled, the server closes the current binary log file and opens a new log file with the next sequence number.
- If general query logging or slow query logging to a log file is enabled, the server closes and reopens the log file.
- If the server was started with the `--log-error` option to cause the error log to be written to a file, the server closes and reopens the log file.

Execution of log-flushing statements or commands requires connecting to the server using an account that has the `RELOAD` privilege. On Unix and Unix-like systems, another way to flush the logs is to send a signal to the server, which can be done by `root` or the account that owns the server process. (See [Section 6.10, “Unix Signal Handling in MySQL”](#).) Signals enable log flushing to be performed without having to connect to the server:

- A `SIGHUP` signal flushes all the logs. However, `SIGHUP` has additional effects other than log flushing that might be undesirable.
- `SIGUSR1` causes the server to flush the error log, general query log, and slow query log. If you are interested in flushing only those logs, `SIGUSR1` can be used as a more “lightweight” signal that does not have the `SIGHUP` effects that are unrelated to logs.

As mentioned previously, flushing the binary log creates a new binary log file, whereas flushing the general query log, slow query log, or error log just closes and reopens the log file. For the latter logs, to cause a new log file to be created on Unix, rename the current log file first before flushing it. At flush time, the server opens the new log file with the original name. For example, if the general query log, slow query log, and error log files are named `mysql.log`, `mysql-slow.log`, and `err.log`, you can use a series of commands like this from the command line:

```
cd mysql-data-directory
mv mysql.log mysql.log.old
mv mysql-slow.log mysql-slow.log.old
mv err.log err.log.old
mysqladmin flush-logs
```

On Windows, use `rename` rather than `mv`.

At this point, you can make a backup of `mysql.log.old`, `mysql-slow.log.old`, and `err.log.old`, then remove them from disk.

To rename the general query log or slow query log at runtime, first connect to the server and disable the log:

```
SET GLOBAL general_log = 'OFF';
SET GLOBAL slow_query_log = 'OFF';
```

With the logs disabled, rename the log files externally (for example, from the command line). Then enable the logs again:

```
SET GLOBAL general_log = 'ON';
SET GLOBAL slow_query_log = 'ON';
```

This method works on any platform and does not require a server restart.

#### Note

For the server to recreate a given log file after you have renamed the file externally, the file location must be writable by the server. This may not always be the case. For example, on Linux, the server might write the error log as `/var/log/mysqld.log`, where `/var/log` is owned by `root` and not writable by `mysqld`. In this case, log-flushing operations fail to create a new log file.

To handle this situation, you must manually create the new log file with the proper ownership after renaming the original log file. For example, execute these commands as `root`:

```
mv /var/log/mysqld.log /var/log/mysqld.log.old
install -omysql -gmysql -m0644 /dev/null /var/log/mysqld.log
```

## 7.5 MySQL Components

MySQL Server includes a component-based infrastructure for extending server capabilities. A component provides services that are available to the server and other components. (With respect to service use, the server is a component, equal to other components.) Components interact with each other only through the services they provide.

MySQL distributions include several components that implement server extensions:

- Components for configuring error logging. See [Section 7.4.2, “The Error Log”](#), and [Section 7.5.3, “Error Log Components”](#).
- A component for checking passwords. See [Section 8.4.3, “The Password Validation Component”](#).
- Keyring components provide secure storage for sensitive information. See [Section 8.4.4, “The MySQL Keyring”](#).
- A component that enables applications to add their own message events to the audit log. See [Section 8.4.6, “The Audit Message Component”](#).
- A component that implements a loadable function for accessing query attributes. See [Section 11.6, “Query Attributes”](#).
- A component for scheduling actively executing tasks. See [Section 7.5.5, “Scheduler Component”](#).
- Components for use with MySQL Replication and MySQL Group Replication. See [Section 7.5.6, “Replication Components”](#).
- A component that enables creation and use of MySQL stored programs written in JavaScript. See [Section 7.5.7, “Multilingual Engine Component \(MLE\)”](#).

System and status variables implemented by a component are exposed when the component is installed and have names that begin with a component-specific prefix. For example, the `log_filter_dragnet`

error log filter component implements a system variable named `log_error_filter_rules`, the full name of which is `dragnet.log_error_filter_rules`. To refer to this variable, use the full name.

The following sections describe how to install and uninstall components, and how to determine at runtime which components are installed and obtain information about them.

For information about the internal implementation of components, see the MySQL Server Doxygen documentation, available at <https://dev.mysql.com/doc/index-other.html>. For example, if you intend to write your own components, this information is important for understanding how components work.

## 7.5.1 Installing and Uninstalling Components

Components must be loaded into the server before they can be used. MySQL supports manual component loading at runtime and automatic loading during server startup.

While a component is loaded, information about it is available as described in [Section 7.5.2, “Obtaining Component Information”](#).

The `INSTALL COMPONENT` and `UNINSTALL COMPONENT` SQL statements enable component loading and unloading. For example:

```
INSTALL COMPONENT 'file://component_validate_password';
UNINSTALL COMPONENT 'file://component_validate_password';
```

A loader service handles component loading and unloading, and also registers loaded components in the `mysql.component` system table.

The SQL statements for component manipulation affect server operation and the `mysql.component` system table as follows:

- `INSTALL COMPONENT` loads components into the server. The components become active immediately. The loader service also registers loaded components in the `mysql.component` system table. For subsequent server restarts, the loader service loads any components listed in `mysql.component` during the startup sequence. This occurs even if the server is started with the `--skip-grant-tables` option. The optional `SET` clause permits setting component system-variable values when you install components.
- `UNINSTALL COMPONENT` deactivates components and unloads them from the server. The loader service also unregisters the components from the `mysql.component` system table so that the server no longer loads them during its startup sequence for subsequent restarts.

Compared to the corresponding `INSTALL PLUGIN` statement for server plugins, the `INSTALL COMPONENT` statement for components offers the significant advantage that it is not necessary to know any platform-specific file name suffix for naming the component. This means that a given `INSTALL COMPONENT` statement can be executed uniformly across platforms.

A component when installed may also automatically install related loadable functions. If so, the component when uninstalled also automatically uninstalls those functions.

## 7.5.2 Obtaining Component Information

The `mysql.component` system table contains information about currently loaded components and shows which components have been registered using `INSTALL COMPONENT`. Selecting from the table shows which components are installed. For example:

```
mysql> SELECT * FROM mysql.component;
+-----+-----+-----+
| component_id | component_group_id | component_urn |
+-----+-----+-----+
```

1	1	file://component_validate_password
2	2	file://component_log_sink_json

The `component_id` and `component_group_id` values are for internal use. The `component_urn` is the URN used in `INSTALL COMPONENT` and `UNINSTALL COMPONENT` statements to load and unload the component.

### 7.5.3 Error Log Components

This section describes the characteristics of individual error log components. For general information about configuring error logging, see [Section 7.4.2, “The Error Log”](#).

A log component can be a filter or a sink:

- A filter processes log events, to add, remove, or modify event fields, or to delete events entirely. The resulting events pass to the next log component in the list of enabled components.
- A sink is a destination (writer) for log events. Typically, a sink processes log events into log messages that have a particular format and writes these messages to its associated output, such as a file or the system log. A sink may also write to the Performance Schema `error_log` table; see [Section 29.12.22.2, “The error\\_log Table”](#). Events pass unmodified to the next log component in the list of enabled components (that is, although a sink formats events to produce output messages, it does not modify events as they pass internally to the next component).

The `log_error_services` system variable lists the enabled log components. Components not named in the list are disabled. `log_error_services` also implicitly loads error log components if they are not already loaded. For more information, see [Section 7.4.2.1, “Error Log Configuration”](#).

The following sections describe individual log components, grouped by component type:

- [Filter Error Log Components](#)
- [Sink Error Log Components](#)

Component descriptions include these types of information:

- The component name and intended purpose.
- Whether the component is built in or must be loaded. For a loadable component, the description specifies the URN to use if explicitly loading or unloading the component with the `INSTALL COMPONENT` and `UNINSTALL COMPONENT` statements. Implicitly loading error log components requires only the component name. For more information, see [Section 7.4.2.1, “Error Log Configuration”](#).
- Whether the component can be listed multiple times in the `log_error_services` value.
- For a sink component, the destination to which the component writes output.
- For a sink component, whether it supports an interface to the Performance Schema `error_log` table.

#### Filter Error Log Components

Error log filter components implement filtering of error log events. If no filter component is enabled, no filtering occurs.

Any enabled filter component affects log events only for components listed later in the `log_error_services` value. In particular, for any log sink component listed in `log_error_services` earlier than any filter component, no log event filtering occurs.

#### The `log_filter_internal` Component

- Purpose: Implements filtering based on log event priority and error code, in combination with the `log_error_verbosity` and `log_error_suppression_list` system variables. See [Section 7.4.2.5, “Priority-Based Error Log Filtering \(log\\_filter\\_internal\)”](#).
- URN: This component is built in and need not be loaded.
- Multiple uses permitted: No.

If `log_filter_internal` is disabled, `log_error_verbosity` and `log_error_suppression_list` have no effect.

### The `log_filter_dragonet` Component

- Purpose: Implements filtering based on the rules defined by the `dragonet.log_error_filter_rules` system variable setting. See [Section 7.4.2.6, “Rule-Based Error Log Filtering \(log\\_filter\\_dragonet\)”](#).
- URN: `file://component_log_filter_dragonet`
- Multiple uses permitted: No.

## Sink Error Log Components

Error log sink components are writers that implement error log output. If no sink component is enabled, no log output occurs.

Some sink component descriptions refer to the default error log destination. This is the console or a file and is indicated by the value of the `log_error` system variable, determined as described in [Section 7.4.2.2, “Default Error Log Destination Configuration”](#).

### The `log_sink_internal` Component

- Purpose: Implements traditional error log message output format.
- URN: This component is built in and need not be loaded.
- Multiple uses permitted: No.
- Output destination: Writes to the default error log destination.
- Performance Schema support: Writes to the `error_log` table. Provides a parser for reading error log files created by previous server instances.

### The `log_sink_json` Component

- Purpose: Implements JSON-format error logging. See [Section 7.4.2.7, “Error Logging in JSON Format”](#).
- URN: `file://component_log_sink_json`
- Multiple uses permitted: Yes.
- Output destination: This sink determines its output destination based on the default error log destination, which is given by the `log_error` system variable:
  - If `log_error` names a file, the sink bases output file naming on that file name, plus a numbered `.NN.json` suffix, with `NN` starting at 00. For example, if `log_error` is `file_name`, successive instances of `log_sink_json` named in the `log_error_services` value write to `file_name.00.json`, `file_name.01.json`, and so forth.
  - If `log_error` is `stderr`, the sink writes to the console. If `log_sink_json` is named multiple times in the `log_error_services` value, they all write to the console, which is likely not useful.

- Performance Schema support: Writes to the `error_log` table. Provides a parser for reading error log files created by previous server instances.

### The `log_sink_syseventlog` Component

- Purpose: Implements error logging to the system log. This is the Event Log on Windows, and `syslog` on Unix and Unix-like systems. See [Section 7.4.2.8, “Error Logging to the System Log”](#).
- URN: `file://component_log_sink_syseventlog`
- Multiple uses permitted: No.
- Output destination: Writes to the system log. Does not use the default error log destination.
- Performance Schema support: Does not write to the `error_log` table. Does not provide a parser for reading error log files created by previous server instances.

### The `log_sink_test` Component

- Purpose: Intended for internal use in writing test cases, not for production use.
- URN: `file://component_log_sink_test`

Sink properties such as whether multiple uses are permitted and the output destination are not specified for `log_sink_test` because, as mentioned, it is for internal use. As such, its behavior is subject to change at any time.

## 7.5.4 Query Attribute Components

A component service provides access to query attributes (see [Section 11.6, “Query Attributes”](#)). The `query_attributes` component uses this service to provide access to query attributes within SQL statements.

- Purpose: Implements the `mysql_query_attribute_string()` function that takes an attribute name argument and returns the attribute value as a string, or `NULL` if the attribute does not exist.
- URN: `file://component_query_attributes`

Developers who wish to incorporate the same query-attribute component service used by `query_attributes` should consult the `mysql_query_attributes.h` file in a MySQL source distribution.

## 7.5.5 Scheduler Component

### Note

The `scheduler` component is included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see <https://www.mysql.com/products/>.

The `scheduler` component provides an implementation of the `mysql_scheduler` service that enables applications, components, or plugins to configure, run, and unconfigure tasks every *N* seconds. For example, the `audit_log` server plugin calls the `scheduler` component at its initialization and configures a regular, recurring flush of its memory cache (see [Enabling the Audit Log Flush Task](#)).

- Purpose: Implements the `component_scheduler.enabled` system variable that controls whether the scheduler is actively executing tasks. At startup, the `scheduler` component registers the `performance_schema.component_scheduler_tasks` table, which lists the currently scheduled tasks and some runtime data about each one.

- URN: `file://component_scheduler`

For installation instructions, see [Section 7.5.1, “Installing and Uninstalling Components”](#).

The `scheduler` component implements the service using these elements:

- A priority queue of the registered, inactive scheduled tasks sorted by the next time to run (in ascending order).
- A list of the registered, active tasks.
- A background thread that:
  - Sleeps if there are no tasks or if the top task needs more time to run. It wakes periodically to check whether it is time to end.
  - Compiles a list of the tasks that need to run, moves them from the inactive queue, adds them to the active queue, and executes each task individually.
  - After executing the task list, removes the tasks from the active list, adds them to the inactive list, and calculates the next time they need to run.

When a caller invokes the `mysql_scheduler.create()` service, it creates a new scheduled task instance to add to the queue, which signals the semaphore of the background thread. A handle to the new task is returned to the caller. The calling code should keep this handle and the service reference to the scheduling service until after calling the `mysql_scheduler.destroy()` service. When the caller invokes `destroy()` and passes in the handle it received from `create()`, the service waits for the task to become inactive (if running) and then removes it from the inactive queue.

The component service calls each application-provided callback (function pointer) into the same scheduler thread, one at a time and in ascending order, based on the time each requires to run.

Developers who wish to incorporate scheduler-queueing capabilities into an application, component, or plugin should consult the `mysql_scheduler.h` file in a MySQL source distribution.

## 7.5.6 Replication Components

The following sections contain information about components intended for use with MySQL Replication or Group Replication.

### 7.5.6.1 Replication Applier Metrics Component

The Replication Applier Metrics component implements two Performance Schema tables, listed here:

- `replication_applier_metrics`: Shows statistics for the replication applier, for a given replication channel.
- `replication_applier_progress_by_worker`: Shows statistics for the replication applier, for the worker with the given ID and channel name.
- Purpose: Provide replication applier statistics tables in the MySQL Performance Schema.
- URN: `file://component_replication_applier_metrics`

For installation instructions, see [Section 7.5.1, “Installing and Uninstalling Components”](#).

This component was added in MySQL 9.1.0, and is available only as part of MySQL Enterprise Edition.

### Important

The `replication_applier_metrics` component does not function when `replica_parallel_workers=0`.

## 7.5.6.2 Group Replication Flow Control Statistics Component

The Group Replication Flow Control Statistics component (`component_group_replication_flow_control_stats`) enables a number of global status variables which provide information on Group Replication flow control execution. This component is available in MySQL 9.1 and later as part of MySQL Enterprise Edition.

- Purpose: Support Group Replication global variables in addition to those normally present for measuring statistics relating to flow control execution.
- URN: `file://component_group_replication_flow_control_stats`

Prior to installing the Group Replication Flow Control Statistics component, the Group Replication plugin must be installed using `INSTALL PLUGIN` or `--plugin-load-add` (see [Section 20.2.1.2, “Configuring an Instance for Group Replication”](#)); otherwise, the `INSTALL COMPONENT` statement is rejected with the error `Cannot satisfy dependency for service 'group_replication_flow_control_metrics_service' required by component 'mysql:group_replication_flow_control_stats'`. If you attempt to uninstall the Group Replication plugin when the Group Replication Flow Control Statistics component is installed, `UNINSTALL PLUGIN` fails with the error `Plugin 'group_replication' cannot be uninstalled now. Please uninstall the component 'component_group_replication_flow_control_stats' and then UNINSTALL PLUGIN group_replication.`

Provided that these conditions are met, The Group Replication Flow Control Statistics component can be installed and uninstalled using `INSTALL COMPONENT` and `UNINSTALL COMPONENT`, respectively. See the descriptions of these statements, as well as [Section 7.5.1, “Installing and Uninstalling Components”](#), for more information.

The Group Replication Flow Control Statistics component provides the global status variables listed here with their meanings:

- `Gr_flow_control_throttle_active_count`: The number of transactions currently being throttled.
- `Gr_flow_control_throttle_count`: The number of transactions which have been throttled.
- `Gr_flow_control_throttle_last_throttle_timestamp`: The most recent date and time that a transaction was throttled.
- `Gr_flow_control_throttle_time_sum`: Time in microseconds that transactions have been throttled.

The values of these variables can be obtained by querying the Performance Schema `global_status` table, as shown here:

```
mysql> SELECT * FROM performance_schema.global_status
-> WHERE VARIABLE_NAME LIKE 'Gr_flow_control%';
```

VARIABLE_NAME	VARIABLE_VALUE
Gr_flow_control_throttle_active_count	10
Gr_flow_control_throttle_count	10
Gr_flow_control_throttle_last_throttle_timestamp	2024-07-01 12:50:56

Gr_flow_control_throttle_time_sum	10
-----------------------------------	----

You can also observe these values in the output of `SHOW GLOBAL STATUS`, like this:

```
mysql> SHOW GLOBAL STATUS LIKE 'Gr_flow_control%';
```

Variable_Name	Value
Gr_flow_control_throttle_active_count	10
Gr_flow_control_throttle_count	10
Gr_flow_control_throttle_last_throttle_timestamp	2024-07-01 12:50:56
Gr_flow_control_throttle_time_sum	10

All of the status variables listed previously are reset whenever any of the following events occurs:

- The server is restarted.
- The group is bootstrapped.
- A new member joins, or a member automatically rejoins.

Since they reflect what the local member observes, all of these status variables have member scope.

## 7.5.7 Multilingual Engine Component (MLE)

The Multilingual Engine component (MLE) provides support for languages other than SQL in MySQL stored procedures and functions. The MLE Component is available as part of MySQL Enterprise Edition.

With the MLE component in MySQL 9.1, you can create and execute MySQL stored programs written in JavaScript. For more information about these, see [Section 27.3, “JavaScript Stored Programs”](#). For general information about MySQL stored routines, see [Section 27.2, “Using Stored Routines”](#).

- Purpose: Provide support for languages other than SQL in stored functions and stored procedures. In MySQL 9.1, only JavaScript (ECMAScript) is supported by MLE.
- URN: `file://component_mle`

For installation instructions, see [Section 7.5.1, “Installing and Uninstalling Components”](#).

The MLE component is available on all platforms supported by MySQL Enterprise Edition, except for Solaris. See [Supported Platforms](#) for more information.

### Note

You should be aware that not all MySQL 9.1 installations support removal of the MLE component. If your installation supports it, you can remove the component using `UNINSTALL COMPONENT`. See [Section 7.5.1, “Installing and Uninstalling Components”](#), for information about how to do this.

For MySQL installations supporting the uninstallation of the MLE component, you should be aware that it is not possible to perform the uninstallation from within a user session that has created or executed any JavaScript stored procedures. For this reason, we recommend that you create and execute JavaScript stored procedures in a session separate from that used to install the MLE component; in this case it is possible, after exiting the session in which JavaScript stored procedures were created or used, to uninstall the component in a separate session.

### 7.5.7.1 MLE Component Option and Variable Reference

The following table lists all MySQL system variables and status variables supported by the ML component. Detailed descriptions of these variables can be found in the next two sections.

**Table 7.7 Multilingual Engine Component Variable Reference**

Name	Cmd-Line	Option File	System Var	Status Var	Var Scope	Dynamic
<a href="#">mle_heap_status</a>				Yes	Global	No
<a href="#">mle_languages_supported</a>				Yes	Global	No
<a href="#">mle_memory_used</a>				Yes	Global	No
<a href="#">mle_oom_errors</a>				Yes	Global	No
<a href="#">mle_session_resets</a>				Yes	Global	No
<a href="#">mle_sessions</a>				Yes	Global	No
<a href="#">mle_sessions_max</a>				Yes	Global	No
<a href="#">mle_status</a>				Yes	Global	No
<a href="#">mle_stored_functions</a>				Yes	Global	No
<a href="#">mle_stored_procedures</a>				Yes	Global	No
<a href="#">mle_stored_program_bytes_max</a>				Yes	Global	No
<a href="#">mle_stored_program_sql_max</a>				Yes	Global	No
<a href="#">mle_stored_programs</a>				Yes	Global	No
<a href="#">mle_threads</a>				Yes	Global	No
<a href="#">mle_threads_max</a>				Yes	Global	No
<a href="#">mle.memory_max</a>	Yes	Yes	Yes		Global	Yes

### MLE Component System Variables

This section provides a description of each system variable specific to the MLE component. For a summary table that lists all system variables supported by the MySQL server, see [Section 7.1.5, “Server System Variable Reference”](#). For general information regarding manipulation of system variables, see [Section 7.1.9, “Using System Variables”](#).

- [mle.memory\\_max](#)

Command-Line Format	<code>--mle.memory-max=value</code>
System Variable	<a href="#">mle.memory_max</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Platform Specific	Linux
Type	Integer
Default Value	<a href="#">1300M</a>
Minimum Value	<a href="#">320M</a>
Maximum Value	<a href="#">64G</a>
Unit	bytes

Determines the maximum amount of memory to allocate to the MLE component. This variable is dynamic, but can be set only when the component is inactive; you can determine whether this is the case by checking the value of the `mle_status` system status variable.

When increasing the value for this variable, you should be bear in mid that you must allow sufficient memory for other uses by the MySQL server such as buffer pools, connection memory, join buffers, and so on. In addition, there must be enough memory to allow system processes to operate correctly.

**Important**

Setting this value greater than the amount of memory available on the system causes undefined behavior.

For more information about memory usage by the MLE component, see [Section 7.5.7.3, “MLE Component Memory and Thread Usage”](#).

## MLE Component Status Variables

This section provides a description of each status variable supported by the MLE component. For a summary table that lists all status variables supported by the MySQL server, see [Section 7.1.6, “Server Status Variable Reference”](#). For information about status variables specific to NDB Cluster, see [Section 25.4.3.9.3, “NDB Cluster Status Variables”](#).

The status variables have the following meanings:

- `mle_languages_supported`

Lists the languages supported by the MLE component. In MySQL 9.1, this is always `JavaScript`.

Available only if the MLE component is installed. See [Section 7.5.7.2, “MLE Component Status and Session Information”](#), for more information.

- `mle_heap_status`

Current status of the heap used by the MLE component. The value is one of: `Not Allocated`, `Allocated`, or `Garbage Collection`. The heap is allocated only if the MLE component is active (that is, if `mle_status` is equal to `Active`).

Available only if the MLE component is installed. See [Section 7.5.7.3, “MLE Component Memory and Thread Usage”](#), for more information.

- `mle_memory_used`

Percentage of allocated memory used by the MLE component, rounded up to the nearest whole number.

Available only if the MLE component is installed. See [Section 7.5.7.3, “MLE Component Memory and Thread Usage”](#), for more information.

- `mle_oom_errors`

The total number of out-of-memory errors thrown by MLE stored programs, across all sessions.

Available only if the MLE component is installed. See [Section 7.5.7.3, “MLE Component Memory and Thread Usage”](#), for more information.

- `mle_session_resets`

The number of times MLE sessions have been cleared using the `mle_session_reset()` function.

Available only if the MLE component is installed. See [Section 7.5.7.2, “MLE Component Status and Session Information”](#), for more information.

- `mle_sessions`

Current number of active MLE sessions. An MLE session is created within a given MySQL user session once the MySQL user creates or executes a JavaScript stored program. It is dropped when the MySQL user calls `mle_session_reset()`, or when the MySQL session ends.

If the MySQL user calls `mle_session_reset()`, then later creates or executes a JavaScript stored program within the same MySQL user session, a new MLE session is created. There can be at most one MLE session per MySQL session.

Available only if the MLE component is installed. See [Section 7.5.7.2, “MLE Component Status and Session Information”](#), for more information.

- `mle_sessions_max`

Maximum number of MLE sessions active at any one time since the MLE component became active.

Available only if the MLE component is installed. See [Section 7.5.7.2, “MLE Component Status and Session Information”](#), for more information.

- `mle_status`

Current status of the MLE component. The value is one of: `Initializing`, `Inactive`, `Active`, or `Pending Shutdown`.

Available only if the MLE component is installed. See [Section 7.5.7.2, “MLE Component Status and Session Information”](#), for more information.

- `mle_stored_functions`

This is the number of MLE stored functions currently cached across all sessions.

Available only if the MLE component is installed. See [Section 7.5.7.4, “MLE Component Stored Program Usage”](#), for more information.

- `mle_stored_procedures`

The number of MLE stored procedures currently cached across all sessions.

Available only if the MLE component is installed. See [Section 7.5.7.4, “MLE Component Stored Program Usage”](#), for more information.

- `mle_stored_programs`

Returns the number of stored programs (stored procedures and stored functions) currently cached across all sessions. An MLE stored program is cached as soon it is executed for the first time, in each session in which it was executed. It is dropped from its session's cache when any of the following happens:

- The stored program is explicitly dropped.
- The MLE session is dropped (see the description of `mle_sessions`)

- An out-of-memory error is thrown in a current MLE session.

If the same stored program is executed again after being dropped from the cache, it is cached again as usual.

Available only if the MLE component is installed. See [Section 7.5.7.4, “MLE Component Stored Program Usage”](#), for more information.

- `mle_stored_program_bytes_max`

The size of the largest MLE stored program, in bytes. This value is equal to the size of the stored program's source text, expressed in bytes.

Available only if the MLE component is installed. See [Section 7.5.7.4, “MLE Component Stored Program Usage”](#), for more information.

- `mle_stored_program_sql_max`

The maximum number of SQL statements executed by any MLE stored program.

Available only if the MLE component is installed. See [Section 7.5.7.4, “MLE Component Stored Program Usage”](#), for more information.

- `mle_threads`

Returns the current number of physical threads attached to GraalVM. A physical thread, provided by the MySQL server's thread manager, is attached to GraalVM whenever it starts executing an operation inside GraalVM. Such operations include heap creation, code parsing, code execution, arguments conversion, memory usage queries, and deinitialization of stored programs. A thread is detached from GraalVM after it exits if the number of threads already attached exceeds the number of megabytes of heap allocated to Graal. The number of attached physical threads cannot exceed 1.5 times the number of megabytes of allocated Graal heap.

Available only if the MLE component is installed. See [Section 7.5.7.3, “MLE Component Memory and Thread Usage”](#), for more information.

- `mle_threads_max`

The maximum number of MLE threads active at any given time, since the MLE component last became active.

Available only if the MLE component is installed. See [Section 7.5.7.3, “MLE Component Memory and Thread Usage”](#), for more information.

## 7.5.7.2 MLE Component Status and Session Information

Once the MLE component is installed, you can obtain information about the component as shown here:

```
mysql> SHOW STATUS LIKE 'mle%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| mle_heap_status | Not Allocated |
| mle_languages_supported | JavaScript |
| mle_memory_used | 0 |
| mle_status | Inactive |
+-----+-----+
4 rows in set (0.01 sec)
```

As with other MySQL status variables, you can also access those shown here by selecting from the Performance Schema `global_status` table.

The MLE component's status is indicated by the `mle_status` status variable. This remains `Inactive` until a user creates or invokes a stored procedure or function using a language supported by MLE, at which time it becomes (very briefly) `Initializing` or (more usually) `Active`. It remains `Active` until the server is shutting down or restarting, at which the value is `Pending shutdown`.

You can obtain status information and console output from an MLE stored program using the loadable function `mle_session_state()` supplied by the MLE component. See the description of this function for more information.

`mle_languages_supported` shows a list of languages supported by this instance of the component; in MySQL 9.1, this is always `JavaScript`.

See [Section 7.5.7.3, “MLE Component Memory and Thread Usage”](#), for information about status variables relating to MLE component memory usage.

You can also obtain information about MLE sessions from system status variables. The `mle_sessions` status variable provides the number of active MLE sessions. `mle_sessions_max` displays the greatest number of MLE sessions simultaneously active at any one time since the MLE component became active. `mle_session_resets` shows the number of times the session state was cleared by calling `mle_session_reset()`. See the descriptions of these status variables for more information.

### 7.5.7.3 MLE Component Memory and Thread Usage

Memory allocation and usage information for the MLE component can be obtained by checking the values of the `mle_heap_status` and `mle_memory_used` status variables. Memory is not allocated until the component is activated by creating or executing a stored program that uses JavaScript. This means that, until the component is active, the value of `mle_heap_status` is `Not Allocated` and `mle_memory_used` is 0. When the component is active, `mle_heap_status` should be `Allocated`, and `mle_memory_used` should be an integer in the range of 0 to 100 inclusive; the latter variable indicates the memory used by the MLE component as a percentage of the amount allocated to it, rounded up to the nearest whole number. It is also possible for `mle_heap_status` to be `Garbage Collection`, should it become necessary to reclaim memory that is no longer being used.

By default, the amount of memory allocated to the MLE component is 64MB (67108864 bytes). You can adjust this by setting the `mle.memory_max` system variable up to a maximum of 8GB (8589934592 bytes); the minimum possible value is 32MB. When increasing this, you should keep in mind that sufficient memory must remain for other uses by the MySQL server, and for system processes to operate correctly.

Setting `mle.memory_max` to a value that is greater than the total amount of memory on the system causes undefined behavior.

#### Important

You can change the amount of memory allocated to the MLE component only when the component is inactive. To set the allocation to a non-default value at install time, use a statement such as `INSTALL COMPONENT 'file://component_mle' SET GLOBAL mle.memory_max = 1024*1024*512`, or set it after installing but before making any use of JavaScript stored programs.

You can obtain the number of out of memory errors that have been raised by MLE stored programs by checking the value of the `mle_oom_errors` status variable.

For information about threads used by the Multilingual Engine Component, you can consult the `mle_threads` status variable, which shows the current number of physical threads attached to GraalVM.

`mle_threads_max` shows the maximum number of simultaneous physical threads attached to GraalVM at any point in time since the component became active.

### 7.5.7.4 MLE Component Stored Program Usage

Several system status variables provide information about usage of MLE stored programs. The `mle_stored_procedures`, `mle_stored_functions`, and `mle_stored_programs` status variables show, respectively, the numbers of MLE stored procedures, MLE stored functions, and MLE stored programs which are presently cached, across all user sessions.

Additional MLE stored program metrics can be obtained from two status variables `mle_stored_program_bytes_max`, which provides the size, in bytes, of the largest current MLE stored program, and `mle_stored_program_sql_max` shows the maximum number of SQL statements executed by any MLE stored program.

## 7.5.8 Option Tracker Component

The Option Tracker component provides information about features of the MySQL server, as well as about MySQL components and plugins that are installed on the system:

- Purpose: Provide information about MySQL features. These may be integral to the MySQL server, and may also be implemented by components or plugins installed on the system.
- URN: `file://component_option_tracker`

#### Note

In this context, we refer to these features as “options”. These should not be confused with command-line options used with MySQL programs such as `mysqld` or the `mysql` client.

This component is available as part of MySQL Enterprise Edition, a commercial offering.

### 7.5.8.1 Option Tracker Tables

The Option Tracker supplies option information in the form of two tables, listed here:

- `performance_schema.mysql_option`: For each option implemented by a component or plugin installed on the system, this Performance Schema table shows the name of the option, the name or the component or plugin that provides the associated feature, and whether this feature is currently enabled. This table is installed by executing `INSTALL COMPONENT 'file://component_option_tracker'`.

This table, like other Performance Schema tables, is read-only, and thus cannot be updated or truncated by users.

See [Section 29.12.22.6, “The mysql\\_option Table”](#), for more detailed information about this table, such as columns and their possible values.

- `mysql_option.option_usage`: Shows, for each option installed, the name of the associated feature, feature usage data in `JSON` format, and other information. This table is installed by executing the SQL script `option_tracker_install.sql`, and uninstalled by executing `option_tracker_uninstall.sql`, both found in the MySQL `share` directory.

This table can be read and written to. Updating the `option_usage` table requires the `OPTION_TRACKER_UPDATER` privilege.

More detailed information about this table is given later in this section.

### Important

`INSTALL COMPONENT 'file://component_option_tracker'` installs the component library and the Performance Schema `mysql_option` table, but does *not* install the `mysql_option.option_usage` table, which requires executing the installation SQL script found in the MySQL Server `share` directory as described in the next few paragraphs.

To perform a complete installation of the Option Tracker component, execute the installation script from the system shell like this:

```
$> mysql -uusername -ppassword < path/to/option_tracker_install.sql
```

(You may need to use additional options, such as `-h`, for the `mysql` client when running the installation script in this way, depending on the circumstances.)

Alternatively, you can execute the script from within a MySQL client session using the `source` or `\.` command, as shown here:

```
mysql> source path/to/option_tracker_install.sql
mysql> \. path/to/option_tracker_install.sql
```

The path is relative to the directory in which the `mysql` client is run.

For more information, see [Section 6.5.1.5, “Executing SQL Statements from a Text File”](#).

The `mysql_option.option_usage` table provides usage information about options available in the MySQL Server, components, and plugins:

```
***** 1. row *****
CLUSTER_ID:
SERVER_ID:
OPTION_NAME: JavaScript Stored Program
USAGE_DATA: {"used": false, "usedDate": "2024-10-11T13:54:11Z"}
```

The `option_usage` table has the following columns:

- `CLUSTER_ID`

The UUID of the MySQL Group Replication cluster of which this server is part. Currently left empty.

- `SERVER_ID`

The server UUID if it is part of a MySQL Group Replication cluster . Currently left empty.

- `OPTION_NAME`

The unique name of the feature.

- `USAGE_DATA`

Option usage data in `JSON` format; the format is specific to a given option. This information is persists between server restarts, and may be present even though the corresponding option is not currently enabled (or even if it is not installed).

This table has a primary key on the `CLUSTER_ID`, `SERVER_ID`, and `OPTION_NAME` columns. The `OPTION_NAME` column value in this table for a given option is the same as the `OPTION_NAME` column value for the same feature in the `performance_schema.mysql_option` table. Thus, you can join the two tables in a manner similar to what is shown here:

```
mysql> SELECT * FROM performance_schema.mysql_option o
-> JOIN mysql_option.option_usage u
-> ON o.OPTION_NAME=u.OPTION_NAME\G
***** 1. row *****
OPTION_NAME: Enterprise AUDIT
OPTION_ENABLED: TRUE
OPTION_CONTAINER: audit_log plugin
CLUSTER_ID:
SERVER_ID:
OPTION_NAME: Enterprise AUDIT
USAGE_DATA: {"used": true, "usedDate": "2024-10-16T09:14:41Z"}
***** 2. row *****
OPTION_NAME: JavaScript Stored Program
OPTION_ENABLED: TRUE
OPTION_CONTAINER: component:mle
CLUSTER_ID:
SERVER_ID:
OPTION_NAME: JavaScript Stored Program
USAGE_DATA: {"used": false, "usedDate": "2024-10-15T13:40:03Z"}
```

Unlike the Performance Schema `mysql_option` table, the `option_usage` table is writeable and can be updated using SQL statements.

In Group Replication, option usage data originates on the primary. It is neither written to the binary log nor replicated, but it is propagated to secondaries using the Group Replication protocol. Individual replicas can write their own option usage data into this table. This includes read/write nodes in Group Replication clusters; read-only nodes cannot write to this table.

User accounts must be granted the necessary privileges to access this table.

### 7.5.8.2 Option Tracker Supported Components

To be shown in the `mysql_option.option_usage` and `mysql_option` tables, a component or plugin must be written and compiled with support for the Option Tracker. Components and plugins providing such support in MySQL 9.1 include those shown in the following table:

**Table 7.8 Components and Plugins with Option Tracker Support**

Name	Container	Enabled
MySQL Server	<code>mysqld</code> binary	always
Enterprise Encryption	<code>component_enterprise_encrypt</code>	always
Enterprise AUDIT	<code>audit_log</code> plugin	<code>audit_log_disable</code> = OFF
Enterprise Thread Pool	<code>thread_pool</code> plugin	always
Enterprise Firewall	<code>firewall</code> plugin	<code>mysql_firewall_mode</code> = ON
Enterprise Data Masking and Deidentification	<code>component_masking</code>	always
LDAP Simple authentication	<code>authentication_ldap_simple</code> plugin	always
SASL LDAP Authentication	<code>authentication_ldap_sasl</code> plugin	always
Kerberos authentication	<code>authentication_kerberos</code> plugin	always
PAM authentication	<code>authentication_pam</code> plugin	always
Windows authentication	<code>authentication_windows</code> plugin	always

Name	Container	Enabled
WebauthN authentication	<code>authentication_webauth</code> plugin	always
OCI Authentication	<code>authentication_oci</code> plugin	always
AWS keyring plugin	<code>keyring_aws</code> plugin	always
Encrypted File keyring	<code>component_keyring_encrypted</code>	always
File keyring	<code>component_keyring_file</code>	always
Hashicorp keyring	<code>keyring_hashicopr</code> plugin	always
Oracle Key Vault keyring	<code>keyring_okv</code> plugin	always
Password validation	<code>component_validate_password</code>	always
Connection DoS control	<code>connection_control</code> plugin	<code>connection_control_failed_connect</code> != 0
MySQL Telemetry	<code>component_telemetry</code>	always
Scheduler	<code>component_scheduler</code>	always
JavaScript Programs (MLE)	<code>component_mle</code>	always

### 7.5.8.3 Option Tracker Status Variables

The Option Tracker component supplies a number of status variables for MySQL Group Replication, which are described in this section.

**Table 7.9 Option Tracker Status Variable Summary**

Variable Name	Variable Type	Variable Scope
<code>option_tracker.gr_complete_table_received</code>	Integer	Global
<code>option_tracker.gr_complete_table_sent</code>	Integer	Global
<code>option_tracker.gr_error_received</code>	Integer	Global
<code>option_tracker.gr_error_sent</code>	Integer	Global
<code>option_tracker.gr_reset_request_received</code>	Integer	Global
<code>option_tracker.gr_reset_request_sent</code>	Integer	Global
<code>option_tracker.gr_single_row_received</code>	Integer	Global
<code>option_tracker.gr_single_row_sent</code>	Integer	Global

- `option_tracker.gr_complete_table_received`

This is the number of complete tables which have been received through Group Replication.

- `option_tracker.gr_complete_table_sent`

This is the number of complete tables which have been sent through Group Replication.

- `option_tracker.gr_error_received`

This is the number of errors which have been received through Group Replication.

- `option_tracker.gr_error_sent`

This is the number of errors which have been sent through Group Replication.

- `option_tracker.gr_reset_request_received`

This is the number of reset requests which have been received through Group Replication.

- `option_tracker.gr_reset_request_sent`

This is the number of reset requests which have been sent through Group Replication.

- `option_tracker.gr_single_row_received`

This is the number of single rows which have been received through Group Replication.

- `option_tracker.gr_single_row_sent`

This is the number of single rows which have been sent through Group Replication.

### 7.5.8.4 Option Tracker Functions

The Option Tracker provides the functions shown in the next table. More detailed information about each function is provided in the list following the table.

These functions provide safe interfaces for reading and updating the `mysql_option.option_usage` table (see [Section 7.5.8.1, “Option Tracker Tables”](#)) and `performance_schema.mysql_option` table; in addition, changes made using the functions are propagated to Group Replication secondaries whereas changes made using SQL are not. For these reasons, you should always use the Option Tracker functions for modifying option usage data instead of attempting to update either of these tables directly.

**Table 7.10 Option Tracker Functions**

Name	Description
<code>option_tracker_option_register()</code>	Register an option with the Option Tracker
<code>option_tracker_option_unregister()</code>	Deregister an option from the Option Tracker
<code>option_tracker_usage_get()</code>	Get usage data for an option registered with the Option Tracker
<code>option_tracker_usage_set()</code>	Set usage data for an option registered with the Option Tracker

- `option_tracker_option_register()`

This function registers the option with the supplied option name, container name and `enabled` value with the Option Tracker; that is, a row corresponding to this option is inserted into the Performance Schema `mysql_option` table.

Syntax:

```
int option_tracker_option_register(
 string option_name,
 string container_name
 int enabled
)
```

Arguments:

- `option_name`: The name of the option. This is a case-insensitive string. This argument cannot be null, although it can be an empty string.
- `container_name`: The name of the container. This argument is case-insensitive, and cannot be an empty string or null.

- `enabled`: 1 if the option is enabled, 0 if disabled.

Return value:

0 on success, a nonzero value otherwise. The nonzero value is usually 1, but this is not guaranteed.

Example:

```
mysql> SELECT option_tracker_option_register('Berry Picker', 'component_berry_picker', 0);
+-----+-----+-----+
| option_tracker_option_register('Berry Picker', 'component_berry_picker', 0) |
+-----+-----+-----+
| 0 |
+-----+-----+-----+
```

You can verify that the option was registered by querying the `mysql_option` table, like this:

```
mysql> SELECT * FROM performance_schema.mysql_option WHERE OPTION_NAME='Berry Picker';
+-----+-----+-----+
| OPTION_NAME | OPTION_ENABLED | OPTION_CONTAINER |
+-----+-----+-----+
| Berry Picker | FALSE | component_berry_picker |
+-----+-----+-----+
```

It is not required that the named container actually exist for this function to work.

The caller must have the `OPTION_TRACKER_UPDATER` privilege; this privilege must always be granted explicitly.

Successive calls to this function have no effect on the `mysql_option` table and return 1, indicating that the function call did not succeed; to change a given option's status from disabled to enabled, it is necessary to deregister it using `option_tracker_option_unregister()`, then to re-register it, like this:

```
mysql> SELECT option_tracker_option_register('Berry Picker', 'component_berry_picker', 0);
+-----+-----+-----+
| option_tracker_option_register('Berry Picker', 'component_berry_picker', 0) |
+-----+-----+-----+
| 0 |
+-----+-----+-----+

mysql> SELECT * FROM performance_schema.mysql_option WHERE OPTION_NAME='Berry Picker';
+-----+-----+-----+
| OPTION_NAME | OPTION_ENABLED | OPTION_CONTAINER |
+-----+-----+-----+
| Berry Picker | FALSE | component_berry_picker |
+-----+-----+-----+

mysql> SELECT option_tracker_option_register('Berry Picker', 'component_berry_picker', 1);
+-----+-----+-----+
| option_tracker_option_register('Berry Picker', 'component_berry_picker', 1) |
+-----+-----+-----+
| 1 |
+-----+-----+-----+

mysql> SELECT * FROM performance_schema.mysql_option WHERE OPTION_NAME='Berry Picker';
+-----+-----+-----+
| OPTION_NAME | OPTION_ENABLED | OPTION_CONTAINER |
+-----+-----+-----+
| Berry Picker | FALSE | component_berry_picker |
+-----+-----+-----+

mysql> SELECT option_tracker_option_unregister('Berry Picker');
```

```

+-----+
| option_tracker_option_unregister('Berry Picker') |
+-----+
| 0 |
+-----+

mysql> SELECT * FROM performance_schema.mysql_option WHERE OPTION_NAME='Berry Picker';
Empty set (0.00 sec)

mysql> SELECT option_tracker_option_register('Berry Picker', 'component_berry_picker', 1);
+-----+
| option_tracker_option_register('Berry Picker', 'component_berry_picker', 1) |
+-----+
| 0 |
+-----+

mysql> SELECT * FROM performance_schema.mysql_option WHERE OPTION_NAME='Berry Picker';
+-----+-----+-----+
| OPTION_NAME | OPTION_ENABLED | OPTION_CONTAINER |
+-----+-----+-----+
| Berry Picker | TRUE | component_berry_picker |
+-----+-----+-----+

```

Calls to this function do not update the `mysql_option.option_usage` table; to add or update usage information, use `option_tracker_usage_set()`.

- `option_tracker_option_unregister()`

This function deregisters an option that was previously registered; that is, it removes the corresponding row from the `mysql_option` table.

Syntax:

```

int option_tracker_option_unregister(
 string option_name
)

```

Arguments:

*option\_name*: The name of the option to be deregistered. This is a case-insensitive string, which cannot be null but can be an empty string.

Return value:

0 on success, a nonzero value otherwise. The nonzero value is usually 1, but this is not guaranteed.

Example:

```

mysql> SELECT * FROM performance_schema.mysql_option
-> WHERE OPTION_NAME='Berry Picker';
+-----+-----+-----+
| OPTION_NAME | OPTION_ENABLED | OPTION_CONTAINER |
+-----+-----+-----+
| Berry Picker | TRUE | component_berry_picker |
+-----+-----+-----+

mysql> SELECT option_tracker_option_unregister('Berry Picker');
+-----+
| option_tracker_option_unregister('berry picker') |
+-----+
| 0 |
+-----+

```

```
mysql> SELECT * FROM performance_schema.mysql_option
-> WHERE OPTION_NAME='Berry Picker';
Empty set (0.00 sec)
```

As noted previously, the option name is case-insensitive, as shown here:

```
mysql> SELECT * FROM performance_schema.mysql_option
-> WHERE OPTION_NAME='Berry Picker';
+-----+-----+-----+
| OPTION_NAME | OPTION_ENABLED | OPTION_CONTAINER |
+-----+-----+-----+
| Berry Picker | TRUE | component_berry_picker |
+-----+-----+-----+

mysql> SELECT option_tracker_option_unregister('berry picker');
+-----+-----+
| option_tracker_option_unregister('berry picker') |
+-----+-----+
| 0 |
+-----+-----+

mysql> SELECT * FROM performance_schema.mysql_option
-> WHERE OPTION_NAME='Berry Picker';
Empty set (0.00 sec)
```

`option_tracker_option_unregister()` returns a nonzero value indicating failure if no row corresponding to the option name is found in the `mysql_option` table.

- `option_tracker_usage_get()`

This function returns the same value as the following query:

```
mysql> SELECT USAGE_DATA FROM mysql_option.option_usage
-> WHERE OPTION_NAME='JavaScript Stored Program';
+-----+
| USAGE_DATA |
+-----+
| {"used": "false", "usedDate": "2024-10-17T20:24:41Z"} |
+-----+
```

Syntax:

```
string option_tracker_usage_get(
 option_name
)
```

Arguments:

`option_name`: A case-insensitive string.

Return value: A string in `JSON` format. See the description of the `option_tracker_usage_set()` function for more information about this value.

Example:

```
mysql> SELECT option_tracker_usage_get('Berry Picker');
+-----+
| option_tracker_usage_get('Berry Picker') |
+-----+
| {"used": true, "usedDate": "2024-10-16T09:14:41Z"} |
+-----+
```

- `option_tracker_usage_set()`

Sets usage data for the named option.

Syntax:

```
int option_tracker_usage_set(
 string option_name,
 string usage_data
)
```

Arguments:

- `option_name`: The option name, a case-insensitive string. This can be an empty string, but must not be null.
- `usage_data`: The usage data to record for the named option. This should be a JSON-formatted string, which usually takes the form shown here:

```
{
 "used": "boolean"
 "usedDate": "ISO8601 date"
}
```

The `used` key should be `true` if the option has been used during the current session, and `false` otherwise. `usedDate` should be a quoted date-and-time value in [ISO 8601 format](#), for example, `"2024-10-17T20:24:41Z"`. While this is not a requirement, it is normally expected that this is the current UTC date and time. You can obtain this value, using `UTC_DATE()` and `UTC_TIME()`, similarly to what is shown here (emphasized text):

```
SELECT option_tracker_option_set(
 'Berry Picker',
 CONCAT(UTC_DATE(), 'T', UTC_TIME(), 'Z')
);
```

The form of `usage_data` shown, with the keys `used` and `usedDate`, is the recommended one. It is possible to include other keys and values in the JSON string, but it is also possible that they may not be read, understood, or even allowed by other applications.

Return type:

An integer: 0 on success, and a nonzero value (usually 1) otherwise.

Example:

```
mysql> SELECT option_tracker_usage_set(
-> 'Berry Picker', '{"used": true, "usedDate": "2024-10-17T20:38:23Z"}');
+-----+-----+
| option_tracker_usage_set('Berry Picker', '{"used": true, "usedDate": "2024-10-17T20:38:23Z"}') |
+-----+-----+
| 0 |
+-----+-----+

mysql> SELECT option_tracker_usage_get('Berry Picker');
+-----+-----+
| option_tracker_usage_get('Berry Picker') |
+-----+-----+
| {"used": true, "usedDate": "2024-10-17T20:38:23Z"} |
+-----+-----+
```

Each of these functions requires that the user calling the function be granted the `OPTION_TRACKER_UPDATER` privilege explicitly. This is true even for the MySQL `root` user.

## 7.6 MySQL Server Plugins

MySQL supports an plugin API that enables creation of server plugins. Plugins can be loaded at server startup, or loaded and unloaded at runtime without restarting the server. The plugins supported by this interface include, but are not limited to, storage engines, `INFORMATION_SCHEMA` tables, full-text parser plugins, and server extensions.

MySQL distributions include several plugins that implement server extensions:

- Plugins for authenticating attempts by clients to connect to MySQL Server. Plugins are available for several authentication protocols. See [Section 8.2.17, “Pluggable Authentication”](#).
- A connection-control plugin that enables administrators to introduce an increasing delay after a certain number of consecutive failed client connection attempts. See [Section 8.4.2, “The Connection-Control Plugins”](#).
- A password-validation plugin implements password strength policies and assesses the strength of potential passwords. See [Section 8.4.3, “The Password Validation Component”](#).
- Semisynchronous replication plugins implement an interface to replication capabilities that permit the source to proceed as long as at least one replica has responded to each transaction. See [Section 19.4.10, “Semisynchronous Replication”](#).
- Group Replication enables you to create a highly available distributed MySQL service across a group of MySQL server instances, with data consistency, conflict detection and resolution, and group membership services all built-in. See [Chapter 20, Group Replication](#).
- MySQL Enterprise Edition includes a thread pool plugin that manages connection threads to increase server performance by efficiently managing statement execution threads for large numbers of client connections. See [Section 7.6.3, “MySQL Enterprise Thread Pool”](#).
- MySQL Enterprise Edition includes an audit plugin for monitoring and logging of connection and query activity. See [Section 8.4.5, “MySQL Enterprise Audit”](#).
- MySQL Enterprise Edition includes a firewall plugin that implements an application-level firewall to enable database administrators to permit or deny SQL statement execution based on matching against allowlists of accepted statement patterns. See [Section 8.4.7, “MySQL Enterprise Firewall”](#).
- Query rewrite plugins examine statements received by MySQL Server and possibly rewrite them before the server executes them. See [Section 7.6.4, “The Rewriter Query Rewrite Plugin”](#), and [Section 7.6.5, “The ddl\\_rewriter Plugin”](#).
- Version Tokens enables creation of and synchronization around server tokens that applications can use to prevent accessing incorrect or out-of-date data. Version Tokens is based on a plugin library that implements a `version_tokens` plugin and a set of loadable functions. See [Section 7.6.6, “Version Tokens”](#).
- Keyring plugins provide secure storage for sensitive information. See [Section 8.4.4, “The MySQL Keyring”](#).
- X Plugin extends MySQL Server to be able to function as a document store. Running X Plugin enables MySQL Server to communicate with clients using the X Protocol, which is designed to expose the ACID compliant storage abilities of MySQL as a document store. See [Section 22.5, “X Plugin”](#).

- Clone permits cloning [InnoDB](#) data from a local or remote MySQL server instance. See [Section 7.6.7](#), “The Clone Plugin”.
- Test framework plugins test server services. For information about these plugins, see the Plugins for Testing Plugin Services section of the MySQL Server Doxygen documentation, available at <https://dev.mysql.com/doc/index-other.html>.

The following sections describe how to install and uninstall plugins, and how to determine at runtime which plugins are installed and obtain information about them. For information about writing plugins, see [The MySQL Plugin API](#).

## 7.6.1 Installing and Uninstalling Plugins

Server plugins must be loaded into the server before they can be used. MySQL supports plugin loading at server startup and runtime. It is also possible to control the activation state of loaded plugins at startup, and to unload them at runtime.

While a plugin is loaded, information about it is available as described in [Section 7.6.2](#), “Obtaining Server Plugin Information”.

- [Installing Plugins](#)
- [Controlling Plugin Activation State](#)
- [Uninstalling Plugins](#)
- [Plugins and Loadable Functions](#)

### Installing Plugins

Before a server plugin can be used, it must be installed using one of the following methods. In the descriptions, *plugin\_name* stands for a plugin name such as [innodb](#), [csv](#), or [validate\\_password](#).

- [Built-in Plugins](#)
- [Plugins Registered in the mysql.plugin System Table](#)
- [Plugins Named with Command-Line Options](#)
- [Plugins Installed with the INSTALL PLUGIN Statement](#)

### Built-in Plugins

A built-in plugin is known by the server automatically. By default, the server enables the plugin at startup. Some built-in plugins permit this to be changed with the `--plugin_name[=activation_state]` option.

### Plugins Registered in the mysql.plugin System Table

The `mysql.plugin` system table serves as a registry of plugins (other than built-in plugins, which need not be registered). During the normal startup sequence, the server loads plugins registered in the table. By default, for a plugin loaded from the `mysql.plugin` table, the server also enables the plugin. This can be changed with the `--plugin_name[=activation_state]` option.

If the server is started with the `--skip-grant-tables` option, plugins registered in the `mysql.plugin` table are not loaded and are unavailable.

## Plugins Named with Command-Line Options

A plugin located in a plugin library file can be loaded at server startup with the `--plugin-load`, `--plugin-load-add`, or `--early-plugin-load` option. Normally, for a plugin loaded at startup, the server also enables the plugin. This can be changed with the `--plugin_name[=activation_state]` option.

The `--plugin-load` and `--plugin-load-add` options load plugins after built-in plugins and storage engines have initialized during the server startup sequence. The `--early-plugin-load` option is used to load plugins that must be available prior to initialization of built-in plugins and storage engines.

The value of each plugin-loading option is a semicolon-separated list of `plugin_library` and `name=plugin_library` values. Each `plugin_library` is the name of a library file that contains plugin code, and each `name` is the name of a plugin to load. If a plugin library is named without any preceding plugin name, the server loads all plugins in the library. With a preceding plugin name, the server loads only the named plugin from the library. The server looks for plugin library files in the directory named by the `plugin_dir` system variable.

Plugin-loading options do not register any plugin in the `mysql.plugin` table. For subsequent restarts, the server loads the plugin again only if `--plugin-load`, `--plugin-load-add`, or `--early-plugin-load` is given again. That is, the option produces a one-time plugin-installation operation that persists for a single server invocation.

`--plugin-load`, `--plugin-load-add`, and `--early-plugin-load` enable plugins to be loaded even when `--skip-grant-tables` is given (which causes the server to ignore the `mysql.plugin` table). `--plugin-load`, `--plugin-load-add`, and `--early-plugin-load` also enable plugins to be loaded at startup that cannot be loaded at runtime.

The `--plugin-load-add` option complements the `--plugin-load` option:

- Each instance of `--plugin-load` resets the set of plugins to load at startup, whereas `--plugin-load-add` adds a plugin or plugins to the set of plugins to be loaded without resetting the current set. Consequently, if multiple instances of `--plugin-load` are specified, only the last one applies. With multiple instances of `--plugin-load-add`, all of them apply.
- The argument format is the same as for `--plugin-load`, but multiple instances of `--plugin-load-add` can be used to avoid specifying a large set of plugins as a single long unwieldy `--plugin-load` argument.
- `--plugin-load-add` can be given in the absence of `--plugin-load`, but any instance of `--plugin-load-add` that appears before `--plugin-load` has no effect because `--plugin-load` resets the set of plugins to load.

For example, these options:

```
--plugin-load=x --plugin-load-add=y
```

are equivalent to these options:

```
--plugin-load-add=x --plugin-load-add=y
```

and are also equivalent to this option:

```
--plugin-load="x;y"
```

But these options:

```
--plugin-load-add=y --plugin-load=x
```

are equivalent to this option:

```
--plugin-load=x
```

## Plugins Installed with the `INSTALL PLUGIN` Statement

A plugin located in a plugin library file can be loaded at runtime with the `INSTALL PLUGIN` statement. The statement also registers the plugin in the `mysql.plugin` table to cause the server to load it on subsequent restarts. For this reason, `INSTALL PLUGIN` requires the `INSERT` privilege for the `mysql.plugin` table.

The plugin library file base name depends on your platform. Common suffixes are `.so` for Unix and Unix-like systems, `.dll` for Windows.

Example: The `--plugin-load-add` option installs a plugin at server startup. To install a plugin named `myplugin` from a plugin library file named `somepluglib.so`, use these lines in a `my.cnf` file:

```
[mysqld]
plugin-load-add=myplugin=somepluglib.so
```

In this case, the plugin is not registered in `mysql.plugin`. Restarting the server without the `--plugin-load-add` option causes the plugin not to be loaded at startup.

Alternatively, the `INSTALL PLUGIN` statement causes the server to load the plugin code from the library file at runtime:

```
INSTALL PLUGIN myplugin SONAME 'somepluglib.so';
```

`INSTALL PLUGIN` also causes “permanent” plugin registration: The plugin is listed in the `mysql.plugin` table to ensure that the server loads it on subsequent restarts.

Many plugins can be loaded either at server startup or at runtime. However, if a plugin is designed such that it must be loaded and initialized during server startup, attempts to load it at runtime using `INSTALL PLUGIN` produce an error:

```
mysql> INSTALL PLUGIN myplugin SONAME 'somepluglib.so';
ERROR 1721 (HY000): Plugin 'myplugin' is marked as not dynamically
installable. You have to stop the server to install it.
```

In this case, you must use `--plugin-load`, `--plugin-load-add`, or `--early-plugin-load`.

If a plugin is named both using a `--plugin-load`, `--plugin-load-add`, or `--early-plugin-load` option and (as a result of an earlier `INSTALL PLUGIN` statement) in the `mysql.plugin` table, the server starts but writes these messages to the error log:

```
[ERROR] Function 'plugin_name' already exists
[Warning] Couldn't load plugin named 'plugin_name'
with soname 'plugin_object_file'.
```

## Controlling Plugin Activation State

If the server knows about a plugin when it starts (for example, because the plugin is named using a `--plugin-load-add` option or is registered in the `mysql.plugin` table), the server loads and enables the plugin by default. It is possible to control activation state for such a plugin using a `--plugin_name[=activation_state]` startup option, where *plugin\_name* is the name of the plugin to affect, such as `innodb`, `csv`, or `validate_password`. As with other options, dashes and underscores are interchangeable in option names. Also, activation state values are not case-sensitive. For example, `--my_plugin=ON` and `--my-plugin=on` are equivalent.

- `--plugin_name=OFF`

Tells the server to disable the plugin.

- `--plugin_name [=ON]`

Tells the server to enable the plugin. (Specifying the option as `--plugin_name` without a value has the same effect.) If the plugin fails to initialize, the server runs with the plugin disabled.

- `--plugin_name=FORCE`

Tells the server to enable the plugin, but if plugin initialization fails, the server does not start. In other words, this option forces the server to run with the plugin enabled or not at all.

- `--plugin_name=FORCE_PLUS_PERMANENT`

Like `FORCE`, but in addition prevents the plugin from being unloaded at runtime. If a user attempts to do so with `UNINSTALL PLUGIN`, an error occurs.

Plugin activation states are visible in the `LOAD_OPTION` column of the Information Schema `PLUGINS` table.

Suppose that `CSV`, `BLACKHOLE`, and `ARCHIVE` are built-in pluggable storage engines and that you want the server to load them at startup, subject to these conditions: The server is permitted to run if `CSV` initialization fails, must require that `BLACKHOLE` initialization succeeds, and should disable `ARCHIVE`. To accomplish that, use these lines in an option file:

```
[mysqld]
csv=ON
blackhole=FORCE
archive=OFF
```

The `--enable-plugin_name` option format is a synonym for `--plugin_name=ON`. The `--disable-plugin_name` and `--skip-plugin_name` option formats are synonyms for `--plugin_name=OFF`.

If a plugin is disabled, either explicitly with `OFF` or implicitly because it was enabled with `ON` but fails to initialize, aspects of server operation requiring the plugin change. For example, if the plugin implements a storage engine, existing tables for the storage engine become inaccessible, and attempts to create new tables for the storage engine result in tables that use the default storage engine unless the `NO_ENGINE_SUBSTITUTION` SQL mode is enabled to cause an error to occur instead.

Disabling a plugin may require adjustment to other options.

## Uninstalling Plugins

At runtime, the `UNINSTALL PLUGIN` statement disables and uninstalls a plugin known to the server. The statement unloads the plugin and removes it from the `mysql.plugin` system table, if it is registered there. For this reason, `UNINSTALL PLUGIN` statement requires the `DELETE` privilege for the `mysql.plugin` table. With the plugin no longer registered in the table, the server does not load the plugin during subsequent restarts.

`UNINSTALL PLUGIN` can unload a plugin regardless of whether it was loaded at runtime with `INSTALL PLUGIN` or at startup with a plugin-loading option, subject to these conditions:

- It cannot unload plugins that are built in to the server. These can be identified as those that have a library name of `NULL` in the output from the Information Schema `PLUGINS` table or `SHOW PLUGINS`.
- It cannot unload plugins for which the server was started with `--plugin_name=FORCE_PLUS_PERMANENT`, which prevents plugin unloading at runtime. These can be identified from the `LOAD_OPTION` column of the `PLUGINS` table.

To uninstall a plugin that currently is loaded at server startup with a plugin-loading option, use this procedure.

1. Remove from the `my.cnf` file any options and system variables related to the plugin. If any plugin system variables were persisted to the `mysqld-auto.cnf` file, remove them using `RESET PERSIST var_name` for each one to remove it.
2. Restart the server.
3. Plugins normally are installed using either a plugin-loading option at startup or with `INSTALL PLUGIN` at runtime, but not both. However, removing options for a plugin from the `my.cnf` file may not be sufficient to uninstall it if at some point `INSTALL PLUGIN` has also been used. If the plugin still appears in the output from `PLUGINS` or `SHOW PLUGINS`, use `UNINSTALL PLUGIN` to remove it from the `mysql.plugin` table. Then restart the server again.

## Plugins and Loadable Functions

A plugin when installed may also automatically install related loadable functions. If so, the plugin when uninstalled also automatically uninstalls those functions.

### 7.6.2 Obtaining Server Plugin Information

There are several ways to determine which plugins are installed in the server:

- The Information Schema `PLUGINS` table contains a row for each loaded plugin. Any that have a `PLUGIN_LIBRARY` value of `NULL` are built in and cannot be unloaded.

```
mysql> TABLE INFORMATION_SCHEMA.PLUGINS\G
***** 1. row *****
 PLUGIN_NAME: binlog
 PLUGIN_VERSION: 1.0
 PLUGIN_STATUS: ACTIVE
 PLUGIN_TYPE: STORAGE ENGINE
 PLUGIN_TYPE_VERSION: 90100.0
 PLUGIN_LIBRARY: NULL
 PLUGIN_LIBRARY_VERSION: NULL
 PLUGIN_AUTHOR: Oracle Corporation
 PLUGIN_DESCRIPTION: This is a pseudo storage engine to represent the binlog in a transaction
 PLUGIN_LICENSE: GPL
 LOAD_OPTION: FORCE
***** 2. row *****
 PLUGIN_NAME: sha256_password
 PLUGIN_VERSION: 1.1
 PLUGIN_STATUS: ACTIVE
 PLUGIN_TYPE: AUTHENTICATION
 PLUGIN_TYPE_VERSION: 2.1
 PLUGIN_LIBRARY: NULL
 PLUGIN_LIBRARY_VERSION: NULL
 PLUGIN_AUTHOR: Oracle Corporation
 PLUGIN_DESCRIPTION: SHA256 password authentication
 PLUGIN_LICENSE: GPL
 LOAD_OPTION: FORCE
...

```

- The `SHOW PLUGINS` statement displays a row for each loaded plugin. Any that have a `Library` value of `NULL` are built in and cannot be unloaded.

```
mysql> SHOW PLUGINS\G
***** 1. row *****
 Name: binlog
 Status: ACTIVE

```

```

Type: STORAGE ENGINE
Library: NULL
License: GPL
***** 2. row *****
Name: sha256_password
Status: ACTIVE
Type: AUTHENTICATION
Library: NULL
License: GPL
...

```

- The `mysql.plugin` table shows which plugins have been registered with `INSTALL PLUGIN`. The table contains only plugin names and library file names, so it does not provide as much information as the `PLUGINS` table or the `SHOW PLUGINS` statement.

## 7.6.3 MySQL Enterprise Thread Pool

### Note

MySQL Enterprise Thread Pool is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, <https://www.mysql.com/products/>.

MySQL Enterprise Edition includes MySQL Enterprise Thread Pool, implemented using a server plugin. The default thread-handling model in MySQL Server executes statements using one thread per client connection. As more clients connect to the server and execute statements, overall performance degrades. The thread pool plugin provides an alternative thread-handling model designed to reduce overhead and improve performance. The plugin implements a thread pool that increases server performance by efficiently managing statement execution threads for large numbers of client connections.

The thread pool addresses several problems of the model that uses one thread per connection:

- Too many thread stacks make CPU caches almost useless in highly parallel execution workloads. The thread pool promotes thread stack reuse to minimize the CPU cache footprint.
- With too many threads executing in parallel, context switching overhead is high. This also presents a challenge to the operating system scheduler. The thread pool controls the number of active threads to keep the parallelism within the MySQL server at a level that it can handle and that is appropriate for the server host on which MySQL is executing.
- Too many transactions executing in parallel increases resource contention. In `InnoDB`, this increases the time spent holding central mutexes. The thread pool controls when transactions start to ensure that not too many execute in parallel.

## Additional Resources

[Section A.15, “MySQL 9.1 FAQ: MySQL Enterprise Thread Pool”](#)

### 7.6.3.1 Thread Pool Elements

MySQL Enterprise Thread Pool comprises these elements:

- A plugin library file implements a plugin for the thread pool code as well as several associated monitoring tables that provide information about thread pool operation:
  - In MySQL 9.1, the monitoring tables are Performance Schema tables; see [Section 29.12.16, “Performance Schema Thread Pool Tables”](#).

- In older versions of MySQL, the monitoring tables were `INFORMATION_SCHEMA` tables (see [Section 28.5, “INFORMATION\\_SCHEMA Thread Pool Tables”](#)). The `INFORMATION_SCHEMA` tables are deprecated; expect them to be removed in a future version of MySQL. Applications should transition away from the `INFORMATION_SCHEMA` tables to the Performance Schema tables. For example, if an application uses this query:

```
SELECT * FROM INFORMATION_SCHEMA.TP_THREAD_STATE;
```

The application should use this query instead:

```
SELECT * FROM performance_schema.tp_thread_state;
```

#### Note

If you do not load all the monitoring tables, some or all MySQL Enterprise Monitor thread pool graphs may be empty.

For a detailed description of how the thread pool works, see [Section 7.6.3.3, “Thread Pool Operation”](#).

- Several system variables are related to the thread pool. The `thread_handling` system variable has a value of `loaded-dynamically` when the server successfully loads the thread pool plugin.

The other related system variables are implemented by the thread pool plugin and are not available unless it is enabled. For information about using these variables, see [Section 7.6.3.3, “Thread Pool Operation”](#), and [Section 7.6.3.4, “Thread Pool Tuning”](#).

- The Performance Schema has instruments that expose information about the thread pool and may be used to investigate operational performance. To identify them, use this query:

```
SELECT * FROM performance_schema.setup_instruments
WHERE NAME LIKE '%thread_pool%';
```

For more information, see [Chapter 29, MySQL Performance Schema](#).

## 7.6.3.2 Thread Pool Installation

This section describes how to install MySQL Enterprise Thread Pool. For general information about installing plugins, see [Section 7.6.1, “Installing and Uninstalling Plugins”](#).

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

The plugin library file base name is `thread_pool`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

The thread pool monitoring tables are Performance Schema tables that are loaded and unloaded along with the thread pool plugin.

To enable thread pool capability, load the plugin by starting the server with the `--plugin-load-add` option. To do this, put these lines in the server `my.cnf` file, adjusting the `.so` suffix for your platform as necessary:

```
[mysqld]
plugin-load-add=thread_pool.so
```

To verify plugin installation, examine the Information Schema `PLUGINS` table or use the `SHOW PLUGINS` statement (see [Section 7.6.2, “Obtaining Server Plugin Information”](#)). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
FROM INFORMATION_SCHEMA.PLUGINS
WHERE PLUGIN_NAME LIKE 'thread%';
```

PLUGIN_NAME	PLUGIN_STATUS
thread_pool	ACTIVE

To verify that the Performance Schema monitoring tables are available, examine the Information Schema `TABLES` table or use the `SHOW TABLES` statement. For example:

```
mysql> SELECT TABLE_NAME
FROM INFORMATION_SCHEMA.TABLES
WHERE TABLE_SCHEMA = 'performance_schema'
AND TABLE_NAME LIKE 'tp%';
```

TABLE_NAME
tp_thread_group_state
tp_thread_group_stats
tp_thread_state

If the server loads the thread pool plugin successfully, it sets the `thread_handling` system variable to `loaded-dynamically`.

If the plugin fails to initialize, check the server error log for diagnostic messages.

### 7.6.3.3 Thread Pool Operation

The thread pool consists of a number of thread groups, each of which manages a set of client connections. As connections are established, the thread pool assigns them to thread groups in round-robin fashion.

The thread pool exposes system variables that may be used to configure its operation:

- `thread_pool_algorithm`: The concurrency algorithm to use for scheduling.
- `thread_pool_dedicated_listeners`: Dedicates a listener thread in each thread group to listen for incoming statements from connections assigned to the group.
- `thread_pool_high_priority_connection`: How to schedule statement execution for a session.
- `thread_pool_max_active_query_threads`: How many active threads per group to permit.
- `thread_pool_max_transactions_limit`: The maximum number of transactions permitted by the thread pool plugin.
- `thread_pool_max_unused_threads`: How many sleeping threads to permit.
- `thread_pool_prio_kickup_timer`: How long before the thread pool moves a statement awaiting execution from the low-priority queue to the high-priority queue.
- `thread_pool_query_threads_per_group`: The number of query threads permitted in a thread group (the default is a single query thread). Consider increasing the value if you experience slower response times due to long-running transactions.
- `thread_pool_size`: The number of thread groups in the thread pool. This is the most important parameter controlling thread pool performance.
- `thread_pool_stall_limit`: The time before an executing statement is considered to be stalled.

- `thread_pool_transaction_delay`: The delay period before starting a new transaction.

To configure the number of thread groups, use the `thread_pool_size` system variable. The default number of groups is 16. For guidelines on setting this variable, see [Section 7.6.3.4, “Thread Pool Tuning”](#).

The maximum number of threads per group is 4096 (or 4095 on some systems where one thread is used internally).

The thread pool separates connections and threads, so there is no fixed relationship between connections and the threads that execute statements received from those connections. This differs from the default thread-handling model that associates one thread with one connection such that a given thread executes all statements from its connection.

By default, the thread pool tries to ensure a maximum of one thread executing in each group at any time, but sometimes permits more threads to execute temporarily for best performance:

- Each thread group has a listener thread that listens for incoming statements from the connections assigned to the group. When a statement arrives, the thread group either begins executing it immediately or queues it for later execution:
  - Immediate execution occurs if the statement is the only one received, and there are no statements queued or currently executing.

Immediate execution can be delayed by configuring `thread_pool_transaction_delay`, which has a throttling effect on transactions. For more information, refer to the description of this variable in the discussion that follows.

- Queuing occurs if the statement cannot begin executing immediately due to concurrently queued or executing statements.
- The `thread_pool_transaction_delay` variable specifies a transaction delay in milliseconds. Worker threads sleep for the specified period before executing a new transaction.

A transaction delay can be used in cases where parallel transactions affect the performance of other operations due to resource contention. For example, if parallel transactions affect index creation or an online buffer pool resizing operation, you can configure a transaction delay to reduce resource contention while those operations are running. The delay has a throttling effect on transactions.

The `thread_pool_transaction_delay` setting does not affect queries issued from a privileged connection (a connection assigned to the `Admin` thread group). These queries are not subject to a configured transaction delay.

- If immediate execution occurs, the listener thread performs it. (This means that temporarily no thread in the group is listening.) If the statement finishes quickly, the executing thread returns to listening for statements. Otherwise, the thread pool considers the statement stalled and starts another thread as a listener thread (creating it if necessary). To ensure that no thread group becomes blocked by stalled statements, the thread pool has a background thread that regularly monitors thread group states.

By using the listening thread to execute a statement that can begin immediately, there is no need to create an additional thread if the statement finishes quickly. This ensures the most efficient execution possible in the case of a low number of concurrent threads.

When the thread pool plugin starts, it creates one thread per group (the listener thread), plus the background thread. Additional threads are created as necessary to execute statements.

- The value of the `thread_pool_stall_limit` system variable determines the meaning of “finishes quickly” in the previous item. The default time before threads are considered stalled is 60ms but can be

set to a maximum of 6s. This parameter is configurable to enable you to strike a balance appropriate for the server work load. Short wait values permit threads to start more quickly. Short values are also better for avoiding deadlock situations. Long wait values are useful for workloads that include long-running statements, to avoid starting too many new statements while the current ones execute.

- If `thread_pool_max_active_query_threads` is 0, the default algorithm applies as just described for determining the maximum number of active threads per group. The default algorithm takes stalled threads into account and may temporarily permit more active threads. If `thread_pool_max_active_query_threads` is greater than 0, it places a limit on the number of active threads per group.
- The thread pool focuses on limiting the number of concurrent short-running statements. Before an executing statement reaches the stall time, it prevents other statements from beginning to execute. If the statement executes past the stall time, it is permitted to continue but no longer prevents other statements from starting. In this way, the thread pool tries to ensure that in each thread group there is never more than one short-running statement, although there might be multiple long-running statements. It is undesirable to let long-running statements prevent other statements from executing because there is no limit on the amount of waiting that might be necessary. For example, on a replication source server, a thread that is sending binary log events to a replica effectively runs forever.
- A statement becomes blocked if it encounters a disk I/O operation or a user level lock (row lock or table lock). The block would cause the thread group to become unused, so there are callbacks to the thread pool to ensure that the thread pool can immediately start a new thread in this group to execute another statement. When a blocked thread returns, the thread pool permits it to restart immediately.
- There are two queues, a high-priority queue and a low-priority queue. The first statement in a transaction goes to the low-priority queue. Any following statements for the transaction go to the high-priority queue if the transaction is ongoing (statements for it have begun executing), or to the low-priority queue otherwise. Queue assignment can be affected by enabling the `thread_pool_high_priority_connection` system variable, which causes all queued statements for a session to go into the high-priority queue.

Statements for a nontransactional storage engine, or a transactional engine if `autocommit` is enabled, are treated as low-priority statements because in this case each statement is a transaction. Thus, given a mix of statements for `InnoDB` and `MyISAM` tables, the thread pool prioritizes those for `InnoDB` over those for `MyISAM` unless `autocommit` is enabled. With `autocommit` enabled, all statements have low priority.

- When the thread group selects a queued statement for execution, it first looks in the high-priority queue, then in the low-priority queue. If a statement is found, it is removed from its queue and begins to execute.
- If a statement stays in the low-priority queue too long, the thread pool moves to the high-priority queue. The value of the `thread_pool_prio_kickup_timer` system variable controls the time before movement. For each thread group, a maximum of one statement per 10ms (100 per second) is moved from the low-priority queue to the high-priority queue.
- The thread pool reuses the most active threads to obtain a much better use of CPU caches. This is a small adjustment that has a great impact on performance.
- While a thread executes a statement from a user connection, Performance Schema instrumentation accounts thread activity to the user connection. Otherwise, Performance Schema accounts activity to the thread pool.

Here are examples of conditions under which a thread group might have multiple threads started to execute statements:

- One thread begins executing a statement, but runs long enough to be considered stalled. The thread group permits another thread to begin executing another statement even though the first thread is still executing.
- One thread begins executing a statement, then becomes blocked and reports this back to the thread pool. The thread group permits another thread to begin executing another statement.
- One thread begins executing a statement, becomes blocked, but does not report back that it is blocked because the block does not occur in code that has been instrumented with thread pool callbacks. In this case, the thread appears to the thread group to be still running. If the block lasts long enough for the statement to be considered stalled, the group permits another thread to begin executing another statement.

The thread pool is designed to be scalable across an increasing number of connections. It is also designed to avoid deadlocks that can arise from limiting the number of actively executing statements. It is important that threads that do not report back to the thread pool do not prevent other statements from executing and thus cause the thread pool to become deadlocked. Examples of such statements follow:

- Long-running statements. These would lead to all resources used by only a few statements and they could prevent all others from accessing the server.
- Binary log dump threads that read the binary log and send it to replicas. This is a kind of long-running “statement” that runs for a very long time, and that should not prevent other statements from executing.
- Statements blocked on a row lock, table lock, sleep, or any other blocking activity that has not been reported back to the thread pool by MySQL Server or a storage engine.

In each case, to prevent deadlock, the statement is moved to the stalled category when it does not complete quickly, so that the thread group can permit another statement to begin executing. With this design, when a thread executes or becomes blocked for an extended time, the thread pool moves the thread to the stalled category and for the rest of the statement's execution, it does not prevent other statements from executing.

The maximum number of threads that can occur is the sum of `max_connections` and `thread_pool_size`. This can happen in a situation where all connections are in execution mode and an extra thread is created per group to listen for more statements. This is not necessarily a state that happens often, but it is theoretically possible.

## Privileged Connections

If the limit defined by `thread_pool_max_transactions_limit` has been reached and new connections or new transactions using existing connections appear to hang until one or more existing transactions are completed, in spite of any adjustments made to `thread_pool_longrun_trx_limit`, so that all existing connections are blocked or long-running, the only way to access the server may be to use a privileged connection.

To establish a privileged connection, the user initiating the connection must have the `TP_CONNECTION_ADMIN` privilege. A privileged connection ignores the limit defined by `thread_pool_max_transactions_limit` and permits connecting to the server to increase the limit, remove the limit, or kill running transactions. `TP_CONNECTION_ADMIN` privilege must be granted explicitly. It is not granted to any user by default.

A privileged connection can execute statements and start transactions, and is assigned to a thread group designated as the `Admin` thread group.

When querying the `performance_schema.tp_thread_group_stats` table, which reports statistics per thread group, `Admin` thread group statistics are reported in the last row of the result set. For example,

if `SELECT * FROM performance_schema.tp_thread_group_stats` returns 17 rows (one row per thread group), the `Admin` thread group statistics are reported in the 17th row.

### 7.6.3.4 Thread Pool Tuning

This section provides guidelines on determining the best configuration for thread pool performance, as measured using a metric such as transactions per second.

Of chief importance is the number of thread groups in the thread pool, which can be set on server startup using the `--thread-pool-size` option; this cannot be changed at runtime. Recommended values for this option depend on whether the primary storage engine in use is `InnoDB` or `MyISAM`:

- If the primary storage engine is `InnoDB`, the recommended value for the thread pool size is the number of physical cores available on the host machine, up to a maximum of 512.
- If the primary storage engine is `MyISAM`, the thread pool size should be fairly low. Optimal performance is often seen with values from 4 to 8. Higher values tend to have a slightly negative but not dramatic impact on performance.

The upper limit on the number of concurrent transactions that can be processed by the thread pool plugin is determined by the value of `thread_pool_max_transactions_limit`. The recommendation initial setting for this system variable is the number of physical cores times 32. You may need to adjust the value from this starting point to suit a given workload; a reasonable upper bound for this value is the maximum number of concurrent connections expected; the value of the `Max_used_connections` status variable can serve as a guide to determining this. A good way to proceed is to start with `thread_pool_max_transactions_limit` set to this value, then adjust it downwards while observing the effect on throughput.

The maximum number of query threads permitted in a thread group is determined by the value of `thread_pool_query_threads_per_group`, which can be adjusted at runtime. The product of this value and the thread pool size is approximately equal to the total number of threads available to process queries. Obtaining the best performance usually means striking the proper balance for your application between `thread_pool_query_threads_per_group` and the thread pool size. Greater values for `thread_pool_query_threads_per_group` value make it less likely that all the threads in the thread group simultaneously execute long running queries while blocking shorter ones when the workload includes both long and short running queries. You should bear in mind that the overhead of the connection polling operation for each thread group increases when using smaller values for the thread pool size with larger values for `thread_pool_query_threads_per_group`. For this reason, we recommend a starting value of 2 for `thread_pool_query_threads_per_group`; setting this variable to a lower value usually does not offer any performance benefit.

For best performance under normal conditions, we also recommend that you set `thread_pool_algorithm` to 1 for high concurrency.

In addition, the value of the `thread_pool_stall_limit` system variable determines the handling of blocked and long-running statements. If all calls blocking the MySQL Server were reported to the thread pool, it would always know when execution threads are blocked, but this may not always be true. For example, blocks could occur in code that has not been instrumented with thread pool callbacks. For such cases, the thread pool must be able to identify threads that appear to be blocked. This is done by means of a timeout determined by the value of `thread_pool_stall_limit`, which ensures that the server does not become completely blocked. The value of `thread_pool_stall_limit` represents a number of 10-millisecond intervals, so that 600 (the maximum) represents 6 seconds.

`thread_pool_stall_limit` also enables the thread pool to handle long-running statements. If a long-running statement were permitted to block a thread group, all other connections assigned to the group would be blocked and unable to start execution until the long-running statement completed. In the worst case, this could take hours or even days.

The value of `thread_pool_stall_limit` should be chosen such that statements that execute longer than its value are considered stalled. Stalled statements generate a lot of extra overhead since they involve extra context switches and in some cases even extra thread creations. On the other hand, setting the `thread_pool_stall_limit` parameter too high means that long-running statements block a number of short-running statements for longer than necessary. Short wait values permit threads to start more quickly. Short values are also better for avoiding deadlock situations. Long wait values are useful for workloads that include long-running statements, to avoid starting too many new statements while the current ones execute.

Suppose a server executes a workload where 99.9% of the statements complete within 100ms even when the server is loaded, and the remaining statements take between 100ms and 2 hours fairly evenly spread. In this case, it would make sense to set `thread_pool_stall_limit` to 10 ( $10 \times 10\text{ms} = 100\text{ms}$ ). The default value of 6 (60ms) is suitable for servers that primarily execute very simple statements.

The `thread_pool_stall_limit` parameter can be changed at runtime to enable you to strike a balance appropriate for the server work load. Assuming that the `tp_thread_group_stats` table is enabled, you can use the following query to determine the fraction of executed statements that stalled:

```
SELECT SUM(STALLED_QUERIES_EXECUTED) / SUM(QUERIES_EXECUTED)
FROM performance_schema.tp_thread_group_stats;
```

This number should be as low as possible. To decrease the likelihood of statements stalling, increase the value of `thread_pool_stall_limit`.

When a statement arrives, what is the maximum time it can be delayed before it actually starts executing? Suppose that the following conditions apply:

- There are 200 statements queued in the low-priority queue.
- There are 10 statements queued in the high-priority queue.
- `thread_pool_prio_kickup_timer` is set to 10000 (10 seconds).
- `thread_pool_stall_limit` is set to 100 (1 second).

In the worst case, the 10 high-priority statements represent 10 transactions that continue executing for a long time. Thus, in the worst case, no statements can be moved to the high-priority queue because it always already contains statements awaiting execution. After 10 seconds, the new statement is eligible to be moved to the high-priority queue. However, before it can be moved, all the statements before it must be moved as well. This could take another 2 seconds because a maximum of 100 statements per second are moved to the high-priority queue. Now when the statement reaches the high-priority queue, there could potentially be many long-running statements ahead of it. In the worst case, every one of those becomes stalled and 1 second is required for each statement before the next statement is retrieved from the high-priority queue. Thus, in this scenario, it takes 222 seconds before the new statement starts executing.

This example shows a worst case for an application. How to handle it depends on the application. If the application has high requirements for the response time, it should most likely throttle users at a higher level itself. Otherwise, it can use the thread pool configuration parameters to set some kind of a maximum waiting time.

## 7.6.4 The Rewriter Query Rewrite Plugin

MySQL supports query rewrite plugins that can examine and possibly modify SQL statements received by the server before the server executes them. See [Query Rewrite Plugins](#).

MySQL distributions include a postparse query rewrite plugin named `Rewriter` and scripts for installing the plugin and its associated elements. These elements work together to provide statement-rewriting capability:

- A server-side plugin named `Rewriter` examines statements and may rewrite them, based on its in-memory cache of rewrite rules.
- These statements are subject to rewriting: `SELECT`, `INSERT`, `REPLACE`, `UPDATE`, and `DELETE`.

Standalone statements and prepared statements are subject to rewriting. Statements occurring within view definitions or stored programs are not subject to rewriting.

- The `Rewriter` plugin uses a database named `query_rewrite` containing a table named `rewrite_rules`. The table provides persistent storage for the rules that the plugin uses to decide whether to rewrite statements. Users communicate with the plugin by modifying the set of rules stored in this table. The plugin communicates with users by setting the `message` column of table rows.
- The `query_rewrite` database contains a stored procedure named `flush_rewrite_rules()` that loads the contents of the rules table into the plugin.
- A loadable function named `load_rewrite_rules()` is used by the `flush_rewrite_rules()` stored procedure.
- The `Rewriter` plugin exposes system variables that enable plugin configuration and status variables that provide runtime operational information. This plugin also supports a privilege (`SKIP_QUERY_REWRITE`) that protects a given user's queries from being rewritten.

The following sections describe how to install and use the `Rewriter` plugin, and provide reference information for its associated elements.

### 7.6.4.1 Installing or Uninstalling the Rewriter Query Rewrite Plugin

#### Note

If installed, the `Rewriter` plugin involves some overhead even when disabled. To avoid this overhead, do not install the plugin unless you plan to use it.

To install or uninstall the `Rewriter` query rewrite plugin, choose the appropriate script located in the `share` directory of your MySQL installation:

- `install_rewriter.sql`: Choose this script to install the `Rewriter` plugin and its associated elements.
- `uninstall_rewriter.sql`: Choose this script to uninstall the `Rewriter` plugin and its associated elements.

Run the chosen script as follows:

```
$> mysql -u root -p < install_rewriter.sql
Enter password: (enter root password here)
```

The example here uses the `install_rewriter.sql` installation script. Substitute `uninstall_rewriter.sql` if you are uninstalling the plugin.

Running an installation script should install and enable the plugin. To verify that, connect to the server and execute this statement:

```
mysql> SHOW GLOBAL VARIABLES LIKE 'rewriter_enabled';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| rewriter_enabled | ON |
+-----+-----+
```

For usage instructions, see [Section 7.6.4.2, “Using the Rewriter Query Rewrite Plugin”](#). For reference information, see [Section 7.6.4.3, “Rewriter Query Rewrite Plugin Reference”](#).

## 7.6.4.2 Using the Rewriter Query Rewrite Plugin

To enable or disable the plugin, enable or disable the `rewriter_enabled` system variable. By default, the `Rewriter` plugin is enabled when you install it (see [Section 7.6.4.1, “Installing or Uninstalling the Rewriter Query Rewrite Plugin”](#)). To set the initial plugin state explicitly, you can set the variable at server startup. For example, to enable the plugin in an option file, use these lines:

```
[mysqld]
rewriter_enabled=ON
```

It is also possible to enable or disable the plugin at runtime:

```
SET GLOBAL rewriter_enabled = ON;
SET GLOBAL rewriter_enabled = OFF;
```

Assuming that the `Rewriter` plugin is enabled, it examines and possibly modifies each rewritable statement received by the server. The plugin determines whether to rewrite statements based on its in-memory cache of rewriting rules, which are loaded from the `rewrite_rules` table in the `query_rewrite` database.

These statements are subject to rewriting: `SELECT`, `INSERT`, `REPLACE`, `UPDATE`, and `DELETE`.

Standalone statements and prepared statements are subject to rewriting. Statements occurring within view definitions or stored programs are not subject to rewriting.

Statements run by users with the `SKIP_QUERY_REWRITE` privilege are not subject to rewriting, provided that the `rewriter_enabled_for_threads_without_privilege_checks` system variable is set to `OFF` (default `ON`). This can be used for control statements and statements that should be replicated unchanged, such as those from the `SOURCE_USER` specified by `CHANGE REPLICATION SOURCE TO`. This is also true for statements executed by MySQL client programs including `mysqlbinlog`, `mysqladmin`, and `mysqldump`; for this reason, you should grant `SKIP_QUERY_REWRITE` to the user account or accounts used by these utilities to connect to MySQL.

- [Adding Rewrite Rules](#)
- [How Statement Matching Works](#)
- [Rewriting Prepared Statements](#)
- [Rewriter Plugin Operational Information](#)
- [Rewriter Plugin Use of Character Sets](#)

### Adding Rewrite Rules

To add rules for the `Rewriter` plugin, add rows to the `rewrite_rules` table, then invoke the `flush_rewrite_rules()` stored procedure to load the rules from the table into the plugin. The following example creates a simple rule to match statements that select a single literal value:

```
INSERT INTO query_rewrite.rewrite_rules (pattern, replacement)
VALUES('SELECT ?', 'SELECT ? + 1');
```

The resulting table contents look like this:

```
mysql> SELECT * FROM query_rewrite.rewrite_rules\G
***** 1. row *****
 id: 1
 pattern: SELECT ?
```

```

pattern_database: NULL
replacement: SELECT ? + 1
enabled: YES
message: NULL
pattern_digest: NULL
normalized_pattern: NULL

```

The rule specifies a pattern template indicating which `SELECT` statements to match, and a replacement template indicating how to rewrite matching statements. However, adding the rule to the `rewrite_rules` table is not sufficient to cause the `Rewriter` plugin to use the rule. You must invoke `flush_rewrite_rules()` to load the table contents into the plugin in-memory cache:

```
mysql> CALL query_rewrite.flush_rewrite_rules();
```

### Tip

If your rewrite rules seem not to be working properly, make sure that you have reloaded the rules table by calling `flush_rewrite_rules()`.

When the plugin reads each rule from the rules table, it computes a normalized (statement digest) form from the pattern and a digest hash value, and uses them to update the `normalized_pattern` and `pattern_digest` columns:

```

mysql> SELECT * FROM query_rewrite.rewrite_rules\G
***** 1. row *****
 id: 1
 pattern: SELECT ?
pattern_database: NULL
 replacement: SELECT ? + 1
 enabled: YES
 message: NULL
pattern_digest: d1b44b0c19af710b5a679907e284acd2ddc285201794bc69a2389d77baedddae
normalized_pattern: select ?

```

For information about statement digesting, normalized statements, and digest hash values, see [Section 29.10, “Performance Schema Statement Digests and Sampling”](#).

If a rule cannot be loaded due to some error, calling `flush_rewrite_rules()` produces an error:

```

mysql> CALL query_rewrite.flush_rewrite_rules();
ERROR 1644 (45000): Loading of some rule(s) failed.

```

When this occurs, the plugin writes an error message to the `message` column of the rule row to communicate the problem. Check the `rewrite_rules` table for rows with non-NULL `message` column values to see what problems exist.

Patterns use the same syntax as prepared statements (see [Section 15.5.1, “PREPARE Statement”](#)). Within a pattern template, `?` characters act as parameter markers that match data values. The `?` characters should not be enclosed within quotation marks. Parameter markers can be used only where data values should appear, and they cannot be used for SQL keywords, identifiers, functions, and so on. The plugin parses a statement to identify the literal values (as defined in [Section 11.1, “Literal Values”](#)), so you can put a parameter marker in place of any literal value.

Like the pattern, the replacement can contain `?` characters. For a statement that matches a pattern template, the plugin rewrites it, replacing `?` parameter markers in the replacement using data values matched by the corresponding markers in the pattern. The result is a complete statement string. The plugin asks the server to parse it, and returns the result to the server as the representation of the rewritten statement.

After adding and loading the rule, check whether rewriting occurs according to whether statements match the rule pattern:

```
mysql> SELECT PI();
+-----+
| PI() |
+-----+
| 3.141593 |
+-----+
1 row in set (0.01 sec)

mysql> SELECT 10;
+-----+
| 10 + 1 |
+-----+
| 11 |
+-----+
1 row in set, 1 warning (0.00 sec)
```

No rewriting occurs for the first `SELECT` statement, but does for the second. The second statement illustrates that when the `Rewriter` plugin rewrites a statement, it produces a warning message. To view the message, use `SHOW WARNINGS`:

```
mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Note
Code: 1105
Message: Query 'SELECT 10' rewritten to 'SELECT 10 + 1' by a query rewrite plugin
```

A statement need not be rewritten to a statement of the same type. The following example loads a rule that rewrites `DELETE` statements to `UPDATE` statements:

```
INSERT INTO query_rewrite.rewrite_rules (pattern, replacement)
VALUES('DELETE FROM dbl.t1 WHERE col = ?',
 'UPDATE dbl.t1 SET col = NULL WHERE col = ?');
CALL query_rewrite.flush_rewrite_rules();
```

To enable or disable an existing rule, modify its `enabled` column and reload the table into the plugin. To disable rule 1:

```
UPDATE query_rewrite.rewrite_rules SET enabled = 'NO' WHERE id = 1;
CALL query_rewrite.flush_rewrite_rules();
```

This enables you to deactivate a rule without removing it from the table.

To re-enable rule 1:

```
UPDATE query_rewrite.rewrite_rules SET enabled = 'YES' WHERE id = 1;
CALL query_rewrite.flush_rewrite_rules();
```

The `rewrite_rules` table contains a `pattern_database` column that `Rewriter` uses for matching table names that are not qualified with a database name:

- Qualified table names in statements match qualified names in the pattern if corresponding database and table names are identical.
- Unqualified table names in statements match unqualified names in the pattern only if the default database is the same as `pattern_database` and the table names are identical.

Suppose that a table named `appdb.users` has a column named `id` and that applications are expected to select rows from the table using a query of one of these forms, where the second can be used when `appdb` is the default database:

```
SELECT * FROM users WHERE appdb.id = id_value;
SELECT * FROM users WHERE id = id_value;
```

Suppose also that the `id` column is renamed to `user_id` (perhaps the table must be modified to add another type of ID and it is necessary to indicate more specifically what type of ID the `id` column represents).

The change means that applications must refer to `user_id` rather than `id` in the `WHERE` clause, but old applications that cannot be updated no longer work properly. The `Rewriter` plugin can solve this problem by matching and rewriting problematic statements. To match the statement `SELECT * FROM appdb.users WHERE id = value` and rewrite it as `SELECT * FROM appdb.users WHERE user_id = value`, you can insert a row representing a replacement rule into the rewrite rules table. If you also want to match this `SELECT` using the unqualified table name, it is also necessary to add an explicit rule. Using `?` as a value placeholder, the two `INSERT` statements needed look like this:

```
INSERT INTO query_rewrite.rewrite_rules
(pattern, replacement) VALUES(
 'SELECT * FROM appdb.users WHERE id = ?',
 'SELECT * FROM appdb.users WHERE user_id = ?'
);
INSERT INTO query_rewrite.rewrite_rules
(pattern, replacement, pattern_database) VALUES(
 'SELECT * FROM users WHERE id = ?',
 'SELECT * FROM users WHERE user_id = ?',
 'appdb'
);
```

After adding the two new rules, execute the following statement to cause them to take effect:

```
CALL query_rewrite.flush_rewrite_rules();
```

`Rewriter` uses the first rule to match statements that use the qualified table name, and the second to match statements that use the unqualified name. The second rule works only when `appdb` is the default database.

## How Statement Matching Works

The `Rewriter` plugin uses statement digests and digest hash values to match incoming statements against rewrite rules in stages. The `max_digest_length` system variable determines the size of the buffer used for computing statement digests. Larger values enable computation of digests that distinguish longer statements. Smaller values use less memory but increase the likelihood of longer statements colliding with the same digest value.

The plugin matches each statement to the rewrite rules as follows:

1. Compute the statement digest hash value and compare it to the rule digest hash values. This is subject to false positives, but serves as a quick rejection test.
2. If the statement digest hash value matches any pattern digest hash values, match the normalized (statement digest) form of the statement to the normalized form of the matching rule patterns.
3. If the normalized statement matches a rule, compare the literal values in the statement and the pattern. A `?` character in the pattern matches any literal value in the statement. If the statement prepares a statement, `?` in the pattern also matches `?` in the statement. Otherwise, corresponding literals must be the same.

If multiple rules match a statement, it is nondeterministic which one the plugin uses to rewrite the statement.

If a pattern contains more markers than the replacement, the plugin discards excess data values. If a pattern contains fewer markers than the replacement, it is an error. The plugin notices this when the rules table is loaded, writes an error message to the `message` column of the rule row to communicate the problem, and sets the `Rewriter_reload_error` status variable to `ON`.

## Rewriting Prepared Statements

Prepared statements are rewritten at parse time (that is, when they are prepared), not when they are executed later.

Prepared statements differ from nonprepared statements in that they may contain `?` characters as parameter markers. To match a `?` in a prepared statement, a [Rewriter](#) pattern must contain `?` in the same location. Suppose that a rewrite rule has this pattern:

```
SELECT ?, 3
```

The following table shows several prepared `SELECT` statements and whether the rule pattern matches them.

Prepared Statement	Whether Pattern Matches Statement
<code>PREPARE s AS 'SELECT 3, 3'</code>	Yes
<code>PREPARE s AS 'SELECT ?, 3'</code>	Yes
<code>PREPARE s AS 'SELECT 3, ?'</code>	No
<code>PREPARE s AS 'SELECT ?, ?'</code>	No

## Rewriter Plugin Operational Information

The [Rewriter](#) plugin makes information available about its operation by means of several status variables:

```
mysql> SHOW GLOBAL STATUS LIKE 'Rewriter%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Rewriter_number_loaded_rules | 1 |
| Rewriter_number_reloads | 5 |
| Rewriter_number_rewritten_queries | 1 |
| Rewriter_reload_error | ON |
+-----+-----+
```

For descriptions of these variables, see [Rewriter Query Rewrite Plugin Status Variables](#).

When you load the rules table by calling the `flush_rewrite_rules()` stored procedure, if an error occurs for some rule, the `CALL` statement produces an error, and the plugin sets the `Rewriter_reload_error` status variable to `ON`:

```
mysql> CALL query_rewrite.flush_rewrite_rules();
ERROR 1644 (45000): Loading of some rule(s) failed.

mysql> SHOW GLOBAL STATUS LIKE 'Rewriter_reload_error';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Rewriter_reload_error | ON |
+-----+-----+
```

In this case, check the `rewrite_rules` table for rows with non-NULL `message` column values to see what problems exist.

## Rewriter Plugin Use of Character Sets

When the `rewrite_rules` table is loaded into the [Rewriter](#) plugin, the plugin interprets statements using the current global value of the `character_set_client` system variable. If the global `character_set_client` value is changed subsequently, the rules table must be reloaded.

A client must have a session `character_set_client` value identical to what the global value was when the rules table was loaded or rule matching does not work for that client.

### 7.6.4.3 Rewriter Query Rewrite Plugin Reference

The following discussion serves as a reference to these elements associated with the `Rewriter` query rewrite plugin:

- The `Rewriter` rules table in the `query_rewrite` database
- `Rewriter` procedures and functions
- `Rewriter` system and status variables

#### Rewriter Query Rewrite Plugin Rules Table

The `rewrite_rules` table in the `query_rewrite` database provides persistent storage for the rules that the `Rewriter` plugin uses to decide whether to rewrite statements.

Users communicate with the plugin by modifying the set of rules stored in this table. The plugin communicates information to users by setting the table's `message` column.

#### Note

The rules table is loaded into the plugin by the `flush_rewrite_rules` stored procedure. Unless that procedure has been called following the most recent table modification, the table contents do not necessarily correspond to the set of rules the plugin is using.

The `rewrite_rules` table has these columns:

- `id`

The rule ID. This column is the table primary key. You can use the ID to uniquely identify any rule.

- `pattern`

The template that indicates the pattern for statements that the rule matches. Use `?` to represent parameter markers that match data values.

- `pattern_database`

The database used to match unqualified table names in statements. Qualified table names in statements match qualified names in the pattern if corresponding database and table names are identical. Unqualified table names in statements match unqualified names in the pattern only if the default database is the same as `pattern_database` and the table names are identical.

- `replacement`

The template that indicates how to rewrite statements matching the `pattern` column value. Use `?` to represent parameter markers that match data values. In rewritten statements, the plugin replaces `?` parameter markers in `replacement` using data values matched by the corresponding markers in `pattern`.

- `enabled`

Whether the rule is enabled. Load operations (performed by invoking the `flush_rewrite_rules()` stored procedure) load the rule from the table into the `Rewriter` in-memory cache only if this column is `YES`.

This column makes it possible to deactivate a rule without removing it: Set the column to a value other than `YES` and reload the table into the plugin.

- `message`

The plugin uses this column for communicating with users. If no error occurs when the rules table is loaded into memory, the plugin sets the `message` column to `NULL`. A non-`NULL` value indicates an error and the column contents are the error message. Errors can occur under these circumstances:

- Either the pattern or the replacement is an incorrect SQL statement that produces syntax errors.
- The replacement contains more `?` parameter markers than the pattern.

If a load error occurs, the plugin also sets the `Rewriter_reload_error` status variable to `ON`.

- `pattern_digest`

This column is used for debugging and diagnostics. If the column exists when the rules table is loaded into memory, the plugin updates it with the pattern digest. This column may be useful if you are trying to determine why some statement fails to be rewritten.

- `normalized_pattern`

This column is used for debugging and diagnostics. If the column exists when the rules table is loaded into memory, the plugin updates it with the normalized form of the pattern. This column may be useful if you are trying to determine why some statement fails to be rewritten.

## Rewriter Query Rewrite Plugin Procedures and Functions

`Rewriter` plugin operation uses a stored procedure that loads the rules table into its in-memory cache, and a helper loadable function. Under normal operation, users invoke only the stored procedure. The function is intended to be invoked by the stored procedure, not directly by users.

- `flush_rewrite_rules()`

This stored procedure uses the `load_rewrite_rules()` function to load the contents of the `rewrite_rules` table into the `Rewriter` in-memory cache.

Calling `flush_rewrite_rules()` implies `COMMIT`.

Invoke this procedure after you modify the rules table to cause the plugin to update its cache from the new table contents. If any errors occur, the plugin sets the `message` column for the appropriate rule rows in the table and sets the `Rewriter_reload_error` status variable to `ON`.

- `load_rewrite_rules()`

This function is a helper routine used by the `flush_rewrite_rules()` stored procedure.

## Rewriter Query Rewrite Plugin System Variables

The `Rewriter` query rewrite plugin supports the following system variables. These variables are available only if the plugin is installed (see [Section 7.6.4.1, “Installing or Uninstalling the Rewriter Query Rewrite Plugin”](#)).

- `rewriter_enabled`

System Variable	<code>rewriter_enabled</code>
-----------------	-------------------------------

Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Boolean
Default Value	<a href="#">ON</a>
Valid Values	<a href="#">OFF</a>

Whether the [Rewriter](#) query rewrite plugin is enabled.

- [rewriter\\_enabled\\_for\\_threads\\_without\\_privilege\\_checks](#)

System Variable	<a href="#">rewriter_enabled_for_threads_without_privilege_checks</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Boolean
Default Value	<a href="#">ON</a>
Valid Values	<a href="#">OFF</a>

Whether to apply rewrites for replication threads which execute with privilege checks disabled. If set to [OFF](#), such rewrites are skipped. Requires the [SYSTEM\\_VARIABLES\\_ADMIN](#) privilege or [SUPER](#) privilege to set.

This variable has no effect if [rewriter\\_enabled](#) is [OFF](#).

- [rewriter\\_verbose](#)

System Variable	<a href="#">rewriter_verbose</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer

For internal use.

## Rewriter Query Rewrite Plugin Status Variables

The [Rewriter](#) query rewrite plugin supports the following status variables. These variables are available only if the plugin is installed (see [Section 7.6.4.1, “Installing or Uninstalling the Rewriter Query Rewrite Plugin”](#)).

- [Rewriter\\_number\\_loaded\\_rules](#)

The number of rewrite plugin rewrite rules successfully loaded from the [rewrite\\_rules](#) table into memory for use by the [Rewriter](#) plugin.

- [Rewriter\\_number\\_reloads](#)

The number of times the [rewrite\\_rules](#) table has been loaded into the in-memory cache used by the [Rewriter](#) plugin.

- `Rewriter_number_rewritten_queries`

The number of queries rewritten by the `Rewriter` query rewrite plugin since it was loaded.

- `Rewriter_reload_error`

Whether an error occurred the most recent time that the `rewrite_rules` table was loaded into the in-memory cache used by the `Rewriter` plugin. If the value is `OFF`, no error occurred. If the value is `ON`, an error occurred; check the `message` column of the `rewriter_rules` table for error messages.

## 7.6.5 The ddl\_rewriter Plugin

MySQL 9.1 includes a `ddl_rewriter` plugin that modifies `CREATE TABLE` statements received by the server before it parses and executes them. The plugin removes `ENCRYPTION`, `DATA DIRECTORY`, and `INDEX DIRECTORY` clauses, which may be helpful when restoring tables from SQL dump files created from databases that are encrypted or that have their tables stored outside the data directory. For example, the plugin may enable restoring such dump files into an unencrypted instance or in an environment where the paths outside the data directory are not accessible.

Before using the `ddl_rewriter` plugin, install it according to the instructions provided in [Section 7.6.5.1, “Installing or Uninstalling ddl\\_rewriter”](#).

`ddl_rewriter` examines SQL statements received by the server prior to parsing, rewriting them according to these conditions:

- `ddl_rewriter` considers only `CREATE TABLE` statements, and only if they are standalone statements that occur at the beginning of an input line or at the beginning of prepared statement text. `ddl_rewriter` does not consider `CREATE TABLE` statements within stored program definitions. Statements can extend over multiple lines.
- Within statements considered for rewrite, instances of the following clauses are rewritten and each instance replaced by a single space:
  - `ENCRYPTION`
  - `DATA DIRECTORY` (at the table and partition levels)
  - `INDEX DIRECTORY` (at the table and partition levels)
- Rewriting does not depend on lettercase.

If `ddl_rewriter` rewrites a statement, it generates a warning:

```
mysql> CREATE TABLE t (i INT) DATA DIRECTORY '/var/mysql/data';
Query OK, 0 rows affected, 1 warning (0.03 sec)

mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Note
Code: 1105
Message: Query 'CREATE TABLE t (i INT) DATA DIRECTORY '/var/mysql/data''
 rewritten to 'CREATE TABLE t (i INT) ' by a query rewrite plugin
1 row in set (0.00 sec)
```

If the general query log or binary log is enabled, the server writes to it statements as they appear after any rewriting by `ddl_rewriter`.

When installed, `ddl_rewriter` exposes the Performance Schema `memory/rewriter/ddl_rewriter` instrument for tracking plugin memory use. See [Section 29.12.20.10, “Memory Summary Tables”](#)

### 7.6.5.1 Installing or Uninstalling ddl\_rewriter

This section describes how to install or uninstall the `ddl_rewriter` plugin. For general information about installing plugins, see [Section 7.6.1, “Installing and Uninstalling Plugins”](#).

#### Note

If installed, the `ddl_rewriter` plugin involves some minimal overhead even when disabled. To avoid this overhead, install `ddl_rewriter` only for the period during which you intend to use it.

The primary use case is modification of statements restored from dump files, so the typical usage pattern is: 1) Install the plugin; 2) restore the dump file or files; 3) uninstall the plugin.

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

The plugin library file base name is `ddl_rewriter`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

To install the `ddl_rewriter` plugin, use the `INSTALL PLUGIN` statement, adjusting the `.so` suffix for your platform as necessary:

```
INSTALL PLUGIN ddl_rewriter SONAME 'ddl_rewriter.so';
```

To verify plugin installation, examine the Information Schema `PLUGINS` table or use the `SHOW PLUGINS` statement (see [Section 7.6.2, “Obtaining Server Plugin Information”](#)). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS, PLUGIN_TYPE
FROM INFORMATION_SCHEMA.PLUGINS
WHERE PLUGIN_NAME LIKE 'ddl%';
```

PLUGIN_NAME	PLUGIN_STATUS	PLUGIN_TYPE
ddl_rewriter	ACTIVE	AUDIT

As the preceding result shows, `ddl_rewriter` is implemented as an audit plugin.

If the plugin fails to initialize, check the server error log for diagnostic messages.

Once installed as just described, `ddl_rewriter` remains installed until uninstalled. To remove it, use `UNINSTALL PLUGIN`:

```
UNINSTALL PLUGIN ddl_rewriter;
```

If `ddl_rewriter` is installed, you can use the `--ddl-rewriter` option for subsequent server startups to control `ddl_rewriter` plugin activation. For example, to prevent the plugin from being enabled at runtime, use this option:

```
[mysqld]
ddl-rewriter=OFF
```

### 7.6.5.2 ddl\_rewriter Plugin Options

This section describes the command options that control operation of the `ddl_rewriter` plugin. If values specified at startup time are incorrect, the `ddl_rewriter` plugin may fail to initialize properly and the server does not load it.

To control activation of the `ddl_rewriter` plugin, use this option:

- `--ddl-rewriter[=value]`

Command-Line Format	<code>--ddl-rewriter[=value]</code>
Type	Enumeration
Default Value	ON
Valid Values	ON  OFF  FORCE  FORCE_PLUS_PERMANENT

This option controls how the server loads the `ddl_rewriter` plugin at startup. It is available only if the plugin has been previously registered with `INSTALL PLUGIN` or is loaded with `--plugin-load` or `--plugin-load-add`. See [Section 7.6.5.1, “Installing or Uninstalling `ddl\_rewriter`”](#).

The option value should be one of those available for plugin-loading options, as described in [Section 7.6.1, “Installing and Uninstalling Plugins”](#). For example, `--ddl-rewriter=OFF` disables the plugin at server startup.

## 7.6.6 Version Tokens

MySQL includes Version Tokens, a feature that enables creation of and synchronization around server tokens that applications can use to prevent accessing incorrect or out-of-date data.

The Version Tokens interface has these characteristics:

- Version tokens are pairs consisting of a name that serves as a key or identifier, plus a value.
- Version tokens can be locked. An application can use token locks to indicate to other cooperating applications that tokens are in use and should not be modified.
- Version token lists are established per server (for example, to specify the server assignment or operational state). In addition, an application that communicates with a server can register its own list of tokens that indicate the state it requires the server to be in. An SQL statement sent by the application to a server not in the required state produces an error. This is a signal to the application that it should seek a different server in the required state to receive the SQL statement.

The following sections describe the elements of Version Tokens, discuss how to install and use it, and provide reference information for its elements.

### 7.6.6.1 Version Tokens Elements

Version Tokens is based on a plugin library that implements these elements:

- A server-side plugin named `version_tokens` holds the list of version tokens associated with the server and subscribes to notifications for statement execution events. The `version_tokens` plugin uses the [audit plugin API](#) to monitor incoming statements from clients and matches each client's session-specific version token list against the server version token list. If there is a match, the plugin lets the statement through and the server continues to process it. Otherwise, the plugin returns an error to the client and the statement fails.

- A set of loadable functions provides an SQL-level API for manipulating and inspecting the list of server version tokens maintained by the plugin. The `VERSION_TOKEN_ADMIN` privilege (or the deprecated `SUPER` privilege) is required to call any of the Version Token functions.
- When the `version_tokens` plugin loads, it defines the `VERSION_TOKEN_ADMIN` dynamic privilege. This privilege can be granted to users of the functions.
- A system variable enables clients to specify the list of version tokens that register the required server state. If the server has a different state when a client sends a statement, the client receives an error.

### 7.6.6.2 Installing or Uninstalling Version Tokens

#### Note

If installed, Version Tokens involves some overhead. To avoid this overhead, do not install it unless you plan to use it.

This section describes how to install or uninstall Version Tokens, which is implemented in a plugin library file containing a plugin and loadable functions. For general information about installing or uninstalling plugins and loadable functions, see [Section 7.6.1, “Installing and Uninstalling Plugins”](#), and [Section 7.7.1, “Installing and Uninstalling Loadable Functions”](#).

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

The plugin library file base name is `version_tokens`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

To install the Version Tokens plugin and functions, use the `INSTALL PLUGIN` and `CREATE FUNCTION` statements, adjusting the `.so` suffix for your platform as necessary:

```
INSTALL PLUGIN version_tokens SONAME 'version_token.so';
CREATE FUNCTION version_tokens_set RETURNS STRING
 SONAME 'version_token.so';
CREATE FUNCTION version_tokens_show RETURNS STRING
 SONAME 'version_token.so';
CREATE FUNCTION version_tokens_edit RETURNS STRING
 SONAME 'version_token.so';
CREATE FUNCTION version_tokens_delete RETURNS STRING
 SONAME 'version_token.so';
CREATE FUNCTION version_tokens_lock_shared RETURNS INT
 SONAME 'version_token.so';
CREATE FUNCTION version_tokens_lock_exclusive RETURNS INT
 SONAME 'version_token.so';
CREATE FUNCTION version_tokens_unlock RETURNS INT
 SONAME 'version_token.so';
```

You must install the functions to manage the server's version token list, but you must also install the plugin because the functions do not work correctly without it.

If the plugin and functions are used on a replication source server, install them on all replica servers as well to avoid replication problems.

Once installed as just described, the plugin and functions remain installed until uninstalled. To remove them, use the `UNINSTALL PLUGIN` and `DROP FUNCTION` statements:

```
UNINSTALL PLUGIN version_tokens;
DROP FUNCTION version_tokens_set;
DROP FUNCTION version_tokens_show;
DROP FUNCTION version_tokens_edit;
DROP FUNCTION version_tokens_delete;
```

```
DROP FUNCTION version_tokens_lock_shared;
DROP FUNCTION version_tokens_lock_exclusive;
DROP FUNCTION version_tokens_unlock;
```

### 7.6.6.3 Using Version Tokens

Before using Version Tokens, install it according to the instructions provided at [Section 7.6.6.2, “Installing or Uninstalling Version Tokens”](#).

A scenario in which Version Tokens can be useful is a system that accesses a collection of MySQL servers but needs to manage them for load balancing purposes by monitoring them and adjusting server assignments according to load changes. Such a system comprises these elements:

- The collection of MySQL servers to be managed.
- An administrative or management application that communicates with the servers and organizes them into high-availability groups. Groups serve different purposes, and servers within each group may have different assignments. Assignment of a server within a certain group can change at any time.
- Client applications that access the servers to retrieve and update data, choosing servers according to the purposes assigned them. For example, a client should not send an update to a read-only server.

Version Tokens permit server access to be managed according to assignment without requiring clients to repeatedly query the servers about their assignments:

- The management application performs server assignments and establishes version tokens on each server to reflect its assignment. The application caches this information to provide a central access point to it.

If at some point the management application needs to change a server assignment (for example, to change it from permitting writes to read only), it changes the server's version token list and updates its cache.

- To improve performance, client applications obtain cache information from the management application, enabling them to avoid having to retrieve information about server assignments for each statement. Based on the type of statements it issues (for example, reads versus writes), a client selects an appropriate server and connects to it.
- In addition, the client sends to the server its own client-specific version tokens to register the assignment it requires of the server. For each statement sent by the client to the server, the server compares its own token list with the client token list. If the server token list contains all tokens present in the client token list with the same values, there is a match and the server executes the statement.

On the other hand, perhaps the management application has changed the server assignment and its version token list. In this case, the new server assignment may now be incompatible with the client requirements. A token mismatch between the server and client token lists occurs and the server returns an error in reply to the statement. This is an indication to the client to refresh its version token information from the management application cache, and to select a new server to communicate with.

The client-side logic for detecting version token errors and selecting a new server can be implemented different ways:

- The client can handle all version token registration, mismatch detection, and connection switching itself.
- The logic for those actions can be implemented in a connector that manages connections between clients and MySQL servers. Such a connector might handle mismatch error detection and statement resending itself, or it might pass the error to the application and leave it to the application to resend the statement.

The following example illustrates the preceding discussion in more concrete form.

When Version Tokens initializes on a given server, the server's version token list is empty. Token list maintenance is performed by calling functions. The `VERSION_TOKEN_ADMIN` privilege (or the deprecated `SUPER` privilege) is required to call any of the Version Token functions, so token list modification is expected to be done by a management or administrative application that has that privilege.

Suppose that a management application communicates with a set of servers that are queried by clients to access employee and product databases (named `emp` and `prod`, respectively). All servers are permitted to process data retrieval statements, but only some of them are permitted to make database updates. To handle this on a database-specific basis, the management application establishes a list of version tokens on each server. In the token list for a given server, token names represent database names and token values are `read` or `write` depending on whether the database must be used in read-only fashion or whether it can take reads and writes.

Client applications register a list of version tokens they require the server to match by setting a system variable. Variable setting occurs on a client-specific basis, so different clients can register different requirements. By default, the client token list is empty, which matches any server token list. When a client sets its token list to a nonempty value, matching may succeed or fail, depending on the server version token list.

To define the version token list for a server, the management application calls the `version_tokens_set()` function. (There are also functions for modifying and displaying the token list, described later.) For example, the application might send these statements to a group of three servers:

Server 1:

```
mysql> SELECT version_tokens_set('emp=read;prod=read');
+-----+
| version_tokens_set('emp=read;prod=read') |
+-----+
| 2 version tokens set. |
+-----+
```

Server 2:

```
mysql> SELECT version_tokens_set('emp=write;prod=read');
+-----+
| version_tokens_set('emp=write;prod=read') |
+-----+
| 2 version tokens set. |
+-----+
```

Server 3:

```
mysql> SELECT version_tokens_set('emp=read;prod=write');
+-----+
| version_tokens_set('emp=read;prod=write') |
+-----+
| 2 version tokens set. |
+-----+
```

The token list in each case is specified as a semicolon-separated list of `name=value` pairs. The resulting token list values result in these server assignments:

- Any server accepts reads for either database.
- Only server 2 accepts updates for the `emp` database.
- Only server 3 accepts updates for the `prod` database.

In addition to assigning each server a version token list, the management application also maintains a cache that reflects the server assignments.

Before communicating with the servers, a client application contacts the management application and retrieves information about server assignments. Then the client selects a server based on those assignments. Suppose that a client wants to perform both reads and writes on the `emp` database. Based on the preceding assignments, only server 2 qualifies. The client connects to server 2 and registers its server requirements there by setting its `version_tokens_session` system variable:

```
mysql> SET @@SESSION.version_tokens_session = 'emp=write';
```

For subsequent statements sent by the client to server 2, the server compares its own version token list to the client list to check whether they match. If so, statements execute normally:

```
mysql> UPDATE emp.employee SET salary = salary * 1.1 WHERE id = 4981;
Query OK, 1 row affected (0.07 sec)
Rows matched: 1 Changed: 1 Warnings: 0

mysql> SELECT last_name, first_name FROM emp.employee WHERE id = 4981;
+-----+-----+
| last_name | first_name |
+-----+-----+
| Smith | Abe |
+-----+-----+
1 row in set (0.01 sec)
```

Discrepancies between the server and client version token lists can occur two ways:

- A token name in the `version_tokens_session` value is not present in the server token list. In this case, an `ER_VTOKEN_PLUGIN_TOKEN_NOT_FOUND` error occurs.
- A token value in the `version_tokens_session` value differs from the value of the corresponding token in the server token list. In this case, an `ER_VTOKEN_PLUGIN_TOKEN_MISMATCH` error occurs.

As long as the assignment of server 2 does not change, the client continues to use it for reads and writes. But suppose that the management application wants to change server assignments so that writes for the `emp` database must be sent to server 1 instead of server 2. To do this, it uses `version_tokens_edit()` to modify the `emp` token value on the two servers (and updates its cache of server assignments):

Server 1:

```
mysql> SELECT version_tokens_edit('emp=write');
+-----+-----+
| version_tokens_edit('emp=write') |
+-----+-----+
| 1 version tokens updated. |
+-----+-----+
```

Server 2:

```
mysql> SELECT version_tokens_edit('emp=read');
+-----+-----+
| version_tokens_edit('emp=read') |
+-----+-----+
| 1 version tokens updated. |
+-----+-----+
```

`version_tokens_edit()` modifies the named tokens in the server token list and leaves other tokens unchanged.

The next time the client sends a statement to server 2, its own token list no longer matches the server token list and an error occurs:

```
mysql> UPDATE emp.employee SET salary = salary * 1.1 WHERE id = 4982;
ERROR 3136 (42000): Version token mismatch for emp. Correct value read
```

In this case, the client should contact the management application to obtain updated information about server assignments, select a new server, and send the failed statement to the new server.

### Note

Each client must cooperate with Version Tokens by sending only statements in accordance with the token list that it registers with a given server. For example, if a client registers a token list of 'emp=read', there is nothing in Version Tokens to prevent the client from sending updates for the emp database. The client itself must refrain from doing so.

For each statement received from a client, the server implicitly uses locking, as follows:

- Take a shared lock for each token named in the client token list (that is, in the `version_tokens_session` value)
- Perform the comparison between the server and client token lists
- Execute the statement or produce an error depending on the comparison result
- Release the locks

The server uses shared locks so that comparisons for multiple sessions can occur without blocking, while preventing changes to the tokens for any session that attempts to acquire an exclusive lock before it manipulates tokens of the same names in the server token list.

The preceding example uses only a few of the functions included in the Version Tokens plugin library, but there are others. One set of functions permits the server's list of version tokens to be manipulated and inspected. Another set of functions permits version tokens to be locked and unlocked.

These functions permit the server's list of version tokens to be created, changed, removed, and inspected:

- `version_tokens_set()` completely replaces the current list and assigns a new list. The argument is a semicolon-separated list of `name=value` pairs.
- `version_tokens_edit()` enables partial modifications to the current list. It can add new tokens or change the values of existing tokens. The argument is a semicolon-separated list of `name=value` pairs.
- `version_tokens_delete()` deletes tokens from the current list. The argument is a semicolon-separated list of token names.
- `version_tokens_show()` displays the current token list. It takes no argument.

Each of those functions, if successful, returns a binary string indicating what action occurred. The following example establishes the server token list, modifies it by adding a new token, deletes some tokens, and displays the resulting token list:

```
mysql> SELECT version_tokens_set('tok1=a;tok2=b');
+-----+
| version_tokens_set('tok1=a;tok2=b') |
+-----+
| 2 version tokens set. |
+-----+
mysql> SELECT version_tokens_edit('tok3=c');
+-----+
| version_tokens_edit('tok3=c') |
+-----+
```

```

| 1 version tokens updated. |
+-----+
mysql> SELECT version_tokens_delete('tok2;tok1');
+-----+
| version_tokens_delete('tok2;tok1') |
+-----+
| 2 version tokens deleted. |
+-----+
mysql> SELECT version_tokens_show();
+-----+
| version_tokens_show() |
+-----+
| tok3=c; |
+-----+

```

Warnings occur if a token list is malformed:

```

mysql> SELECT version_tokens_set('tok1=a; =c');
+-----+
| version_tokens_set('tok1=a; =c') |
+-----+
| 1 version tokens set. |
+-----+
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Warning
Code: 42000
Message: Invalid version token pair encountered. The list provided
 is only partially updated.
1 row in set (0.00 sec)

```

As mentioned previously, version tokens are defined using a semicolon-separated list of *name=value* pairs. Consider this invocation of `version_tokens_set()`:

```

mysql> SELECT version_tokens_set('tok1=b;;; tok2= a = b ; tok1 = 1\'2 3"4')
+-----+
| version_tokens_set('tok1=b;;; tok2= a = b ; tok1 = 1\'2 3"4') |
+-----+
| 3 version tokens set. |
+-----+

```

Version Tokens interprets the argument as follows:

- Whitespace around names and values is ignored. Whitespace within names and values is permitted. (For `version_tokens_delete()`, which takes a list of names without values, whitespace around names is ignored.)
- There is no quoting mechanism.
- Order of tokens is not significant except that if a token list contains multiple instances of a given token name, the last value takes precedence over earlier values.

Given those rules, the preceding `version_tokens_set()` call results in a token list with two tokens: `tok1` has the value `1'2 3"4`, and `tok2` has the value `a = b`. To verify this, call `version_tokens_show()`:

```

mysql> SELECT version_tokens_show();
+-----+
| version_tokens_show() |
+-----+
| tok2=a = b;tok1=1'2 3"4; |
+-----+

```

If the token list contains two tokens, why did `version_tokens_set()` return the value 3 `version_tokens_set`? That occurred because the original token list contained two definitions for `tok1`, and the second definition replaced the first.

The Version Tokens token-manipulation functions place these constraints on token names and values:

- Token names cannot contain `=` or `;` characters and have a maximum length of 64 characters.
- Token values cannot contain `;` characters. Length of values is constrained by the value of the `max_allowed_packet` system variable.
- Version Tokens treats token names and values as binary strings, so comparisons are case-sensitive.

Version Tokens also includes a set of functions enabling tokens to be locked and unlocked:

- `version_tokens_lock_exclusive()` acquires exclusive version token locks. It takes a list of one or more lock names and a timeout value.
- `version_tokens_lock_shared()` acquires shared version token locks. It takes a list of one or more lock names and a timeout value.
- `version_tokens_unlock()` releases version token locks (exclusive and shared). It takes no argument.

Each locking function returns nonzero for success. Otherwise, an error occurs:

```
mysql> SELECT version_tokens_lock_shared('lock1', 'lock2', 0);
+-----+
| version_tokens_lock_shared('lock1', 'lock2', 0) |
+-----+
| 1 |
+-----+

mysql> SELECT version_tokens_lock_shared(NULL, 0);
ERROR 3131 (42000): Incorrect locking service lock name '(null)'.
```

Locking using Version Tokens locking functions is advisory; applications must agree to cooperate.

It is possible to lock nonexistent token names. This does not create the tokens.

#### Note

Version Tokens locking functions are based on the locking service described at [Section 7.6.9.1, “The Locking Service”](#), and thus have the same semantics for shared and exclusive locks. (Version Tokens uses the locking service routines built into the server, not the locking service function interface, so those functions need not be installed to use Version Tokens.) Locks acquired by Version Tokens use a locking service namespace of `version_token_locks`. Locking service locks can be monitored using the Performance Schema, so this is also true for Version Tokens locks. For details, see [Locking Service Monitoring](#).

For the Version Tokens locking functions, token name arguments are used exactly as specified. Surrounding whitespace is not ignored and `=` and `;` characters are permitted. This is because Version Tokens simply passes the token names to be locked as is to the locking service.

## 7.6.6.4 Version Tokens Reference

The following discussion serves as a reference to these Version Tokens elements:

- [Version Tokens Functions](#)

- [Version Tokens System Variables](#)

## Version Tokens Functions

The Version Tokens plugin library includes several functions. One set of functions permits the server's list of version tokens to be manipulated and inspected. Another set of functions permits version tokens to be locked and unlocked. The `VERSION_TOKEN_ADMIN` privilege (or the deprecated `SUPER` privilege) is required to invoke any Version Tokens function.

The following functions permit the server's list of version tokens to be created, changed, removed, and inspected. Interpretation of `name_list` and `token_list` arguments (including whitespace handling) occurs as described in [Section 7.6.6.3, "Using Version Tokens"](#), which provides details about the syntax for specifying tokens, as well as additional examples.

- `version_tokens_delete(name_list)`

Deletes tokens from the server's list of version tokens using the `name_list` argument and returns a binary string that indicates the outcome of the operation. `name_list` is a semicolon-separated list of version token names to delete.

```
mysql> SELECT version_tokens_delete('tok1;tok3');
+-----+
| version_tokens_delete('tok1;tok3') |
+-----+
| 2 version tokens deleted. |
+-----+
```

An argument of `NULL` is treated as an empty string, which has no effect on the token list.

`version_tokens_delete()` deletes the tokens named in its argument, if they exist. (It is not an error to delete nonexistent tokens.) To clear the token list entirely without knowing which tokens are in the list, pass `NULL` or a string containing no tokens to `version_tokens_set()`:

```
mysql> SELECT version_tokens_set(NULL);
+-----+
| version_tokens_set(NULL) |
+-----+
| Version tokens list cleared. |
+-----+
mysql> SELECT version_tokens_set('');
+-----+
| version_tokens_set('') |
+-----+
| Version tokens list cleared. |
+-----+
```

- `version_tokens_edit(token_list)`

Modifies the server's list of version tokens using the `token_list` argument and returns a binary string that indicates the outcome of the operation. `token_list` is a semicolon-separated list of `name=value` pairs specifying the name of each token to be defined and its value. If a token exists, its value is updated with the given value. If a token does not exist, it is created with the given value. If the argument is `NULL` or a string containing no tokens, the token list remains unchanged.

```
mysql> SELECT version_tokens_set('tok1=value1;tok2=value2');
+-----+
| version_tokens_set('tok1=value1;tok2=value2') |
+-----+
| 2 version tokens set. |
+-----+
mysql> SELECT version_tokens_edit('tok2=new_value2;tok3=new_value3');
+-----+
```

```
| version_tokens_edit('tok2=new_value2;tok3=new_value3') |
+-----+
| 2 version tokens updated. |
+-----+
```

- `version_tokens_set(token_list)`

Replaces the server's list of version tokens with the tokens defined in the `token_list` argument and returns a binary string that indicates the outcome of the operation. `token_list` is a semicolon-separated list of `name=value` pairs specifying the name of each token to be defined and its value. If the argument is `NULL` or a string containing no tokens, the token list is cleared.

```
mysql> SELECT version_tokens_set('tok1=value1;tok2=value2');
+-----+
| version_tokens_set('tok1=value1;tok2=value2') |
+-----+
| 2 version tokens set. |
+-----+
```

- `version_tokens_show()`

Returns the server's list of version tokens as a binary string containing a semicolon-separated list of `name=value` pairs.

```
mysql> SELECT version_tokens_show();
+-----+
| version_tokens_show() |
+-----+
| tok2=value2;tok1=value1; |
+-----+
```

The following functions permit version tokens to be locked and unlocked:

- `version_tokens_lock_exclusive(token_name[, token_name] ..., timeout)`

Acquires exclusive locks on one or more version tokens, specified by name as strings, timing out with an error if the locks are not acquired within the given timeout value.

```
mysql> SELECT version_tokens_lock_exclusive('lock1', 'lock2', 10);
+-----+
| version_tokens_lock_exclusive('lock1', 'lock2', 10) |
+-----+
| 1 |
+-----+
```

- `version_tokens_lock_shared(token_name[, token_name] ..., timeout)`

Acquires shared locks on one or more version tokens, specified by name as strings, timing out with an error if the locks are not acquired within the given timeout value.

```
mysql> SELECT version_tokens_lock_shared('lock1', 'lock2', 10);
+-----+
| version_tokens_lock_shared('lock1', 'lock2', 10) |
+-----+
| 1 |
+-----+
```

- `version_tokens_unlock()`

Releases all locks that were acquired within the current session using `version_tokens_lock_exclusive()` and `version_tokens_lock_shared()`.

```
mysql> SELECT version_tokens_unlock();
```

```

+-----+
| version_tokens_unlock() |
+-----+
| 1 |
+-----+

```

The locking functions share these characteristics:

- The return value is nonzero for success. Otherwise, an error occurs.
- Token names are strings.
- In contrast to argument handling for the functions that manipulate the server token list, whitespace surrounding token name arguments is not ignored and `=` and `;` characters are permitted.
- It is possible to lock nonexistent token names. This does not create the tokens.
- Timeout values are nonnegative integers representing the time in seconds to wait to acquire locks before timing out with an error. If the timeout is 0, there is no waiting and the function produces an error if locks cannot be acquired immediately.
- Version Tokens locking functions are based on the locking service described at [Section 7.6.9.1, “The Locking Service”](#).

## Version Tokens System Variables

Version Tokens supports the following system variables. These variables are unavailable unless the Version Tokens plugin is installed (see [Section 7.6.6.2, “Installing or Uninstalling Version Tokens”](#)).

System variables:

- `version_tokens_session`

Command-Line Format	<code>--version-tokens-session=value</code>
System Variable	<code>version_tokens_session</code>
Scope	Global, Session
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value	<code>NULL</code>

The session value of this variable specifies the client version token list and indicates the tokens that the client session requires the server version token list to have.

If the `version_tokens_session` variable is `NULL` (the default) or has an empty value, any server version token list matches. (In effect, an empty value disables matching requirements.)

If the `version_tokens_session` variable has a nonempty value, any mismatch between its value and the server version token list results in an error for any statement the session sends to the server. A mismatch occurs under these conditions:

- A token name in the `version_tokens_session` value is not present in the server token list. In this case, an `ER_VTOKEN_PLUGIN_TOKEN_NOT_FOUND` error occurs.
- A token value in the `version_tokens_session` value differs from the value of the corresponding token in the server token list. In this case, an `ER_VTOKEN_PLUGIN_TOKEN_MISMATCH` error occurs.

It is not a mismatch for the server version token list to include a token not named in the `version_tokens_session` value.

Suppose that a management application has set the server token list as follows:

```
mysql> SELECT version_tokens_set('tok1=a;tok2=b;tok3=c');
+-----+
| version_tokens_set('tok1=a;tok2=b;tok3=c') |
+-----+
| 3 version tokens set. |
+-----+
```

A client registers the tokens it requires the server to match by setting its `version_tokens_session` value. Then, for each subsequent statement sent by the client, the server checks its token list against the client `version_tokens_session` value and produces an error if there is a mismatch:

```
mysql> SET @@SESSION.version_tokens_session = 'tok1=a;tok2=b';
mysql> SELECT 1;
+----+
| 1 |
+----+

mysql> SET @@SESSION.version_tokens_session = 'tok1=b';
mysql> SELECT 1;
ERROR 3136 (42000): Version token mismatch for tok1. Correct value a
```

The first `SELECT` succeeds because the client tokens `tok1` and `tok2` are present in the server token list and each token has the same value in the server list. The second `SELECT` fails because, although `tok1` is present in the server token list, it has a different value than specified by the client.

At this point, any statement sent by the client fails, unless the server token list changes such that it matches again. Suppose that the management application changes the server token list as follows:

```
mysql> SELECT version_tokens_edit('tok1=b');
+-----+
| version_tokens_edit('tok1=b') |
+-----+
| 1 version tokens updated. |
+-----+

mysql> SELECT version_tokens_show();
+-----+
| version_tokens_show() |
+-----+
| tok3=c;tok1=b;tok2=b; |
+-----+
```

Now the client `version_tokens_session` value matches the server token list and the client can once again successfully execute statements:

```
mysql> SELECT 1;
+----+
| 1 |
+----+

| 1 |
+----+
```

- `version_tokens_session_number`

Command-Line Format	<code>--version-tokens-session-number=#</code>
---------------------	------------------------------------------------

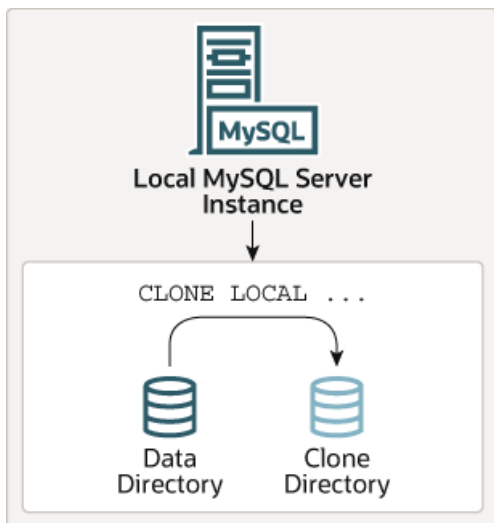

System Variable	<code>version_tokens_session_number</code>
Scope	Global, Session
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	0

This variable is for internal use.

## 7.6.7 The Clone Plugin

The clone plugin permits cloning data locally or from a remote MySQL server instance. Cloned data is a physical snapshot of data stored in `InnoDB` that includes schemas, tables, tablespaces, and data dictionary metadata. The cloned data comprises a fully functional data directory, which permits using the clone plugin for MySQL server provisioning.

**Figure 7.1 Local Cloning Operation**

A local cloning operation clones data from the MySQL server instance where the cloning operation is initiated to a directory on the same server or node where MySQL server instance runs.

**Figure 7.2 Remote Cloning Operation**

A remote cloning operation involves a local MySQL server instance (the “recipient”) where the cloning operation is initiated, and a remote MySQL server instance (the “donor”) where the source data is located. When a remote cloning operation is initiated on the recipient, cloned data is transferred over the network from the donor to the recipient. By default, a remote cloning operation removes existing user-created data (schemas, tables, tablespaces) and binary logs from the recipient data directory before cloning data from the donor. Optionally, you can clone data to a different directory on the recipient to avoid removing data from the current recipient data directory.

There is no difference with respect to data that is cloned by a local cloning operation as compared to a remote cloning operation. Both operations clone the same set of data.

The clone plugin supports replication. In addition to cloning data, a cloning operation extracts and transfers replication coordinates from the donor and applies them on the recipient, which enables using the clone plugin for provisioning Group Replication members and replicas. Using the clone plugin for provisioning is considerably faster and more efficient than replicating a large number of transactions (see [Section 7.6.7.7, “Cloning for Replication”](#)). Group Replication members can also be configured to use the clone plugin as an alternative method of recovery, so that members automatically choose the most efficient way to retrieve group data from seed members. For more information, see [Section 20.5.4.2, “Cloning for Distributed Recovery”](#).

The clone plugin supports cloning of encrypted and page-compressed data. See [Section 7.6.7.5, “Cloning Encrypted Data”](#), and [Section 7.6.7.6, “Cloning Compressed Data”](#).

The clone plugin must be installed before you can use it. For installation instructions, see [Section 7.6.7.1, “Installing the Clone Plugin”](#). For cloning instructions, see [Section 7.6.7.2, “Cloning Data Locally”](#), and [Section 7.6.7.3, “Cloning Remote Data”](#).

Performance Schema tables and instrumentation are provided for monitoring cloning operations. See [Section 7.6.7.10, “Monitoring Cloning Operations”](#).

### 7.6.7.1 Installing the Clone Plugin

This section describes how to install and configure the clone plugin. For remote cloning operations, the clone plugin must be installed on the donor and recipient MySQL server instances.

For general information about installing or uninstalling plugins, see [Section 7.6.1, “Installing and Uninstalling Plugins”](#).

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, set the value of `plugin_dir` at server startup to tell the server the plugin directory location.

The plugin library file base name is `mysql_clone.so`. The file name suffix differs by platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

To load the plugin at server startup, use the `--plugin-load-add` option to name the library file that contains it. With this plugin-loading method, the option must be given each time the server starts. For example, put these lines in your `my.cnf` file, adjusting the plugin library file name extension for your platform as necessary. (The plugin library file name extension depends on your platform. Common suffixes are `.so` for Unix and Unix-like systems, `.dll` for Windows.)

```
[mysqld]
plugin-load-add=mysql_clone.so
```

After modifying `my.cnf`, restart the server to cause the new settings to take effect.

#### Note

The `--plugin-load-add` option cannot be used to load the clone plugin when restarting the server during an upgrade from a previous MySQL version. In such cases, attempting to restart the server with `plugin-load-add=mysql_clone.so` raises the error `[ERROR] [MY-013238] [Server] Error installing plugin 'clone': Cannot install during upgrade`. To keep this from happening, upgrade the server before attempting to start the server with `plugin-load-add=mysql_clone.so`.

Alternatively, to load the plugin at runtime, use this statement, adjusting the `.so` suffix for your platform as necessary:

```
INSTALL PLUGIN clone SONAME 'mysql_clone.so';
```

`INSTALL PLUGIN` loads the plugin, and also registers it in the `mysql.plugins` system table to cause the plugin to be loaded for each subsequent normal server startup without the need for `--plugin-load-add`.

To verify plugin installation, examine the Information Schema `PLUGINS` table or use the `SHOW PLUGINS` statement (see [Section 7.6.2, “Obtaining Server Plugin Information”](#)). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
FROM INFORMATION_SCHEMA.PLUGINS
WHERE PLUGIN_NAME = 'clone';
```

PLUGIN_NAME	PLUGIN_STATUS
clone	ACTIVE

If the plugin fails to initialize, check the server error log for clone or plugin-related diagnostic messages.

If the plugin has been previously registered with `INSTALL PLUGIN` or is loaded with `--plugin-load-add`, you can use the `--clone` option at server startup to control the plugin activation state. For example, to load the plugin at startup and prevent it from being removed at runtime, use these options:

```
[mysqld]
plugin-load-add=mysql_clone.so
clone=FORCE_PLUS_PERMANENT
```

If you want to prevent the server from running without the clone plugin, use `--clone` with a value of `FORCE` or `FORCE_PLUS_PERMANENT` to force server startup to fail if the plugin does not initialize successfully.

For more information about plugin activation states, see [Controlling Plugin Activation State](#).

### 7.6.7.2 Cloning Data Locally

The clone plugin supports the following syntax for cloning data locally; that is, cloning data from the local MySQL data directory to another directory on the same server or node where the MySQL server instance runs:

```
CLONE LOCAL DATA DIRECTORY [=] 'clone_dir';
```

To use `CLONE` syntax, the clone plugin must be installed. For installation instructions, see [Section 7.6.7.1, “Installing the Clone Plugin”](#).

The `BACKUP_ADMIN` privilege is required to execute `CLONE LOCAL DATA DIRECTORY` statements.

```
mysql> GRANT BACKUP_ADMIN ON *.* TO 'clone_user';
```

where `clone_user` is the MySQL user that performs the cloning operation. The user you select to perform the cloning operation can be any MySQL user with the `BACKUP_ADMIN` privilege on \*.\*.

The following example demonstrates cloning data locally:

```
mysql> CLONE LOCAL DATA DIRECTORY = '/path/to/clone_dir';
```

where `/path/to/clone_dir` is the full path of the local directory that data is cloned to. An absolute path is required, and the specified directory (“`clone_dir`”) must not exist, but the specified path must be an existent path. The MySQL server must have the necessary write access to create the directory.

#### Note

A local cloning operation does not support cloning of user-created tables or tablespaces that reside outside of the data directory. Attempting to clone such tables or tablespaces causes the following error: `ERROR 1086 (HY000): File '/path/to/tablespace_name.ibd' already exists`. Cloning a tablespace with the same path as the source tablespace would cause a conflict and is therefore prohibited.

All other user-created `InnoDB` tables and tablespaces, the `InnoDB` system tablespace, redo logs, and undo tablespaces are cloned to the specified directory.

If desired, you can start the MySQL server on the cloned directory after the cloning operation is complete.

```
$> mysqld_safe --datadir=clone_dir
```

where `clone_dir` is the directory that data was cloned to.

For information about monitoring cloning operation status and progress, see [Section 7.6.7.10, “Monitoring Cloning Operations”](#).

### 7.6.7.3 Cloning Remote Data

The clone plugin supports the following syntax for cloning remote data; that is, cloning data from a remote MySQL server instance (the donor) and transferring it to the MySQL instance where the cloning operation was initiated (the recipient).

```
CLONE INSTANCE FROM 'user'@'host':port
IDENTIFIED BY 'password'
[DATA DIRECTORY [=] 'clone_dir']
```

```
[REQUIRE [NO] SSL];
```

where:

- `user` is the clone user on the donor MySQL server instance.
- `password` is the `user` password.
- `host` is the `hostname` address of the donor MySQL server instance. Internet Protocol version 6 (IPv6) address format is not supported. An alias to the IPv6 address can be used instead. An IPv4 address can be used as is.
- `port` is the `port` number of the donor MySQL server instance. (The X Protocol port specified by `mysqlx_port` is not supported. Connecting to the donor MySQL server instance through MySQL Router is also not supported.)
- `DATA DIRECTORY [=] 'clone_dir'` is an optional clause used to specify a directory on the recipient for the data you are cloning. Use this option if you do not want to remove existing user-created data (schemas, tables, tablespaces) and binary logs from the recipient data directory. An absolute path is required, and the directory must not exist. The MySQL server must have the necessary write access to create the directory.

When the optional `DATA DIRECTORY [=] 'clone_dir'` clause is not used, a cloning operation removes user-created data (schemas, tables, tablespaces) and binary logs from the recipient data directory, clones the new data to the recipient data directory, and automatically restarts the server afterward.

- `[REQUIRE [NO] SSL]` explicitly specifies whether an encrypted connection is to be used or not when transferring cloned data over the network. An error is returned if the explicit specification cannot be satisfied. If an SSL clause is not specified, clone attempts to establish an encrypted connection by default, falling back to an insecure connection if the secure connection attempt fails. A secure connection is required when cloning encrypted data regardless of whether this clause is specified. For more information, see [Configuring an Encrypted Connection for Cloning](#).

#### Note

By default, user-created `InnoDB` tables and tablespaces that reside in the data directory on the donor MySQL server instance are cloned to the data directory on the recipient MySQL server instance. If the `DATA DIRECTORY [=] 'clone_dir'` clause is specified, they are cloned to the specified directory.

User-created `InnoDB` tables and tablespaces that reside outside of the data directory on the donor MySQL server instance are cloned to the same path on the recipient MySQL server instance. An error is reported if a table or tablespace already exists.

By default, the `InnoDB` system tablespace, redo logs, and undo tablespaces are cloned to the same locations that are configured on the donor (as defined by `innodb_data_home_dir` and `innodb_data_file_path`, `innodb_log_group_home_dir`, and `innodb_undo_directory`, respectively). If the `DATA DIRECTORY [=] 'clone_dir'` clause is specified, those tablespaces and logs are cloned to the specified directory.

## Remote Cloning Prerequisites

To perform a cloning operation, the clone plugin must be active on both the donor and recipient MySQL server instances. For installation instructions, see [Section 7.6.7.1, “Installing the Clone Plugin”](#).

A MySQL user on the donor and recipient is required for executing the cloning operation (the “clone user”).

- On the donor, the clone user requires the `BACKUP_ADMIN` privilege for accessing and transferring data from the donor and blocking concurrent DDL during the cloning operation. Concurrent DDL is permitted on the donor by default. See [Section 7.6.7.4, “Cloning and Concurrent DDL”](#).
- On the recipient, the clone user requires the `CLONE_ADMIN` privilege for replacing recipient data, blocking DDL on the recipient during the cloning operation, and automatically restarting the server. The `CLONE_ADMIN` privilege includes `BACKUP_ADMIN` and `SHUTDOWN` privileges implicitly.

Instructions for creating the clone user and granting the required privileges are included in the remote cloning example that follows this prerequisite information.

The following prerequisites are checked when the `CLONE INSTANCE` statement is executed:

- The donor and recipient must be the same MySQL server series, such as 8.4.0 and 8.4.11. To determine the MySQL server version, issue the following query:

```
mysql> SHOW VARIABLES LIKE 'version';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| version | 9.1.0 |
+-----+-----+
```

- The donor and recipient MySQL server instances must run on the same operating system and platform. For example, if the donor instance runs on a Linux 64-bit platform, the recipient instance must also run on that platform. Refer to your operating system documentation for information about how to determine your operating system platform.
- The recipient must have enough disk space for the cloned data. By default, user-created data (schemas, tables, tablespaces) and binary logs are removed on the recipient prior to cloning the donor data, so you only require enough space for the donor data. If you clone to a named directory using the `DATA DIRECTORY` clause, you must have enough disk space for the existing recipient data and the cloned data. You can estimate the size of your data by checking the data directory size on your file system and the size of any tablespaces that reside outside of the data directory. When estimating data size on the donor, remember that only `InnoDB` data is cloned. If you store data in other storage engines, adjust your data size estimate accordingly.
- `InnoDB` permits creating some tablespace types outside of the data directory. If the donor MySQL server instance has tablespaces that reside outside of the data directory, the cloning operation must be able access those tablespaces. You can query the Information Schema `FILES` table to identify tablespaces that reside outside of the data directory. Files that reside outside of the data directory have a fully qualified path to a directory other than the data directory.

```
mysql> SELECT FILE_NAME FROM INFORMATION_SCHEMA.FILES;
```

- Plugins that are active on the donor, including any keyring plugin, must also be active on the recipient. You can identify active plugins by issuing a `SHOW PLUGINS` statement or by querying the Information Schema `PLUGINS` table.
- The donor and recipient must have the same MySQL server character set and collation. For information about MySQL server character set and collation configuration, see [Section 12.15, “Character Set Configuration”](#).
- The same `innodb_page_size` and `innodb_data_file_path` settings are required on the donor and recipient. The `innodb_data_file_path` setting on the donor and recipient must specify the same number of data files of an equivalent size. You can check variable settings using `SHOW VARIABLES` syntax.

```
mysql> SHOW VARIABLES LIKE 'innodb_page_size';
mysql> SHOW VARIABLES LIKE 'innodb_data_file_path';
```

- If cloning encrypted or page-compressed data, the donor and recipient must have the same file system block size. For page-compressed data, the recipient file system must support sparse files and hole punching for hole punching to occur on the recipient. For information about these features and how to identify tables and tablespaces that use them, see [Section 7.6.7.5, “Cloning Encrypted Data”](#), and [Section 7.6.7.6, “Cloning Compressed Data”](#). To determine your file system block size, refer to your operating system documentation.
- A secure connection is required if you are cloning encrypted data. See [Configuring an Encrypted Connection for Cloning](#).
- The `clone_valid_donor_list` setting on the recipient must include the host address of the donor MySQL server instance. You can only clone data from a host on the valid donor list. A MySQL user with the `SYSTEM_VARIABLES_ADMIN` privilege is required to configure this variable. Instructions for setting the `clone_valid_donor_list` variable are provided in the remote cloning example that follows this section. You can check the `clone_valid_donor_list` setting using `SHOW VARIABLES` syntax.

```
mysql> SHOW VARIABLES LIKE 'clone_valid_donor_list';
```

- There must be no other cloning operation running. Only a single cloning operation is permitted at a time. To determine if a clone operation is running, query the `clone_status` table. See [Monitoring Cloning Operations using Performance Schema Clone Tables](#).
- The clone plugin transfers data in 1MB packets plus metadata. The minimum required `max_allowed_packet` value is therefore 2MB on the donor and the recipient MySQL server instances. A `max_allowed_packet` value less than 2MB results in an error. Use the following query to check your `max_allowed_packet` setting:

```
mysql> SHOW VARIABLES LIKE 'max_allowed_packet';
```

The following prerequisites also apply:

- Undo tablespace file names on the donor must be unique. When data is cloned to the recipient, undo tablespaces, regardless of their location on the donor, are cloned to the `innodb_undo_directory` location on the recipient or to the directory specified by the `DATA DIRECTORY [=] 'clone_dir'` clause, if used. Duplicate undo tablespace file names on the donor are not permitted for this reason. An error is reported if duplicate undo tablespace file names are encountered during a cloning operation.

To view undo tablespace file names on the donor to ensure that they are unique, query the `FILES` table:

```
mysql> SELECT TABLESPACE_NAME, FILE_NAME FROM INFORMATION_SCHEMA.FILES
 WHERE FILE_TYPE LIKE 'UNDO LOG';
```

For information about dropping and adding undo tablespace files, see [Section 17.6.3.4, “Undo Tablespaces”](#).

- By default, the recipient MySQL server instance is restarted (stopped and started) automatically after the data is cloned. For an automatic restart to occur, a monitoring process must be available on the recipient to detect server shutdowns. Otherwise, the cloning operation halts with the following error after the data is cloned, and the recipient MySQL server instance is shut down:

```
ERROR 3707 (HY000): Restart server failed (mysqld is not managed by supervisor process).
```

This error does not indicate a cloning failure. It means that the recipient MySQL server instance must be started again manually after the data is cloned. After starting the server manually, you can connect

to the recipient MySQL server instance and check the Performance Schema clone tables to verify that the cloning operation completed successfully (see [Monitoring Cloning Operations using Performance Schema Clone Tables](#).) The `RESTART` statement has the same monitoring process requirement. For more information, see [Section 15.7.8.8, “RESTART Statement”](#). This requirement is not applicable if cloning to a named directory using the `DATA DIRECTORY` clause, as an automatic restart is not performed in this case.

- Several variables control various aspects of a remote cloning operation. Before performing a remote cloning operation, review the variables and adjust settings as necessary to suit your computing environment. Clone variables are set on recipient MySQL server instance where the cloning operation is executed. See [Section 7.6.7.13, “Clone System Variables”](#).

## Cloning Remote Data

The following example demonstrates cloning remote data. By default, a remote cloning operation removes user-created data (schemas, tables, tablespaces) and binary logs on the recipient, clones the new data to the recipient data directory, and restarts the MySQL server afterward.

The example assumes that remote cloning prerequisites are met. See [Remote Cloning Prerequisites](#).

1. Login to the donor MySQL server instance with an administrative user account.

- a. Create a clone user with the `BACKUP_ADMIN` privilege.

```
mysql> CREATE USER 'donor_clone_user'@'example.donor.host.com' IDENTIFIED BY 'password';
mysql> GRANT BACKUP_ADMIN on *.* to 'donor_clone_user'@'example.donor.host.com';
```

- b. Install the clone plugin:

```
mysql> INSTALL PLUGIN clone SONAME 'mysql_clone.so';
```

2. Login to the recipient MySQL server instance with an administrative user account.

- a. Create a clone user with the `CLONE_ADMIN` privilege.

```
mysql> CREATE USER 'recipient_clone_user'@'example.recipient.host.com' IDENTIFIED BY 'password';
mysql> GRANT CLONE_ADMIN on *.* to 'recipient_clone_user'@'example.recipient.host.com';
```

- b. Install the clone plugin:

```
mysql> INSTALL PLUGIN clone SONAME 'mysql_clone.so';
```

- c. Add the host address of the donor MySQL server instance to the `clone_valid_donor_list` variable setting.

```
mysql> SET GLOBAL clone_valid_donor_list = 'example.donor.host.com:3306';
```

3. Log on to the recipient MySQL server instance as the clone user you created previously (`recipient_clone_user'@'example.recipient.host.com`) and execute the `CLONE INSTANCE` statement.

```
mysql> CLONE INSTANCE FROM 'donor_clone_user'@'example.donor.host.com':3306
IDENTIFIED BY 'password';
```

After the data is cloned, the MySQL server instance on the recipient is restarted automatically.

For information about monitoring cloning operation status and progress, see [Section 7.6.7.10, “Monitoring Cloning Operations”](#).

## Cloning to a Named Directory

By default, a remote cloning operation removes user-created data (schemas, tables, tablespaces) and binary logs from the recipient data directory before cloning data from the donor MySQL Server instance. By cloning to a named directory, you can avoid removing data from the current recipient data directory.

The procedure for cloning to a named directory is the same procedure described in [Cloning Remote Data](#) with one exception: The `CLONE INSTANCE` statement must include the `DATA DIRECTORY` clause. For example:

```
mysql> CLONE INSTANCE FROM 'user'@'example.donor.host.com':3306
 IDENTIFIED BY 'password'
 DATA DIRECTORY = '/path/to/clone_dir';
```

An absolute path is required, and the directory must not exist. The MySQL server must have the necessary write access to create the directory.

When cloning to a named directory, the recipient MySQL server instance is not restarted automatically after the data is cloned. If you want to restart the MySQL server on the named directory, you must do so manually:

```
$> mysqld_safe --datadir=/path/to/clone_dir
```

where `/path/to/clone_dir` is the path to the named directory on the recipient.

## Configuring an Encrypted Connection for Cloning

You can configure an encrypted connection for remote cloning operations to protect data as it is cloned over the network. An encrypted connection is required by default when cloning encrypted data. (see [Section 7.6.7.5, “Cloning Encrypted Data”](#).)

The instructions that follow describe how to configure the recipient MySQL server instance to use an encrypted connection. It is assumed that the donor MySQL server instance is already configured to use encrypted connections. If not, refer to [Section 8.3.1, “Configuring MySQL to Use Encrypted Connections”](#) for server-side configuration instructions.

To configure the recipient MySQL server instance to use an encrypted connection:

1. Make the client certificate and key files of the donor MySQL server instance available to the recipient host. Either distribute the files to the recipient host using a secure channel or place them on a mounted partition that is accessible to the recipient host. The client certificate and key files to make available include:

- `ca.pem`

The self-signed certificate authority (CA) file.

- `client-cert.pem`

The client public key certificate file.

- `client-key.pem`

The client private key file.

2. Configure the following SSL options on the recipient MySQL server instance.

- `clone_ssl_ca`

Specifies the path to the self-signed certificate authority (CA) file.

- `clone_ssl_cert`

Specifies the path to the client public key certificate file.

- `clone_ssl_key`

Specifies the path to the client private key file.

For example:

```
clone_ssl_ca=/path/to/ca.pem
clone_ssl_cert=/path/to/client-cert.pem
clone_ssl_key=/path/to/client-key.pem
```

3. To require that an encrypted connection is used, include the `REQUIRE SSL` clause when issuing the `CLONE` statement on the recipient.

```
mysql> CLONE INSTANCE FROM 'user'@'example.donor.host.com':3306
 IDENTIFIED BY 'password'
 DATA DIRECTORY = '/path/to/clone_dir'
 REQUIRE SSL;
```

If an SSL clause is not specified, the clone plugin attempts to establish an encrypted connection by default, falling back to an unencrypted connection if the encrypted connection attempt fails.

#### Note

If you are cloning encrypted data, an encrypted connection is required by default regardless of whether the `REQUIRE SSL` clause is specified. Using `REQUIRE NO SSL` causes an error if you attempt to clone encrypted data.

### 7.6.7.4 Cloning and Concurrent DDL

In MySQL 9.1, concurrent DDL is permitted on the donor by default. Concurrent DDL support on the donor is controlled by the `clone_block_ddl` variable. Concurrent DDL support can be enabled and disabled dynamically using a `SET` statement like this one:

```
SET GLOBAL clone_block_ddl={OFF|ON}
```

The default setting is `clone_block_ddl=OFF`, which permits concurrent DDL on the donor.

Whether the effect of a concurrent DDL operation is cloned or not depends on whether the DDL operation finishes before the dynamic snapshot is taken by the cloning operation.

DDL operations that are not permitted during a cloning operation regardless of the `clone_block_ddl` setting include:

- `ALTER TABLE tbl_name DISCARD TABLESPACE;`
- `ALTER TABLE tbl_name IMPORT TABLESPACE;`
- `ALTER INSTANCE DISABLE INNODB REDO_LOG;`

### 7.6.7.5 Cloning Encrypted Data

Cloning of encrypted data is supported. The following requirements apply:

- A secure connection is required when cloning remote data to ensure safe transfer of unencrypted tablespace keys over the network. Tablespace keys are decrypted at the donor before transport and re-

encrypted at the recipient using the recipient master key. An error is reported if an encrypted connection is not available or the `REQUIRE NO SSL` clause is used in the `CLONE INSTANCE` statement. For information about configuring an encrypted connection for cloning, see [Configuring an Encrypted Connection for Cloning](#).

- When cloning data to a local data directory that uses a locally managed keyring, the same keyring must be used when starting the MySQL server on the clone directory.
- When cloning data to a remote data directory (the recipient directory) that uses a locally managed keyring, the recipient keyring must be used when starting the MySQL server on the cloned directory.

#### Note

The `innodb_redo_log_encrypt` and `innodb_undo_log_encrypt` variable settings cannot be modified while a cloning operation is in progress.

For information about the data encryption feature, see [Section 17.13, “InnoDB Data-at-Rest Encryption”](#).

### 7.6.7.6 Cloning Compressed Data

Cloning of page-compressed data is supported. The following requirements apply when cloning remote data:

- The recipient file system must support sparse files and hole punching for hole punching to occur on the recipient.
- The donor and recipient file systems must have the same block size. If file system block sizes differ, an error similar to the following is reported: `ERROR 3868 (HY000): Clone Configuration FS Block Size: Donor value: 114688 is different from Recipient value: 4096`.

For information about the page compression feature, see [Section 17.9.2, “InnoDB Page Compression”](#).

### 7.6.7.7 Cloning for Replication

The clone plugin supports replication. In addition to cloning data, a cloning operation extracts replication coordinates from the donor and transfers them to the recipient, which enables using the clone plugin for provisioning Group Replication members and replicas. Using the clone plugin for provisioning is considerably faster and more efficient than replicating a large number of transactions.

Group Replication members can also be configured to use the clone plugin as an option for distributed recovery, in which case joining members automatically choose the most efficient way to retrieve group data from existing group members. For more information, see [Section 20.5.4.2, “Cloning for Distributed Recovery”](#).

During the cloning operation, both the binary log position (filename, offset) and the `gtid_executed` GTID set are extracted and transferred from the donor MySQL server instance to the recipient. This data permits initiating replication at a consistent position in the replication stream. The binary logs and relay logs, which are held in files, are not copied from the donor to the recipient. To initiate replication, the binary logs required for the recipient to catch up to the donor must not be purged between the time that the data is cloned and the time that replication is started. If the required binary logs are not available, a replication handshake error is reported. A cloned instance should therefore be added to a replication group without excessive delay to avoid required binary logs being purged or the new member lagging behind significantly, requiring more recovery time.

- Issue this query on a cloned MySQL server instance to check the binary log position that was transferred to the recipient:

```
mysql> SELECT BINLOG_FILE, BINLOG_POSITION FROM performance_schema.clone_status;
```

- Issue this query on a cloned MySQL server instance to check the `gtid_executed` GTID set that was transferred to the recipient:

```
mysql> SELECT @@GLOBAL.GTID_EXECUTED;
```

By default, the replication metadata repositories are held in tables that are copied from the donor to the recipient during the cloning operation. The replication metadata repositories hold replication-related configuration settings that can be used to resume replication correctly after the cloning operation. The tables `mysql.slave_master_info`, `mysql.slave_relay_log_info`, and `mysql.slave_worker_info` are all copied.

For a list of what is included in each table, see [Section 19.2.4.2, “Replication Metadata Repositories”](#).

To clone for replication, perform the following steps:

1. For a new group member for Group Replication, first configure the MySQL Server instance for Group Replication, following the instructions in [Section 20.2.1.6, “Adding Instances to the Group”](#). Also set up the prerequisites for cloning described in [Section 20.5.4.2, “Cloning for Distributed Recovery”](#). When you issue `START GROUP_REPLICATION` on the joining member, the cloning operation is managed automatically by Group Replication, so you do not need to carry out the operation manually, and you do not need to perform any further setup steps on the joining member.
2. For a replica in a source/replica MySQL replication topology, first clone the data from the donor MySQL server instance to the recipient manually. The donor must be a source or replica in the replication topology. For cloning instructions, see [Section 7.6.7.3, “Cloning Remote Data”](#).
3. After the cloning operation completes successfully, if you want to use the same replication channels on the recipient MySQL server instance that were present on the donor, verify which of them can resume replication automatically in the source/replica MySQL replication topology, and which need to be set up manually.
  - For GTID-based replication, if the recipient is configured with `gtid_mode=ON` and has cloned from a donor with `gtid_mode=ON`, `ON_PERMISSIVE`, or `OFF_PERMISSIVE`, the `gtid_executed` GTID set from the donor is applied on the recipient. If the recipient is cloned from a replica already in the topology, replication channels on the recipient that use GTID auto-positioning can resume replication automatically after the cloning operation when the channel is started. You do not need to perform any manual setup if you just want to use these same channels.
  - For binary log file position based replication, the binary log position from the donor is applied on the recipient. Replication channels on the recipient that use binary log file position based replication automatically attempt to carry out the relay log recovery process, using the cloned relay log information, before restarting replication. For a single-threaded replica (`replica_parallel_workers` is set to 0), relay log recovery should succeed in the absence of any other issues, enabling the channel to resume replication with no further setup. For a multithreaded replica (`replica_parallel_workers` is greater than 0), relay log recovery is likely to fail because it cannot usually be completed automatically. In this case, an error message is issued, and you must set the channel up manually.
4. If you need to set up cloned replication channels manually, or want to use different replication channels on the recipient, the following instructions provide a summary and abbreviated examples for adding a recipient MySQL server instance to a replication topology. Also refer to the detailed instructions that apply to your replication setup.
  - To add a recipient MySQL server instance to a MySQL replication topology that uses GTID-based transactions as the replication data source, configure the instance as required, following the instructions in [Section 19.1.3.4, “Setting Up Replication Using GTIDs”](#). Add replication channels

for the instance as shown in the following abbreviated example. The `CHANGE REPLICATION SOURCE TO` statement must define the host address and port number of the source, and the `SOURCE_AUTO_POSITION` option should be enabled, as shown:

```
CHANGE SOURCE TO SOURCE_HOST = 'source_host_name', SOURCE_PORT = source_port_num,
...
SOURCE_AUTO_POSITION = 1,
FOR CHANNEL 'setup_channel';
START REPLICA USER = 'user_name' PASSWORD = 'password' FOR CHANNEL 'setup_channel';
```

- To add a recipient MySQL server instance to a MySQL replication topology that uses binary log file position based replication, configure the instance as required, following the instructions in [Section 19.1.2, “Setting Up Binary Log File Position Based Replication”](#). Add replication channels for the instance as shown in the following abbreviated example, using the binary log position that was transferred to the recipient during the cloning operation:

```
SELECT BINLOG_FILE, BINLOG_POSITION FROM performance_schema.clone_status;
CHANGE SOURCE TO SOURCE_HOST = 'source_host_name', SOURCE_PORT = source_port_num,
...
SOURCE_LOG_FILE = 'source_log_name',
SOURCE_LOG_POS = source_log_pos,
FOR CHANNEL 'setup_channel';
START REPLICA USER = 'user_name' PASSWORD = 'password' FOR CHANNEL 'setup_channel';
```

### 7.6.7.8 Directories and Files Created During a Cloning Operation

When data is cloned, the following directories and files are created for internal use. They should not be modified.

- `#clone`: Contains internal clone files used by the cloning operation. Created in the directory that data is cloned to.
- `#ib_archive`: Contains internally archived log files, archived on the donor during the cloning operation.
- `*.#clone` files: Temporary data files created on the recipient while data is removed from the recipient data directory and new data is cloned during a remote cloning operation.

### 7.6.7.9 Remote Cloning Operation Failure Handling

This section describes failure handing at different stages of a cloning operation.

1. Prerequisites are checked (see [Remote Cloning Prerequisites](#)).
  - If a failure occurs during the prerequisite check, the `CLONE INSTANCE` operation reports an error.
2. Concurrent DDL on the donor is blocked only if the `clone_block_ddl` variable is set to `ON` (the default setting is `OFF`). See [Section 7.6.7.4, “Cloning and Concurrent DDL”](#).

If the cloning operation is unable to obtain a DDL lock within the time limit specified by the `clone_ddl_timeout` variable, an error is reported.

3. User-created data (schemas, tables, tablespaces) and binary logs on the recipient are removed before data is cloned to the recipient data directory.

When user-created data and binary logs are removed from the recipient data directory during a remote cloning operation, the data is not saved and may be lost if a failure occurs. If the data is of importance, a backup should be taken before initiating a remote cloning operation.

For informational purposes, warnings are printed to the server error log to specify when data removal starts and finishes:

```
[Warning] [MY-013453] [InnoDB] Clone removing all user data for provisioning:
Started...

[Warning] [MY-013453] [InnoDB] Clone removing all user data for provisioning:
Finished
```

If a failure occurs while removing data, the recipient may be left with a partial set of schemas, tables, and tablespaces that existed before the cloning operation. Any time during the execution of a cloning operation or after a failure, the server is always in a consistent state.

4. Data is cloned from the donor. User-created data, dictionary metadata, and other system data are cloned.

If a failure occurs while cloning data, the cloning operation is rolled back and all cloned data removed. At this stage, the previously existing user-created data and binary logs on the recipient have also been removed.

Should this scenario occur, you can either rectify the cause of the failure and re-execute the cloning operation, or forgo the cloning operation and restore the recipient data from a backup taken before the cloning operation.

5. The server is restarted automatically (applies to remote cloning operations that do not clone to a named directory). During startup, typical server startup tasks are performed.

If the automatic server restart fails, you can restart the server manually to complete the cloning operation.

If a network error occurs during a cloning operation, the operation resumes if the error is resolved within the time specified by the `clone_donor_timeout_after_network_failure` variable defined on the donor instance. The `clone_donor_timeout_after_network_failure` default setting is 5 minutes but a range of 0 to 30 minutes is supported. If the operation does not resume within the allotted time, it aborts and returns an error, and the donor drops the snapshot. A setting of zero causes the donor to drop the snapshot immediately when a network error occurs. Configuring a longer timeout allows more time for resolving network issues but also increases the size of the delta on the donor instance, which increases clone recovery time as well as replication lag in cases where the clone is intended as a replica or replication group member.

The Clone idle timeout is set to the default `wait_timeout` setting, which is 28800 seconds (8 hours).

### 7.6.7.10 Monitoring Cloning Operations

This section describes options for monitoring cloning operations.

- [Monitoring Cloning Operations using Performance Schema Clone Tables](#)
- [Monitoring Cloning Operations Using Performance Schema Stage Events](#)
- [Monitoring Cloning Operations Using Performance Schema Clone Instrumentation](#)
- [The Com\\_clone Status Variable](#)

#### Monitoring Cloning Operations using Performance Schema Clone Tables

A cloning operation may take some time to complete, depending on the amount of data and other factors related to data transfer. You can monitor the status and progress of a cloning operation on the recipient MySQL server instance using the `clone_status` and `clone_progress` Performance Schema tables.

**Note**

The `clone_status` and `clone_progress` Performance Schema tables can be used to monitor a cloning operation on the recipient MySQL server instance only. To monitor a cloning operation on the donor MySQL server instance, use the clone stage events, as described in [Monitoring Cloning Operations Using Performance Schema Stage Events](#).

- The `clone_status` table provides the state of the current or last executed cloning operation. A clone operation has four possible states: `Not Started`, `In Progress`, `Completed`, and `Failed`.
- The `clone_progress` table provides progress information for the current or last executed clone operation, by stage. The stages of a cloning operation include `DROP DATA`, `FILE COPY`, `PAGE_COPY`, `REDO_COPY`, `FILE_SYNC`, `RESTART`, and `RECOVERY`.

The `SELECT` and `EXECUTE` privileges on the Performance Schema is required to access the Performance Schema clone tables.

To check the state of a cloning operation:

1. Connect to the recipient MySQL server instance.
2. Query the `clone_status` table:

```
mysql> SELECT STATE FROM performance_schema.clone_status;
+-----+
| STATE |
+-----+
| Completed |
+-----+
```

Should a failure occur during a cloning operation, you can query the `clone_status` table for error information:

```
mysql> SELECT STATE, ERROR_NO, ERROR_MESSAGE FROM performance_schema.clone_status;
+-----+-----+-----+
| STATE | ERROR_NO | ERROR_MESSAGE |
+-----+-----+-----+
| Failed | xxx | "xxxxxxxxxxxxx" |
+-----+-----+-----+
```

To review the details of each stage of a cloning operation:

1. Connect to the recipient MySQL server instance.
2. Query the `clone_progress` table. For example, the following query provides state and end time data for each stage of the cloning operation:

```
mysql> SELECT STAGE, STATE, END_TIME FROM performance_schema.clone_progress;
+-----+-----+-----+
| stage | state | end_time |
+-----+-----+-----+
| DROP DATA | Completed | 2019-01-27 22:45:43.141261 |
| FILE COPY | Completed | 2019-01-27 22:45:44.457572 |
| PAGE_COPY | Completed | 2019-01-27 22:45:44.577330 |
| REDO_COPY | Completed | 2019-01-27 22:45:44.679570 |
| FILE_SYNC | Completed | 2019-01-27 22:45:44.918547 |
| RESTART | Completed | 2019-01-27 22:45:48.583565 |
| RECOVERY | Completed | 2019-01-27 22:45:49.626595 |
+-----+-----+-----+
```

For other clone status and progress data points that you can monitor, refer to [Section 29.12.19, “Performance Schema Clone Tables”](#).

## Monitoring Cloning Operations Using Performance Schema Stage Events

A cloning operation may take some time to complete, depending on the amount of data and other factors related to data transfer. There are three stage events for monitoring the progress of a cloning operation. Each stage event reports `WORK_COMPLETED` and `WORK_ESTIMATED` values. Reported values are revised as the operation progresses.

This method of monitoring a cloning operation can be used on the donor or recipient MySQL server instance.

In order of occurrence, cloning operation stage events include:

- `stage/innodb/clone (file copy)`: Indicates progress of the file copy phase of the cloning operation. `WORK_ESTIMATED` and `WORK_COMPLETED` units are file chunks. The number of files to be transferred is known at the start of the file copy phase, and the number of chunks is estimated based on the number of files. `WORK_ESTIMATED` is set to the number of estimated file chunks. `WORK_COMPLETED` is updated after each chunk is sent.
- `stage/innodb/clone (page copy)`: Indicates progress of the page copy phase of cloning operation. `WORK_ESTIMATED` and `WORK_COMPLETED` units are pages. Once the file copy phase is completed, the number of pages to be transferred is known, and `WORK_ESTIMATED` is set to this value. `WORK_COMPLETED` is updated after each page is sent.
- `stage/innodb/clone (redo copy)`: Indicates progress of the redo copy phase of cloning operation. `WORK_ESTIMATED` and `WORK_COMPLETED` units are redo chunks. Once the page copy phase is completed, the number of redo chunks to be transferred is known, and `WORK_ESTIMATED` is set to this value. `WORK_COMPLETED` is updated after each chunk is sent.

The following example demonstrates how to enable `stage/innodb/clone%` event instruments and related consumer tables to monitor a cloning operation. For information about Performance Schema stage event instruments and related consumers, see [Section 29.12.5, “Performance Schema Stage Event Tables”](#).

1. Enable the `stage/innodb/clone%` instruments:

```
mysql> UPDATE performance_schema.setup_instruments SET ENABLED = 'YES'
 WHERE NAME LIKE 'stage/innodb/clone%';
```

2. Enable the stage event consumer tables, which include `events_stages_current`, `events_stages_history`, and `events_stages_history_long`.

```
mysql> UPDATE performance_schema.setup_consumers SET ENABLED = 'YES'
 WHERE NAME LIKE '%stages%';
```

3. Run a cloning operation. In this example, a local data directory is cloned to a directory named `cloned_dir`.

```
mysql> CLONE LOCAL DATA DIRECTORY = '/path/to/cloned_dir';
```

4. Check the progress of the cloning operation by querying the Performance Schema `events_stages_current` table. The stage event shown differs depending on the cloning phase that is in progress. The `WORK_COMPLETED` column shows the work completed. The `WORK_ESTIMATED` column shows the work required in total.

```
mysql> SELECT EVENT_NAME, WORK_COMPLETED, WORK_ESTIMATED FROM performance_schema.events_stages_current
 WHERE EVENT_NAME LIKE 'stage/innodb/clone%';
```

EVENT_NAME	WORK_COMPLETED	WORK_ESTIMATED
stage/innodb/clone (file copy)		
stage/innodb/clone (page copy)		
stage/innodb/clone (redo copy)		

stage/innodb/clone (redo copy)	1	1
--------------------------------	---	---

The `events_stages_current` table returns an empty set if the cloning operation has finished. In this case, you can check the `events_stages_history` table to view event data for the completed operation. For example:

```
mysql> SELECT EVENT_NAME, WORK_COMPLETED, WORK_ESTIMATED FROM events_stages_history
WHERE EVENT_NAME LIKE 'stage/innodb/clone%';
```

EVENT_NAME	WORK_COMPLETED	WORK_ESTIMATED
stage/innodb/clone (file copy)	301	301
stage/innodb/clone (page copy)	0	0
stage/innodb/clone (redo copy)	1	1

## Monitoring Cloning Operations Using Performance Schema Clone Instrumentation

**Performance Schema** provides instrumentation for advanced performance monitoring of clone operations. To view the available clone instrumentation, and issue the following query:

```
mysql> SELECT NAME,ENABLED FROM performance_schema.setup_instruments
WHERE NAME LIKE '%clone%';
```

NAME	ENABLED
wait/synch/mutex/innodb/clone_snapshot_mutex	NO
wait/synch/mutex/innodb/clone_sys_mutex	NO
wait/synch/mutex/innodb/clone_task_mutex	NO
wait/synch/mutex/group_rpl/LOCK_clone_donor_list	NO
wait/synch/mutex/group_rpl/LOCK_clone_handler_run	NO
wait/synch/mutex/group_rpl/LOCK_clone_query	NO
wait/synch/mutex/group_rpl/LOCK_clone_read_mode	NO
wait/synch/cond/group_rpl/COND_clone_handler_run	NO
wait/io/file/innodb/innodb_clone_file	YES
stage/innodb/clone (file copy)	YES
stage/innodb/clone (redo copy)	YES
stage/innodb/clone (page copy)	YES
statement/abstract/clone	YES
statement/clone/local	YES
statement/clone/client	YES
statement/clone/server	YES
memory/innodb/clone	YES
memory/clone/data	YES

## Wait Instruments

Performance schema wait instruments track events that take time. Clone wait event instruments include:

- `wait/synch/mutex/innodb/clone_snapshot_mutex`: Tracks wait events for the clone snapshot mutex, which synchronizes access to the dynamic snapshot object (on the donor and recipient) between multiple clone threads.
- `wait/synch/mutex/innodb/clone_sys_mutex`: Tracks wait events for the clone sys mutex. There is one clone system object in a MySQL server instance. This mutex synchronizes access to the clone system object on the donor and recipient. It is acquired by clone threads and other foreground and background threads.
- `wait/synch/mutex/innodb/clone_task_mutex`: Tracks wait events for the clone task mutex, used for clone task management. The `clone_task_mutex` is acquired by clone threads.

- `wait/io/file/innodb/innodb_clone_file`: Tracks all I/O wait operations for files that clone operates on.

For information about monitoring InnoDB mutex waits, see [Section 17.16.2, “Monitoring InnoDB Mutex Waits Using Performance Schema”](#). For information about monitoring wait events in general, see [Section 29.12.4, “Performance Schema Wait Event Tables”](#).

## Stage Instruments

Performance Schema stage events track steps that occur during the statement-execution process. Clone stage event instruments include:

- `stage/innodb/clone (file copy)`: Indicates progress of the file copy phase of the cloning operation.
- `stage/innodb/clone (redo copy)`: Indicates progress of the redo copy phase of cloning operation.
- `stage/innodb/clone (page copy)`: Indicates progress of the page copy phase of cloning operation.

For information about monitoring cloning operations using stage events, see [Monitoring Cloning Operations Using Performance Schema Stage Events](#). For general information about monitoring stage events, see [Section 29.12.5, “Performance Schema Stage Event Tables”](#).

## Statement Instruments

Performance Schema statement events track statement execution. When a clone operation is initiated, the different statement types tracked by clone statement instruments may be executed in parallel. You can observe these statement events in the Performance Schema statement event tables. The number of statements that execute depends on the `clone_max_concurrency` and `clone_autotune_concurrency` settings.

Clone statement event instruments include:

- `statement/abstract/clone`: Tracks statement events for any clone operation before it is classified as a local, client, or server operation type.
- `statement/clone/local`: Tracks clone statement events for local clone operations; generated when executing a `CLONE LOCAL` statement.
- `statement/clone/client`: Tracks remote cloning statement events that occur on the recipient MySQL server instance; generated when executing a `CLONE INSTANCE` statement on the recipient.
- `statement/clone/server`: Tracks remote cloning statement events that occur on the donor MySQL server instance; generated when executing a `CLONE INSTANCE` statement on the recipient.

For information about monitoring Performance Schema statement events, see [Section 29.12.6, “Performance Schema Statement Event Tables”](#).

## Memory Instruments

Performance Schema memory instruments track memory usage. Clone memory usage instruments include:

- `memory/innodb/clone`: Tracks memory allocated by InnoDB for the dynamic snapshot.
- `memory/clone/data`: Tracks memory allocated by the clone plugin during a clone operation.

For information about monitoring memory usage using Performance Schema, see [Section 29.12.20.10, “Memory Summary Tables”](#).

## The Com\_clone Status Variable

The `Com_clone` status variable provides a count of `CLONE` statement executions.

For more information, refer to the discussion about `Com_xxx` statement counter variables in [Section 7.1.10, “Server Status Variables”](#).

### 7.6.7.11 Stopping a Cloning Operation

If necessary, you can stop a cloning operation with a `KILL QUERY processlist_id` statement.

On the recipient MySQL server instance, you can retrieve the processlist identifier (PID) for a cloning operation from the `PID` column of the `clone_status` table.

```
mysql> SELECT * FROM performance_schema.clone_status\G
***** 1. row *****
 ID: 1
 PID: 8
 STATE: In Progress
 BEGIN_TIME: 2019-07-15 11:58:36.767
 END_TIME: NULL
 SOURCE: LOCAL INSTANCE
 DESTINATION: /path/to/clone_dir/
 ERROR_NO: 0
 ERROR_MESSAGE:
 BINLOG_FILE:
 BINLOG_POSITION: 0
 GTID_EXECUTED:
```

You can also retrieve the processlist identifier from the `ID` column of the `INFORMATION_SCHEMA.PROCESSLIST` table, the `id` column of `SHOW PROCESSLIST` output, or the `PROCESSLIST_ID` column of the Performance Schema `threads` table. These methods of obtaining the PID information can be used on the donor or recipient MySQL server instance.

### 7.6.7.12 Clone System Variable Reference

Table 7.11 Clone System Variable Reference

Name	Cmd-Line	Option File	System Var	Status Var	Var Scope	Dynamic
<a href="#">clone_autotune_concurrency</a>	Yes	Yes	Yes		Global	Yes
<a href="#">clone_block_size</a>	Yes	Yes	Yes		Global	Yes
<a href="#">clone_buffer_size</a>	Yes	Yes	Yes		Global	Yes
<a href="#">clone_ddl_timeout</a>	Yes	Yes	Yes		Global	Yes
<a href="#">clone_delay_after_data_drop</a>	Yes	Yes	Yes		Global	Yes
<a href="#">clone_donor_timeout_after_network_failure</a>	Yes	Yes	Yes		Global	Yes
<a href="#">clone_enable_compression</a>	Yes	Yes	Yes		Global	Yes
<a href="#">clone_max_concurrency</a>	Yes	Yes	Yes		Global	Yes
<a href="#">clone_max_data_bandwidth</a>	Yes	Yes	Yes		Global	Yes
<a href="#">clone_max_network_bandwidth</a>	Yes	Yes	Yes		Global	Yes
<a href="#">clone_ssl_ca</a>	Yes	Yes	Yes		Global	Yes
<a href="#">clone_ssl_cert</a>	Yes	Yes	Yes		Global	Yes
<a href="#">clone_ssl_key</a>	Yes	Yes	Yes		Global	Yes

Name	Cmd-Line	Option File	System Var	Status Var	Var Scope	Dynamic
<code>clone_valid_dones_list</code>	Yes	Yes	Yes		Global	Yes

### 7.6.7.13 Clone System Variables

This section describes the system variables that control operation of the clone plugin. If values specified at startup are incorrect, the clone plugin may fail to initialize properly and the server does not load it. In this case, the server may also produce error messages for other clone settings because it does not recognize them.

Each system variable has a default value. System variables can be set at server startup using options on the command line or in an option file. They can be changed dynamically at runtime using the `SET` statement, which enables you to modify operation of the server without having to stop and restart it.

Setting a global system variable runtime value normally requires the `SYSTEM_VARIABLES_ADMIN` privilege (or the deprecated `SUPER` privilege). For more information, see [Section 7.1.9.1, “System Variable Privileges”](#).

Clone variables are configured on the recipient MySQL server instance where the cloning operation is executed.

- `clone_autotune_concurrency`

Command-Line Format	<code>--clone-autotune-concurrency</code>
System Variable	<code>clone_autotune_concurrency</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>ON</code>

When `clone_autotune_concurrency` is enabled (the default), additional threads for remote cloning operations are spawned dynamically to optimize data transfer speed. The setting is applicable to recipient MySQL server instance only.

During a cloning operation, the number of threads increases incrementally toward a target of double the current thread count. The effect on the data transfer speed is evaluated at each increment. The process either continues or stops according to the following rules:

- If the data transfer speed degrades more than 5% with an incremental increase, the process stops.
- If there is at least a 5% improvement after reaching 25% of the target, the process continues. Otherwise, the process stops.
- If there is at least a 10% improvement after reaching 50% of the target, the process continues. Otherwise, the process stops.
- If there is at least a 25% improvement after reaching the target, the process continues toward a new target of double the current thread count. Otherwise, the process stops.

The autotuning process does not support decreasing the number of threads.

The `clone_max_concurrency` variable defines the maximum number of threads that can be spawned.

If `clone_autotune_concurrency` is disabled, `clone_max_concurrency` defines the number of threads spawned for a remote cloning operation.

- `clone_buffer_size`

Command-Line Format	<code>--clone-buffer-size</code>
System Variable	<code>clone_buffer_size</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	4194304
Minimum Value	1048576
Maximum Value	268435456
Unit	bytes

Defines the size of the intermediate buffer used when transferring data during a local cloning operation. The default value is 4 mebibytes (MiB). A larger buffer size may permit I/O device drivers to fetch data in parallel, which can improve cloning performance.

- `clone_block_ddl`

Command-Line Format	<code>--clone-block-ddl</code>
System Variable	<code>clone_block_ddl</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Enables an exclusive backup lock on the donor MySQL Server instance during a cloning operation, which blocks concurrent DDL operations on the donor. See [Section 7.6.7.4, “Cloning and Concurrent DDL”](#).

- `clone_delay_after_data_drop`

Command-Line Format	<code>--clone-delay-after-data-drop</code>
System Variable	<code>clone_delay_after_data_drop</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	3600

Unit	bytes
------	-------

Specifies a delay period immediately after removing existing data on the recipient MySQL Server instance at the start of a remote cloning operation. The delay is intended to provide enough time for the file system on the recipient host to free space before data is cloned from the donor MySQL Server instance. Certain file systems such as VxFS free space asynchronously in a background process. On these file systems, cloning data too soon after dropping existing data can result in clone operation failures due to insufficient space. The maximum delay period is 3600 seconds (1 hour). The default setting is 0 (no delay).

This variable is applicable to remote cloning operation only and is configured on the recipient MySQL Server instance.

- `clone_ddl_timeout`

Command-Line Format	<code>--clone-ddl-timeout</code>
System Variable	<code>clone_ddl_timeout</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	300
Minimum Value	0
Maximum Value	2592000
Unit	seconds

The time in seconds that a cloning operation waits for a backup lock. The backup lock blocks concurrent DDL when executing a cloning operation. This setting is applied on both the donor and recipient MySQL server instances.

A setting of 0 means that the cloning operation does not wait for a backup lock. In this case, executing a concurrent DDL operation can cause the cloning operation to fail.

Concurrent DDL is permitted on the donor during a cloning operation if `clone_block_ddl` is set to `OFF` (the default). In this case, the cloning operation does not have to wait for a backup lock on the donor. See [Section 7.6.7.4, “Cloning and Concurrent DDL”](#).

- `clone_donor_timeout_after_network_failure`

Command-Line Format	<code>--clone-donor-timeout-after-network-failure</code>
System Variable	<code>clone_donor_timeout_after_network_failure</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	5
Minimum Value	0

Maximum Value	30
Unit	minutes

Defines the amount of time in minutes the donor allows for the recipient to reconnect and restart a cloning operation after a network failure. For more information, see [Section 7.6.7.9, “Remote Cloning Operation Failure Handling”](#).

This variable is set on the donor MySQL server instance. Setting it on the recipient MySQL server instance has no effect.

- `clone_enable_compression`

Command-Line Format	<code>--clone-enable-compression</code>
System Variable	<code>clone_enable_compression</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	OFF

Enables compression of data at the network layer during a remote cloning operation. Compression saves network bandwidth at the cost of CPU. Enabling compression may improve the data transfer rate. This setting is only applied on the recipient MySQL server instance.

- `clone_max_concurrency`

Command-Line Format	<code>--clone-max-concurrency</code>
System Variable	<code>clone_max_concurrency</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	16
Minimum Value	1
Maximum Value	128
Unit	threads

Defines the maximum number of concurrent threads for a remote cloning operation. The default value is 16. A greater number of threads can improve cloning performance but also reduces the number of permitted simultaneous client connections, which can affect the performance of existing client connections. This setting is only applied on the recipient MySQL server instance.

If `clone_autotune_concurrency` is enabled (the default), `clone_max_concurrency` is the maximum number of threads that can be dynamically spawned for a remote cloning operation. If

`clone_autotune_concurrency` is disabled, `clone_max_concurrency` defines the number of threads spawned for a remote cloning operation.

A minimum data transfer rate of 1 mebibyte (MiB) per thread is recommended for remote cloning operations. The data transfer rate for a remote cloning operation is controlled by the `clone_max_data_bandwidth` variable.

- `clone_max_data_bandwidth`

Command-Line Format	<code>--clone-max-data-bandwidth</code>
System Variable	<code>clone_max_data_bandwidth</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	1048576
Unit	miB/second

Defines the maximum data transfer rate in mebibytes (MiB) per second for a remote cloning operation. This variable helps manage the performance impact of a cloning operation. A limit should be set only when donor disk I/O bandwidth is saturated, affecting performance. A value of 0 means “unlimited”, which permits cloning operations to run at the highest possible data transfer rate. This setting is only applicable to the recipient MySQL server instance.

The minimum data transfer rate is 1 MiB per second, per thread. For example, if there are 8 threads, the minimum transfer rate is 8 MiB per second. The `clone_max_concurrency` variable controls the maximum number threads spawned for a remote cloning operation.

The requested data transfer rate specified by `clone_max_data_bandwidth` may differ from the actual data transfer rate reported by the `DATA_SPEED` column in the `performance_schema.clone_progress` table. If your cloning operation is not achieving the desired data transfer rate and you have available bandwidth, check I/O usage on the recipient and donor. If there is underutilized bandwidth, I/O is the next mostly likely bottleneck.

- `clone_max_network_bandwidth`

Command-Line Format	<code>--clone-max-network-bandwidth</code>
System Variable	<code>clone_max_network_bandwidth</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	1048576
Unit	miB/second

Specifies the maximum approximate network transfer rate in mebibytes (MiB) per second for a remote cloning operation. This variable can be used to manage the performance impact of a cloning operation on network bandwidth. It should be set only when network bandwidth is saturated, affecting performance on the donor instance. A value of 0 means “unlimited”, which permits cloning at the highest possible data transfer rate over the network, providing the best performance. This setting is only applicable to the recipient MySQL server instance.

- `clone_ssl_ca`

Command-Line Format	<code>--clone-ssl-ca=file_name</code>
System Variable	<code>clone_ssl_ca</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	File name
Default Value	<code>empty string</code>

Specifies the path to the certificate authority (CA) file. Used to configure an encrypted connection for a remote cloning operation. This setting configured on the recipient and used when connecting to the donor.

- `clone_ssl_cert`

Command-Line Format	<code>--clone-ssl-cert=file_name</code>
System Variable	<code>clone_ssl_cert</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	File name
Default Value	<code>empty string</code>

Specifies the path to the public key certificate. Used to configure an encrypted connection for a remote cloning operation. This setting configured on the recipient and used when connecting to the donor.

- `clone_ssl_key`

Command-Line Format	<code>--clone-ssl-key=file_name</code>
System Variable	<code>clone_ssl_key</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	File name
Default Value	<code>empty string</code>

Specifies the path to the private key file. Used to configure an encrypted connection for a remote cloning operation. This setting configured on the recipient and used when connecting to the donor.

- `clone_valid_donor_list`

Command-Line Format	<code>--clone-valid-donor-list=value</code>
System Variable	<code>clone_valid_donor_list</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value	NULL

Defines valid donor host addresses for remote cloning operations. This setting is applied on the recipient MySQL server instance. A comma-separated list of values is permitted in the following format: “HOST1:PORT1,HOST2:PORT2,HOST3:PORT3”. Spaces are not permitted.

The `clone_valid_donor_list` variable adds a layer of security by providing control over the sources of cloned data. The privilege required to configure `clone_valid_donor_list` is different from the privilege required to execute remote cloning operations, which permits assigning those responsibilities to different roles. Configuring `clone_valid_donor_list` requires the `SYSTEM_VARIABLES_ADMIN` privilege, whereas executing a remote cloning operation requires the `CLONE_ADMIN` privilege.

Internet Protocol version 6 (IPv6) address format is not supported. Internet Protocol version 6 (IPv6) address format is not supported. An alias to the IPv6 address can be used instead. An IPv4 address can be used as is.

#### 7.6.7.14 Clone Plugin Limitations

The clone plugin is subject to these limitations:

- An instance cannot be cloned from a different MySQL server series. For example, you cannot clone between MySQL 8.0 and MySQL 8.4, but can clone within a series such as MySQL 8.4.1 and MySQL 8.4.13.
- Only a single MySQL instance can be cloned at a time. Cloning multiple MySQL instances in a single cloning operation is not supported.
- The X Protocol port specified by `mysqlx_port` is not supported for remote cloning operations (when specifying the port number of the donor MySQL server instance in a `CLONE INSTANCE` statement).
- The clone plugin does not support cloning of MySQL server configurations. The recipient MySQL server instance retains its configuration, including persisted system variable settings (see [Section 7.1.9.3](#), “Persisted System Variables”).
- The clone plugin does not support cloning of binary logs.
- The clone plugin only clones data stored in `InnoDB`. Other storage engine data is not cloned. `MyISAM` and `CSV` tables stored in any schema including the `sys` schema are cloned as empty tables.
- Connecting to the donor MySQL server instance through MySQL Router is not supported.
- Local cloning operations do not support cloning of general tablespaces that were created with an absolute path. A cloned tablespace file with the same path as the source tablespace file would cause a conflict.

#### 7.6.8 The Keyring Proxy Bridge Plugin

MySQL Keyring originally implemented keystore capabilities using server plugins, but began transitioning to use the component infrastructure in MySQL 8.0. The transition includes revising the underlying implementation of keyring plugins to use the component infrastructure. This is facilitated using the plugin named `daemon_keyring_proxy_plugin` that acts as a bridge between the plugin and component service APIs, and enables keyring plugins to continue to be used with no change to user-visible characteristics.

`daemon_keyring_proxy_plugin` is built in and nothing need be done to install or enable it.

## 7.6.9 MySQL Plugin Services

MySQL server plugins have access to server “plugin services.” The plugin services interface complements the plugin API by exposing server functionality that plugins can call. For developer information about writing plugin services, see [MySQL Services for Plugins](#). The following sections describe plugin services available at the SQL and C-language levels.

### 7.6.9.1 The Locking Service

MySQL distributions provide a locking interface that is accessible at two levels:

- At the SQL level, as a set of loadable functions that each map onto calls to the service routines.
- As a C language interface, callable as a plugin service from server plugins or loadable functions.

For general information about plugin services, see [Section 7.6.9, “MySQL Plugin Services”](#). For general information about loadable functions, see [Adding a Loadable Function](#).

The locking interface has these characteristics:

- Locks have three attributes: Lock namespace, lock name, and lock mode:
  - Locks are identified by the combination of namespace and lock name. The namespace enables different applications to use the same lock names without colliding by creating locks in separate namespaces. For example, if applications A and B use namespaces of `ns1` and `ns2`, respectively, each application can use lock names `lock1` and `lock2` without interfering with the other application.
  - A lock mode is either read or write. Read locks are shared: If a session has a read lock on a given lock identifier, other sessions can acquire a read lock on the same identifier. Write locks are exclusive: If a session has a write lock on a given lock identifier, other sessions cannot acquire a read or write lock on the same identifier.
- Namespace and lock names must be non-`NULL`, nonempty, and have a maximum length of 64 characters. A namespace or lock name specified as `NULL`, the empty string, or a string longer than 64 characters results in an `ER_LOCKING_SERVICE_WRONG_NAME` error.
- The locking interface treats namespace and lock names as binary strings, so comparisons are case-sensitive.
- The locking interface provides functions to acquire locks and release locks. No special privilege is required to call these functions. Privilege checking is the responsibility of the calling application.
- Locks can be waited for if not immediately available. Lock acquisition calls take an integer timeout value that indicates how many seconds to wait to acquire locks before giving up. If the timeout is reached without successful lock acquisition, an `ER_LOCKING_SERVICE_TIMEOUT` error occurs. If the timeout is 0, there is no waiting and the call produces an error if locks cannot be acquired immediately.
- The locking interface detects deadlock between lock-acquisition calls in different sessions. In this case, the locking service chooses a caller and terminates its lock-acquisition request with an

[ER\\_LOCKING\\_SERVICE\\_DEADLOCK](#) error. This error does not cause transactions to roll back. To choose a session in case of deadlock, the locking service prefers sessions that hold read locks over sessions that hold write locks.

- A session can acquire multiple locks with a single lock-acquisition call. For a given call, lock acquisition is atomic: The call succeeds if all locks are acquired. If acquisition of any lock fails, the call acquires no locks and fails, typically with an [ER\\_LOCKING\\_SERVICE\\_TIMEOUT](#) or [ER\\_LOCKING\\_SERVICE\\_DEADLOCK](#) error.
- A session can acquire multiple locks for the same lock identifier (namespace and lock name combination). These lock instances can be read locks, write locks, or a mix of both.
- Locks acquired within a session are released explicitly by calling a release-locks function, or implicitly when the session terminates (either normally or abnormally). Locks are not released when transactions commit or roll back.
- Within a session, all locks for a given namespace when released are released together.

The interface provided by the locking service is distinct from that provided by [GET\\_LOCK\(\)](#) and related SQL functions (see [Section 14.14, “Locking Functions”](#)). For example, [GET\\_LOCK\(\)](#) does not implement namespaces and provides only exclusive locks, not distinct read and write locks.

## The Locking Service C Interface

This section describes how to use the locking service C language interface. To use the function interface instead, see [The Locking Service Function Interface](#). For general characteristics of the locking service interface, see [Section 7.6.9.1, “The Locking Service”](#). For general information about plugin services, see [Section 7.6.9, “MySQL Plugin Services”](#).

Source files that use the locking service should include this header file:

```
#include <mysql/service_locking.h>
```

To acquire one or more locks, call this function:

```
int mysql_acquire_locking_service_locks(MYSQL_THD opaque_thd,
 const char* lock_namespace,
 const char**lock_names,
 size_t lock_num,
 enum enum_locking_service_lock_type lock_type,
 unsigned long lock_timeout);
```

The arguments have these meanings:

- [opaque\\_thd](#): A thread handle. If specified as [NULL](#), the handle for the current thread is used.
- [lock\\_namespace](#): A null-terminated string that indicates the lock namespace.
- [lock\\_names](#): An array of null-terminated strings that provides the names of the locks to acquire.
- [lock\\_num](#): The number of names in the [lock\\_names](#) array.
- [lock\\_type](#): The lock mode, either [LOCKING\\_SERVICE\\_READ](#) or [LOCKING\\_SERVICE\\_WRITE](#) to acquire read locks or write locks, respectively.
- [lock\\_timeout](#): An integer number of seconds to wait to acquire the locks before giving up.

To release locks acquired for a given namespace, call this function:

```
int mysql_release_locking_service_locks(MYSQL_THD opaque_thd,
 const char* lock_namespace);
```

The arguments have these meanings:

- `opaque_thd`: A thread handle. If specified as `NULL`, the handle for the current thread is used.
- `lock_namespace`: A null-terminated string that indicates the lock namespace.

Locks acquired or waited for by the locking service can be monitored at the SQL level using the Performance Schema. For details, see [Locking Service Monitoring](#).

## The Locking Service Function Interface

This section describes how to use the locking service interface provided by its loadable functions. To use the C language interface instead, see [The Locking Service C Interface](#). For general characteristics of the locking service interface, see [Section 7.6.9.1, “The Locking Service”](#). For general information about loadable functions, see [Adding a Loadable Function](#).

- [Installing or Uninstalling the Locking Service Function Interface](#)
- [Using the Locking Service Function Interface](#)
- [Locking Service Monitoring](#)
- [Locking Service Interface Function Reference](#)

## Installing or Uninstalling the Locking Service Function Interface

The locking service routines described in [The Locking Service C Interface](#) need not be installed because they are built into the server. The same is not true of the loadable functions that map onto calls to the service routines: The functions must be installed before use. This section describes how to do that. For general information about loadable function installation, see [Section 7.7.1, “Installing and Uninstalling Loadable Functions”](#).

The locking service functions are implemented in a plugin library file located in the directory named by the `plugin_dir` system variable. The file base name is `locking_service`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

To install the locking service functions, use the `CREATE FUNCTION` statement, adjusting the `.so` suffix for your platform as necessary:

```
CREATE FUNCTION service_get_read_locks RETURNS INT
 SONAME 'locking_service.so';
CREATE FUNCTION service_get_write_locks RETURNS INT
 SONAME 'locking_service.so';
CREATE FUNCTION service_release_locks RETURNS INT
 SONAME 'locking_service.so';
```

If the functions are used on a replication source server, install them on all replica servers as well to avoid replication problems.

Once installed, the functions remain installed until uninstalled. To remove them, use the `DROP FUNCTION` statement:

```
DROP FUNCTION service_get_read_locks;
DROP FUNCTION service_get_write_locks;
DROP FUNCTION service_release_locks;
```

## Using the Locking Service Function Interface

Before using the locking service functions, install them according to the instructions provided at [Installing or Uninstalling the Locking Service Function Interface](#).

To acquire one or more read locks, call this function:

```
mysql> SELECT service_get_read_locks('myspace', 'rlock1', 'rlock2', 10);
+-----+
| service_get_read_locks('myspace', 'rlock1', 'rlock2', 10) |
+-----+
| 1 |
+-----+
```

The first argument is the lock namespace. The final argument is an integer timeout indicating how many seconds to wait to acquire the locks before giving up. The arguments in between are the lock names.

For the example just shown, the function acquires locks with lock identifiers (`myspace, rlock1`) and (`myspace, rlock2`).

To acquire write locks rather than read locks, call this function:

```
mysql> SELECT service_get_write_locks('myspace', 'wlock1', 'wlock2', 10);
+-----+
| service_get_write_locks('myspace', 'wlock1', 'wlock2', 10) |
+-----+
| 1 |
+-----+
```

In this case, the lock identifiers are (`myspace, wlock1`) and (`myspace, wlock2`).

To release all locks for a namespace, use this function:

```
mysql> SELECT service_release_locks('myspace');
+-----+
| service_release_locks('myspace') |
+-----+
| 1 |
+-----+
```

Each locking function returns nonzero for success. If the function fails, an error occurs. For example, the following error occurs because lock names cannot be empty:

```
mysql> SELECT service_get_read_locks('myspace', '', 10);
ERROR 3131 (42000): Incorrect locking service lock name ''.
```

A session can acquire multiple locks for the same lock identifier. As long as a different session does not have a write lock for an identifier, the session can acquire any number of read or write locks. Each lock request for the identifier acquires a new lock. The following statements acquire three write locks with the same identifier, then three read locks for the same identifier:

```
SELECT service_get_write_locks('ns', 'lock1', 'lock1', 'lock1', 0);
SELECT service_get_read_locks('ns', 'lock1', 'lock1', 'lock1', 0);
```

If you examine the Performance Schema `metadata_locks` table at this point, you should find that the session holds six distinct locks with the same (`ns, lock1`) identifier. (For details, see [Locking Service Monitoring](#).)

Because the session holds at least one write lock on (`ns, lock1`), no other session can acquire a lock for it, either read or write. If the session held only read locks for the identifier, other sessions could acquire read locks for it, but not write locks.

Locks for a single lock-acquisition call are acquired atomically, but atomicity does not hold across calls. Thus, for a statement such as the following, where `service_get_write_locks()` is called once per row of the result set, atomicity holds for each individual call, but not for the statement as a whole:

```
SELECT service_get_write_locks('ns', 'lock1', 'lock2', 0) FROM t1 WHERE ... ;
```

### Caution

Because the locking service returns a separate lock for each successful request for a given lock identifier, it is possible for a single statement to acquire a large number of locks. For example:

```
INSERT INTO ... SELECT service_get_write_locks('ns', t1.col_name, 0) FROM t1;
```

These types of statements may have certain adverse effects. For example, if the statement fails part way through and rolls back, locks acquired up to the point of failure still exist. If the intent is for there to be a correspondence between rows inserted and locks acquired, that intent is not satisfied. Also, if it is important that locks are granted in a certain order, be aware that result set order may differ depending on which execution plan the optimizer chooses. For these reasons, it may be best to limit applications to a single lock-acquisition call per statement.

## Locking Service Monitoring

The locking service is implemented using the MySQL Server metadata locks framework, so you monitor locking service locks acquired or waited for by examining the Performance Schema `metadata_locks` table.

First, enable the metadata lock instrument:

```
mysql> UPDATE performance_schema.setup_instruments SET ENABLED = 'YES'
-> WHERE NAME = 'wait/lock/metadata/sql/mdl';
```

Then acquire some locks and check the contents of the `metadata_locks` table:

```
mysql> SELECT service_get_write_locks('myspace', 'lock1', 0);
+-----+
| service_get_write_locks('myspace', 'lock1', 0) |
+-----+
| 1 |
+-----+
mysql> SELECT service_get_read_locks('myspace', 'lock2', 0);
+-----+
| service_get_read_locks('myspace', 'lock2', 0) |
+-----+
| 1 |
+-----+
mysql> SELECT OBJECT_TYPE, OBJECT_SCHEMA, OBJECT_NAME, LOCK_TYPE, LOCK_STATUS
-> FROM performance_schema.metadata_locks
-> WHERE OBJECT_TYPE = 'LOCKING SERVICE'\G
***** 1. row *****
OBJECT_TYPE: LOCKING SERVICE
OBJECT_SCHEMA: myspace
OBJECT_NAME: lock1
LOCK_TYPE: EXCLUSIVE
LOCK_STATUS: GRANTED
***** 2. row *****
OBJECT_TYPE: LOCKING SERVICE
OBJECT_SCHEMA: myspace
OBJECT_NAME: lock2
LOCK_TYPE: SHARED
LOCK_STATUS: GRANTED
```

Locking service locks have an `OBJECT_TYPE` value of `LOCKING SERVICE`. This is distinct from, for example, locks acquired with the `GET_LOCK()` function, which have an `OBJECT_TYPE` of `USER LEVEL LOCK`.

The lock namespace, name, and mode appear in the `OBJECT_SCHEMA`, `OBJECT_NAME`, and `LOCK_TYPE` columns. Read and write locks have `LOCK_TYPE` values of `SHARED` and `EXCLUSIVE`, respectively.

The `LOCK_STATUS` value is `GRANTED` for an acquired lock, `PENDING` for a lock that is being waited for. You can expect to see `PENDING` if one session holds a write lock and another session is attempting to acquire a lock having the same identifier.

### Locking Service Interface Function Reference

The SQL interface to the locking service implements the loadable functions described in this section. For usage examples, see [Using the Locking Service Function Interface](#).

The functions share these characteristics:

- The return value is nonzero for success. Otherwise, an error occurs.
- Namespace and lock names must be non-`NULL`, nonempty, and have a maximum length of 64 characters.
- Timeout values must be integers indicating how many seconds to wait to acquire locks before giving up with an error. If the timeout is 0, there is no waiting and the function produces an error if locks cannot be acquired immediately.

These locking service functions are available:

- `service_get_read_locks(namespace, lock_name[, lock_name] ..., timeout)`

Acquires one or more read (shared) locks in the given namespace using the given lock names, timing out with an error if the locks are not acquired within the given timeout value.

- `service_get_write_locks(namespace, lock_name[, lock_name] ..., timeout)`

Acquires one or more write (exclusive) locks in the given namespace using the given lock names, timing out with an error if the locks are not acquired within the given timeout value.

- `service_release_locks(namespace)`

For the given namespace, releases all locks that were acquired within the current session using `service_get_read_locks()` and `service_get_write_locks()`.

It is not an error for there to be no locks in the namespace.

### 7.6.9.2 The Keyring Service

MySQL Server supports a keyring service that enables internal components and plugins to securely store sensitive information for later retrieval. MySQL distributions provide a keyring interface that is accessible at two levels:

- At the SQL level, as a set of loadable functions that each map onto calls to the service routines.
- As a C language interface, callable as a plugin service from server plugins or loadable functions.

This section describes how to use the keyring service functions to store, retrieve, and remove keys in the MySQL keyring keystore. For information about the SQL interface that uses functions, [Section 8.4.4.13, “General-Purpose Keyring Key-Management Functions”](#). For general keyring information, see [Section 8.4.4, “The MySQL Keyring”](#).

The keyring service uses whatever underlying keyring plugin is enabled, if any. If no keyring plugin is enabled, keyring service calls fail.

A “record” in the keystore consists of data (the key itself) and a unique identifier through which the key is accessed. The identifier has two parts:

- `key_id`: The key ID or name. `key_id` values that begin with `mysql_` are reserved by MySQL Server.
- `user_id`: The session effective user ID. If there is no user context, this value can be `NULL`. The value need not actually be a “user”; the meaning depends on the application.

Functions that implement the keyring function interface pass the value of `CURRENT_USER()` as the `user_id` value to keyring service functions.

The keyring service functions have these characteristics in common:

- Each function returns 0 for success, 1 for failure.
- The `key_id` and `user_id` arguments form a unique combination indicating which key in the keyring to use.
- The `key_type` argument provides additional information about the key, such as its encryption method or intended use.
- Keyring service functions treat key IDs, user names, types, and values as binary strings, so comparisons are case-sensitive. For example, IDs of `MyKey` and `mykey` refer to different keys.

These keyring service functions are available:

- `my_key_fetch()`

Deobfuscates and retrieves a key from the keyring, along with its type. The function allocates the memory for the buffers used to store the returned key and key type. The caller should zero or obfuscate the memory when it is no longer needed, then free it.

Syntax:

```
bool my_key_fetch(const char *key_id, const char **key_type,
 const char* user_id, void **key, size_t *key_len)
```

Arguments:

- `key_id`, `user_id`: Null-terminated strings that as a pair form a unique identifier indicating which key to fetch.
- `key_type`: The address of a buffer pointer. The function stores into it a pointer to a null-terminated string that provides additional information about the key (stored when the key was added).
- `key`: The address of a buffer pointer. The function stores into it a pointer to the buffer containing the fetched key data.
- `key_len`: The address of a variable into which the function stores the size in bytes of the `*key` buffer.

Return value:

Returns 0 for success, 1 for failure.

- `my_key_generate()`

Generates a new random key of a given type and length and stores it in the keyring. The key has a length of `key_len` and is associated with the identifier formed from `key_id` and `user_id`. The type and length values must be consistent with the values supported by the underlying keyring plugin. See [Section 8.4.4.11, “Supported Keyring Key Types and Lengths”](#).

Syntax:

```
bool my_key_generate(const char *key_id, const char *key_type,
 const char *user_id, size_t key_len)
```

Arguments:

- `key_id`, `user_id`: Null-terminated strings that as a pair form a unique identifier for the key to be generated.
- `key_type`: A null-terminated string that provides additional information about the key.
- `key_len`: The size in bytes of the key to be generated.

Return value:

Returns 0 for success, 1 for failure.

- `my_key_remove( )`

Removes a key from the keyring.

Syntax:

```
bool my_key_remove(const char *key_id, const char* user_id)
```

Arguments:

- `key_id`, `user_id`: Null-terminated strings that as a pair form a unique identifier for the key to be removed.

Return value:

Returns 0 for success, 1 for failure.

- `my_key_store( )`

Obfuscates and stores a key in the keyring.

Syntax:

```
bool my_key_store(const char *key_id, const char *key_type,
 const char* user_id, void *key, size_t key_len)
```

Arguments:

- `key_id`, `user_id`: Null-terminated strings that as a pair form a unique identifier for the key to be stored.
- `key_type`: A null-terminated string that provides additional information about the key.
- `key`: The buffer containing the key data to be stored.
- `key_len`: The size in bytes of the `key` buffer.

Return value:

Returns 0 for success, 1 for failure.

## 7.7 MySQL Server Loadable Functions

MySQL supports loadable functions, that is, functions that are not built in but can be loaded at runtime (either during startup or later) to extend server capabilities, or unloaded to remove capabilities. For a table describing the available loadable functions, see [Section 14.2, “Loadable Function Reference”](#). Loadable functions contrast with built-in (native) functions, which are implemented as part of the server and are always available; for a table, see [Section 14.1, “Built-In Function and Operator Reference”](#).

**Note**

Loadable functions previously were known as user-defined functions (UDFs). That terminology was something of a misnomer because “user-defined” also can apply to other types of functions, such as stored functions (a type of stored object written using SQL) and native functions added by modifying the server source code.

MySQL distributions include loadable functions that implement, in whole or in part, these server capabilities:

- Group Replication enables you to create a highly available distributed MySQL service across a group of MySQL server instances, with data consistency, conflict detection and resolution, and group membership services all built-in. See [Chapter 20, Group Replication](#).
- MySQL Enterprise Edition includes functions that perform encryption operations based on the OpenSSL library. See [Section 8.6, “MySQL Enterprise Encryption”](#).
- MySQL Enterprise Edition includes functions that provide an SQL-level API for masking and de-identification operations. See [Section 8.5, “MySQL Enterprise Data Masking and De-Identification”](#).
- MySQL Enterprise Edition includes audit logging for monitoring and logging of connection and query activity. See [Section 8.4.5, “MySQL Enterprise Audit”](#), and [Section 8.4.6, “The Audit Message Component”](#).
- MySQL Enterprise Edition includes a firewall capability that implements an application-level firewall to enable database administrators to permit or deny SQL statement execution based on matching against patterns for accepted statement. See [Section 8.4.7, “MySQL Enterprise Firewall”](#).
- A query rewriter examines statements received by MySQL Server and possibly rewrites them before the server executes them. See [Section 7.6.4, “The Rewriter Query Rewrite Plugin”](#).
- Version Tokens enables creation of and synchronization around server tokens that applications can use to prevent accessing incorrect or out-of-date data. See [Section 7.6.6, “Version Tokens”](#).
- The MySQL Keyring provides secure storage for sensitive information. See [Section 8.4.4, “The MySQL Keyring”](#).
- A locking service provides a locking interface for application use. See [Section 7.6.9.1, “The Locking Service”](#).
- A function provides access to query attributes. See [Section 11.6, “Query Attributes”](#).

The following sections describe how to install and uninstall loadable functions, and how to determine at runtime which loadable functions are installed and obtain information about them.

In some cases, a loadable function is loaded by installing the component that implements the function, rather than by loading the function directly. For details about a particular loadable function, see the installation instructions for the server feature that includes it.

For information about writing loadable functions, see [Adding Functions to MySQL](#).

## 7.7.1 Installing and Uninstalling Loadable Functions

Loadable functions, as the name implies, must be loaded into the server before they can be used. MySQL supports automatic function loading during server startup and manual loading thereafter.

While a loadable function is loaded, information about it is available as described in [Section 7.7.2, “Obtaining Information About Loadable Functions”](#).

- [Installing Loadable Functions](#)
- [Uninstalling Loadable Functions](#)
- [Reinstalling or Upgrading Loadable Functions](#)

### Installing Loadable Functions

To load a loadable function manually, use the `CREATE FUNCTION` statement. For example:

```
CREATE FUNCTION metaphon
 RETURNS STRING
 SONAME 'udf_example.so';
```

The file base name depends on your platform. Common suffixes are `.so` for Unix and Unix-like systems, `.dll` for Windows.

`CREATE FUNCTION` has these effects:

- It loads the function into the server to make it available immediately.
- It registers the function in the `mysql.func` system table to make it persistent across server restarts. For this reason, `CREATE FUNCTION` requires the `INSERT` privilege for the `mysql` system database.
- It adds the function to the Performance Schema `user_defined_functions` table that provides runtime information about installed loadable functions. See [Section 7.7.2, “Obtaining Information About Loadable Functions”](#).

Automatic loading of loadable functions occurs during the normal server startup sequence:

- Functions registered in the `mysql.func` table are installed.
- Components or plugins that are installed at startup may automatically install related functions.
- Automatic function installation adds the functions to the Performance Schema `user_defined_functions` table that provides runtime information about installed functions.

If the server is started with the `--skip-grant-tables` option, functions registered in the `mysql.func` table are not loaded and are unavailable. This does not apply to functions installed automatically by a component or plugin.

### Uninstalling Loadable Functions

To remove a loadable function, use the `DROP FUNCTION` statement. For example:

```
DROP FUNCTION metaphon;
```

`DROP FUNCTION` has these effects:

- It unloads the function to make it unavailable.
- It removes the function from the `mysql.func` system table. For this reason, `DROP FUNCTION` requires the `DELETE` privilege for the `mysql` system database. With the function no longer registered in the `mysql.func` table, the server does not load the function during subsequent restarts.
- It removes the function from the Performance Schema `user_defined_functions` table that provides runtime information about installed loadable functions.

`DROP FUNCTION` cannot be used to drop a loadable function that is installed automatically by components or plugins rather than by using `CREATE FUNCTION`. Such a function is also dropped automatically, when the component or plugin that installed it is uninstalled.

## Reinstalling or Upgrading Loadable Functions

To reinstall or upgrade the shared library associated with a loadable function, issue a `DROP FUNCTION` statement, upgrade the shared library, and then issue a `CREATE FUNCTION` statement. If you upgrade the shared library first and then use `DROP FUNCTION`, the server may unexpectedly shut down.

### 7.7.2 Obtaining Information About Loadable Functions

The Performance Schema `user_defined_functions` table contains information about the currently installed loadable functions:

```
SELECT * FROM performance_schema.user_defined_functions;
```

The `mysql.func` system table also lists installed loadable functions, but only those installed using `CREATE FUNCTION`. The `user_defined_functions` table lists loadable functions installed using `CREATE FUNCTION` as well as loadable functions installed automatically by components or plugins. This difference makes `user_defined_functions` preferable to `mysql.func` for checking which loadable functions are installed. See [Section 29.12.22.11, “The user\\_defined\\_functions Table”](#).

## 7.8 Running Multiple MySQL Instances on One Machine

In some cases, you might want to run multiple instances of MySQL on a single machine. You might want to test a new MySQL release while leaving an existing production setup undisturbed. Or you might want to give different users access to different `mysqld` servers that they manage themselves. (For example, you might be an Internet Service Provider that wants to provide independent MySQL installations for different customers.)

It is possible to use a different MySQL server binary per instance, or use the same binary for multiple instances, or any combination of the two approaches. For example, you might run a server from MySQL 9.0 and one from MySQL 9.1, to see how different versions handle a given workload. Or you might run multiple instances of the current production version, each managing a different set of databases.

Whether or not you use distinct server binaries, each instance that you run must be configured with unique values for several operating parameters. This eliminates the potential for conflict between instances. Parameters can be set on the command line, in option files, or by setting environment variables. See [Section 6.2.2, “Specifying Program Options”](#). To see the values used by a given instance, connect to it and execute a `SHOW VARIABLES` statement.

The primary resource managed by a MySQL instance is the data directory. Each instance should use a different data directory, the location of which is specified using the `--datadir=dir_name` option. For methods of configuring each instance with its own data directory, and warnings about the dangers of failing to do so, see [Section 7.8.1, “Setting Up Multiple Data Directories”](#).

In addition to using different data directories, several other options must have different values for each server instance:

- `--port=port_num`

`--port` controls the port number for TCP/IP connections. Alternatively, if the host has multiple network addresses, you can set the `bind_address` system variable to cause each server to listen to a different address.

- `--socket={file_name|pipe_name}`

`--socket` controls the Unix socket file path on Unix or the named-pipe name on Windows. On Windows, it is necessary to specify distinct pipe names only for those servers configured to permit named-pipe connections.

- `--shared-memory-base-name=name`

This option is used only on Windows. It designates the shared-memory name used by a Windows server to permit clients to connect using shared memory. It is necessary to specify distinct shared-memory names only for those servers configured to permit shared-memory connections.

- `--pid-file=file_name`

This option indicates the path name of the file in which the server writes its process ID.

If you use the following log file options, their values must differ for each server:

- `--general_log_file=file_name`
- `--log-bin[=file_name]`
- `--slow_query_log_file=file_name`
- `--log-error[=file_name]`

For further discussion of log file options, see [Section 7.4, “MySQL Server Logs”](#).

To achieve better performance, you can specify the following option differently for each server, to spread the load between several physical disks:

- `--tmpdir=dir_name`

Having different temporary directories also makes it easier to determine which MySQL server created any given temporary file.

If you have multiple MySQL installations in different locations, you can specify the base directory for each installation with the `--basedir=dir_name` option. This causes each instance to automatically use a different data directory, log files, and PID file because the default for each of those parameters is relative to the base directory. In that case, the only other options you need to specify are the `--socket` and `--port` options. Suppose that you install different versions of MySQL using `tar` file binary distributions. These install in different locations, so you can start the server for each installation using the command `bin/mysqld_safe` under its corresponding base directory. `mysqld_safe` determines the proper `--basedir` option to pass to `mysqld`, and you need specify only the `--socket` and `--port` options to `mysqld_safe`.

As discussed in the following sections, it is possible to start additional servers by specifying appropriate command options or by setting environment variables. However, if you need to run multiple servers on

a more permanent basis, it is more convenient to use option files to specify for each server those option values that must be unique to it. The `--defaults-file` option is useful for this purpose.

## 7.8.1 Setting Up Multiple Data Directories

Each MySQL Instance on a machine should have its own data directory. The location is specified using the `--datadir=dir_name` option.

There are different methods of setting up a data directory for a new instance:

- Create a new data directory.
- Copy an existing data directory.

The following discussion provides more detail about each method.

### Warning

Normally, you should never have two servers that update data in the same databases. This may lead to unpleasant surprises if your operating system does not support fault-free system locking. If (despite this warning) you run multiple servers using the same data directory and they have logging enabled, you must use the appropriate options to specify log file names that are unique to each server. Otherwise, the servers try to log to the same files.

Even when the preceding precautions are observed, this kind of setup works only with `MyISAM` and `MERGE` tables, and not with any of the other storage engines. Also, this warning against sharing a data directory among servers always applies in an NFS environment. Permitting multiple MySQL servers to access a common data directory over NFS is a *very bad idea*. The primary problem is that NFS is the speed bottleneck. It is not meant for such use. Another risk with NFS is that you must devise a way to ensure that two or more servers do not interfere with each other. Usually NFS file locking is handled by the `lockd` daemon, but at the moment there is no platform that performs locking 100% reliably in every situation.

## Create a New Data Directory

With this method, the data directory is in the same state as when you first install MySQL, and has the default set of MySQL accounts and no user data.

On Unix, initialize the data directory. See [Section 2.9, “Postinstallation Setup and Testing”](#).

On Windows, the data directory is included in the MySQL distribution:

- MySQL Zip archive distributions for Windows contain an unmodified data directory. You can unpack such a distribution into a temporary location, then copy it `data` directory to where you are setting up the new instance.
- Windows MSI package installers create and set up the data directory that the installed server uses, but also create a pristine “template” data directory named `data` under the installation directory. After an installation has been performed using an MSI package, the template data directory can be copied to set up additional MySQL instances.

## Copy an Existing Data Directory

With this method, any MySQL accounts or user data present in the data directory are carried over to the new data directory.

1. Stop the existing MySQL instance using the data directory. This must be a clean shutdown so that the instance flushes any pending changes to disk.
2. Copy the data directory to the location where the new data directory should be.
3. Copy the `my.cnf` or `my.ini` option file used by the existing instance. This serves as a basis for the new instance.
4. Modify the new option file so that any pathnames referring to the original data directory refer to the new data directory. Also, modify any other options that must be unique per instance, such as the TCP/IP port number and the log files. For a list of parameters that must be unique per instance, see [Section 7.8, “Running Multiple MySQL Instances on One Machine”](#).
5. Start the new instance, telling it to use the new option file.

## 7.8.2 Running Multiple MySQL Instances on Windows

You can run multiple servers on Windows by starting them manually from the command line, each with appropriate operating parameters, or by installing several servers as Windows services and running them that way. General instructions for running MySQL from the command line or as a service are given in [Section 2.3, “Installing MySQL on Microsoft Windows”](#). The following sections describe how to start each server with different values for those options that must be unique per server, such as the data directory. These options are listed in [Section 7.8, “Running Multiple MySQL Instances on One Machine”](#).

### 7.8.2.1 Starting Multiple MySQL Instances at the Windows Command Line

The procedure for starting a single MySQL server manually from the command line is described in [Section 2.3.3.6, “Starting MySQL from the Windows Command Line”](#). To start multiple servers this way, you can specify the appropriate options on the command line or in an option file. It is more convenient to place the options in an option file, but it is necessary to make sure that each server gets its own set of options. To do this, create an option file for each server and tell the server the file name with a `--defaults-file` option when you run it.

Suppose that you want to run one instance of `mysqld` on port 3307 with a data directory of `C:\mydata1`, and another instance on port 3308 with a data directory of `C:\mydata2`. Use this procedure:

1. Make sure that each data directory exists, including its own copy of the `mysql` database that contains the grant tables.
2. Create two option files. For example, create one file named `C:\my-opts1.cnf` that looks like this:

```
[mysqld]
datadir = C:/mydata1
port = 3307
```

Create a second file named `C:\my-opts2.cnf` that looks like this:

```
[mysqld]
datadir = C:/mydata2
port = 3308
```

3. Use the `--defaults-file` option to start each server with its own option file:

```
C:\> C:\mysql\bin\mysqld --defaults-file=C:\my-opts1.cnf
C:\> C:\mysql\bin\mysqld --defaults-file=C:\my-opts2.cnf
```

Each server starts in the foreground (no new prompt appears until the server exits later), so you need to issue those two commands in separate console windows.

To shut down the servers, connect to each using the appropriate port number:

```
C:\> C:\mysql\bin\mysqladmin --port=3307 --host=127.0.0.1 --user=root --password shutdown
C:\> C:\mysql\bin\mysqladmin --port=3308 --host=127.0.0.1 --user=root --password shutdown
```

Servers configured as just described permit clients to connect over TCP/IP. If your version of Windows supports named pipes and you also want to permit named-pipe connections, specify options that enable the named pipe and specify its name. Each server that supports named-pipe connections must use a unique pipe name. For example, the `C:\my-opts1.cnf` file might be written like this:

```
[mysqld]
datadir = C:/mydata1
port = 3307
enable-named-pipe
socket = mypipe1
```

Modify `C:\my-opts2.cnf` similarly for use by the second server. Then start the servers as described previously.

A similar procedure applies for servers that you want to permit shared-memory connections. Enable such connections by starting the server with the `shared_memory` system variable enabled and specify a unique shared-memory name for each server by setting the `shared_memory_base_name` system variable.

### 7.8.2.2 Starting Multiple MySQL Instances as Windows Services

On Windows, a MySQL server can run as a Windows service. The procedures for installing, controlling, and removing a single MySQL service are described in [Section 2.3.3.8, “Starting MySQL as a Windows Service”](#).

To set up multiple MySQL services, you must make sure that each instance uses a different service name in addition to the other parameters that must be unique per instance.

For the following instructions, suppose that you want to run the `mysqld` server from two different versions of MySQL that are installed at `C:\mysql-5.7.9` and `C:\mysql-9.1.0`, respectively. (This might be the case if you are running 5.7.9 as your production server, but also want to conduct tests using 9.1.0.)

To install MySQL as a Windows service, use the `--install` or `--install-manual` option. For information about these options, see [Section 2.3.3.8, “Starting MySQL as a Windows Service”](#).

Based on the preceding information, you have several ways to set up multiple services. The following instructions describe some examples. Before trying any of them, shut down and remove any existing MySQL services.

- **Approach 1:** Specify the options for all services in one of the standard option files. To do this, use a different service name for each server. Suppose that you want to run the 5.7.9 `mysqld` using the service name of `mysqld1` and the 9.1.0 `mysqld` using the service name `mysqld2`. In this case, you can use the `[mysqld1]` group for 5.7.9 and the `[mysqld2]` group for 9.1.0. For example, you can set up `C:\my.cnf` like this:

```
options for mysqld1 service
[mysqld1]
basedir = C:/mysql-5.7.9
port = 3307
enable-named-pipe
socket = mypipe1

options for mysqld2 service
[mysqld2]
```

```
basedir = C:/mysql-9.1.0
port = 3308
enable-named-pipe
socket = mypipe2
```

Install the services as follows, using the full server path names to ensure that Windows registers the correct executable program for each service:

```
C:\> C:\mysql-5.7.9\bin\mysqld --install mysqld1
C:\> C:\mysql-9.1.0\bin\mysqld --install mysqld2
```

To start the services, use the services manager, or `NET START` or `SC START` with the appropriate service names:

```
C:\> SC START mysqld1
C:\> SC START mysqld2
```

To stop the services, use the services manager, or use `NET STOP` or `SC STOP` with the appropriate service names:

```
C:\> SC STOP mysqld1
C:\> SC STOP mysqld2
```

- **Approach 2:** Specify options for each server in separate files and use `--defaults-file` when you install the services to tell each server what file to use. In this case, each file should list options using a `[mysqld]` group.

With this approach, to specify options for the 5.7.9 `mysqld`, create a file `C:\my-opts1.cnf` that looks like this:

```
[mysqld]
basedir = C:/mysql-5.7.9
port = 3307
enable-named-pipe
socket = mypipe1
```

For the 9.1.0 `mysqld`, create a file `C:\my-opts2.cnf` that looks like this:

```
[mysqld]
basedir = C:/mysql-9.1.0
port = 3308
enable-named-pipe
socket = mypipe2
```

Install the services as follows (enter each command on a single line):

```
C:\> C:\mysql-5.7.9\bin\mysqld --install mysqld1
--defaults-file=C:\my-opts1.cnf
C:\> C:\mysql-9.1.0\bin\mysqld --install mysqld2
--defaults-file=C:\my-opts2.cnf
```

When you install a MySQL server as a service and use a `--defaults-file` option, the service name must precede the option.

After installing the services, start and stop them the same way as in the preceding example.

To remove multiple services, use `SC DELETE mysqld_service_name` for each one. Alternatively, use `mysqld --remove` for each one, specifying a service name following the `--remove` option. If the service name is the default (`MySQL`), you can omit it when using `mysqld --remove`.

## 7.8.3 Running Multiple MySQL Instances on Unix

**Note**

The discussion here uses `mysqld_safe` to launch multiple instances of MySQL. For MySQL installation using an RPM distribution, server startup and shutdown is managed by `systemd` on several Linux platforms. On these platforms, `mysqld_safe` is not installed because it is unnecessary. For information about using `systemd` to handle multiple MySQL instances, see [Section 2.5.9, “Managing MySQL Server with systemd”](#).

One way is to run multiple MySQL instances on Unix is to compile different servers with different default TCP/IP ports and Unix socket files so that each one listens on different network interfaces. Compiling in different base directories for each installation also results automatically in a separate, compiled-in data directory, log file, and PID file location for each server.

Assume that an existing 9.0 server is configured for the default TCP/IP port number (3306) and Unix socket file (`/tmp/mysql.sock`). To configure a new 9.1.0 server to have different operating parameters, use a `CMake` command something like this:

```
$> cmake . -DMYSQL_TCP_PORT=port_number \
 -DMYSQL_UNIX_ADDR=file_name \
 -DCMAKE_INSTALL_PREFIX=/usr/local/mysql-9.1.0
```

Here, `port_number` and `file_name` must be different from the default TCP/IP port number and Unix socket file path name, and the `CMAKE_INSTALL_PREFIX` value should specify an installation directory different from the one under which the existing MySQL installation is located.

If you have a MySQL server listening on a given port number, you can use the following command to find out what operating parameters it is using for several important configurable variables, including the base directory and Unix socket file name:

```
$> mysqladmin --host=host_name --port=port_number variables
```

With the information displayed by that command, you can tell what option values *not* to use when configuring an additional server.

If you specify `localhost` as the host name, `mysqladmin` defaults to using a Unix socket file rather than TCP/IP. To explicitly specify the transport protocol, use the `--protocol={TCP|SOCKET|PIPE|MEMORY}` option.

You need not compile a new MySQL server just to start with a different Unix socket file and TCP/IP port number. It is also possible to use the same server binary and start each invocation of it with different parameter values at runtime. One way to do so is by using command-line options:

```
$> mysqld_safe --socket=file_name --port=port_number
```

To start a second server, provide different `--socket` and `--port` option values, and pass a `--datadir=dir_name` option to `mysqld_safe` so that the server uses a different data directory.

Alternatively, put the options for each server in a different option file, then start each server using a `--defaults-file` option that specifies the path to the appropriate option file. For example, if the option files for two server instances are named `/usr/local/mysql/my.cnf` and `/usr/local/mysql/my.cnf2`, start the servers like this: command:

```
$> mysqld_safe --defaults-file=/usr/local/mysql/my.cnf
$> mysqld_safe --defaults-file=/usr/local/mysql/my.cnf2
```

Another way to achieve a similar effect is to use environment variables to set the Unix socket file name and TCP/IP port number:

```
$> MYSQL_UNIX_PORT=/tmp/mysqld-new.sock
$> MYSQL_TCP_PORT=3307
$> export MYSQL_UNIX_PORT MYSQL_TCP_PORT
$> bin/mysqld --initialize --user=mysql
$> mysqld_safe --datadir=/path/to/datadir &
```

This is a quick way of starting a second server to use for testing. The nice thing about this method is that the environment variable settings apply to any client programs that you invoke from the same shell. Thus, connections for those clients are automatically directed to the second server.

[Section 6.9, “Environment Variables”](#), includes a list of other environment variables you can use to affect MySQL programs.

On Unix, the `mysqld_multi` script provides another way to start multiple servers. See [Section 6.3.4, “mysqld\\_multi — Manage Multiple MySQL Servers”](#).

## 7.8.4 Using Client Programs in a Multiple-Server Environment

To connect with a client program to a MySQL server that is listening to different network interfaces from those compiled into your client, you can use one of the following methods:

- Start the client with `--host=host_name --port=port_number` to connect using TCP/IP to a remote server, with `--host=127.0.0.1 --port=port_number` to connect using TCP/IP to a local server, or with `--host=localhost --socket=file_name` to connect to a local server using a Unix socket file or a Windows named pipe.
- Start the client with `--protocol=TCP` to connect using TCP/IP, `--protocol=SOCKET` to connect using a Unix socket file, `--protocol=PIPE` to connect using a named pipe, or `--protocol=MEMORY` to connect using shared memory. For TCP/IP connections, you may also need to specify `--host` and `--port` options. For the other types of connections, you may need to specify a `--socket` option to specify a Unix socket file or Windows named-pipe name, or a `--shared-memory-base-name` option to specify the shared-memory name. Shared-memory connections are supported only on Windows.
- On Unix, set the `MYSQL_UNIX_PORT` and `MYSQL_TCP_PORT` environment variables to point to the Unix socket file and TCP/IP port number before you start your clients. If you normally use a specific socket file or port number, you can place commands to set these environment variables in your `.login` file so that they apply each time you log in. See [Section 6.9, “Environment Variables”](#).
- Specify the default Unix socket file and TCP/IP port number in the `[client]` group of an option file. For example, you can use `C:\my.cnf` on Windows, or the `.my.cnf` file in your home directory on Unix. See [Section 6.2.2.2, “Using Option Files”](#).
- In a C program, you can specify the socket file or port number arguments in the `mysql_real_connect()` call. You can also have the program read option files by calling `mysql_options()`. See [C API Basic Function Descriptions](#).
- If you are using the Perl `DBD::mysql` module, you can read options from MySQL option files. For example:

```
$dsn = "DBI:mysql:test;mysql_read_default_group=client;"
 . "mysql_read_default_file=/usr/local/mysql/data/my.cnf";
$dbh = DBI->connect($dsn, $user, $password);
```

See [Section 31.9, “MySQL Perl API”](#).

Other programming interfaces may provide similar capabilities for reading option files.

## 7.9 Debugging MySQL

This section describes debugging techniques that assist efforts to track down problems in MySQL.

## 7.9.1 Debugging a MySQL Server

If you are using some functionality that is very new in MySQL, you can try to run `mysqld` with the `--skip-new` option (which disables all new, potentially unsafe functionality). See [Section B.3.3.3, “What to Do If MySQL Keeps Crashing”](#).

If `mysqld` does not want to start, verify that you have no `my.cnf` files that interfere with your setup! You can check your `my.cnf` arguments with `mysqld --print-defaults` and avoid using them by starting with `mysqld --no-defaults ....`

If `mysqld` starts to eat up CPU or memory or if it “hangs,” you can use `mysqladmin processlist status` to find out if someone is executing a query that takes a long time. It may be a good idea to run `mysqladmin -i10 processlist status` in some window if you are experiencing performance problems or problems when new clients cannot connect.

The command `mysqladmin debug` dumps some information about locks in use, used memory and query usage to the MySQL log file. This may help solve some problems. This command also provides some useful information even if you have not compiled MySQL for debugging!

If the problem is that some tables are getting slower and slower you should try to optimize the table with `OPTIMIZE TABLE` or `myisamchk`. See [Chapter 7, MySQL Server Administration](#). You should also check the slow queries with `EXPLAIN`.

You should also read the OS-specific section in this manual for problems that may be unique to your environment. See [Section 2.1, “General Installation Guidance”](#).

### 7.9.1.1 Compiling MySQL for Debugging

If you have some very specific problem, you can always try to debug MySQL. To do this you must configure MySQL with the `-DWITH_DEBUG=1` option. You can check whether MySQL was compiled with debugging by doing: `mysqld --help`. If the `--debug` flag is listed with the options then you have debugging enabled. `mysqladmin ver` also lists the `mysqld` version as `mysql ... --debug` in this case.

If `mysqld` stops crashing when you configure it with the `-DWITH_DEBUG=1` CMake option, you probably have found a compiler bug or a timing bug within MySQL. In this case, you can try to add `-g` using the `CMAKE_C_FLAGS` and `CMAKE_CXX_FLAGS` CMake options and not use `-DWITH_DEBUG=1`. If `mysqld` dies, you can at least attach to it with `gdb` or use `gdb` on the core file to find out what happened.

When you configure MySQL for debugging you automatically enable a lot of extra safety check functions that monitor the health of `mysqld`. If they find something “unexpected,” an entry is written to `stderr`, which `mysqld_safe` directs to the error log! This also means that if you are having some unexpected problems with MySQL and are using a source distribution, the first thing you should do is to configure MySQL for debugging. If you believe that you have found a bug, please use the instructions at [Section 1.6, “How to Report Bugs or Problems”](#).

In the Windows MySQL distribution, `mysqld.exe` is by default compiled with support for trace files.

### 7.9.1.2 Creating Trace Files

If the `mysqld` server does not start or it crashes easily, you can try to create a trace file to find the problem.

To do this, you must have a `mysqld` that has been compiled with debugging support. You can check this by executing `mysqld -V`. If the version number ends with `-debug`, it is compiled with support for trace files. (On Windows, the debugging server is named `mysqld-debug` rather than `mysqld`.)

Start the `mysqld` server with a trace log in `/tmp/mysqld.trace` on Unix or `\mysqld.trace` on Windows:

```
$> mysqld --debug
```

On Windows, you should also use the `--standalone` flag to not start `mysqld` as a service. In a console window, use this command:

```
C:\> mysqld-debug --debug --standalone
```

After this, you can use the `mysql.exe` command-line tool in a second console window to reproduce the problem. You can stop the `mysqld` server with `mysqladmin shutdown`.

The trace file can become **very large**! To generate a smaller trace file, you can use debugging options something like this:

```
mysqld --debug=d,info,error,query,general,where:0,/tmp/mysqld.trace
```

This only prints information with the most interesting tags to the trace file.

If you file a bug, please add only those lines from the trace file to the bug report that indicate where something seems to go wrong. If you cannot locate the wrong place, open a bug report and upload the whole trace file to the report, so that a MySQL developer can take a look at it. For instructions, see [Section 1.6, “How to Report Bugs or Problems”](#).

The trace file is made with the `DEBUG` package by Fred Fish. See [Section 7.9.4, “The DEBUG Package”](#).

### 7.9.1.3 Using WER with PDB to create a Windows crashdump

Program Database files (with suffix `.pdb`) are included in the **ZIP Archive Debug Binaries & Test Suite** distribution of MySQL. These files provide information for debugging your MySQL installation in the event of a problem. This is a separate download from the standard MSI or Zip file.

#### Note

The PDB files are available in a separate file labeled "ZIP Archive Debug Binaries & Test Suite".

The PDB file contains more detailed information about `mysqld` and other tools that enables more detailed trace and dump files to be created. You can use these with `WinDbg` or Visual Studio to debug `mysqld`.

For more information on PDB files, see [Microsoft Knowledge Base Article 121366](#). For more information on the debugging options available, see [Debugging Tools for Windows](#).

To use `WinDbg`, either install the full Windows Driver Kit (WDK) or install the standalone version.

#### Important

The `.exe` and `.pdb` files must be an exact match (both version number and MySQL server edition); otherwise, `WinDBG` complains while attempting to load the symbols.

1. To generate a minidump `mysqld.dmp`, enable the `core-file` option under the `[mysqld]` section in `my.ini`. Restart the MySQL server after making these changes.
2. Create a directory to store the generated files, such as `c:\symbols`
3. Determine the path to your `windbg.exe` executable using the Find GUI or from the command line, for example: `dir /s /b windbg.exe` -- a common default is `C:\Program Files\Debugging Tools for Windows (x64)\windbg.exe`
4. Launch `windbg.exe` giving it the paths to `mysqld.exe`, `mysqld.pdb`, `mysqld.dmp`, and the source code. Alternatively, pass in each path from the WinDbg GUI. For example:

```
windbg.exe -i "C:\mysql-9.1.0-winx64\bin\"^
-z "C:\mysql-9.1.0-winx64\data\mysqld.dmp"^
-srcpath "E:\ade\mysql_archives\9.1\9.1.0\mysql-9.1.0"^
-y "C:\mysql-9.1.0-winx64\bin;SRV*c:\symbols*http://msdl.microsoft.com/download/symbols"^
-v -n -c "!analyze -vvvvv"
```

#### Note

The ^ character and newline are removed by the Windows command line processor, so be sure the spaces remain intact.

### 7.9.1.4 Debugging mysqld under gdb

On most systems you can also start `mysqld` from `gdb` to get more information if `mysqld` crashes.

With some older `gdb` versions on Linux you must use `run --one-thread` if you want to be able to debug `mysqld` threads. In this case, you can only have one thread active at a time.

NPTL threads (the new thread library on Linux) may cause problems while running `mysqld` under `gdb`. Some symptoms are:

- `mysqld` hangs during startup (before it writes `ready for connections`).
- `mysqld` crashes during a `pthread_mutex_lock()` or `pthread_mutex_unlock()` call.

In this case, you should set the following environment variable in the shell before starting `gdb`:

```
LD_ASSUME_KERNEL=2.4.1
export LD_ASSUME_KERNEL
```

When running `mysqld` under `gdb`, you should disable the stack trace with `--skip-stack-trace` to be able to catch segfaults within `gdb`.

Use the `--gdb` option to `mysqld` to install an interrupt handler for `SIGINT` (needed to stop `mysqld` with `^C` to set breakpoints) and disable stack tracing and core file handling.

It is very hard to debug MySQL under `gdb` if you do a lot of new connections the whole time as `gdb` does not free the memory for old threads. You can avoid this problem by starting `mysqld` with `thread_cache_size` set to a value equal to `max_connections + 1`. In most cases just using `--thread_cache_size=5` helps a lot!

If you want to get a core dump on Linux if `mysqld` dies with a `SIGSEGV` signal, you can start `mysqld` with the `--core-file` option. This core file can be used to make a backtrace that may help you find out why `mysqld` died:

```
$> gdb mysqld core
```

```
gdb> backtrace full
gdb> quit
```

See [Section B.3.3.3, “What to Do If MySQL Keeps Crashing”](#).

If you are using `gdb` on Linux, you should install a `.gdb` file, with the following information, in your current directory:

```
set print sevenbit off
handle SIGUSR1 nostop noprint
handle SIGUSR2 nostop noprint
handle SIGWAITING nostop noprint
handle SIGLWP nostop noprint
handle SIGPIPE nostop
handle SIGALRM nostop
handle SIGHUP nostop
handle SIGTERM nostop noprint
```

Here is an example how to debug `mysqld`:

```
$> gdb /usr/local/libexec/mysqld
gdb> run
...
backtrace full # Do this when mysqld crashes
```

Include the preceding output in a bug report, which you can file using the instructions in [Section 1.6, “How to Report Bugs or Problems”](#).

If `mysqld` hangs, you can try to use some system tools like `strace` or `/usr/proc/bin/pstack` to examine where `mysqld` has hung.

```
strace /tmp/log libexec/mysqld
```

If you are using the Perl `DBI` interface, you can turn on debugging information by using the `trace` method or by setting the `DBI_TRACE` environment variable.

### 7.9.1.5 Using a Stack Trace

On some operating systems, the error log contains a stack trace if `mysqld` dies unexpectedly. You can use this to find out where (and maybe why) `mysqld` died. See [Section 7.4.2, “The Error Log”](#). To get a stack trace, you must not compile `mysqld` with the `-fomit-frame-pointer` option to gcc. See [Section 7.9.1.1, “Compiling MySQL for Debugging”](#).

A stack trace in the error log looks something like this:

```
mysqld got signal 11;
Attempting backtrace. You can use the following information
to find out where mysqld died. If you see no messages after
this, something went terribly wrong...

stack_bottom = 0x41fd0110 thread_stack 0x40000
mysqld(my_print_stacktrace+0x32)[0x9da402]
mysqld(handle_segfault+0x28a)[0x6648e9]
/lib/libpthread.so.0[0x7f1a5af00f0]
/lib/libc.so.6(strcmp+0x2)[0x7f1a5a10f0f2]
mysqld(_Z21check_change_passwordP3THDPKcS2_Pcj+0x7c)[0x7412cb]
mysqld(_ZN16set_var_password5checkEP3THD+0xd0)[0x688354]
mysqld(_Z17sql_set_variablesP3THDP4ListI12set_var_baseE+0x68)[0x688494]
mysqld(_Z21mysql_execute_commandP3THD+0x41a0)[0x67a170]
mysqld(_Z11mysql_parseP3THDPKcPS2_+0x282)[0x67f0ad]
mysqld(_Z16dispatch_command19enum_server_commandP3THDPcj+0xbb7[0x67fdf8]
```

```
mysqld(_Z10do_commandP3THD+0x24d)[0x6811b6]
mysqld(handle_one_connection+0x11c)[0x66e05e]
```

If resolution of function names for the trace fails, the trace contains less information:

```
mysqld got signal 11;
Attempting backtrace. You can use the following information
to find out where mysqld died. If you see no messages after
this, something went terribly wrong...

stack_bottom = 0x41fd0110 thread_stack 0x40000
[0x9da402]
[0x6648e9]
[0x7f1a5af00f0]
[0x7f1a5a10f0f2]
[0x7412cb]
[0x688354]
[0x688494]
[0x67a170]
[0x67f0ad]
[0x67fdf8]
[0x6811b6]
[0x66e05e]
```

Newer versions of [glibc](#) stack trace functions also print the address as relative to the object. On [glibc](#)-based systems (Linux), the trace for an unexpected exit within a plugin looks something like:

```
plugin/auth/auth_test_plugin.so(+0x9a6)[0x7ff4d11c29a6]
```

To translate the relative address (+0x9a6) into a file name and line number, use this command:

```
$> addr2line -fie auth_test_plugin.so 0x9a6
auth_test_plugin
mysql-trunk/plugin/auth/test_plugin.c:65
```

The [addr2line](#) utility is part of the [binutils](#) package on Linux.

On Solaris, the procedure is similar. The Solaris [printstack\(\)](#) already prints relative addresses:

```
plugin/auth/auth_test_plugin.so:0x1510
```

To translate, use this command:

```
$> gaddr2line -fie auth_test_plugin.so 0x1510
mysql-trunk/plugin/auth/test_plugin.c:88
```

Windows already prints the address, function name and line:

```
000007FEF07E10A4 auth_test_plugin.dll!auth_test_plugin()[test_plugin.c:72]
```

### 7.9.1.6 Using Server Logs to Find Causes of Errors in mysqld

Note that before starting [mysqld](#) with the general query log enabled, you should check all your tables with [myisamchk](#). See [Chapter 7, MySQL Server Administration](#).

If [mysqld](#) dies or hangs, you should start [mysqld](#) with the general query log enabled. See [Section 7.4.3, “The General Query Log”](#). When [mysqld](#) dies again, you can examine the end of the log file for the query that killed [mysqld](#).

If you use the default general query log file, the log is stored in the database directory as [host\\_name.log](#). In most cases it is the last query in the log file that killed [mysqld](#), but if possible you should verify this by

restarting `mysqld` and executing the found query from the `mysql` command-line tools. If this works, you should also test all complicated queries that did not complete.

You can also try the command `EXPLAIN` on all `SELECT` statements that takes a long time to ensure that `mysqld` is using indexes properly. See [Section 15.8.2, “EXPLAIN Statement”](#).

You can find the queries that take a long time to execute by starting `mysqld` with the slow query log enabled. See [Section 7.4.5, “The Slow Query Log”](#).

If you find the text `mysqld restarted` in the error log (normally a file named `host_name.err`) you probably have found a query that causes `mysqld` to fail. If this happens, you should check all your tables with `myisamchk` (see [Chapter 7, MySQL Server Administration](#)), and test the queries in the MySQL log files to see whether one fails. If you find such a query, try first upgrading to the newest MySQL version. If this does not help, report a bug, see [Section 1.6, “How to Report Bugs or Problems”](#).

If you have started `mysqld` with the `myisam_recover_options` system variable set, MySQL automatically checks and tries to repair MyISAM tables if they are marked as 'not closed properly' or 'crashed'. If this happens, MySQL writes an entry in the `hostname.err` file 'Warning: Checking table ...' which is followed by `Warning: Repairing table` if the table needs to be repaired. If you get a lot of these errors, without `mysqld` having died unexpectedly just before, then something is wrong and needs to be investigated further. See [Section 7.1.7, “Server Command Options”](#).

When the server detects MyISAM table corruption, it writes additional information to the error log, such as the name and line number of the source file, and the list of threads accessing the table. Example: `Got an error from thread_id=1, mi_dynrec.c:368`. This is useful information to include in bug reports.

It is not a good sign if `mysqld` did die unexpectedly, but in this case, you should not investigate the `Checking table...` messages, but instead try to find out why `mysqld` died.

### 7.9.1.7 Making a Test Case If You Experience Table Corruption

The following procedure applies to MyISAM tables. For information about steps to take when encountering InnoDB table corruption, see [Section 1.6, “How to Report Bugs or Problems”](#).

If you encounter corrupted MyISAM tables or if `mysqld` always fails after some update statements, you can test whether the issue is reproducible by doing the following:

1. Stop the MySQL daemon with `mysqldadmin shutdown`.
2. Make a backup of the tables to guard against the very unlikely case that the repair does something bad.
3. Check all tables with `myisamchk -s database/*.MYI`. Repair any corrupted tables with `myisamchk -r database/table.MYI`.
4. Make a second backup of the tables.
5. Remove (or move away) any old log files from the MySQL data directory if you need more space.
6. Start `mysqld` with the binary log enabled. If you want to find a statement that crashes `mysqld`, you should start the server with the general query log enabled as well. See [Section 7.4.3, “The General Query Log”](#), and [Section 7.4.4, “The Binary Log”](#).
7. When you have gotten a crashed table, stop the `mysqld` server.
8. Restore the backup.
9. Restart the `mysqld` server *without* the binary log enabled.

10. Re-execute the statements with `mysqlbinlog binary-log-file | mysql`. The binary log is saved in the MySQL database directory with the name `hostname-bin.NNNNNNN`.
11. If the tables are corrupted again or you can get `mysqld` to die with the above command, you have found a reproducible bug. FTP the tables and the binary log to our bugs database using the instructions given in [Section 1.6, “How to Report Bugs or Problems”](#). If you are a support customer, you can use the MySQL Customer Support Center (<https://www.mysql.com/support/>) to alert the MySQL team about the problem and have it fixed as soon as possible.

## 7.9.2 Debugging a MySQL Client

To be able to debug a MySQL client with the integrated debug package, you should configure MySQL with `-DWITH_DEBUG=1`. See [Section 2.8.7, “MySQL Source-Configuration Options”](#).

Before running a client, you should set the `MYSQL_DEBUG` environment variable:

```
$> MYSQL_DEBUG=d:t:O,/tmp/client.trace
$> export MYSQL_DEBUG
```

This causes clients to generate a trace file in `/tmp/client.trace`.

If you have problems with your own client code, you should attempt to connect to the server and run your query using a client that is known to work. Do this by running `mysql` in debugging mode (assuming that you have compiled MySQL with debugging on):

```
$> mysql --debug=d:t:O,/tmp/client.trace
```

This provides useful information in case you mail a bug report. See [Section 1.6, “How to Report Bugs or Problems”](#).

If your client crashes at some 'legal' looking code, you should check that your `mysql.h` include file matches your MySQL library file. A very common mistake is to use an old `mysql.h` file from an old MySQL installation with new MySQL library.

## 7.9.3 The LOCK\_ORDER Tool

The MySQL server is a multithreaded application that uses numerous internal locking and lock-related primitives, such as mutexes, rwlocks (including prlocks and sxlocks), conditions, and files. Within the server, the set of lock-related objects changes with implementation of new features and code refactoring for performance improvements. As with any multithreaded application that uses locking primitives, there is always a risk of encountering a deadlock during execution when multiple locks are held at once. For MySQL, the effect of a deadlock is catastrophic, causing a complete loss of service.

To enable detection of lock-acquisition deadlocks and enforcement that runtime execution is free of them, MySQL supports `LOCK_ORDER` tooling. This enables a lock-order dependency graph to be defined as part of server design, and server runtime checking to ensure that lock acquisition is acyclic and that execution paths comply with the graph.

This section provides information about using the `LOCK_ORDER` tool, but only at a basic level. For complete details, see the Lock Order section of the MySQL Server Doxygen documentation, available at <https://dev.mysql.com/doc/index-other.html>.

The `LOCK_ORDER` tool is intended for debugging the server, not for production use.

To use the `LOCK_ORDER` tool, follow this procedure:

1. Build MySQL from source, configuring it with the `-DWITH_LOCK_ORDER=ON` CMake option so that the build includes `LOCK_ORDER` tooling.

**Note**

With the `WITH_LOCK_ORDER` option enabled, MySQL builds require the `flex` program.

2. To run the server with the `LOCK_ORDER` tool enabled, enable the `lock_order` system variable at server startup. Several other system variables for `LOCK_ORDER` configuration are available as well.
3. For MySQL test suite operation, `mysql-test-run.pl` has a `--lock-order` option that controls whether to enable the `LOCK_ORDER` tool during test case execution.

The system variables described following configure operation of the `LOCK_ORDER` tool, assuming that MySQL has been built to include `LOCK_ORDER` tooling. The primary variable is `lock_order`, which indicates whether to enable the `LOCK_ORDER` tool at runtime:

- If `lock_order` is disabled (the default), no other `LOCK_ORDER` system variables have any effect.
- If `lock_order` is enabled, the other system variables configure which `LOCK_ORDER` features to enable.

**Note**

In general, it is intended that the `LOCK_ORDER` tool be configured by executing `mysql-test-run.pl` with the `--lock-order` option, and for `mysql-test-run.pl` to set `LOCK_ORDER` system variables to appropriate values.

All `LOCK_ORDER` system variables must be set at server startup. At runtime, their values are visible but cannot be changed.

Some system variables exist in pairs, such as `lock_order_debug_loop` and `lock_order_trace_loop`. For such pairs, the variables are distinguished as follows when the condition occurs with which they are associated:

- If the `_debug_` variable is enabled, a debug assertion is raised.
- If the `_trace_` variable is enabled, an error is printed to the logs.

**Table 7.12 LOCK\_ORDER System Variable Summary**

Variable Name	Variable Type	Variable Scope
<code>lock_order</code>	Boolean	Global
<code>lock_order_debug_loop</code>	Boolean	Global
<code>lock_order_debug_missing_arc</code>	Boolean	Global
<code>lock_order_debug_missing_key</code>	Boolean	Global
<code>lock_order_debug_missing_unlock</code>	Boolean	Global
<code>lock_order_dependencies</code>	File name	Global
<code>lock_order_extra_dependencies</code>	File name	Global
<code>lock_order_output_directory</code>	Directory name	Global
<code>lock_order_print_txt</code>	Boolean	Global
<code>lock_order_trace_loop</code>	Boolean	Global
<code>lock_order_trace_missing_arc</code>	Boolean	Global
<code>lock_order_trace_missing_key</code>	Boolean	Global
<code>lock_order_trace_missing_unlock</code>	Boolean	Global

- `lock_order`

Command-Line Format	<code>--lock-order[={OFF ON} ]</code>
System Variable	<code>lock_order</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Whether to enable the `LOCK_ORDER` tool at runtime. If `lock_order` is disabled (the default), no other `LOCK_ORDER` system variables have any effect. If `lock_order` is enabled, the other system variables configure which `LOCK_ORDER` features to enable.

If `lock_order` is enabled, an error is raised if the server encounters a lock-acquisition sequence that is not declared in the lock-order graph.

- `lock_order_debug_loop`

Command-Line Format	<code>--lock-order-debug-loop[={OFF ON} ]</code>
System Variable	<code>lock_order_debug_loop</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Whether the `LOCK_ORDER` tool causes a debug assertion failure when it encounters a dependency that is flagged as a loop in the lock-order graph.

- `lock_order_debug_missing_arc`

Command-Line Format	<code>--lock-order-debug-missing-arc[={OFF ON} ]</code>
System Variable	<code>lock_order_debug_missing_arc</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Whether the `LOCK_ORDER` tool causes a debug assertion failure when it encounters a dependency that is not declared in the lock-order graph.

- `lock_order_debug_missing_key`

Command-Line Format	<code>--lock-order-debug-missing-key[={OFF ON} ]</code>
---------------------	---------------------------------------------------------

System Variable	<code>lock_order_debug_missing_key</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Whether the `LOCK_ORDER` tool causes a debug assertion failure when it encounters an object that is not properly instrumented with the Performance Schema.

- `lock_order_debug_missing_unlock`

Command-Line Format	<code>--lock-order-debug-missing-unlock[={OFF ON}]</code>
System Variable	<code>lock_order_debug_missing_unlock</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	Boolean
Default Value	OFF

Whether the `LOCK_ORDER` tool causes a debug assertion failure when it encounters a lock that is destroyed while still held.

- `lock_order_dependencies`

Command-Line Format	<code>--lock-order-dependencies=file_name</code>
System Variable	<code>lock_order_dependencies</code>
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	File name
Default Value	empty string

The path to the `lock_order_dependencies.txt` file that defines the server lock-order dependency graph.

It is permitted to specify no dependencies. An empty dependency graph is used in this case.

- `lock_order_extra_dependencies`

Command-Line Format	<code>--lock-order-extra-dependencies=file_name</code>
System Variable	<code>lock_order_extra_dependencies</code>
Scope	Global
Dynamic	No

<a href="#">SET_VAR</a> Hint Applies	No
Type	File name
Default Value	<code>empty string</code>

The path to a file containing additional dependencies for the lock-order dependency graph. This is useful to amend the primary server dependency graph, defined in the `lock_order_dependencies.txt` file, with additional dependencies describing the behavior of third party code. (The alternative is to modify `lock_order_dependencies.txt` itself, which is not encouraged.)

If this variable is not set, no secondary file is used.

- `lock_order_output_directory`

Command-Line Format	<code>--lock-order-output-directory=dir_name</code>
System Variable	<code>lock_order_output_directory</code>
Scope	Global
Dynamic	No
<a href="#">SET_VAR</a> Hint Applies	No
Type	Directory name
Default Value	<code>empty string</code>

The directory where the `LOCK_ORDER` tool writes its logs. If this variable is not set, the default is the current directory.

- `lock_order_print_txt`

Command-Line Format	<code>--lock-order-print-txt[={OFF ON}]</code>
System Variable	<code>lock_order_print_txt</code>
Scope	Global
Dynamic	No
<a href="#">SET_VAR</a> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Whether the `LOCK_ORDER` tool performs a lock-order graph analysis and prints a textual report. The report includes any lock-acquisition cycles detected.

- `lock_order_trace_loop`

Command-Line Format	<code>--lock-order-trace-loop[={OFF ON}]</code>
System Variable	<code>lock_order_trace_loop</code>
Scope	Global
Dynamic	No
<a href="#">SET_VAR</a> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Whether the `LOCK_ORDER` tool prints a trace in the log file when it encounters a dependency that is flagged as a loop in the lock-order graph.

- `lock_order_trace_missing_arc`

Command-Line Format	<code>--lock-order-trace-missing-arc[={OFF ON}]</code>
System Variable	<code>lock_order_trace_missing_arc</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>ON</code>

Whether the `LOCK_ORDER` tool prints a trace in the log file when it encounters a dependency that is not declared in the lock-order graph.

- `lock_order_trace_missing_key`

Command-Line Format	<code>--lock-order-trace-missing-key[={OFF ON}]</code>
System Variable	<code>lock_order_trace_missing_key</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>OFF</code>

Whether the `LOCK_ORDER` tool prints a trace in the log file when it encounters an object that is not properly instrumented with the Performance Schema.

- `lock_order_trace_missing_unlock`

Command-Line Format	<code>--lock-order-trace-missing-unlock[={OFF ON}]</code>
System Variable	<code>lock_order_trace_missing_unlock</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>ON</code>

Whether the `LOCK_ORDER` tool prints a trace in the log file when it encounters a lock that is destroyed while still held.

## 7.9.4 The DBUG Package

The MySQL server and most MySQL clients are compiled with the `DEBUG` package originally created by Fred Fish. When you have configured MySQL for debugging, this package makes it possible to get a trace file of what the program is doing. See [Section 7.9.1.2, “Creating Trace Files”](#).

This section summarizes the argument values that you can specify in debug options on the command line for MySQL programs that have been built with debugging support.

The `DEBUG` package can be used by invoking a program with the `--debug[=debug_options]` or `-# [debug_options]` option. If you specify the `--debug` or `-#` option without a `debug_options` value, most MySQL programs use a default value. The server default is `d:t:i:o,/tmp/mysqlld.trace` on Unix and `d:t:i:O,\\mysqlld.trace` on Windows. The effect of this default is:

- `d`: Enable output for all debug macros
- `t`: Trace function calls and exits
- `i`: Add PID to output lines
- `o,/tmp/mysqlld.trace,O,\\mysqlld.trace`: Set the debug output file.

Most client programs use a default `debug_options` value of `d:t:o,/tmp/program_name.trace`, regardless of platform.

Here are some example debug control strings as they might be specified on a shell command line:

```
--debug=d:t
--debug=d:f,main,subr1:F:L:t,20
--debug=d,input,output,files:n
--debug=d:t:i:O,\\mysqlld.trace
```

For `mysqlld`, it is also possible to change `DEBUG` settings at runtime by setting the `debug` system variable. This variable has global and session values:

```
mysql> SET GLOBAL debug = 'debug_options';
mysql> SET SESSION debug = 'debug_options';
```

Changing the global `debug` value requires privileges sufficient to set global system variables. Changing the session `debug` value requires privileges sufficient to set restricted session system variables. See [Section 7.1.9.1, “System Variable Privileges”](#).

The `debug_options` value is a sequence of colon-separated fields:

```
field_1:field_2:...:field_N
```

Each field within the value consists of a mandatory flag character, optionally preceded by a `+` or `-` character, and optionally followed by a comma-separated list of modifiers:

```
[+|-]flag[,modifier,modifier,...,modifier]
```

The following table describes the permitted flag characters. Unrecognized flag characters are silently ignored.

Flag	Description
<code>d</code>	Enable output from <code>DEBUG_XXX</code> macros for the current state. May be followed by a list of keywords, which enables output only for the <code>DEBUG</code> macros with that keyword. An empty list of keywords enables output for all macros.

Flag	Description
	In MySQL, common debug macro keywords to enable are <code>enter</code> , <code>exit</code> , <code>error</code> , <code>warning</code> , <code>info</code> , and <code>loop</code> .
<code>D</code>	Delay after each debugger output line. The argument is the delay, in tenths of seconds, subject to machine capabilities. For example, <code>D, 20</code> specifies a delay of two seconds.
<code>f</code>	Limit debugging, tracing, and profiling to the list of named functions. An empty list enables all functions. The appropriate <code>d</code> or <code>t</code> flags must still be given; this flag only limits their actions if they are enabled.
<code>F</code>	Identify the source file name for each line of debug or trace output.
<code>i</code>	Identify the process with the PID or thread ID for each line of debug or trace output.
<code>L</code>	Identify the source file line number for each line of debug or trace output.
<code>n</code>	Print the current function nesting depth for each line of debug or trace output.
<code>N</code>	Number each line of debug output.
<code>o</code>	Redirect the debugger output stream to the specified file. The default output is <code>stderr</code> .
<code>O</code>	Like <code>o</code> , but the file is really flushed between each write. When needed, the file is closed and reopened between each write.
<code>a</code>	Like <code>o</code> , but opens for append.
<code>A</code>	Like <code>O</code> , but opens for append.
<code>p</code>	Limit debugger actions to specified processes. A process must be identified with the <code>DEBUG_PROCESS</code> macro and match one in the list for debugger actions to occur.
<code>P</code>	Print the current process name for each line of debug or trace output.
<code>r</code>	When pushing a new state, do not inherit the previous state's function nesting level. Useful when the output is to start at the left margin.
<code>t</code>	Enable function call/exit trace lines. May be followed by a list (containing only one modifier) giving a numeric maximum trace level, beyond which no output occurs for either debugging or tracing macros. The default is a compile time option.
<code>T</code>	Print the current timestamp for every line of output.

The leading `+` or `-` character and trailing list of modifiers are used for flag characters such as `d` or `f` that can enable a debug operation for all applicable modifiers or just some of them:

- With no leading `+` or `-`, the flag value is set to exactly the modifier list as given.

- With a leading + or −, the modifiers in the list are added to or subtracted from the current modifier list.

The following examples show how this works for the `d` flag. An empty `d` list enabled output for all debug macros. A nonempty list enables output only for the macro keywords in the list.

These statements set the `d` value to the modifier list as given:

```
mysql> SET debug = 'd';
mysql> SELECT @@debug;
+-----+
| @@debug |
+-----+
| d |
+-----+
mysql> SET debug = 'd,error,warning';
mysql> SELECT @@debug;
+-----+
| @@debug |
+-----+
| d,error,warning |
+-----+
```

A leading + or − adds to or subtracts from the current `d` value:

```
mysql> SET debug = '+d,loop';
mysql> SELECT @@debug;
+-----+
| @@debug |
+-----+
| d,error,warning,loop |
+-----+

mysql> SET debug = '-d,error,loop';
mysql> SELECT @@debug;
+-----+
| @@debug |
+-----+
| d,warning |
+-----+
```

Adding to “all macros enabled” results in no change:

```
mysql> SET debug = 'd';
mysql> SELECT @@debug;
+-----+
| @@debug |
+-----+
| d |
+-----+

mysql> SET debug = '+d,loop';
mysql> SELECT @@debug;
+-----+
| @@debug |
+-----+
| d |
+-----+
```

Disabling all enabled macros disables the `d` flag entirely:

```
mysql> SET debug = 'd,error,loop';
mysql> SELECT @@debug;
+-----+
| @@debug |
+-----+
```

```
+-----+
| d,error,loop |
+-----+

mysql> SET debug = '-d,error,loop';
mysql> SELECT @@debug;
+-----+
| @@debug |
+-----+
| |
+-----+
```

When thinking about security within a MySQL installation, you should consider a wide range of possible topics and how they affect the security of your MySQL server and related applications:

- General factors that affect security. These include choosing good passwords, not granting unnecessary privileges to users, ensuring application security by preventing SQL injections and data corruption, and others. See [Section 8.1, “General Security Issues”](#).
- Security of the installation itself. The data files, log files, and the all the application files of your installation should be protected to ensure that they are not readable or writable by unauthorized parties. For more information, see [Section 2.9, “Postinstallation Setup and Testing”](#).
- Access control and security within the database system itself, including the users and databases granted with access to the databases, views and stored programs in use within the database. For more information, see [Section 8.2, “Access Control and Account Management”](#).
- The features offered by security-related plugins. See [Section 8.4, “Security Components and Plugins”](#).
- Network security of MySQL and your system. The security is related to the grants for individual users, but you may also wish to restrict MySQL so that it is available only locally on the MySQL server host, or to a limited set of other hosts.
- Ensure that you have adequate and appropriate backups of your database files, configuration and log files. Also be sure that you have a recovery solution in place and test that you are able to successfully recover the information from your backups. See [Chapter 9, Backup and Recovery](#).

**Note**

Several topics in this chapter are also addressed in the [Secure Deployment Guide](#), which provides procedures for deploying a generic binary distribution of MySQL Enterprise Edition Server with features for managing the security of your MySQL installation.

## 8.1 General Security Issues

This section describes general security issues to be aware of and what you can do to make your MySQL installation more secure against attack or misuse. For information specifically about the access control system that MySQL uses for setting up user accounts and checking database access, see [Section 2.9, “Postinstallation Setup and Testing”](#).

For answers to some questions that are often asked about MySQL Server security issues, see [Section A.9, “MySQL 9.1 FAQ: Security”](#).

## 8.1.1 Security Guidelines

Anyone using MySQL on a computer connected to the Internet should read this section to avoid the most common security mistakes.

In discussing security, it is necessary to consider fully protecting the entire server host (not just the MySQL server) against all types of applicable attacks: eavesdropping, altering, playback, and denial of service. We do not cover all aspects of availability and fault tolerance here.

MySQL uses security based on Access Control Lists (ACLs) for all connections, queries, and other operations that users can attempt to perform. There is also support for SSL-encrypted connections between MySQL clients and servers. Many of the concepts discussed here are not specific to MySQL at all; the same general ideas apply to almost all applications.

When running MySQL, follow these guidelines:

- **Do not ever give anyone (except MySQL `root` accounts) access to the `user` table in the `mysql` system database!** This is critical.
- Learn how the MySQL access privilege system works (see [Section 8.2, “Access Control and Account Management”](#)). Use the `GRANT` and `REVOKE` statements to control access to MySQL. Do not grant more privileges than necessary. Never grant privileges to all hosts.

Checklist:

- Try `mysql -u root`. If you are able to connect successfully to the server without being asked for a password, anyone can connect to your MySQL server as the MySQL `root` user with full privileges! Review the MySQL installation instructions, paying particular attention to the information about setting a `root` password. See [Section 2.9.4, “Securing the Initial MySQL Account”](#).
- Use the `SHOW GRANTS` statement to check which accounts have access to what. Then use the `REVOKE` statement to remove those privileges that are not necessary.
- Do not store cleartext passwords in your database. If your computer becomes compromised, the intruder can take the full list of passwords and use them. Instead, use `SHA2 ( )` or some other one-way hashing function and store the hash value.

To prevent password recovery using rainbow tables, do not use these functions on a plain password; instead, choose some string to be used as a salt, and use `hash(hash(password)+salt)` values.

- Assume that all passwords will be subject to automated cracking attempts using lists of known passwords, and also to targeted guessing using publicly available information about you, such as social media posts. Do not choose passwords that consist of easily cracked or guessed items such as a dictionary word, proper name, sports team name, acronym, or commonly known phrase, particularly if they are relevant to you. The use of upper case letters, number substitutions and additions, and special characters does not help if these are used in predictable ways. Also do not choose any password you have seen used as an example anywhere, or a variation on it, even if it was presented as an example of a strong password.

Instead, choose passwords that are as long and as unpredictable as possible. That does not mean the combination needs to be a random string of characters that is difficult to remember and reproduce, although this is a good approach if you have, for example, password manager software that can generate and fill such passwords and store them securely. A passphrase containing multiple words is easy to create, remember, and reproduce, and is much more secure than a typical user-selected

password consisting of a single modified word or a predictable sequence of characters. To create a secure passphrase, ensure that the words and other items in it are not a known phrase or quotation, do not occur in a predictable order, and preferably have no previous relationship to each other at all.

- Invest in a firewall. This protects you from at least 50% of all types of exploits in any software. Put MySQL behind the firewall or in a demilitarized zone (DMZ).

Checklist:

- Try to scan your ports from the Internet using a tool such as [nmap](#). MySQL uses port 3306 by default. This port should not be accessible from untrusted hosts. As a simple way to check whether your MySQL port is open, try the following command from some remote machine, where [server\\_host](#) is the host name or IP address of the host on which your MySQL server runs:

```
$> telnet server_host 3306
```

If [telnet](#) hangs or the connection is refused, the port is blocked, which is how you want it to be. If you get a connection and some garbage characters, the port is open, and should be closed on your firewall or router, unless you really have a good reason to keep it open.

- Applications that access MySQL should not trust any data entered by users, and should be written using proper defensive programming techniques. See [Section 8.1.7, “Client Programming Security Guidelines”](#).
- Do not transmit plain (unencrypted) data over the Internet. This information is accessible to everyone who has the time and ability to intercept it and use it for their own purposes. Instead, use an encrypted protocol such as SSL or SSH. MySQL supports internal SSL connections. Another technique is to use SSH port-forwarding to create an encrypted (and compressed) tunnel for the communication.
- Learn to use the [tcpdump](#) and [strings](#) utilities. In most cases, you can check whether MySQL data streams are unencrypted by issuing a command like the following:

```
$> tcpdump -l -i eth0 -w - src or dst port 3306 | strings
```

This works under Linux and should work with small modifications under other systems.

#### Warning

If you do not see cleartext data, this does not always mean that the information actually is encrypted. If you need high security, consult with a security expert.

## 8.1.2 Keeping Passwords Secure

Passwords occur in several contexts within MySQL. The following sections provide guidelines that enable end users and administrators to keep these passwords secure and avoid exposing them. In addition, the [validate\\_password](#) plugin can be used to enforce a policy on acceptable password. See [Section 8.4.3, “The Password Validation Component”](#).

### 8.1.2.1 End-User Guidelines for Password Security

MySQL users should use the following guidelines to keep passwords secure.

When you run a client program to connect to the MySQL server, it is inadvisable to specify your password in a way that exposes it to discovery by other users. The methods you can use to specify your password when you run client programs are listed here, along with an assessment of the risks of each method. In short, the safest methods are to have the client program prompt for the password or to specify the password in a properly protected option file.

- Use the `mysql_config_editor` utility, which enables you to store authentication credentials in an encrypted login path file named `.mylogin.cnf`. The file can be read later by MySQL client programs to obtain authentication credentials for connecting to MySQL Server. See [Section 6.6.7, “mysql\\_config\\_editor — MySQL Configuration Utility”](#).
- Use a `--password=password` or `-ppassword` option on the command line. For example:

```
$> mysql -u francis -pfrank db_name
```

### Warning

This is convenient *but insecure*. On some systems, your password becomes visible to system status programs such as `ps` that may be invoked by other users to display command lines. MySQL clients typically overwrite the command-line password argument with zeros during their initialization sequence. However, there is still a brief interval during which the value is visible. Also, on some systems this overwriting strategy is ineffective and the password remains visible to `ps`. (SystemV Unix systems and perhaps others are subject to this problem.)

If your operating environment is set up to display your current command in the title bar of your terminal window, the password remains visible as long as the command is running, even if the command has scrolled out of view in the window content area.

- Use the `--password` or `-p` option on the command line with no password value specified. In this case, the client program solicits the password interactively:

```
$> mysql -u francis -p db_name
Enter password: *****
```

The `*` characters indicate where you enter your password. The password is not displayed as you enter it.

It is more secure to enter your password this way than to specify it on the command line because it is not visible to other users. However, this method of entering a password is suitable only for programs that you run interactively. If you want to invoke a client from a script that runs noninteractively, there is no opportunity to enter the password from the keyboard. On some systems, you may even find that the first line of your script is read and interpreted (incorrectly) as your password.

- Store your password in an option file. For example, on Unix, you can list your password in the `[client]` section of the `.my.cnf` file in your home directory:

```
[client]
password=password
```

To keep the password safe, the file should not be accessible to anyone but yourself. To ensure this, set the file access mode to `400` or `600`. For example:

```
$> chmod 600 .my.cnf
```

To name from the command line a specific option file containing the password, use the `--defaults-file=file_name` option, where `file_name` is the full path name to the file. For example:

```
$> mysql --defaults-file=/home/francis/mysql-opts
```

[Section 6.2.2.2, “Using Option Files”](#), discusses option files in more detail.

On Unix, the `mysql` client writes a record of executed statements to a history file (see [Section 6.5.1.3, “mysql Client Logging”](#)). By default, this file is named `.mysql_history` and is created in your home directory. Passwords can be written as plain text in SQL statements such as `CREATE USER` and `ALTER`

`USER`, so if you use these statements, they are logged in the history file. To keep this file safe, use a restrictive access mode, the same way as described earlier for the `.my.cnf` file.

If your command interpreter maintains a history, any file in which the commands are saved contains MySQL passwords entered on the command line. For example, `bash` uses `~/.bash_history`. Any such file should have a restrictive access mode.

### 8.1.2.2 Administrator Guidelines for Password Security

Database administrators should use the following guidelines to keep passwords secure.

MySQL stores passwords for user accounts in the `mysql.user` system table. Access to this table should never be granted to any nonadministrative accounts.

Account passwords can be expired so that users must reset them. See [Section 8.2.15, “Password Management”](#), and [Section 8.2.16, “Server Handling of Expired Passwords”](#).

The `validate_password` plugin can be used to enforce a policy on acceptable password. See [Section 8.4.3, “The Password Validation Component”](#).

A user who has access to modify the plugin directory (the value of the `plugin_dir` system variable) or the `my.cnf` file that specifies the plugin directory location can replace plugins and modify the capabilities provided by plugins, including authentication plugins.

Files such as log files to which passwords might be written should be protected. See [Section 8.1.2.3, “Passwords and Logging”](#).

### 8.1.2.3 Passwords and Logging

Passwords can be written as plain text in SQL statements such as `CREATE USER`, `GRANT` and `SET PASSWORD`. If such statements are logged by the MySQL server as written, passwords in them become visible to anyone with access to the logs.

Statement logging avoids writing passwords as cleartext for the following statements:

```
CREATE USER ... IDENTIFIED BY ...
ALTER USER ... IDENTIFIED BY ...
SET PASSWORD ...
START REPLICA ... PASSWORD = ...
CREATE SERVER ... OPTIONS(... PASSWORD ...)
ALTER SERVER ... OPTIONS(... PASSWORD ...)
```

Passwords in those statements are rewritten to not appear literally in statement text written to the general query log, slow query log, and binary log. Rewriting does not apply to other statements. In particular, `INSERT` or `UPDATE` statements for the `mysql.user` system table that refer to literal passwords are logged as is, so you should avoid such statements. (Direct modification of grant tables is discouraged, anyway.)

For the general query log, password rewriting can be suppressed by starting the server with the `--log-raw` option. For security reasons, this option is not recommended for production use. For diagnostic purposes, it may be useful to see the exact text of statements as received by the server.

By default, contents of audit log files produced by the audit log plugin are not encrypted and may contain sensitive information, such as the text of SQL statements. For security reasons, audit log files should be written to a directory accessible only to the MySQL server and to users with a legitimate reason to view the log. See [Section 8.4.5.3, “MySQL Enterprise Audit Security Considerations”](#).

Statements received by the server may be rewritten if a query rewrite plugin is installed (see [Query Rewrite Plugins](#)). In this case, the `--log-raw` option affects statement logging as follows:

- Without `--log-raw`, the server logs the statement returned by the query rewrite plugin. This may differ from the statement as received.
- With `--log-raw`, the server logs the original statement as received.

An implication of password rewriting is that statements that cannot be parsed (due, for example, to syntax errors) are not written to the general query log because they cannot be known to be password free. Use cases that require logging of all statements including those with errors should use the `--log-raw` option, bearing in mind that this also bypasses password rewriting.

Password rewriting occurs only when plain text passwords are expected. For statements with syntax that expect a password hash value, no rewriting occurs. If a plain text password is supplied erroneously for such syntax, the password is logged as given, without rewriting.

To guard log files against unwarranted exposure, locate them in a directory that restricts access to the server and the database administrator. If the server logs to tables in the `mysql` database, grant access to those tables only to the database administrator.

Replicas store the password for the replication source server in their connection metadata repository, which by default is a table in the `mysql` database named `slave_master_info`. The use of a file in the data directory for the connection metadata repository is now deprecated, but still possible (see [Section 19.2.4, “Relay Log and Replication Metadata Repositories”](#)). Ensure that the connection metadata repository can be accessed only by the database administrator. An alternative to storing the password in the connection metadata repository is to use the `START REPLICA` or `START GROUP_REPLICATION` statement to specify credentials for connecting to the source.

Use a restricted access mode to protect database backups that include log tables or log files containing passwords.

### 8.1.3 Making MySQL Secure Against Attackers

When you connect to a MySQL server, you should use a password. The password is not transmitted as cleartext over the connection.

All other information is transferred as text, and can be read by anyone who is able to watch the connection. If the connection between the client and the server goes through an untrusted network, and you are concerned about this, you can use the compressed protocol to make traffic much more difficult to decipher. You can also use MySQL's internal SSL support to make the connection even more secure. See [Section 8.3, “Using Encrypted Connections”](#). Alternatively, use SSH to get an encrypted TCP/IP connection between a MySQL server and a MySQL client. You can find an Open Source SSH client at <http://www.openssh.org/>, and a comparison of both Open Source and Commercial SSH clients at [http://en.wikipedia.org/wiki/Comparison\\_of\\_SSH\\_clients](http://en.wikipedia.org/wiki/Comparison_of_SSH_clients).

To make a MySQL system secure, you should strongly consider the following suggestions:

- Require all MySQL accounts to have a password. A client program does not necessarily know the identity of the person running it. It is common for client/server applications that the user can specify any user name to the client program. For example, anyone can use the `mysql` program to connect as any other person simply by invoking it as `mysql -u other_user db_name` if `other_user` has no password. If all accounts have a password, connecting using another user's account becomes much more difficult.

For a discussion of methods for setting passwords, see [Section 8.2.14, “Assigning Account Passwords”](#).

- Make sure that the only Unix user account with read or write privileges in the database directories is the account that is used for running `mysqld`.

- Never run the MySQL server as the Unix `root` user. This is extremely dangerous, because any user with the `FILE` privilege is able to cause the server to create files as `root` (for example, `~root/.bashrc`). To prevent this, `mysqld` refuses to run as `root` unless that is specified explicitly using the `--user=root` option.

`mysqld` can (and should) be run as an ordinary, unprivileged user instead. You can create a separate Unix account named `mysql` to make everything even more secure. Use this account only for administering MySQL. To start `mysqld` as a different Unix user, add a `user` option that specifies the user name in the `[mysqld]` group of the `my.cnf` option file where you specify server options. For example:

```
[mysqld]
user=mysql
```

This causes the server to start as the designated user whether you start it manually or by using `mysqld_safe` or `mysql.server`. For more details, see [Section 8.1.5, “How to Run MySQL as a Normal User”](#).

Running `mysqld` as a Unix user other than `root` does not mean that you need to change the `root` user name in the `user` table. *User names for MySQL accounts have nothing to do with user names for Unix accounts.*

- Do not grant the `FILE` privilege to nonadministrative users. Any user that has this privilege can write a file anywhere in the file system with the privileges of the `mysqld` daemon. This includes the server's data directory containing the files that implement the privilege tables. To make `FILE`-privilege operations a bit safer, files generated with `SELECT ... INTO OUTFILE` do not overwrite existing files and are writable by everyone.

The `FILE` privilege may also be used to read any file that is world-readable or accessible to the Unix user that the server runs as. With this privilege, you can read any file into a database table. This could be abused, for example, by using `LOAD DATA` to load `/etc/passwd` into a table, which then can be displayed with `SELECT`.

To limit the location in which files can be read and written, set the `secure_file_priv` system to a specific directory. See [Section 7.1.8, “Server System Variables”](#).

- Encrypt binary log files and relay log files. Encryption helps to protect these files and the potentially sensitive data contained in them from being misused by outside attackers, and also from unauthorized viewing by users of the operating system where they are stored. You enable encryption on a MySQL server by setting the `binlog_encryption` system variable to `ON`. For more information, see [Section 19.3.2, “Encrypting Binary Log Files and Relay Log Files”](#).
- Do not grant the `PROCESS` or `SUPER` privilege to nonadministrative users. The output of `mysqladmin processlist` and `SHOW PROCESSLIST` shows the text of any statements currently being executed, so any user who is permitted to see the server process list might be able to see statements issued by other users.

`mysqld` reserves an extra connection for users who have the `CONNECTION_ADMIN` or `SUPER` privilege, so that a MySQL `root` user can log in and check server activity even if all normal connections are in use.

The `SUPER` privilege can be used to terminate client connections, change server operation by changing the value of system variables, and control replication servers.

- Do not permit the use of symlinks to tables. (This capability can be disabled with the `--skip-symbolic-links` option.) This is especially important if you run `mysqld` as `root`, because anyone

that has write access to the server's data directory then could delete any file in the system! See [Section 10.12.2.2, “Using Symbolic Links for MyISAM Tables on Unix”](#).

- Stored programs and views should be written using the security guidelines discussed in [Section 27.7, “Stored Object Access Control”](#).
- If you do not trust your DNS, you should use IP addresses rather than host names in the grant tables. In any case, you should be very careful about creating grant table entries using host name values that contain wildcards.
- If you want to restrict the number of connections permitted to a single account, you can do so by setting the `max_user_connections` variable in `mysqld`. The `CREATE USER` and `ALTER USER` statements also support resource control options for limiting the extent of server use permitted to an account. See [Section 15.7.1.3, “CREATE USER Statement”](#), and [Section 15.7.1.1, “ALTER USER Statement”](#).
- If the plugin directory is writable by the server, it may be possible for a user to write executable code to a file in the directory using `SELECT ... INTO DUMPFILE`. This can be prevented by making `plugin_dir` read only to the server or by setting `secure_file_priv` to a directory where `SELECT` writes can be made safely.

## 8.1.4 Security-Related `mysqld` Options and Variables

The following table shows `mysqld` options and system variables that affect security. For descriptions of each of these, see [Section 7.1.7, “Server Command Options”](#), and [Section 7.1.8, “Server System Variables”](#).

**Table 8.1 Security Option and Variable Summary**

Name	Cmd-Line	Option File	System Var	Status Var	Var Scope	Dynamic
<a href="#">allow-suspicious-udfs</a>	Yes	Yes				
<a href="#">automatic_sp_privileges</a>	Yes	Yes	Yes		Global	Yes
<a href="#">chroot</a>	Yes	Yes				
<a href="#">local_infile</a>	Yes	Yes	Yes		Global	Yes
<a href="#">safe-user-create</a>	Yes	Yes				
<a href="#">secure_file_priv</a>	Yes	Yes	Yes		Global	No
<a href="#">skip-grant-tables</a>	Yes	Yes				
<a href="#">skip_name_resolve</a>	Yes	Yes	Yes		Global	No
<a href="#">skip_networking</a>	Yes	Yes	Yes		Global	No
<a href="#">skip_show_database</a>	Yes	Yes	Yes		Global	No

## 8.1.5 How to Run MySQL as a Normal User

On Windows, you can run the server as a Windows service using a normal user account.

On Linux, for installations performed using a MySQL repository or RPM packages, the MySQL server `mysqld` should be started by the local `mysql` operating system user. Starting by another operating system user is not supported by the init scripts that are included as part of the MySQL repositories.

On Unix (or Linux for installations performed using `tar.gz` packages) , the MySQL server `mysqld` can be started and run by any user. However, you should avoid running the server as the Unix `root` user for security reasons. To change `mysqld` to run as a normal unprivileged Unix user `user_name`, you must do the following:

1. Stop the server if it is running (use `mysqladmin shutdown`).
2. Change the database directories and files so that `user_name` has privileges to read and write files in them (you might need to do this as the Unix `root` user):

```
$> chown -R user_name /path/to/mysql/datadir
```

If you do not do this, the server cannot access databases or tables when it runs as `user_name`.

If directories or files within the MySQL data directory are symbolic links, `chown -R` might not follow symbolic links for you. If it does not, you must also follow those links and change the directories and files they point to.

3. Start the server as user `user_name`. Another alternative is to start `mysqld` as the Unix `root` user and use the `--user=user_name` option. `mysqld` starts, then switches to run as the Unix user `user_name` before accepting any connections.
4. To start the server as the given user automatically at system startup time, specify the user name by adding a `user` option to the `[mysqld]` group of the `/etc/my.cnf` option file or the `my.cnf` option file in the server's data directory. For example:

```
[mysqld]
user=user_name
```

If your Unix machine itself is not secured, you should assign passwords to the MySQL `root` account in the grant tables. Otherwise, any user with a login account on that machine can run the `mysql` client with a `--user=root` option and perform any operation. (It is a good idea to assign passwords to MySQL accounts in any case, but especially so when other login accounts exist on the server host.) See [Section 2.9.4](#), “Securing the Initial MySQL Account”.

## 8.1.6 Security Considerations for LOAD DATA LOCAL

The `LOAD DATA` statement loads a data file into a table. The statement can load a file located on the server host, or, if the `LOCAL` keyword is specified, on the client host.

The `LOCAL` version of `LOAD DATA` has two potential security issues:

- Because `LOAD DATA LOCAL` is an SQL statement, parsing occurs on the server side, and transfer of the file from the client host to the server host is initiated by the MySQL server, which tells the client the file named in the statement. In theory, a patched server could tell the client program to transfer a file of the server's choosing rather than the file named in the statement. Such a server could access any file on the client host to which the client user has read access. (A patched server could in fact reply with a file-transfer request to any statement, not just `LOAD DATA LOCAL`, so a more fundamental issue is that clients should not connect to untrusted servers.)
- In a Web environment where the clients are connecting from a Web server, a user could use `LOAD DATA LOCAL` to read any files that the Web server process has read access to (assuming that a user could run any statement against the SQL server). In this environment, the client with respect to the MySQL server actually is the Web server, not a remote program being run by users who connect to the Web server.

To avoid connecting to untrusted servers, clients can establish a secure connection and verify the server identity by connecting using the `--ssl-mode=VERIFY_IDENTITY` option and the appropriate CA

certificate. To implement this level of verification, you must first ensure that the CA certificate for the server is reliably available to the replica, otherwise availability issues will result. For more information, see [Command Options for Encrypted Connections](#).

To avoid `LOAD DATA` issues, clients should avoid using `LOCAL` unless proper client-side precautions have been taken.

For control over local data loading, MySQL permits the capability to be enabled or disabled. MySQL also enables clients to restrict local data loading operations to files located in a designated directory.

- [Enabling or Disabling Local Data Loading Capability](#)
- [Restricting Files Permitted for Local Data Loading](#)
- [MySQL Shell and Local Data Loading](#)

## Enabling or Disabling Local Data Loading Capability

Administrators and applications can configure whether to permit local data loading as follows:

- On the server side:
  - The `local_infile` system variable controls server-side `LOCAL` capability. Depending on the `local_infile` setting, the server refuses or permits local data loading by clients that request local data loading.
  - By default, `local_infile` is disabled. (This is a change from previous versions of MySQL.) To cause the server to refuse or permit `LOAD DATA LOCAL` statements explicitly (regardless of how client programs and libraries are configured at build time or runtime), start `mysqld` with `local_infile` disabled or enabled. `local_infile` can also be set at runtime.
- On the client side:
  - The `ENABLED_LOCAL_INFILE` CMake option controls the compiled-in default `LOCAL` capability for the MySQL client library (see [Section 2.8.7, “MySQL Source-Configuration Options”](#)). Clients that make no explicit arrangements therefore have `LOCAL` capability disabled or enabled according to the `ENABLED_LOCAL_INFILE` setting specified at MySQL build time.
  - By default, the client library in MySQL binary distributions is compiled with `ENABLED_LOCAL_INFILE` disabled. If you compile MySQL from source, configure it with `ENABLED_LOCAL_INFILE` disabled or enabled based on whether clients that make no explicit arrangements should have `LOCAL` capability disabled or enabled.
  - For client programs that use the C API, local data loading capability is determined by the default compiled into the MySQL client library. To enable or disable it explicitly, invoke the `mysql_options()` C API function to disable or enable the `MYSQL_OPT_LOCAL_INFILE` option. See [mysql\\_options\(\)](#).
  - For the `mysql` client, local data loading capability is determined by the default compiled into the MySQL client library. To disable or enable it explicitly, use the `--local-infile=0` or `--local-infile[=1]` option.
  - For the `mysqlimport` client, local data loading is not used by default. To disable or enable it explicitly, use the `--local=0` or `--local[=1]` option.
  - If you use `LOAD DATA LOCAL` in Perl scripts or other programs that read the `[client]` group from option files, you can add a `local-infile` option setting to that group. To prevent problems for programs that do not understand this option, specify it using the `loose-` prefix:

```
[client]
loose-local-infile=0
```

or:

```
[client]
loose-local-infile=1
```

- In all cases, successful use of a [LOCAL](#) load operation by a client also requires that the server permits local loading.

If [LOCAL](#) capability is disabled, on either the server or client side, a client that attempts to issue a [LOAD DATA LOCAL](#) statement receives the following error message:

```
ERROR 3950 (42000): Loading local data is disabled; this must be
enabled on both the client and server side
```

## Restricting Files Permitted for Local Data Loading

The MySQL client library enables client applications to restrict local data loading operations to files located in a designated directory. Certain MySQL client programs take advantage of this capability.

Client programs that use the C API can control which files to permit for load data loading using the [MYSQL\\_OPT\\_LOCAL\\_INFILE](#) and [MYSQL\\_OPT\\_LOAD\\_DATA\\_LOCAL\\_DIR](#) options of the [mysql\\_options\(\)](#) C API function (see [mysql\\_options\(\)](#)).

The effect of [MYSQL\\_OPT\\_LOAD\\_DATA\\_LOCAL\\_DIR](#) depends on whether [LOCAL](#) data loading is enabled or disabled:

- If [LOCAL](#) data loading is enabled, either by default in the MySQL client library or by explicitly enabling [MYSQL\\_OPT\\_LOCAL\\_INFILE](#), the [MYSQL\\_OPT\\_LOAD\\_DATA\\_LOCAL\\_DIR](#) option has no effect.
- If [LOCAL](#) data loading is disabled, either by default in the MySQL client library or by explicitly disabling [MYSQL\\_OPT\\_LOCAL\\_INFILE](#), the [MYSQL\\_OPT\\_LOAD\\_DATA\\_LOCAL\\_DIR](#) option can be used to designate a permitted directory for locally loaded files. In this case, [LOCAL](#) data loading is permitted but restricted to files located in the designated directory. Interpretation of the [MYSQL\\_OPT\\_LOAD\\_DATA\\_LOCAL\\_DIR](#) value is as follows:
  - If the value is the null pointer (the default), it names no directory, with the result that no files are permitted for [LOCAL](#) data loading.
  - If the value is a directory path name, [LOCAL](#) data loading is permitted but restricted to files located in the named directory. Comparison of the directory path name and the path name of files to be loaded is case-sensitive regardless of the case sensitivity of the underlying file system.

MySQL client programs use the preceding [mysql\\_options\(\)](#) options as follows:

- The [mysql](#) client has a [--load-data-local-dir](#) option that takes a directory path or an empty string. [mysql](#) uses the option value to set the [MYSQL\\_OPT\\_LOAD\\_DATA\\_LOCAL\\_DIR](#) option (with an empty string setting the value to the null pointer). The effect of [--load-data-local-dir](#) depends on whether [LOCAL](#) data loading is enabled:
  - If [LOCAL](#) data loading is enabled, either by default in the MySQL client library or by specifying [--local-infile\[=1\]](#), the [--load-data-local-dir](#) option is ignored.
  - If [LOCAL](#) data loading is disabled, either by default in the MySQL client library or by specifying [--local-infile=0](#), the [--load-data-local-dir](#) option applies.

When `--load-data-local-dir` applies, the option value designates the directory in which local data files must be located. Comparison of the directory path name and the path name of files to be loaded is case-sensitive regardless of the case sensitivity of the underlying file system. If the option value is the empty string, it names no directory, with the result that no files are permitted for local data loading.

- `mysqlimport` sets `MYSQL_OPT_LOAD_DATA_LOCAL_DIR` for each file that it processes so that the directory containing the file is the permitted local loading directory.
- For data loading operations corresponding to `LOAD DATA` statements, `mysqlbinlog` extracts the files from the binary log events, writes them as temporary files to the local file system, and writes `LOAD DATA LOCAL` statements to cause the files to be loaded. By default, `mysqlbinlog` writes these temporary files to an operating system-specific directory. The `--local-load` option can be used to explicitly specify the directory where `mysqlbinlog` should prepare local temporary files.

Because other processes can write files to the default system-specific directory, it is advisable to specify the `--local-load` option to `mysqlbinlog` to designate a different directory for data files, and then designate that same directory by specifying the `--load-data-local-dir` option to `mysql` when processing the output from `mysqlbinlog`.

## MySQL Shell and Local Data Loading

MySQL Shell provides a number of utilities to dump tables, schemas, or server instances and load them into other instances. When you use these utilities to handle the data, MySQL Shell provides additional functions such as input preprocessing, multithreaded parallel loading, file compression and decompression, and handling access to Oracle Cloud Infrastructure Object Storage buckets. To get the best functionality, always use the most recent version available of MySQL Shell's dump and dump loading utilities.

MySQL Shell's data upload utilities use `LOAD DATA LOCAL INFILE` statements to upload data, so the `local_infile` system variable must be set to `ON` on the target server instance. You can do this before uploading the data, and remove it again afterwards. The utilities handle the file transfer requests safely to deal with the security considerations discussed in this topic.

MySQL Shell includes these dump and dump loading utilities:

Table export utility <code>util.exportTable()</code>	Exports a MySQL relational table into a data file, which can be uploaded to a MySQL server instance using MySQL Shell's parallel table import utility, imported to a different application, or used as a logical backup. The utility has preset options and customization options to produce different output formats.
Parallel table import utility <code>util.importTable()</code>	Imports a data file to a MySQL relational table. The data file can be the output from MySQL Shell's table export utility or another format supported by the utility's preset and customization options. The utility can carry out input preprocessing before adding the data to the table. It can accept multiple data files to merge into a single relational table, and automatically decompresses compressed files.
Instance dump utility <code>util.dumpInstance()</code> , schema dump utility <code>util.dumpSchemas()</code> , and table dump utility <code>util.dumpTables()</code>	Export an instance, schema, or table to a set of dump files, which can then be uploaded to a MySQL instance using MySQL Shell's dump loading utility. The utilities provide Oracle Cloud Infrastructure Object Storage streaming, HeatWave Service compatibility checks and modifications, and the ability to carry out a dry run to identify issues before proceeding with the dump.

Dump loading utility  
`util.loadDump()`

Import dump files created using MySQL Shell's instance, schema, or table dump utility into a HeatWave Service DB System or a MySQL Server instance. The utility manages the upload process and provides data streaming from remote storage, parallel loading of tables or table chunks, progress state tracking, resume and reset capability, and the option of concurrent loading while the dump is still taking place. MySQL Shell's parallel table import utility can be used in combination with the dump loading utility to modify data before uploading it to the target MySQL instance.

For details of the utilities, see [MySQL Shell Utilities](#).

## 8.1.7 Client Programming Security Guidelines

Client applications that access MySQL should use the following guidelines to avoid interpreting external data incorrectly or exposing sensitive information.

- [Handle External Data Properly](#)
- [Handle MySQL Error Messages Properly](#)

### Handle External Data Properly

Applications that access MySQL should not trust any data entered by users, who can try to trick your code by entering special or escaped character sequences in Web forms, URLs, or whatever application you have built. Be sure that your application remains secure if a user tries to perform SQL injection by entering something like  `; DROP DATABASE mysql ;` into a form. This is an extreme example, but large security leaks and data loss might occur as a result of hackers using similar techniques, if you do not prepare for them.

A common mistake is to protect only string data values. Remember to check numeric data as well. If an application generates a query such as `SELECT * FROM table WHERE ID=234` when a user enters the value `234`, the user can enter the value `234 OR 1=1` to cause the application to generate the query `SELECT * FROM table WHERE ID=234 OR 1=1`. As a result, the server retrieves every row in the table. This exposes every row and causes excessive server load. The simplest way to protect from this type of attack is to use single quotation marks around the numeric constants: `SELECT * FROM table WHERE ID='234'`. If the user enters extra information, it all becomes part of the string. In a numeric context, MySQL automatically converts this string to a number and strips any trailing nonnumeric characters from it.

Sometimes people think that if a database contains only publicly available data, it need not be protected. This is incorrect. Even if it is permissible to display any row in the database, you should still protect against denial of service attacks (for example, those that are based on the technique in the preceding paragraph that causes the server to waste resources). Otherwise, your server becomes unresponsive to legitimate users.

Checklist:

- Enable strict SQL mode to tell the server to be more restrictive of what data values it accepts. See [Section 7.1.11, “Server SQL Modes”](#).
- Try to enter single and double quotation marks ( `'` and `"` ) in all of your Web forms. If you get any kind of MySQL error, investigate the problem right away.
- Try to modify dynamic URLs by adding `%22` ( `"` ), `%23` ( `#` ), and `%27` ( `'` ) to them.

- Try to modify data types in dynamic URLs from numeric to character types using the characters shown in the previous examples. Your application should be safe against these and similar attacks.
- Try to enter characters, spaces, and special symbols rather than numbers in numeric fields. Your application should remove them before passing them to MySQL or else generate an error. Passing unchecked values to MySQL is very dangerous!
- Check the size of data before passing it to MySQL.
- Have your application connect to the database using a user name different from the one you use for administrative purposes. Do not give your applications any access privileges they do not need.

Many application programming interfaces provide a means of escaping special characters in data values. Properly used, this prevents application users from entering values that cause the application to generate statements that have a different effect than you intend:

- MySQL SQL statements: Use SQL prepared statements and accept data values only by means of placeholders; see [Section 15.5, “Prepared Statements”](#).
- MySQL C API: Use the `mysql_real_escape_string_quote()` API call. Alternatively, use the C API prepared statement interface and accept data values only by means of placeholders; see [C API Prepared Statement Interface](#).
- MySQL++: Use the `escape` and `quote` modifiers for query streams.
- PHP: Use either the `mysqli` or `pdo_mysql` extensions, and not the older `ext/mysql` extension. The preferred API's support the improved MySQL authentication protocol and passwords, as well as prepared statements with placeholders. See also [MySQL and PHP](#).

If the older `ext/mysql` extension must be used, then for escaping use the `mysql_real_escape_string_quote()` function and not `mysql_escape_string()` or `addslashes()` because only `mysql_real_escape_string_quote()` is character set-aware; the other functions can be “bypassed” when using (invalid) multibyte character sets.

- Perl DBI: Use placeholders or the `quote()` method.
- Java JDBC: Use a `PreparedStatement` object and placeholders.

Other programming interfaces might have similar capabilities.

## Handle MySQL Error Messages Properly

It is the application's responsibility to intercept errors that occur as a result of executing SQL statements with the MySQL database server and handle them appropriately.

The information returned in a MySQL error is not gratuitous because that information is key in debugging MySQL using applications. It would be nearly impossible, for example, to debug a common 10-way join `SELECT` statement without providing information regarding which databases, tables, and other objects are involved with problems. Thus, MySQL errors must sometimes necessarily contain references to the names of those objects.

A simple but insecure approach for an application when it receives such an error from MySQL is to intercept it and display it verbatim to the client. However, revealing error information is a known application vulnerability type ([CWE-209](#)) and the application developer must ensure the application does not have this vulnerability.

For example, an application that displays a message such as this exposes both a database name and a table name to clients, which is information a client might attempt to exploit:

```
ERROR 1146 (42S02): Table 'mydb.mytable' doesn't exist
```

Instead, the proper behavior for an application when it receives such an error from MySQL is to log appropriate information, including the error information, to a secure audit location only accessible to trusted personnel. The application can return something more generic such as “Internal Error” to the user.

## 8.2 Access Control and Account Management

MySQL enables the creation of accounts that permit client users to connect to the server and access data managed by the server. The primary function of the MySQL privilege system is to authenticate a user who connects from a given host and to associate that user with privileges on a database such as [SELECT](#), [INSERT](#), [UPDATE](#), and [DELETE](#). Additional functionality includes the ability to grant privileges for administrative operations.

To control which users can connect, each account can be assigned authentication credentials such as a password. The user interface to MySQL accounts consists of SQL statements such as [CREATE USER](#), [GRANT](#), and [REVOKE](#). See [Section 15.7.1, “Account Management Statements”](#).

The MySQL privilege system ensures that all users may perform only the operations permitted to them. As a user, when you connect to a MySQL server, your identity is determined by *the host from which you connect* and *the user name you specify*. When you issue requests after connecting, the system grants privileges according to your identity and *what you want to do*.

MySQL considers both your host name and user name in identifying you because there is no reason to assume that a given user name belongs to the same person on all hosts. For example, the user [joe](#) who connects from [office.example.com](#) need not be the same person as the user [joe](#) who connects from [home.example.com](#). MySQL handles this by enabling you to distinguish users on different hosts that happen to have the same name: You can grant one set of privileges for connections by [joe](#) from [office.example.com](#), and a different set of privileges for connections by [joe](#) from [home.example.com](#). To see what privileges a given account has, use the [SHOW GRANTS](#) statement. For example:

```
SHOW GRANTS FOR 'joe'@'office.example.com';
SHOW GRANTS FOR 'joe'@'home.example.com';
```

Internally, the server stores privilege information in the grant tables of the [mysql](#) system database. The MySQL server reads the contents of these tables into memory when it starts and bases access-control decisions on the in-memory copies of the grant tables.

MySQL access control involves two stages when you run a client program that connects to the server:

**Stage 1:** The server accepts or rejects the connection based on your identity and whether you can verify your identity by supplying the correct password.

**Stage 2:** Assuming that you can connect, the server checks each statement you issue to determine whether you have sufficient privileges to perform it. For example, if you try to select rows from a table in a database or drop a table from the database, the server verifies that you have the [SELECT](#) privilege for the table or the [DROP](#) privilege for the database.

For a more detailed description of what happens during each stage, see [Section 8.2.6, “Access Control, Stage 1: Connection Verification”](#), and [Section 8.2.7, “Access Control, Stage 2: Request Verification”](#). For help in diagnosing privilege-related problems, see [Section 8.2.22, “Troubleshooting Problems Connecting to MySQL”](#).

If your privileges are changed (either by yourself or someone else) while you are connected, those changes do not necessarily take effect immediately for the next statement that you issue. For details about the conditions under which the server reloads the grant tables, see [Section 8.2.13, “When Privilege Changes Take Effect”](#).

There are some things that you cannot do with the MySQL privilege system:

- You cannot explicitly specify that a given user should be denied access. That is, you cannot explicitly match a user and then refuse the connection.
- You cannot specify that a user has privileges to create or drop tables in a database but not to create or drop the database itself.
- A password applies globally to an account. You cannot associate a password with a specific object such as a database, table, or routine.

## 8.2.1 Account User Names and Passwords

MySQL stores accounts in the `user` table of the `mysql` system database. An account is defined in terms of a user name and the client host or hosts from which the user can connect to the server. For information about account representation in the `user` table, see [Section 8.2.3, “Grant Tables”](#).

An account may also have authentication credentials such as a password. The credentials are handled by the account authentication plugin. MySQL supports multiple authentication plugins. Some of them use built-in authentication methods, whereas others enable authentication using external authentication methods. See [Section 8.2.17, “Pluggable Authentication”](#).

There are several distinctions between the way user names and passwords are used by MySQL and your operating system:

- User names, as used by MySQL for authentication purposes, have nothing to do with user names (login names) as used by Windows or Unix. On Unix, most MySQL clients by default try to log in using the current Unix user name as the MySQL user name, but that is for convenience only. The default can be overridden easily, because client programs permit any user name to be specified with a `-u` or `--user` option. This means that anyone can attempt to connect to the server using any user name, so you cannot make a database secure in any way unless all MySQL accounts have passwords. Anyone who specifies a user name for an account that has no password can connect successfully to the server.
- MySQL user names are up to 32 characters long. Operating system user names may have a different maximum length.

### Warning

The MySQL user name length limit is hardcoded in MySQL servers and clients, and trying to circumvent it by modifying the definitions of the tables in the `mysql` database *does not work*.

You should never alter the structure of tables in the `mysql` database in any manner whatsoever except by means of the procedure that is described in [Chapter 3, Upgrading MySQL](#). Attempting to redefine the MySQL system tables in any other fashion results in undefined and unsupported behavior. The server is free to ignore rows that become malformed as a result of such modifications.

- To authenticate client connections for accounts that use built-in authentication methods, the server uses passwords stored in the `user` table. These passwords are distinct from passwords for logging in to your operating system. There is no necessary connection between the “external” password you use to log in to a Windows or Unix machine and the password you use to access the MySQL server on that machine.

If the server authenticates a client using some other plugin, the authentication method that the plugin implements may or may not use a password stored in the `user` table. In this case, it is possible that an external password is also used to authenticate to the MySQL server.

- Passwords stored in the `user` table are encrypted using plugin-specific algorithms.
- If the user name and password contain only ASCII characters, it is possible to connect to the server regardless of character set settings. To enable connections when the user name or password contain non-ASCII characters, client applications should call the `mysql_options()` C API function with the `MYSQL_SET_CHARSET_NAME` option and appropriate character set name as arguments. This causes authentication to take place using the specified character set. Otherwise, authentication fails unless the server default character set is the same as the encoding in the authentication defaults.

Standard MySQL client programs support a `--default-character-set` option that causes `mysql_options()` to be called as just described. In addition, character set autodetection is supported as described in [Section 12.4, “Connection Character Sets and Collations”](#). For programs that use a connector that is not based on the C API, the connector may provide an equivalent to `mysql_options()` that can be used instead. Check the connector documentation.

The preceding notes do not apply for `ucs2`, `utf16`, and `utf32`, which are not permitted as client character sets.

The MySQL installation process populates the grant tables with an initial `root` account, as described in [Section 2.9.4, “Securing the Initial MySQL Account”](#), which also discusses how to assign a password to it. Thereafter, you normally set up, modify, and remove MySQL accounts using statements such as `CREATE USER`, `DROP USER`, `GRANT`, and `REVOKE`. See [Section 8.2.8, “Adding Accounts, Assigning Privileges, and Dropping Accounts”](#), and [Section 15.7.1, “Account Management Statements”](#).

To connect to a MySQL server with a command-line client, specify user name and password options as necessary for the account that you want to use:

```
$> mysql --user=finley --password db_name
```

If you prefer short options, the command looks like this:

```
$> mysql -u finley -p db_name
```

If you omit the password value following the `--password` or `-p` option on the command line (as just shown), the client prompts for one. Alternatively, the password can be specified on the command line:

```
$> mysql --user=finley --password=password db_name
$> mysql -u finley -ppassword db_name
```

If you use the `-p` option, there must be *no space* between `-p` and the following password value.

Specifying a password on the command line should be considered insecure. See [Section 8.1.2.1, “End-User Guidelines for Password Security”](#). To avoid giving the password on the command line, use an option file or a login path file. See [Section 6.2.2.2, “Using Option Files”](#), and [Section 6.6.7, “mysql\\_config\\_editor — MySQL Configuration Utility”](#).

For additional information about specifying user names, passwords, and other connection parameters, see [Section 6.2.4, “Connecting to the MySQL Server Using Command Options”](#).

## 8.2.2 Privileges Provided by MySQL

The privileges granted to a MySQL account determine which operations the account can perform. MySQL privileges differ in the contexts in which they apply and at different levels of operation:

- Administrative privileges enable users to manage operation of the MySQL server. These privileges are global because they are not specific to a particular database.
- Database privileges apply to a database and to all objects within it. These privileges can be granted for specific databases, or globally so that they apply to all databases.

- Privileges for database objects such as tables, indexes, views, and stored routines can be granted for specific objects within a database, for all objects of a given type within a database (for example, all tables in a database), or globally for all objects of a given type in all databases.

Privileges also differ in terms of whether they are static (built in to the server) or dynamic (defined at runtime). Whether a privilege is static or dynamic affects its availability to be granted to user accounts and roles. For information about the differences between static and dynamic privileges, see [Static Versus Dynamic Privileges](#).)

Information about account privileges is stored in the grant tables in the `mysql` system database. For a description of the structure and contents of these tables, see [Section 8.2.3, “Grant Tables”](#). The MySQL server reads the contents of the grant tables into memory when it starts, and reloads them under the circumstances indicated in [Section 8.2.13, “When Privilege Changes Take Effect”](#). The server bases access-control decisions on the in-memory copies of the grant tables.

### Important

Some MySQL releases introduce changes to the grant tables to add new privileges or features. To make sure that you can take advantage of any new capabilities, update your grant tables to the current structure whenever you upgrade MySQL. See [Chapter 3, Upgrading MySQL](#).

The following sections summarize the available privileges, provide more detailed descriptions of each privilege, and offer usage guidelines.

- [Summary of Available Privileges](#)
- [Static Privilege Descriptions](#)
- [Dynamic Privilege Descriptions](#)
- [Privilege-Granting Guidelines](#)
- [Static Versus Dynamic Privileges](#)
- [Migrating Accounts from SUPER to Dynamic Privileges](#)

## Summary of Available Privileges

The following table shows the static privilege names used in `GRANT` and `REVOKE` statements, along with the column name associated with each privilege in the grant tables and the context in which the privilege applies.

**Table 8.2 Permissible Static Privileges for GRANT and REVOKE**

Privilege	Grant Table Column	Context
<code>ALL [PRIVILEGES]</code>	Synonym for “all privileges”	Server administration
<code>ALTER</code>	<code>Alter_priv</code>	Tables
<code>ALTER ROUTINE</code>	<code>Alter_routine_priv</code>	Stored routines
<code>CREATE</code>	<code>Create_priv</code>	Databases, tables, or indexes
<code>CREATE ROLE</code>	<code>Create_role_priv</code>	Server administration
<code>CREATE ROUTINE</code>	<code>Create_routine_priv</code>	Stored routines
<code>CREATE TABLESPACE</code>	<code>Create_tablespace_priv</code>	Server administration
<code>CREATE TEMPORARY TABLES</code>	<code>Create_tmp_table_priv</code>	Tables
<code>CREATE USER</code>	<code>Create_user_priv</code>	Server administration

Privilege	Grant Table Column	Context
CREATE VIEW	Create_view_priv	Views
DELETE	Delete_priv	Tables
DROP	Drop_priv	Databases, tables, or views
DROP ROLE	Drop_role_priv	Server administration
EVENT	Event_priv	Databases
EXECUTE	Execute_priv	Stored routines
FILE	File_priv	File access on server host
GRANT OPTION	Grant_priv	Databases, tables, or stored routines
INDEX	Index_priv	Tables
INSERT	Insert_priv	Tables or columns
LOCK TABLES	Lock_tables_priv	Databases
PROCESS	Process_priv	Server administration
PROXY	See proxies_priv table	Server administration
REFERENCES	References_priv	Databases or tables
RELOAD	Reload_priv	Server administration
REPLICATION CLIENT	Repl_client_priv	Server administration
REPLICATION SLAVE	Repl_slave_priv	Server administration
SELECT	Select_priv	Tables or columns
SHOW DATABASES	Show_db_priv	Server administration
SHOW VIEW	Show_view_priv	Views
SHUTDOWN	Shutdown_priv	Server administration
SUPER	Super_priv	Server administration
TRIGGER	Trigger_priv	Tables
UPDATE	Update_priv	Tables or columns
USAGE	Synonym for “no privileges”	Server administration

The following table shows the dynamic privilege names used in [GRANT](#) and [REVOKE](#) statements, along with the context in which the privilege applies.

**Table 8.3 Permissible Dynamic Privileges for GRANT and REVOKE**

Privilege	Context
ALLOW_NONEXISTENT_DEFINER	Orphan object protection
APPLICATION_PASSWORD_ADMIN	Dual password administration
AUDIT_ABORT_EXEMPT	Allow queries blocked by audit log filter
AUDIT_ADMIN	Audit log administration
AUTHENTICATION_POLICY_ADMIN	Authentication administration
BACKUP_ADMIN	Backup administration
BINLOG_ADMIN	Backup and Replication administration
BINLOG_ENCRYPTION_ADMIN	Backup and Replication administration

Privilege	Context
CLONE_ADMIN	Clone administration
CONNECTION_ADMIN	Server administration
ENCRYPTION_KEY_ADMIN	Server administration
EXPORT_QUERY_RESULTS	Allow user to export query results
FIREWALL_ADMIN	Firewall administration
FIREWALL_EXEMPT	Firewall administration
FIREWALL_USER	Firewall administration
FLUSH_OPTIMIZER_COSTS	Server administration
FLUSH_PRIVILEGES	Server administration
FLUSH_STATUS	Server administration
FLUSH_TABLES	Server administration
FLUSH_USER_RESOURCES	Server administration
GROUP_REPLICATION_ADMIN	Replication administration
GROUP_REPLICATION_STREAM	Replication administration
INNODB_REDO_LOG_ARCHIVE	Redo log archiving administration
INNODB_REDO_LOG_ENABLE	Redo log administration
MASKING_DICTIONARIES_ADMIN	Server administration
NDB_STORED_USER	NDB Cluster
OPTIMIZE_LOCAL_TABLE	OPTIMIZE LOCAL TABLE statements
OPTION_TRACKER_UPDATER	Option Tracker <code>mysql_option.option_usage</code> table write access
PASSWORDLESS_USER_ADMIN	Authentication administration
PERSIST_RO_VARIABLES_ADMIN	Server administration
REPLICATION_APPLIER	PRIVILEGE_CHECKS_USER for a replication channel
REPLICATION_SLAVE_ADMIN	Replication administration
RESOURCE_GROUP_ADMIN	Resource group administration
RESOURCE_GROUP_USER	Resource group administration
ROLE_ADMIN	Server administration
SENSITIVE_VARIABLES_OBSERVER	Server administration
SESSION_VARIABLES_ADMIN	Server administration
SET_ANY_DEFINER	Server administration
SHOW_ROUTINE	Server administration
SKIP_QUERY_REWRITE	Server administration
SYSTEM_USER	Server administration
SYSTEM_VARIABLES_ADMIN	Server administration
TABLE_ENCRYPTION_ADMIN	Server administration
TELEMETRY_LOG_ADMIN	Telemetry log administration for HeatWave on AWS

Privilege	Context
TP_CONNECTION_ADMIN	Thread pool administration
TRANSACTION_GTID_TAG	Replication administration
VERSION_TOKEN_ADMIN	Server administration
XA_RECOVER_ADMIN	Server administration

## Static Privilege Descriptions

Static privileges are built in to the server, in contrast to dynamic privileges, which are defined at runtime. The following list describes each static privilege available in MySQL.

Particular SQL statements might have more specific privilege requirements than indicated here. If so, the description for the statement in question provides the details.

- [ALL, ALL PRIVILEGES](#)

These privilege specifiers are shorthand for “all privileges available at a given privilege level” (except [GRANT OPTION](#)). For example, granting [ALL](#) at the global or table level grants all global privileges or all table-level privileges, respectively.

- [ALTER](#)

Enables use of the [ALTER TABLE](#) statement to change the structure of tables. [ALTER TABLE](#) also requires the [CREATE](#) and [INSERT](#) privileges. Renaming a table requires [ALTER](#) and [DROP](#) on the old table, [CREATE](#), and [INSERT](#) on the new table.

- [ALTER ROUTINE](#)

Enables use of statements that alter or drop stored routines (stored procedures and functions). For routines that fall within the scope at which the privilege is granted and for which the user is not the user named as the routine [DEFINER](#), also enables access to routine properties other than the routine definition.

- [CREATE](#)

Enables use of statements that create new databases and tables.

- [CREATE ROLE](#)

Enables use of the [CREATE ROLE](#) statement. (The [CREATE USER](#) privilege also enables use of the [CREATE ROLE](#) statement.) See [Section 8.2.10, “Using Roles”](#).

The [CREATE ROLE](#) and [DROP ROLE](#) privileges are not as powerful as [CREATE USER](#) because they can be used only to create and drop accounts. They cannot be used as [CREATE USER](#) can be modify account attributes or rename accounts. See [User and Role Interchangeability](#).

- [CREATE ROUTINE](#)

Enables use of statements that create stored routines (stored procedures and functions). For routines that fall within the scope at which the privilege is granted and for which the user is not the user named as the routine [DEFINER](#), also enables access to routine properties other than the routine definition.

- [CREATE TABLESPACE](#)

Enables use of statements that create, alter, or drop tablespaces and log file groups.

- `CREATE TEMPORARY TABLES`

Enables the creation of temporary tables using the `CREATE TEMPORARY TABLE` statement.

After a session has created a temporary table, the server performs no further privilege checks on the table. The creating session can perform any operation on the table, such as `DROP TABLE`, `INSERT`, `UPDATE`, or `SELECT`. For more information, see [Section 15.1.20.2, “CREATE TEMPORARY TABLE Statement”](#).

- `CREATE USER`

Enables use of the `ALTER USER`, `CREATE ROLE`, `CREATE USER`, `DROP ROLE`, `DROP USER`, `RENAME USER`, and `REVOKE ALL PRIVILEGES` statements.

- `CREATE VIEW`

Enables use of the `CREATE VIEW` statement.

- `DELETE`

Enables rows to be deleted from tables in a database.

- `DROP`

Enables use of statements that drop (remove) existing databases, tables, and views. The `DROP` privilege is required to use the `ALTER TABLE ... DROP PARTITION` statement on a partitioned table. The `DROP` privilege is also required for `TRUNCATE TABLE`.

- `DROP ROLE`

Enables use of the `DROP ROLE` statement. (The `CREATE USER` privilege also enables use of the `DROP ROLE` statement.) See [Section 8.2.10, “Using Roles”](#).

The `CREATE ROLE` and `DROP ROLE` privileges are not as powerful as `CREATE USER` because they can be used only to create and drop accounts. They cannot be used as `CREATE USER` can be modify account attributes or rename accounts. See [User and Role Interchangeability](#).

- `EVENT`

Enables use of statements that create, alter, drop, or display events for the Event Scheduler.

- `EXECUTE`

Enables use of statements that execute stored routines (stored procedures and functions). For routines that fall within the scope at which the privilege is granted and for which the user is not the user named as the routine `DEFINER`, also enables access to routine properties other than the routine definition.

- `FILE`

Affects the following operations and server behaviors:

- Enables reading and writing files on the server host using the `LOAD DATA` and `SELECT ... INTO OUTFILE` statements and the `LOAD_FILE()` function. A user who has the `FILE` privilege can read any file on the server host that is either world-readable or readable by the MySQL server. (This implies

the user can read any file in any database directory, because the server can access any of those files.)

- Enables creating new files in any directory where the MySQL server has write access. This includes the server's data directory containing the files that implement the privilege tables.
- Enables use of the `DATA DIRECTORY` or `INDEX DIRECTORY` table option for the `CREATE TABLE` statement.

As a security measure, the server does not overwrite existing files.

To limit the location in which files can be read and written, set the `secure_file_priv` system variable to a specific directory. See [Section 7.1.8, “Server System Variables”](#).

- **GRANT OPTION**

Enables you to grant to or revoke from other users those privileges that you yourself possess.

- **INDEX**

Enables use of statements that create or drop (remove) indexes. `INDEX` applies to existing tables. If you have the `CREATE` privilege for a table, you can include index definitions in the `CREATE TABLE` statement.

- **INSERT**

Enables rows to be inserted into tables in a database. `INSERT` is also required for the `ANALYZE TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` table-maintenance statements.

- **LOCK TABLES**

Enables use of explicit `LOCK TABLES` statements to lock tables for which you have the `SELECT` privilege. This includes use of write locks, which prevents other sessions from reading the locked table.

- **PROCESS**

The `PROCESS` privilege controls access to information about threads executing within the server (that is, information about statements being executed by sessions). Thread information available using the `SHOW PROCESSLIST` statement, the `mysqladmin processlist` command, the Information Schema `PROCESSLIST` table, and the Performance Schema `processlist` table is accessible as follows:

- With the `PROCESS` privilege, a user has access to information about all threads, even those belonging to other users.
- Without the `PROCESS` privilege, nonanonymous users have access to information about their own threads but not threads for other users, and anonymous users have no access to thread information.

**Note**

The Performance Schema `threads` table also provides thread information, but table access uses a different privilege model. See [Section 29.12.22.9, “The threads Table”](#).

The `PROCESS` privilege also enables use of the `SHOW ENGINE` statement, access to the `INFORMATION_SCHEMA InnoDB` tables (tables with names that begin with `INNODB_`), and access to the `INFORMATION_SCHEMA FILES` table.

- **PROXY**

Enables one user to impersonate or become known as another user. See [Section 8.2.19, “Proxy Users”](#).

- [REFERENCES](#)

Creation of a foreign key constraint requires the [REFERENCES](#) privilege for the parent table.

- [RELOAD](#)

The [RELOAD](#) enables the following operations:

- Use of the [FLUSH](#) statement.
- Use of [mysqladmin](#) commands that are equivalent to [FLUSH](#) operations: [flush-hosts](#), [flush-logs](#), [flush-privileges](#), [flush-status](#), [flush-tables](#), [refresh](#), and [reload](#).

The [reload](#) command tells the server to reload the grant tables into memory. [flush-privileges](#) is a synonym for [reload](#). The [refresh](#) command closes and reopens the log files and flushes all tables. The other [flush-xxx](#) commands perform functions similar to [refresh](#), but are more specific and may be preferable in some instances. For example, if you want to flush just the log files, [flush-logs](#) is a better choice than [refresh](#).

- Use of [mysqldump](#) options that perform various [FLUSH](#) operations: [--flush-logs](#) and [--source-data](#).
- Use of the [RESET BINARY LOGS AND GTIDS](#) and [RESET REPLICA](#) statements.

- [REPLICATION CLIENT](#)

Enables use of the [SHOW BINARY LOG STATUS](#), [SHOW REPLICA STATUS](#), and [SHOW BINARY LOGS](#) statements.

- [REPLICATION SLAVE](#)

Enables the account to request updates that have been made to databases on the replication source server, using the [SHOW REPLICAS](#), [SHOW RELAYLOG EVENTS](#), and [SHOW BINLOG EVENTS](#) statements. This privilege is also required to use the [mysqlbinlog](#) options [--read-from-remote-server](#) ([-R](#)) and [--read-from-remote-source](#). Grant this privilege to accounts that are used by replicas to connect to the current server as their replication source server.

- [SELECT](#)

Enables rows to be selected from tables in a database. [SELECT](#) statements require the [SELECT](#) privilege only if they actually access tables. Some [SELECT](#) statements do not access tables and can be executed without permission for any database. For example, you can use [SELECT](#) as a simple calculator to evaluate expressions that make no reference to tables:

```
SELECT 1+1;
SELECT PI()*2;
```

The [SELECT](#) privilege is also needed for other statements that read column values. For example, [SELECT](#) is needed for columns referenced on the right hand side of [col\\_name=expr](#) assignment in [UPDATE](#) statements or for columns named in the [WHERE](#) clause of [DELETE](#) or [UPDATE](#) statements.

The [SELECT](#) privilege is needed for tables or views used with [EXPLAIN](#), including any underlying tables in view definitions.

- [SHOW DATABASES](#)

Enables the account to see database names by issuing the `SHOW DATABASE` statement. Accounts that do not have this privilege see only databases for which they have some privileges, and cannot use the statement at all if the server was started with the `--skip-show-database` option.

**Caution**

Because any static global privilege is considered a privilege for all databases, any static global privilege enables a user to see all database names with `SHOW DATABASES` or by examining the `SCHEMATA` table of `INFORMATION_SCHEMA`, except databases that have been restricted at the database level by partial revokes.

- `SHOW VIEW`

Enables use of the `SHOW CREATE VIEW` statement. This privilege is also needed for views used with `EXPLAIN`.

- `SHUTDOWN`

Enables use of the `SHUTDOWN` and `RESTART` statements, the `mysqladmin shutdown` command, and the `mysql_shutdown()` C API function.

- `SUPER`

`SUPER` is a powerful and far-reaching privilege and should not be granted lightly. If an account needs to perform only a subset of `SUPER` operations, it may be possible to achieve the desired privilege set by

instead granting one or more dynamic privileges, each of which confers more limited capabilities. See [Dynamic Privilege Descriptions](#).

**Note**

`SUPER` is deprecated, and you should expect it to be removed in a future version of MySQL. See [Migrating Accounts from SUPER to Dynamic Privileges](#).

`SUPER` affects the following operations and server behaviors:

- Enables system variable changes at runtime:
  - Enables server configuration changes to global system variables with `SET GLOBAL` and `SET PERSIST`.

The corresponding dynamic privilege is `SYSTEM_VARIABLES_ADMIN`.

- Enables setting restricted session system variables that require a special privilege.

The corresponding dynamic privilege is `SESSION_VARIABLES_ADMIN`.

See also [Section 7.1.9.1, “System Variable Privileges”](#).

- Enables changes to global transaction characteristics (see [Section 15.3.7, “SET TRANSACTION Statement”](#)).

The corresponding dynamic privilege is `SYSTEM_VARIABLES_ADMIN`.

- Enables the account to start and stop replication, including Group Replication.

The corresponding dynamic privilege is `REPLICATION_SLAVE_ADMIN` for regular replication, `GROUP_REPLICATION_ADMIN` for Group Replication.

- Enables use of `CHANGE REPLICATION SOURCE TO` and `CHANGE REPLICATION FILTER` statements.

The corresponding dynamic privilege is `REPLICATION_SLAVE_ADMIN`.

- Enables binary log control by means of the `PURGE BINARY LOGS` and `BINLOG` statements.

The corresponding dynamic privilege is `BINLOG_ADMIN`.

- Enables setting the effective authorization ID when executing a view or stored program. A user with this privilege can specify any account in the `DEFINER` attribute of a view or stored program.

The corresponding dynamic privileges are `SET_ANY_DEFINER` and `ALLOW_NONEXISTENT_DEFINER`.

- Enables use of the `CREATE SERVER`, `ALTER SERVER`, and `DROP SERVER` statements.
- Enables use of the `mysqladmin debug` command.
- Enables InnoDB encryption key rotation.

The corresponding dynamic privilege is `ENCRYPTION_KEY_ADMIN`.

- Enables execution of Version Tokens functions.

The corresponding dynamic privilege is `VERSION_TOKEN_ADMIN`.

- Enables granting and revoking roles, use of the `WITH ADMIN OPTION` clause of the `GRANT` statement, and nonempty `<graphml>` element content in the result from the `ROLES_GRAPHML()` function.

The corresponding dynamic privilege is `ROLE_ADMIN`.

- Enables control over client connections not permitted to non-`SUPER` accounts:
  - Enables use of the `KILL` statement or `mysqladmin kill` command to kill threads belonging to other accounts. (An account can always kill its own threads.)
  - The server does not execute `init_connect` system variable content when `SUPER` clients connect.
  - The server accepts one connection from a `SUPER` client even if the connection limit configured by the `max_connections` system variable is reached.
  - A server in offline mode (`offline_mode` enabled) does not terminate `SUPER` client connections at the next client request, and accepts new connections from `SUPER` clients.
  - Updates can be performed even when the `read_only` system variable is enabled. This applies to explicit table updates, and to use of account-management statements such as `GRANT` and `REVOKE` that update tables implicitly.

The corresponding dynamic privilege for the preceding connection-control operations is `CONNECTION_ADMIN`.

You may also need the `SUPER` privilege to create or alter stored functions if binary logging is enabled, as described in [Section 27.8, “Stored Program Binary Logging”](#).

- `TRIGGER`

Enables trigger operations. You must have this privilege for a table to create, drop, execute, or display triggers for that table.

When a trigger is activated (by a user who has privileges to execute `INSERT`, `UPDATE`, or `DELETE` statements for the table associated with the trigger), trigger execution requires that the user who defined the trigger still have the `TRIGGER` privilege for the table.

- `UPDATE`

Enables rows to be updated in tables in a database.

- `USAGE`

This privilege specifier stands for “no privileges.” It is used at the global level with `GRANT` to specify clauses such as `WITH GRANT OPTION` without naming specific account privileges in the privilege list. `SHOW GRANTS` displays `USAGE` to indicate that an account has no privileges at a privilege level.

## Dynamic Privilege Descriptions

Dynamic privileges are defined at runtime, in contrast to static privileges, which are built in to the server. The following list describes each dynamic privilege available in MySQL.

Most dynamic privileges are defined at server startup. Others are defined by a particular component or plugin, as indicated in the privilege descriptions. In such cases, the privilege is unavailable unless the component or plugin that defines it is enabled.

Particular SQL statements might have more specific privilege requirements than indicated here. If so, the description for the statement in question provides the details.

- [ALLOW\\_NONEXISTENT\\_DEFINER](#)

Enables overriding security checks designed to prevent operations that (perhaps inadvertently) cause stored objects to become orphaned or that cause adoption of stored objects that are currently orphaned. Without this privilege, any attempt to produce an orphaned SQL procedure, function, or view results in an error. An attempt to produce orphaned objects using [CREATE PROCEDURE](#), [CREATE FUNCTION](#), [CREATE TRIGGER](#), [CREATE EVENT](#), or [CREATE VIEW](#) also requires [SET\\_ANY\\_DEFINER](#) in addition to [ALLOW\\_NONEXISTENT\\_DEFINER](#), so that a definer different from the current user is permissible.

For details, see [Orphan Stored Objects](#).

- [APPLICATION\\_PASSWORD\\_ADMIN](#)

For dual-password capability, this privilege enables use of the [RETAIN CURRENT PASSWORD](#) and [DISCARD OLD PASSWORD](#) clauses for [ALTER USER](#) and [SET PASSWORD](#) statements that apply to your own account. This privilege is required to manipulate your own secondary password because most users require only one password.

If an account is to be permitted to manipulate secondary passwords for all accounts, it should be granted the [CREATE USER](#) privilege rather than [APPLICATION\\_PASSWORD\\_ADMIN](#).

For more information about use of dual passwords, see [Section 8.2.15, “Password Management”](#).

- [AUDIT\\_ABORT\\_EXEMPT](#)

Allows queries blocked by an “abort” item in the audit log filter. This privilege is defined by the [audit\\_log](#) plugin; see [Section 8.4.5, “MySQL Enterprise Audit”](#).

Accounts created with the [SYSTEM\\_USER](#) privilege have the [AUDIT\\_ABORT\\_EXEMPT](#) privilege assigned automatically when they are created. The [AUDIT\\_ABORT\\_EXEMPT](#) privilege is also assigned to existing accounts with the [SYSTEM\\_USER](#) privilege when you carry out an upgrade procedure, if no existing accounts have that privilege assigned. Accounts with the [SYSTEM\\_USER](#) privilege can therefore be used to regain access to a system following an audit misconfiguration.

- [AUDIT\\_ADMIN](#)

Enables audit log configuration. This privilege is defined by the [audit\\_log](#) plugin; see [Section 8.4.5, “MySQL Enterprise Audit”](#).

- [BACKUP\\_ADMIN](#)

Enables execution of the [LOCK INSTANCE FOR BACKUP](#) statement and access to the Performance Schema [log\\_status](#) table.

**Note**

Besides [BACKUP\\_ADMIN](#), the [SELECT](#) privilege on the [log\\_status](#) table is also needed for its access.

The [BACKUP\\_ADMIN](#) privilege is automatically granted to users with the [RELOAD](#) privilege when performing an in-place upgrade to MySQL 9.1 from an earlier version.

- `AUTHENTICATION_POLICY_ADMIN`

The `authentication_policy` system variable places certain constraints on how the authentication-related clauses of `CREATE USER` and `ALTER USER` statements may be used. A user who has the `AUTHENTICATION_POLICY_ADMIN` privilege is not subject to these constraints. (A warning does occur for statements that otherwise would not be permitted.)

For details about the constraints imposed by `authentication_policy`, see the description of that variable.

- `BINLOG_ADMIN`

Enables binary log control by means of the `PURGE BINARY LOGS` and `BINLOG` statements.

- `BINLOG_ENCRYPTION_ADMIN`

Enables setting the system variable `binlog_encryption`, which activates or deactivates encryption for binary log files and relay log files. This ability is not provided by the `BINLOG_ADMIN`, `SYSTEM_VARIABLES_ADMIN`, or `SESSION_VARIABLES_ADMIN` privileges. The related system variable `binlog_rotate_encryption_master_key_at_startup`, which rotates the binary log master key automatically when the server is restarted, does not require this privilege.

- `CLONE_ADMIN`

Enables execution of the `CLONE` statements. Includes `BACKUP_ADMIN` and `SHUTDOWN` privileges.

- `CONNECTION_ADMIN`

Enables use of the `KILL` statement or `mysqladmin kill` command to kill threads belonging to other accounts. (An account can always kill its own threads.)

Enables setting system variables related to client connections, or circumventing restrictions related to client connections. `CONNECTION_ADMIN` is required to activate MySQL Server's offline mode, which is done by changing the value of the `offline_mode` system variable to `ON`.

The `CONNECTION_ADMIN` privilege enables administrators with it to bypass effects of these system variables:

- `init_connect`: The server does not execute `init_connect` system variable content when `CONNECTION_ADMIN` clients connect.
- `max_connections`: The server accepts one connection from a `CONNECTION_ADMIN` client even if the connection limit configured by the `max_connections` system variable is reached.
- `offline_mode`: A server in offline mode (`offline_mode` enabled) does not terminate `CONNECTION_ADMIN` client connections at the next client request, and accepts new connections from `CONNECTION_ADMIN` clients.
- `read_only`: Updates from `CONNECTION_ADMIN` clients can be performed even when the `read_only` system variable is enabled. This applies to explicit table updates, and to account management statements such as `GRANT` and `REVOKE` that update tables implicitly.

Group Replication group members need the `CONNECTION_ADMIN` privilege so that Group Replication connections are not terminated if one of the servers involved is placed in offline mode. If the MySQL communication stack is in use (`group_replication_communication_stack = MYSQL`), without this privilege, a member that is placed in offline mode is expelled from the group.

- `ENCRYPTION_KEY_ADMIN`

Enables `InnoDB` encryption key rotation.

- `EXPORT_QUERY_RESULTS`

Allows the user to export query results to an OCI or AWS object store.

Added in MySQL 9.1.1. Applies to MySQL HeatWave only.

- `FIREWALL_ADMIN`

Enables a user to administer firewall rules for any user. This privilege is defined by the `MYSQL_FIREWALL` plugin; see [Section 8.4.7, “MySQL Enterprise Firewall”](#).

- `FIREWALL_EXEMPT`

A user with this privilege is exempt from firewall restrictions. This privilege is defined by the `MYSQL_FIREWALL` plugin; see [Section 8.4.7, “MySQL Enterprise Firewall”](#).

- `FIREWALL_USER`

Enables users to update their own firewall rules. This privilege is defined by the `MYSQL_FIREWALL` plugin; see [Section 8.4.7, “MySQL Enterprise Firewall”](#).

- `FLUSH_OPTIMIZER_COSTS`

Enables use of the `FLUSH OPTIMIZER_COSTS` statement.

- `FLUSH_PRIVILEGES`

Enables use of the `FLUSH PRIVILEGES` statement.

- `FLUSH_STATUS`

Enables use of the `FLUSH STATUS` statement.

- `FLUSH_TABLES`

Enables use of the `FLUSH TABLES` statement.

- `FLUSH_USER_RESOURCES`

Enables use of the `FLUSH USER_RESOURCES` statement.

- `GROUP_REPLICATION_ADMIN`

Enables the account to start and stop Group Replication using the `START GROUP REPLICATION` and `STOP GROUP REPLICATION` statements, to change the global setting for the `group_replication_consistency` system variable, and to use the `group_replication_set_write_concurrency()` and `group_replication_set_communication_protocol()` functions. Grant this privilege to accounts that are used to administer servers that are members of a replication group.

- `GROUP_REPLICATION_STREAM`

Allows a user account to be used for establishing Group Replication's group communication connections. It must be granted to a recovery user when the MySQL communication stack is used for Group Replication (`group_replication_communication_stack=MYSQL`).

- `INNODB_REDO_LOG_ARCHIVE`

Enables the account to activate and deactivate redo log archiving.

- `INNODB_REDO_LOG_ENABLE`

Enables use of the `ALTER INSTANCE {ENABLE|DISABLE} INNODB REDO_LOG` statement to enable or disable redo logging.

See [Disabling Redo Logging](#).

- `MASKING_DICTIONARIES_ADMIN`

Enables the account to add and remove dictionary terms using the `masking_dictionary_term_add()` and `masking_dictionary_term_remove()` component functions. Accounts also require this dynamic privilege to remove a full dictionary using the `masking_dictionary_remove()` function, which removes all of the terms associated with the named dictionary currently in the `mysql.masking_dictionaries` table.

See [Section 8.5, “MySQL Enterprise Data Masking and De-Identification”](#).

- `NDB_STORED_USER`

Enables the user or role and its privileges to be shared and synchronized between all NDB-enabled MySQL servers as soon as they join a given NDB Cluster. This privilege is available only if the NDB storage engine is enabled.

Any changes to or revocations of privileges made for the given user or role are synchronized immediately with all connected MySQL servers (SQL nodes). You should be aware that there is no guarantee that multiple statements affecting privileges originating from different SQL nodes are executed on all SQL nodes in the same order. For this reason, it is highly recommended that all user administration be done from a single designated SQL node.

`NDB_STORED_USER` is a global privilege and must be granted or revoked using `ON *.*`. Trying to set any other scope for this privilege results in an error. This privilege can be given to most application and administrative users, but it cannot be granted to system reserved accounts such as `mysql.session@localhost` or `mysql.infoschema@localhost`.

A user that has been granted the `NDB_STORED_USER` privilege is stored in NDB (and thus shared by all SQL nodes), as is a role with this privilege. A user that is merely granted a role that has `NDB_STORED_USER` is *not* stored in NDB; each NDB stored user must be granted the privilege explicitly.

For more detailed information about how this works in NDB, see [Section 25.6.13, “Privilege Synchronization and NDB\\_STORED\\_USER”](#).

- `OPTIMIZE_LOCAL_TABLE`

Enables use of `OPTIMIZE LOCAL TABLE` and `OPTIMIZE NO_WRITE_TO_BINLOG TABLE` statements.

- `OPTION_TRACKER_UPDATER`

This privilege is required for write access to the `mysql_option.option_usage` table; both the privilege and the table are supplied by the Option Tracker component. For more information, see [Section 7.5.8, “Option Tracker Component”](#).

- `PASSWORDLESS_USER_ADMIN`

This privilege applies to passwordless user accounts:

- For account creation, a user who executes `CREATE USER` to create a passwordless account must possess the `PASSWORDLESS_USER_ADMIN` privilege.
- In replication context, the `PASSWORDLESS_USER_ADMIN` privilege applies to replication users and enables replication of `ALTER USER ... MODIFY` statements for user accounts that are configured for passwordless authentication.

For information about passwordless authentication, see [WebAuthn Passwordless Authentication](#).

- `PERSIST_RO_VARIABLES_ADMIN`

For users who also have `SYSTEM_VARIABLES_ADMIN`, `PERSIST_RO_VARIABLES_ADMIN` enables use of `SET PERSIST_ONLY` to persist global system variables to the `mysqld-auto.cnf` option file in the data directory. This statement is similar to `SET PERSIST` but does not modify the runtime global system variable value. This makes `SET PERSIST_ONLY` suitable for configuring read-only system variables that can be set only at server startup.

See also [Section 7.1.9.1, “System Variable Privileges”](#).

- `REPLICATION_APPLIER`

Enables the account to act as the `PRIVILEGE_CHECKS_USER` for a replication channel, and to execute `BINLOG` statements in `mysqlbinlog` output. Grant this privilege to accounts that are assigned using `CHANGE REPLICATION SOURCE TO` to provide a security context for replication channels, and to handle replication errors on those channels. As well as the `REPLICATION_APPLIER` privilege, you must also give the account the required privileges to execute the transactions received by the replication channel or contained in the `mysqlbinlog` output, for example to update the affected tables. For more information, see [Section 19.3.3, “Replication Privilege Checks”](#).

- `REPLICATION_SLAVE_ADMIN`

Enables the account to connect to the replication source server, start and stop replication using the `START REPLICA` and `STOP REPLICA` statements, and use the `CHANGE REPLICATION SOURCE TO` and `CHANGE REPLICATION FILTER` statements. Grant this privilege to accounts that are used by replicas to connect to the current server as their replication source server. This privilege does not apply to Group Replication; use `GROUP_REPLICATION_ADMIN` for that.

- `RESOURCE_GROUP_ADMIN`

Enables resource group management, consisting of creating, altering, and dropping resource groups, and assignment of threads and statements to resource groups. A user with this privilege can perform any operation relating to resource groups.

- `RESOURCE_GROUP_USER`

Enables assigning threads and statements to resource groups. A user with this privilege can use the `SET RESOURCE GROUP` statement and the `RESOURCE_GROUP` optimizer hint.

- `ROLE_ADMIN`

Enables granting and revoking roles, use of the `WITH ADMIN OPTION` clause of the `GRANT` statement, and nonempty `<graphml>` element content in the result from the `ROLES_GRAPHML( )` function. Required to set the value of the `mandatory_roles` system variable.

- [SENSITIVE\\_VARIABLES\\_OBSERVER](#)

Enables a holder to view the values of sensitive system variables in the Performance Schema tables [global\\_variables](#), [session\\_variables](#), [variables\\_by\\_thread](#), and [persisted\\_variables](#), to issue [SELECT](#) statements to return their values, and to track changes to them in session trackers for connections. Users without this privilege cannot view or track those system variable values. See [Persisting Sensitive System Variables](#).

- [SERVICE\\_CONNECTION\\_ADMIN](#)

Enables connections to the network interface that permits only administrative connections (see [Section 7.1.12.1, “Connection Interfaces”](#)).

- [SESSION\\_VARIABLES\\_ADMIN](#)

For most system variables, setting the session value requires no special privileges and can be done by any user to affect the current session. For some system variables, setting the session value can have effects outside the current session and thus is a restricted operation. For these, the [SESSION\\_VARIABLES\\_ADMIN](#) privilege enables the user to set the session value.

If a system variable is restricted and requires a special privilege to set the session value, the variable description indicates that restriction. Examples include [binlog\\_format](#), [sql\\_log\\_bin](#), and [sql\\_log\\_off](#).

The [SESSION\\_VARIABLES\\_ADMIN](#) privilege is a subset of the [SYSTEM\\_VARIABLES\\_ADMIN](#) and [SUPER](#) privileges. A user who has either of those privileges is also permitted to set restricted session variables and effectively has [SESSION\\_VARIABLES\\_ADMIN](#) by implication and need not be granted [SESSION\\_VARIABLES\\_ADMIN](#) explicitly.

See also [Section 7.1.9.1, “System Variable Privileges”](#).

- [SET\\_ANY\\_DEFINER](#)

Enables setting the effective authorization ID when executing a view or stored program. A user with this privilege can specify any account as the [DEFINER](#) attribute for [CREATE PROCEDURE](#), [CREATE FUNCTION](#), [CREATE TRIGGER](#), [CREATE EVENT](#), [ALTER EVENT](#), [CREATE VIEW](#), and [ALTER VIEW](#). Without this privilege, only the effective authentication ID can be specified.

Stored programs execute with the privileges of the specified account, so ensure that you follow the risk minimization guidelines listed in [Section 27.7, “Stored Object Access Control”](#).

- [SHOW\\_ROUTINE](#)

Enables a user to access definitions and properties of all stored routines (stored procedures and functions), even those for which the user is not named as the routine [DEFINER](#). This access includes:

- The contents of the Information Schema [ROUTINES](#) table.
- The [SHOW CREATE FUNCTION](#) and [SHOW CREATE PROCEDURE](#) statements.
- The [SHOW FUNCTION CODE](#) and [SHOW PROCEDURE CODE](#) statements.
- The [SHOW FUNCTION STATUS](#) and [SHOW PROCEDURE STATUS](#) statements.

[SHOW\\_ROUTINE](#) may be granted instead as a privilege with a more restricted scope that permits access to routine definitions. (That is, an administrator can rescind global [SELECT](#) from users that do not

otherwise require it and grant [SHOW\\_ROUTINE](#) instead.) This enables an account to back up stored routines without requiring a broad privilege.

- [SKIP\\_QUERY\\_REWRITE](#)

Queries issued by a user with this privilege are not subject to being rewritten by the [Rewriter](#) plugin (see [Section 7.6.4, “The Rewriter Query Rewrite Plugin”](#)).

This privilege should be granted to users issuing administrative or control statements that should not be rewritten, as well as to [PRIVILEGE\\_CHECKS\\_USER](#) accounts (see [Section 19.3.3, “Replication Privilege Checks”](#)) used to apply statements from a replication source.

- [SYSTEM\\_USER](#)

The [SYSTEM\\_USER](#) privilege distinguishes system users from regular users:

- A user with the [SYSTEM\\_USER](#) privilege is a system user.
- A user without the [SYSTEM\\_USER](#) privilege is a regular user.

The [SYSTEM\\_USER](#) privilege has an effect on the accounts to which a given user can apply its other privileges, as well as whether the user is protected from other accounts:

- A system user can modify both system and regular accounts. That is, a user who has the appropriate privileges to perform a given operation on regular accounts is enabled by possession of [SYSTEM\\_USER](#) to also perform the operation on system accounts. A system account can be modified only by system users with appropriate privileges, not by regular users.
- A regular user with appropriate privileges can modify regular accounts, but not system accounts. A regular account can be modified by both system and regular users with appropriate privileges.

This also means that database objects created by users with the [SYSTEM\\_USER](#) privilege cannot be modified or dropped by users without the privilege. This also applies to routines for which the definer has this privilege.

For more information, see [Section 8.2.11, “Account Categories”](#).

The protection against modification by regular accounts that is afforded to system accounts by the [SYSTEM\\_USER](#) privilege does not apply to regular accounts that have privileges on the `mysql` system schema and thus can directly modify the grant tables in that schema. For full protection, do not grant `mysql` schema privileges to regular accounts. See [Protecting System Accounts Against Manipulation by Regular Accounts](#).

If the `audit_log` plugin is in use (see [Section 8.4.5, “MySQL Enterprise Audit”](#)), accounts with the [SYSTEM\\_USER](#) privilege are automatically assigned the [AUDIT\\_ABORT\\_EXEMPT](#) privilege, which permits their queries to be executed even if an “abort” item configured in the filter would block them. Accounts with the [SYSTEM\\_USER](#) privilege can therefore be used to regain access to a system following an audit misconfiguration.

- [SYSTEM\\_VARIABLES\\_ADMIN](#)

Affects the following operations and server behaviors:

- Enables system variable changes at runtime:
  - Enables server configuration changes to global system variables with [SET GLOBAL](#) and [SET PERSIST](#).

- Enables server configuration changes to global system variables with `SET PERSIST_ONLY`, if the user also has `PERSIST_RO_VARIABLES_ADMIN`.
- Enables setting restricted session system variables that require a special privilege. In effect, `SYSTEM_VARIABLES_ADMIN` implies `SESSION_VARIABLES_ADMIN` without explicitly granting `SESSION_VARIABLES_ADMIN`.

See also [Section 7.1.9.1, “System Variable Privileges”](#).

- Enables changes to global transaction characteristics (see [Section 15.3.7, “SET TRANSACTION Statement”](#)).
- `TABLE_ENCRYPTION_ADMIN`

Enables a user to override default encryption settings when `table_encryption_privilege_check` is enabled; see [Defining an Encryption Default for Schemas and General Tablespaces](#).

- `TELEMETRY_LOG_ADMIN`

Enables telemetry log configuration. This privilege is defined by the `telemetry_log` plugin, which is deployed through HeatWave on AWS.

- `TP_CONNECTION_ADMIN`

Enables connecting to the server with a privileged connection. When the limit defined by `thread_pool_max_transactions_limit` has been reached, new connections are not permitted, unless overridden by `thread_pool_longrun_trx_limit`. A privileged connection ignores the transaction limit and permits connecting to the server to increase the transaction limit, remove the limit, or kill running transactions. This privilege is not granted to any user by default. To establish a privileged connection, the user initiating a connection must have the `TP_CONNECTION_ADMIN` privilege.

A privileged connection can execute statements and start transactions when the limit defined by `thread_pool_max_transactions_limit` has been reached. A privileged connection is placed in the `Admin` thread group. See [Privileged Connections](#).

- `TRANSACTION_GTID_TAG`

Required for setting the `gtid_next` system variable to `AUTOMATIC:TAG` or `UUID:TAG:NUMBER` on a replication source server. In addition, at least one of `SYSTEM_VARIABLES_ADMIN`, `SESSION_VARIABLES_ADMIN`, or `REPLICATION_APPLIER` is also required to set `gtid_next` to one of these values on the source.

The `REPLICATION_CHECKS_APPLIER` must also have this privilege as well as the `REPLICATION_APPLIER` privilege to set `gtid_next` to `AUTOMATIC:TAG`. This is checked when starting the replication applier thread.

This privilege is also required to set the `gtid_purged` server system variable.

For more information about using tagged GTIDs, see the description of `gtid_next`, as well as [Section 19.1.4, “Changing GTID Mode on Online Servers”](#).

- `VERSION_TOKEN_ADMIN`

Enables execution of Version Tokens functions. This privilege is defined by the `version_tokens` plugin; see [Section 7.6.6, “Version Tokens”](#).

- `XA_RECOVER_ADMIN`

Enables execution of the `XA RECOVER` statement; see [Section 15.3.8.1, “XA Transaction SQL Statements”](#).

Prior to MySQL 9.1, any user could execute the `XA RECOVER` statement to discover the XID values for outstanding prepared XA transactions, possibly leading to commit or rollback of an XA transaction by a user other than the one who started it. In MySQL 9.1, `XA RECOVER` is permitted only to users who have the `XA_RECOVER_ADMIN` privilege, which is expected to be granted only to administrative users who have need for it. This might be the case, for example, for administrators of an XA application if it has crashed and it is necessary to find outstanding transactions started by the application so they can be rolled back. This privilege requirement prevents users from discovering the XID values for outstanding prepared XA transactions other than their own. It does not affect normal commit or rollback of an XA transaction because the user who started it knows its XID.

## Privilege-Granting Guidelines

It is a good idea to grant to an account only those privileges that it needs. You should exercise particular caution in granting the `FILE` and administrative privileges:

- `FILE` can be abused to read into a database table any files that the MySQL server can read on the server host. This includes all world-readable files and files in the server's data directory. The table can then be accessed using `SELECT` to transfer its contents to the client host.
- `GRANT OPTION` enables users to give their privileges to other users. Two users that have different privileges and with the `GRANT OPTION` privilege are able to combine privileges.
- `ALTER` may be used to subvert the privilege system by renaming tables.
- `SHUTDOWN` can be abused to deny service to other users entirely by terminating the server.
- `PROCESS` can be used to view the plain text of currently executing statements, including statements that set or change passwords.
- `SUPER` can be used to terminate other sessions or change how the server operates.
- Privileges granted for the `mysql` system database itself can be used to change passwords and other access privilege information:
  - Passwords are stored encrypted, so a malicious user cannot simply read them to know the plain text password. However, a user with write access to the `mysql.user` system table `authentication_string` column can change an account's password, and then connect to the MySQL server using that account.
  - `INSERT` or `UPDATE` granted for the `mysql` system database enable a user to add privileges or modify existing privileges, respectively.
  - `DROP` for the `mysql` system database enables a user to remove privilege tables, or even the database itself.

## Static Versus Dynamic Privileges

MySQL supports static and dynamic privileges:

- Static privileges are built in to the server. They are always available to be granted to user accounts and cannot be unregistered.
- Dynamic privileges can be registered and unregistered at runtime. This affects their availability: A dynamic privilege that has not been registered cannot be granted.

For example, the `SELECT` and `INSERT` privileges are static and always available, whereas a dynamic privilege becomes available only if the component that implements it has been enabled.

The remainder of this section describes how dynamic privileges work in MySQL. The discussion uses the term “components” but applies equally to plugins.

**Note**

Server administrators should be aware of which server components define dynamic privileges. For MySQL distributions, documentation of components that define dynamic privileges describes those privileges.

Third-party components may also define dynamic privileges; an administrator should understand those privileges and not install components that might conflict or compromise server operation. For example, one component conflicts with another if both define a privilege with the same name. Component developers can reduce the likelihood of this occurrence by choosing privilege names having a prefix based on the component name.

The server maintains the set of registered dynamic privileges internally in memory. Unregistration occurs at server shutdown.

Normally, a component that defines dynamic privileges registers them when it is installed, during its initialization sequence. When uninstalled, a component does not unregister its registered dynamic privileges. (This is current practice, not a requirement. That is, components could, but do not, unregister at any time privileges they register.)

No warning or error occurs for attempts to register an already registered dynamic privilege. Consider the following sequence of statements:

```
INSTALL COMPONENT 'my_component';
UNINSTALL COMPONENT 'my_component';
INSTALL COMPONENT 'my_component';
```

The first `INSTALL COMPONENT` statement registers any privileges defined by component `my_component`, but `UNINSTALL COMPONENT` does not unregister them. For the second `INSTALL COMPONENT` statement, the component privileges it registers are found to be already registered, but no warnings or errors occur.

Dynamic privileges apply only at the global level. The server stores information about current assignments of dynamic privileges to user accounts in the `mysql.global_grants` system table:

- The server automatically registers privileges named in `global_grants` during server startup (unless the `--skip-grant-tables` option is given).
- The `GRANT` and `REVOKE` statements modify the contents of `global_grants`.
- Dynamic privilege assignments listed in `global_grants` are persistent. They are not removed at server shutdown.

Example: The following statement grants to user `u1` the privileges required to control replication (including Group Replication) on a replica, and to modify system variables:

```
GRANT REPLICATION_SLAVE_ADMIN, GROUP_REPLICATION_ADMIN, BINLOG_ADMIN
ON *.* TO 'u1'@'localhost';
```

Granted dynamic privileges appear in the output from the `SHOW GRANTS` statement and the `INFORMATION_SCHEMA.USER_PRIVILEGES` table.

For [GRANT](#) and [REVOKE](#) at the global level, any named privileges not recognized as static are checked against the current set of registered dynamic privileges and granted if found. Otherwise, an error occurs to indicate an unknown privilege identifier.

For [GRANT](#) and [REVOKE](#) the meaning of [ALL \[PRIVILEGES\]](#) at the global level includes all static global privileges, as well as all currently registered dynamic privileges:

- [GRANT ALL](#) at the global level grants all static global privileges and all currently registered dynamic privileges. A dynamic privilege registered subsequent to execution of the [GRANT](#) statement is not granted retroactively to any account.
- [REVOKE ALL](#) at the global level revokes all granted static global privileges and all granted dynamic privileges.

The [FLUSH PRIVILEGES](#) statement reads the `global_grants` table for dynamic privilege assignments and registers any unregistered privileges found there.

For descriptions of the dynamic privileges provided by MySQL Server and components included in MySQL distributions, see [Section 8.2.2, “Privileges Provided by MySQL”](#).

## Migrating Accounts from SUPER to Dynamic Privileges

In MySQL 9.1, many operations that previously required the [SUPER](#) privilege are also associated with a dynamic privilege of more limited scope. (For descriptions of these privileges, see [Section 8.2.2, “Privileges Provided by MySQL”](#).) Each such operation can be permitted to an account by granting the associated dynamic privilege rather than [SUPER](#). This change improves security by enabling DBAs to avoid granting [SUPER](#) and tailor user privileges more closely to the operations permitted. [SUPER](#) is now deprecated; expect it to be removed in a future version of MySQL.

When removal of [SUPER](#) occurs, operations that formerly required [SUPER](#) fail unless accounts granted [SUPER](#) are migrated to the appropriate dynamic privileges. Use the following instructions to accomplish that goal so that accounts are ready prior to [SUPER](#) removal:

1. Execute this query to identify accounts that are granted [SUPER](#):

```
SELECT GRANTEE FROM INFORMATION_SCHEMA.USER_PRIVILEGES
WHERE PRIVILEGE_TYPE = 'SUPER';
```

2. For each account identified by the preceding query, determine the operations for which it needs [SUPER](#). Then grant the dynamic privileges corresponding to those operations, and revoke [SUPER](#).

For example, if `'u1'@'localhost'` requires [SUPER](#) for binary log purging and system variable modification, these statements make the required changes to the account:

```
GRANT BINLOG_ADMIN, SYSTEM_VARIABLES_ADMIN ON *.* TO 'u1'@'localhost';
REVOKE SUPER ON *.* FROM 'u1'@'localhost';
```

After you have modified all applicable accounts, the `INFORMATION_SCHEMA` query in the first step should produce an empty result set.

## 8.2.3 Grant Tables

The `mysql` system database includes several grant tables that contain information about user accounts and the privileges held by them. This section describes those tables. For information about other tables in the system database, see [Section 7.3, “The mysql System Schema”](#).

The discussion here describes the underlying structure of the grant tables and how the server uses their contents when interacting with clients. However, normally you do not modify the grant tables

directly. Modifications occur indirectly when you use account-management statements such as [CREATE USER](#), [GRANT](#), and [REVOKE](#) to set up accounts and control the privileges available to each one. See [Section 15.7.1, “Account Management Statements”](#). When you use such statements to perform account manipulations, the server modifies the grant tables on your behalf.

**Note**

Direct modification of grant tables using statements such as [INSERT](#), [UPDATE](#), or [DELETE](#) is discouraged and done at your own risk. The server is free to ignore rows that become malformed as a result of such modifications.

For any operation that modifies a grant table, the server checks whether the table has the expected structure and produces an error if not. To update the tables to the expected structure, perform the MySQL upgrade procedure. See [Chapter 3, Upgrading MySQL](#).

- [Grant Table Overview](#)
- [The user and db Grant Tables](#)
- [The tables\\_priv and columns\\_priv Grant Tables](#)
- [The procs\\_priv Grant Table](#)
- [The proxies\\_priv Grant Table](#)
- [The global\\_grants Grant Table](#)
- [The default\\_roles Grant Table](#)
- [The role\\_edges Grant Table](#)
- [The password\\_history Grant Table](#)
- [Grant Table Scope Column Properties](#)
- [Grant Table Privilege Column Properties](#)
- [Grant Table Concurrency](#)

## Grant Table Overview

These `mysql` database tables contain grant information:

- `user`: User accounts, static global privileges, and other nonprivilege columns.
- `global_grants`: Dynamic global privileges.
- `db`: Database-level privileges.
- `tables_priv`: Table-level privileges.
- `columns_priv`: Column-level privileges.
- `procs_priv`: Stored procedure and function privileges.
- `proxies_priv`: Proxy-user privileges.
- `default_roles`: Default user roles.
- `role_edges`: Edges for role subgraphs.

- `password_history`: Password change history.

For information about the differences between static and dynamic global privileges, see [Static Versus Dynamic Privileges](#).)

Grant tables use the `InnoDB` storage engine and are transactional. Each statement either succeeds for all named users or rolls back and has no effect if any error occurs.

Each grant table contains scope columns and privilege columns:

- Scope columns determine the scope of each row in the tables; that is, the context in which the row applies. For example, a `user` table row with `Host` and `User` values of `'h1.example.net'` and `'bob'` applies to authenticating connections made to the server from the host `h1.example.net` by a client that specifies a user name of `bob`. Similarly, a `db` table row with `Host`, `User`, and `Db` column values of `'h1.example.net'`, `'bob'` and `'reports'` applies when `bob` connects from the host `h1.example.net` to access the `reports` database. The `tables_priv` and `columns_priv` tables contain scope columns indicating tables or table/column combinations to which each row applies. The `procs_priv` scope columns indicate the stored routine to which each row applies.
- Privilege columns indicate which privileges a table row grants; that is, which operations it permits to be performed. The server combines the information in the various grant tables to form a complete description of a user's privileges. [Section 8.2.7, "Access Control, Stage 2: Request Verification"](#), describes the rules for this.

In addition, a grant table may contain columns used for purposes other than scope or privilege assessment.

The server uses the grant tables in the following manner:

- The `user` table scope columns determine whether to reject or permit incoming connections. For permitted connections, any privileges granted in the `user` table indicate the user's static global privileges. Any privileges granted in this table apply to *all* databases on the server.

#### Caution

Because any static global privilege is considered a privilege for all databases, any static global privilege enables a user to see all database names with `SHOW DATABASES` or by examining the `SCHEMATA` table of `INFORMATION_SCHEMA`, except databases that have been restricted at the database level by partial revokes.

- The `global_grants` table lists current assignments of dynamic global privileges to user accounts. For each row, the scope columns determine which user has the privilege named in the privilege column.
- The `db` table scope columns determine which users can access which databases from which hosts. The privilege columns determine the permitted operations. A privilege granted at the database level applies to the database and to all objects in the database, such as tables and stored programs.
- The `tables_priv` and `columns_priv` tables are similar to the `db` table, but are more fine-grained: They apply at the table and column levels rather than at the database level. A privilege granted at the table level applies to the table and to all its columns. A privilege granted at the column level applies only to a specific column.
- The `procs_priv` table applies to stored routines (stored procedures and functions). A privilege granted at the routine level applies only to a single procedure or function.
- The `proxies_priv` table indicates which users can act as proxies for other users and whether a user can grant the `PROXY` privilege to other users.

- The `default_roles` and `role_edges` tables contain information about role relationships.
- The `password_history` table retains previously chosen passwords to enable restrictions on password reuse. See [Section 8.2.15, “Password Management”](#).

The server reads the contents of the grant tables into memory when it starts. You can tell it to reload the tables by issuing a `FLUSH PRIVILEGES` statement or executing a `mysqladmin flush-privileges` or `mysqladmin reload` command. Changes to the grant tables take effect as indicated in [Section 8.2.13, “When Privilege Changes Take Effect”](#).

When you modify an account, it is a good idea to verify that your changes have the intended effect. To check the privileges for a given account, use the `SHOW GRANTS` statement. For example, to determine the privileges that are granted to an account with user name and host name values of `bob` and `pc84.example.com`, use this statement:

```
SHOW GRANTS FOR 'bob'@'pc84.example.com';
```

To display nonprivilege properties of an account, use `SHOW CREATE USER`:

```
SHOW CREATE USER 'bob'@'pc84.example.com';
```

## The user and db Grant Tables

The server uses the `user` and `db` tables in the `mysql` database at both the first and second stages of access control (see [Section 8.2, “Access Control and Account Management”](#)). The columns in the `user` and `db` tables are shown here.

**Table 8.4 user and db Table Columns**

Table Name	<code>user</code>	<code>db</code>
<b>Scope columns</b>		
	Host	Host
	User	Db
		User
<b>Privilege columns</b>	Select_priv	Select_priv
	Insert_priv	Insert_priv
	Update_priv	Update_priv
	Delete_priv	Delete_priv
	Index_priv	Index_priv
	Alter_priv	Alter_priv
	Create_priv	Create_priv
	Drop_priv	Drop_priv
	Grant_priv	Grant_priv
	Create_view_priv	Create_view_priv
	Show_view_priv	Show_view_priv
	Create_routine_priv	Create_routine_priv
	Alter_routine_priv	Alter_routine_priv
	Execute_priv	Execute_priv
	Trigger_priv	Trigger_priv

Table Name	user	db
	Event_priv	Event_priv
	Create_tmp_table_priv	Create_tmp_table_priv
	Lock_tables_priv	Lock_tables_priv
	References_priv	References_priv
	Reload_priv	
	Shutdown_priv	
	Process_priv	
	File_priv	
	Show_db_priv	
	Super_priv	
	Repl_slave_priv	
	Repl_client_priv	
	Create_user_priv	
	Create_tablespace_priv	
	Create_role_priv	
	Drop_role_priv	
Security columns	ssl_type	
	ssl_cipher	
	x509_issuer	
	x509_subject	
	plugin	
	authentication_string	
	password_expired	
	password_last_changed	
	password_lifetime	
	account_locked	
	Password_reuse_history	
	Password_reuse_time	
	Password_require_current	
	User_attributes	
Resource control columns	max_questions	
	max_updates	
	max_connections	
	max_user_connections	

The `user` table `plugin` and `authentication_string` columns store authentication plugin and credential information.

The server uses the plugin named in the `plugin` column of an account row to authenticate connection attempts for the account.

The `plugin` column must be nonempty. At startup, and at runtime when `FLUSH PRIVILEGES` is executed, the server checks `user` table rows. For any row with an empty `plugin` column, the server writes a warning to the error log of this form:

```
[Warning] User entry 'user_name'@'host_name' has an empty plugin
value. The user will be ignored and no one can login with this user
anymore.
```

To assign a plugin to an account that is missing one, use the `ALTER USER` statement.

The `password_expired` column permits DBAs to expire account passwords and require users to reset their password. The default `password_expired` value is `'N'`, but can be set to `'Y'` with the `ALTER USER` statement. After an account's password has been expired, all operations performed by the account in subsequent connections to the server result in an error until the user issues an `ALTER USER` statement to establish a new account password.

#### Note

Although it is possible to “reset” an expired password by setting it to its current value, it is preferable, as a matter of good policy, to choose a different password. DBAs can enforce non-reuse by establishing an appropriate password-reuse policy. See [Password Reuse Policy](#).

`password_last_changed` is a `TIMESTAMP` column indicating when the password was last changed. The value is non-`NULL` only for accounts that use a MySQL built-in authentication plugin (`sha256_password` or `caching_sha2_password`). The value is `NULL` for other accounts, such as those authenticated using an external authentication system.

`password_last_changed` is updated by the `CREATE USER`, `ALTER USER`, and `SET PASSWORD` statements, and by `GRANT` statements that create an account or change an account password.

`password_lifetime` indicates the account password lifetime, in days. If the password is past its lifetime (assessed using the `password_last_changed` column), the server considers the password expired when clients connect using the account. A value of `N` greater than zero means that the password must be changed every `N` days. A value of 0 disables automatic password expiration. If the value is `NULL` (the default), the global expiration policy applies, as defined by the `default_password_lifetime` system variable.

`account_locked` indicates whether the account is locked (see [Section 8.2.20, “Account Locking”](#)).

`Password_reuse_history` is the value of the `PASSWORD HISTORY` option for the account, or `NULL` for the default history.

`Password_reuse_time` is the value of the `PASSWORD REUSE INTERVAL` option for the account, or `NULL` for the default interval.

`Password_require_current` corresponds to the value of the `PASSWORD REQUIRE` option for the account, as shown by the following table.

**Table 8.5 Permitted Password\_require\_current Values**

Password_require_current Value	Corresponding PASSWORD REQUIRE Option
<code>'Y'</code>	<code>PASSWORD REQUIRE CURRENT</code>
<code>'N'</code>	<code>PASSWORD REQUIRE CURRENT OPTIONAL</code>

Password_require_current Value	Corresponding PASSWORD REQUIRE Option
NULL	PASSWORD REQUIRE CURRENT DEFAULT

`User_attributes` is a JSON-format column that stores account attributes not stored in other columns. The `INFORMATION_SCHEMA` exposes these attributes through the `USER_ATTRIBUTES` table.

The `User_attributes` column may contain these attributes:

- `additional_password`: The secondary password, if any. See [Dual Password Support](#).
- `Restrictions`: Restriction lists, if any. Restrictions are added by partial-revoke operations. The attribute value is an array of elements that each have `Database` and `Restrictions` keys indicating the name of a restricted database and the applicable restrictions on it (see [Section 8.2.12, “Privilege Restriction Using Partial Revokes”](#)).
- `Password_locking`: The conditions for failed-login tracking and temporary account locking, if any (see [Failed-Login Tracking and Temporary Account Locking](#)). The `Password_locking` attribute is updated according to the `FAILED_LOGIN_ATTEMPTS` and `PASSWORD_LOCK_TIME` options of the `CREATE USER` and `ALTER USER` statements. The attribute value is a hash with `failed_login_attempts` and `password_lock_time_days` keys indicating the value of such options as have been specified for the account. If a key is missing, its value is implicitly 0. If a key value is implicitly or explicitly 0, the corresponding capability is disabled.
- `multi_factor_authentication`: Rows in the `mysql.user` system table have a `plugin` column that indicates an authentication plugin. For single-factor authentication, that plugin is the only authentication factor. For two-factor or three-factor forms of multifactor authentication, that plugin corresponds to the first authentication factor, but additional information must be stored for the second and third factors. The `multi_factor_authentication` attribute holds this information.

The `multi_factor_authentication` value is an array, where each array element is a hash that describes an authentication factor using these attributes:

- `plugin`: The name of the authentication plugin.
- `authentication_string`: The authentication string value.
- `passwordless`: A flag that denotes whether the user is meant to be used without a password (with a security token as the only authentication method).
- `requires_registration`: a flag that defines whether the user account has registered a security token.

The first and second array elements describe multifactor authentication factors 2 and 3.

If no attributes apply, `User_attributes` is `NULL`.

Example: An account that has a secondary password and partially revoked database privileges has `additional_password` and `Restrictions` attributes in the column value:

```
mysql> SELECT User_attributes FROM mysql.User WHERE User = 'u'\G
***** 1. row *****
User_attributes: {"Restrictions":
 [{"Database": "mysql", "Privileges": ["SELECT"]}],
 "additional_password": "hashed_credentials"}
```

To determine which attributes are present, use the `JSON_KEYS()` function:

```
SELECT User, Host, JSON_KEYS(User_attributes)
```

```
FROM mysql.user WHERE User_attributes IS NOT NULL;
```

To extract a particular attribute, such as [Restrictions](#), do this:

```
SELECT User, Host, User_attributes->>'$.Restrictions'
FROM mysql.user WHERE User_attributes->>'$.Restrictions' <> '';
```

Here is an example of the kind of information stored for [multi\\_factor\\_authentication](#):

```
{
 "multi_factor_authentication": [
 {
 "plugin": "authentication_ldap_simple",
 "passwordless": 0,
 "authentication_string": "ldap auth string",
 "requires_registration": 0
 },
 {
 "plugin": "authentication_webauthn",
 "passwordless": 0,
 "authentication_string": "",
 "requires_registration": 1
 }
]
}
```

## The tables\_priv and columns\_priv Grant Tables

During the second stage of access control, the server performs request verification to ensure that each client has sufficient privileges for each request that it issues. In addition to the [user](#) and [db](#) grant tables, the server may also consult the [tables\\_priv](#) and [columns\\_priv](#) tables for requests that involve tables. The latter tables provide finer privilege control at the table and column levels. They have the columns shown in the following table.

**Table 8.6 tables\_priv and columns\_priv Table Columns**

Table Name	<a href="#">tables_priv</a>	<a href="#">columns_priv</a>
<b>Scope columns</b>	<a href="#">Host</a>	<a href="#">Host</a>
	<a href="#">Db</a>	<a href="#">Db</a>
	<a href="#">User</a>	<a href="#">User</a>
	<a href="#">Table_name</a>	<a href="#">Table_name</a>
		<a href="#">Column_name</a>
<b>Privilege columns</b>	<a href="#">Table_priv</a>	<a href="#">Column_priv</a>
	<a href="#">Column_priv</a>	
<b>Other columns</b>	<a href="#">Timestamp</a>	<a href="#">Timestamp</a>
	<a href="#">Grantor</a>	

The [Timestamp](#) and [Grantor](#) columns are set to the current timestamp and the [CURRENT\\_USER](#) value, respectively, but are otherwise unused.

## The procs\_priv Grant Table

For verification of requests that involve stored routines, the server may consult the [procs\\_priv](#) table, which has the columns shown in the following table.

**Table 8.7 procs\_priv Table Columns**

<b>Table Name</b>	<code>procs_priv</code>
<b>Scope columns</b>	<code>Host</code>
	<code>Db</code>
	<code>User</code>
	<code>Routine_name</code>
	<code>Routine_type</code>
<b>Privilege columns</b>	<code>Proc_priv</code>
<b>Other columns</b>	<code>Timestamp</code>
	<code>Grantor</code>

The `Routine_type` column is an `ENUM` column with values of `'FUNCTION'` or `'PROCEDURE'` to indicate the type of routine the row refers to. This column enables privileges to be granted separately for a function and a procedure with the same name.

The `Timestamp` and `Grantor` columns are unused.

## The proxies\_priv Grant Table

The `proxies_priv` table records information about proxy accounts. It has these columns:

- `Host`, `User`: The proxy account; that is, the account that has the `PROXY` privilege for the proxied account.
- `Proxied_host`, `Proxied_user`: The proxied account.
- `Grantor`, `Timestamp`: Unused.
- `With_grant`: Whether the proxy account can grant the `PROXY` privilege to other accounts.

For an account to be able to grant the `PROXY` privilege to other accounts, it must have a row in the `proxies_priv` table with `With_grant` set to 1 and `Proxied_host` and `Proxied_user` set to indicate the account or accounts for which the privilege can be granted. For example, the `'root'@'localhost'` account created during MySQL installation has a row in the `proxies_priv` table that enables granting the `PROXY` privilege for `'@'`, that is, for all users and all hosts. This enables `root` to set up proxy users, as well as to delegate to other accounts the authority to set up proxy users. See [Section 8.2.19, “Proxy Users”](#).

## The global\_grants Grant Table

The `global_grants` table lists current assignments of dynamic global privileges to user accounts. The table has these columns:

- `USER`, `HOST`: The user name and host name of the account to which the privilege is granted.
- `PRIV`: The privilege name.
- `WITH_GRANT_OPTION`: Whether the account can grant the privilege to other accounts.

## The default\_roles Grant Table

The `default_roles` table lists default user roles. It has these columns:

- `HOST`, `USER`: The account or role to which the default role applies.
- `DEFAULT_ROLE_HOST`, `DEFAULT_ROLE_USER`: The default role.

## The `role_edges` Grant Table

The `role_edges` table lists edges for role subgraphs. It has these columns:

- `FROM_HOST`, `FROM_USER`: The account that is granted a role.
- `TO_HOST`, `TO_USER`: The role that is granted to the account.
- `WITH_ADMIN_OPTION`: Whether the account can grant the role to and revoke it from other accounts by using `WITH ADMIN OPTION`.

## The `password_history` Grant Table

The `password_history` table contains information about password changes. It has these columns:

- `Host`, `User`: The account for which the password change occurred.
- `Password_timestamp`: The time when the password change occurred.
- `Password`: The new password hash value.

The `password_history` table accumulates a sufficient number of nonempty passwords per account to enable MySQL to perform checks against both the account password history length and reuse interval. Automatic pruning of entries that are outside both limits occurs when password-change attempts occur.

### Note

The empty password does not count in the password history and is subject to reuse at any time.

If an account is renamed, its entries are renamed to match. If an account is dropped or its authentication plugin is changed, its entries are removed.

## Grant Table Scope Column Properties

Scope columns in the grant tables contain strings. The default value for each is the empty string. The following table shows the number of characters permitted in each column.

**Table 8.8 Grant Table Scope Column Lengths**

Column Name	Maximum Permitted Characters
<code>Host</code> , <code>Proxied_host</code>	255
<code>User</code> , <code>Proxied_user</code>	32
<code>Db</code>	64
<code>Table_name</code>	64
<code>Column_name</code>	64
<code>Routine_name</code>	64

`Host` and `Proxied_host` values are converted to lowercase before being stored in the grant tables.

For access-checking purposes, comparisons of `User`, `Proxied_user`, `authentication_string`, `Db`, and `Table_name` values are case-sensitive. Comparisons of `Host`, `Proxied_host`, `Column_name`, and `Routine_name` values are not case-sensitive.

## Grant Table Privilege Column Properties

The `user` and `db` tables list each privilege in a separate column that is declared as `ENUM( 'N', 'Y' ) DEFAULT 'N'`. In other words, each privilege can be disabled or enabled, with the default being disabled.

The `tables_priv`, `columns_priv`, and `procs_priv` tables declare the privilege columns as `SET` columns. Values in these columns can contain any combination of the privileges controlled by the table. Only those privileges listed in the column value are enabled.

**Table 8.9 Set-Type Privilege Column Values**

Table Name	Column Name	Possible Set Elements
<code>tables_priv</code>	<code>Table_priv</code>	'Select', 'Insert', 'Update', 'Delete', 'Create', 'Drop', 'Grant', 'References', 'Index', 'Alter', 'Create View', 'Show view', 'Trigger'
<code>tables_priv</code>	<code>Column_priv</code>	'Select', 'Insert', 'Update', 'References'
<code>columns_priv</code>	<code>Column_priv</code>	'Select', 'Insert', 'Update', 'References'
<code>procs_priv</code>	<code>Proc_priv</code>	'Execute', 'Alter Routine', 'Grant'

Only the `user` and `global_grants` tables specify administrative privileges, such as `RELOAD`, `SHUTDOWN`, and `SYSTEM_VARIABLES_ADMIN`. Administrative operations are operations on the server itself and are not database-specific, so there is no reason to list these privileges in the other grant tables. Consequently, the server need consult only the `user` and `global_grants` tables to determine whether a user can perform an administrative operation.

The `FILE` privilege also is specified only in the `user` table. It is not an administrative privilege as such, but a user's ability to read or write files on the server host is independent of the database being accessed.

## Grant Table Concurrency

To permit concurrent DML and DDL operations on MySQL grant tables, read operations that previously acquired row locks on MySQL grant tables are executed as non-locking reads. Operations that are performed as non-locking reads on MySQL grant tables include:

- `SELECT` statements and other read-only statements that read data from grant tables through join lists and subqueries, including `SELECT ... FOR SHARE` statements, using any transaction isolation level.
- DML operations that read data from grant tables (through join lists or subqueries) but do not modify them, using any transaction isolation level.

Statements that no longer acquire row locks when reading data from grant tables report a warning if executed while using statement-based replication.

When using `-binlog_format=mixed`, DML operations that read data from grant tables are written to the binary log as row events to make the operations safe for mixed-mode replication.

`SELECT ... FOR SHARE` statements that read data from grant tables report a warning. With the `FOR SHARE` clause, read locks are not supported on grant tables.

DML operations that read data from grant tables and are executed using the `SERIALIZABLE` isolation level report a warning. Read locks that would normally be acquired when using the `SERIALIZABLE` isolation level are not supported on grant tables.

## 8.2.4 Specifying Account Names

MySQL account names consist of a user name and a host name, which enables creation of distinct accounts for users with the same user name who connect from different hosts. This section describes the syntax for account names, including special values and wildcard rules.

In most respects, account names are similar to MySQL role names, with some differences described at [Section 8.2.5, “Specifying Role Names”](#).

Account names appear in SQL statements such as `CREATE USER`, `GRANT`, and `SET PASSWORD` and follow these rules:

- Account name syntax is `'user_name'@'host_name'`.
- The `@'host_name'` part is optional. An account name consisting only of a user name is equivalent to `'user_name'@' % '`. For example, `'me'` is equivalent to `'me'@' % '`.
- The user name and host name need not be quoted if they are legal as unquoted identifiers. Quotes must be used if a `user_name` string contains special characters (such as space or `-`), or a `host_name` string contains special characters or wildcard characters (such as `.` or `%`). For example, in the account name `'test-user'@' % .com '`, both the user name and host name parts require quotes.
- Quote user names and host names as identifiers or as strings, using either backticks (```), single quotation marks (`'`), or double quotation marks (`"`). For string-quoting and identifier-quoting guidelines, see [Section 11.1.1, “String Literals”](#), and [Section 11.2, “Schema Object Names”](#). In `SHOW` statement results, user names and host names are quoted using backticks (```).
- The user name and host name parts, if quoted, must be quoted separately. That is, write `'me'@'localhost'`, not `'me@localhost'`. (The latter is actually equivalent to `'me@localhost'@' % '`, although this behavior is now deprecated.)
- A reference to the `CURRENT_USER` or `CURRENT_USER()` function is equivalent to specifying the current client's user name and host name literally.

MySQL stores account names in grant tables in the `mysql` system database using separate columns for the user name and host name parts:

- The `user` table contains one row for each account. The `User` and `Host` columns store the user name and host name. This table also indicates which global privileges the account has.
- Other grant tables indicate privileges an account has for databases and objects within databases. These tables have `User` and `Host` columns to store the account name. Each row in these tables associates with the account in the `user` table that has the same `User` and `Host` values.
- For access-checking purposes, comparisons of User values are case-sensitive. Comparisons of Host values are not case-sensitive.

For additional detail about the properties of user names and host names as stored in the grant tables, such as maximum length, see [Grant Table Scope Column Properties](#).

User names and host names have certain special values or wildcard conventions, as described following.

The user name part of an account name is either a nonblank value that literally matches the user name for incoming connection attempts, or a blank value (the empty string) that matches any user name. An account with a blank user name is an anonymous user. To specify an anonymous user in SQL statements, use a quoted empty user name part, such as `'@'localhost'`.

The host name part of an account name can take many forms, and wildcards are permitted:

- A host value can be a host name or an IP address (IPv4 or IPv6). The name `'localhost'` indicates the local host. The IP address `'127.0.0.1'` indicates the IPv4 loopback interface. The IP address `:::1` indicates the IPv6 loopback interface.
- Use of the `%` and `_` wildcard characters is permitted in host name or IP address values, but is deprecated and thus subject to removal in a future version of MySQL. These characters have the same meaning as for pattern-matching operations performed with the `LIKE` operator. For example, a host value of `'%'` matches any host name, whereas a value of `'%.mysql.com'` matches any host in the `mysql.com` domain. `'198.51.100.%'` matches any host in the 198.51.100 class C network.

Because IP wildcard values are permitted in host values (for example, `'198.51.100.%'` to match every host on a subnet), someone could try to exploit this capability by naming a host `198.51.100.somewhere.com`. To foil such attempts, MySQL does not perform matching on host names that start with digits and a dot. For example, if a host is named `1.2.example.com`, its name never matches the host part of account names. An IP wildcard value can match only IP addresses, not host names.

If `partial_revokes` is `ON`, MySQL treats `%` and `_` in grants as literal characters, and not as wildcards. Use of these wildcards is deprecated (regardless of this variable's value); you should expect this functionality to be removed in a future version of MySQL.

- For a host value specified as an IPv4 address, a netmask can be given to indicate how many address bits to use for the network number. Netmask notation cannot be used for IPv6 addresses.

The syntax is `host_ip/netmask`. For example:

```
CREATE USER 'david'@'198.51.100.0/255.255.255.0';
```

This enables `david` to connect from any client host having an IP address `client_ip` for which the following condition is true:

```
client_ip & netmask = host_ip
```

That is, for the `CREATE USER` statement just shown:

```
client_ip & 255.255.255.0 = 198.51.100.0
```

IP addresses that satisfy this condition range from `198.51.100.0` to `198.51.100.255`.

A netmask typically begins with bits set to 1, followed by bits set to 0. Examples:

- `198.0.0.0/255.0.0.0`: Any host on the 198 class A network
- `198.51.0.0/255.255.0.0`: Any host on the 198.51 class B network
- `198.51.100.0/255.255.255.0`: Any host on the 198.51.100 class C network
- `198.51.100.1`: Only the host with this specific IP address
- A host value specified as an IPv4 address can be written using CIDR notation, such as `198.51.100.44/24`.

The server performs matching of host values in account names against the client host using the value returned by the system DNS resolver for the client host name or IP address. Except in the case that the account host value is specified using netmask notation, the server performs this comparison as a string match, even for an account host value given as an IP address. This means that you should specify account host values in the same format used by DNS. Here are examples of problems to watch out for:

- Suppose that a host on the local network has a fully qualified name of `host1.example.com`. If DNS returns name lookups for this host as `host1.example.com`, use that name in account host values. If DNS returns just `host1`, use `host1` instead.
- If DNS returns the IP address for a given host as `198.51.100.2`, that matches an account host value of `198.51.100.2` but not `198.051.100.2`. Similarly, it matches an account host pattern like `198.51.100.%` but not `198.051.100.%`.

To avoid problems like these, it is advisable to check the format in which your DNS returns host names and addresses. Use values in the same format in MySQL account names.

## 8.2.5 Specifying Role Names

MySQL role names refer to roles, which are named collections of privileges. For role usage examples, see [Section 8.2.10, “Using Roles”](#).

Role names have syntax and semantics similar to account names; see [Section 8.2.4, “Specifying Account Names”](#). As stored in the grant tables, they have the same properties as account names, which are described in [Grant Table Scope Column Properties](#).

Role names differ from account names in these respects:

- The user part of role names cannot be blank. Thus, there is no “anonymous role” analogous to the concept of “anonymous user.”
- As for an account name, omitting the host part of a role name results in a host part of `'%'`. But unlike `'%'` in an account name, a host part of `'%'` in a role name has no wildcard properties. For example, for a name `'me'@'%'` used as a role name, the host part (`'%'`) is just a literal value; it has no “any host” matching property.
- Netmask notation in the host part of a role name has no significance.
- An account name is permitted to be `CURRENT_USER()` in several contexts. A role name is not.

It is possible for a row in the `mysql.user` system table to serve as both an account and a role. In this case, any special user or host name matching properties do not apply in contexts for which the name is used as a role name. For example, you cannot execute the following statement with the expectation that it sets the current session roles using all roles that have a user part of `myrole` and any host name:

```
SET ROLE 'myrole'@'%' ;
```

Instead, the statement sets the active role for the session to the role with exactly the name `'myrole'@'%'`.

For this reason, role names are often specified using only the user name part and letting the host name part implicitly be `'%'`. Specifying a role with a non-`'%'` host part can be useful if you intend to create a name that works both as a role and as a user account that is permitted to connect from the given host.

## 8.2.6 Access Control, Stage 1: Connection Verification

When you attempt to connect to a MySQL server, the server accepts or rejects the connection based on these conditions:

- Your identity and whether you can verify it by supplying the proper credentials.
- Whether your account is locked or unlocked.

The server checks credentials first, then account locking state. A failure at either step causes the server to deny access to you completely. Otherwise, the server accepts the connection, and then enters Stage 2 and waits for requests.

The server performs identity and credentials checking using columns in the `user` table, accepting the connection only if these conditions are satisfied:

- The client host name and user name match the `Host` and `User` columns in some `user` table row. For the rules governing permissible `Host` and `User` values, see [Section 8.2.4, “Specifying Account Names”](#).
- The client supplies the credentials specified in the row (for example, a password), as indicated by the `authentication_string` column. Credentials are interpreted using the authentication plugin named in the `plugin` column.
- The row indicates that the account is unlocked. Locking state is recorded in the `account_locked` column, which must have a value of `'N'`. Account locking can be set or changed with the `CREATE USER` or `ALTER USER` statement.

Your identity is based on two pieces of information:

- Your MySQL user name.
- The client host from which you connect.

If the `User` column value is nonblank, the user name in an incoming connection must match exactly. If the `User` value is blank, it matches any user name. If the `user` table row that matches an incoming connection has a blank user name, the user is considered to be an anonymous user with no name, not a user with the name that the client actually specified. This means that a blank user name is used for all further access checking for the duration of the connection (that is, during Stage 2).

The `authentication_string` column can be blank. This is not a wildcard and does not mean that any password matches. It means that the user must connect without specifying a password. The authentication method implemented by the plugin that authenticates the client may or may not use the password in the `authentication_string` column. In this case, it is possible that an external password is also used to authenticate to the MySQL server.

Nonblank password values stored in the `authentication_string` column of the `user` table are encrypted. MySQL does not store passwords as cleartext for anyone to see. Rather, the password supplied by a user who is attempting to connect is encrypted (using the password hashing method implemented by the account authentication plugin). The encrypted password then is used during the connection process when checking whether the password is correct. This is done without the encrypted password ever traveling over the connection. See [Section 8.2.1, “Account User Names and Passwords”](#).

From the MySQL server's point of view, the encrypted password is the *real* password, so you should never give anyone access to it. In particular, *do not give nonadministrative users read access to tables in the `mysql` system database*.

The following table shows how various combinations of `User` and `Host` values in the `user` table apply to incoming connections.

User Value	Host Value	Permissible Connections
'fred'	'h1.example.net'	fred, connecting from h1.example.net
' '	'h1.example.net'	Any user, connecting from h1.example.net
'fred'	'%'	fred, connecting from any host
' '	'%'	Any user, connecting from any host
'fred'	'%.example.net'	fred, connecting from any host in the example.net domain
'fred'	'x.example.%'	fred, connecting from x.example.net, x.example.com, x.example.edu, and so on; this is probably not useful
'fred'	'198.51.100.177'	fred, connecting from the host with IP address 198.51.100.177
'fred'	'198.51.100.%'	fred, connecting from any host in the 198.51.100 class C subnet
'fred'	'198.51.100.0/255.255.255.0'	Same as previous example

It is possible for the client host name and user name of an incoming connection to match more than one row in the `user` table. The preceding set of examples demonstrates this: Several of the entries shown match a connection from `h1.example.net` by `fred`.

When multiple matches are possible, the server must determine which of them to use. It resolves this issue as follows:

- Whenever the server reads the `user` table into memory, it sorts the rows.
- When a client attempts to connect, the server looks through the rows in sorted order.
- The server uses the first row that matches the client host name and user name.

The server uses sorting rules that order rows with the most-specific `Host` values first:

- Literal IP addresses and host names are the most specific.
- Accounts with an IP address in the host part have this order of specificity:
  - Accounts that have the host part given as an IP address:

```
CREATE USER 'user_name'@'127.0.0.1';
CREATE USER 'user_name'@'198.51.100.44';
```

- Accounts that have the host part given as an IP address using CIDR notation:

```
CREATE USER 'user_name'@'192.0.2.21/8';
CREATE USER 'user_name'@'198.51.100.44/16';
```

- Accounts that have the host part given as an IP address with a subnet mask:

```
CREATE USER 'user_name'@'192.0.2.0/255.255.255.0';
```

```
CREATE USER 'user_name'@'198.51.0.0/255.255.0.0';
```

- The pattern '%' means “any host” and is least specific.
- The empty string '' also means “any host” but sorts after '%’.

Non-TCP (socket file, named pipe, and shared memory) connections are treated as local connections and match a host part of `localhost` if there are any such accounts, or host parts with wildcards that match `localhost` otherwise (for example, `local%`, `l%`, `%`).

The treatment of '%' as equivalent to `localhost` is deprecated; you should expect this behavior to be removed from a future version of MySQL.

Rows with the same `Host` value are ordered with the most-specific `User` values first. A blank `User` value means “any user” and is least specific, so for rows with the same `Host` value, nonanonymous users sort before anonymous users.

For rows with equally-specific `Host` and `User` values, the order is nondeterministic.

To see how this works, suppose that the `user` table looks like this:

Host	User	...
%	root	...
%	jeffrey	...
localhost	root	...
localhost		...

When the server reads the table into memory, it sorts the rows using the rules just described. The result after sorting looks like this:

Host	User	...
localhost	root	...
localhost		...
%	jeffrey	...
%	root	...

When a client attempts to connect, the server looks through the sorted rows and uses the first match found. For a connection from `localhost` by `jeffrey`, two of the rows from the table match: the one with `Host` and `User` values of '`localhost`' and '', and the one with values of '%' and '`jeffrey`'. The '`localhost`' row appears first in sorted order, so that is the one the server uses.

Here is another example. Suppose that the `user` table looks like this:

Host	User	...
%	jeffrey	...
h1.example.net		...

The sorted table looks like this:

Host	User	...
------	------	-----

```

+-----+-----+
| h1.example.net | | ...
| % | jeffrey | ...
+-----+-----+

```

The first row matches a connection by any user from `h1.example.net`, whereas the second row matches a connection by `jeffrey` from any host.

#### Note

It is a common misconception to think that, for a given user name, all rows that explicitly name that user are used first when the server attempts to find a match for the connection. This is not true. The preceding example illustrates this, where a connection from `h1.example.net` by `jeffrey` is first matched not by the row containing '`jeffrey`' as the `User` column value, but by the row with no user name. As a result, `jeffrey` is authenticated as an anonymous user, even though he specified a user name when connecting.

If you are able to connect to the server, but your privileges are not what you expect, you probably are being authenticated as some other account. To find out what account the server used to authenticate you, use the `CURRENT_USER()` function. (See [Section 14.15, “Information Functions”](#).) It returns a value in `user_name@host_name` format that indicates the `User` and `Host` values from the matching `user` table row. Suppose that `jeffrey` connects and issues the following query:

```

mysql> SELECT CURRENT_USER();
+-----+
| CURRENT_USER() |
+-----+
| @localhost |
+-----+

```

The result shown here indicates that the matching `user` table row had a blank `User` column value. In other words, the server is treating `jeffrey` as an anonymous user.

Another way to diagnose authentication problems is to print out the `user` table and sort it by hand to see where the first match is being made.

## 8.2.7 Access Control, Stage 2: Request Verification

After the server accepts a connection, it enters Stage 2 of access control. For each request that you issue through the connection, the server determines what operation you want to perform, then checks whether your privileges are sufficient. This is where the privilege columns in the grant tables come into play. These privileges can come from any of the `user`, `global_grants`, `db`, `tables_priv`, `columns_priv`, or `procs_priv` tables. (You may find it helpful to refer to [Section 8.2.3, “Grant Tables”](#), which lists the columns present in each grant table.)

The `user` and `global_grants` tables grant global privileges. The rows in these tables for a given account indicate the account privileges that apply on a global basis no matter what the default database is. For example, if the `user` table grants you the `DELETE` privilege, you can delete rows from any table in any database on the server host. It is wise to grant privileges in the `user` table only to people who need them, such as database administrators. For other users, leave all privileges in the `user` table set to '`N`' and grant privileges at more specific levels only (for particular databases, tables, columns, or routines). It is also possible to grant database privileges globally but use partial revokes to restrict them from being exercised on specific databases (see [Section 8.2.12, “Privilege Restriction Using Partial Revokes”](#)).

The `db` table grants database-specific privileges. Values in the scope columns of this table can take the following forms:

- A blank `User` value matches the anonymous user. A nonblank value matches literally; there are no wildcards in user names.
- The wildcard characters `%` and `_` can be used in the `Host` and `Db` columns. These have the same meaning as for pattern-matching operations performed with the `LIKE` operator. If you want to use either character literally when granting privileges, you must escape it with a backslash. For example, to include the underscore character (`_`) as part of a database name, specify it as `\_` in the `GRANT` statement.
- A `'%'` or blank `Host` value means “any host.”
- A `'%'` or blank `Db` value means “any database.”

The server reads the `db` table into memory and sorts it at the same time that it reads the `user` table. The server sorts the `db` table based on the `Host`, `Db`, and `User` scope columns. As with the `user` table, sorting puts the most-specific values first and least-specific values last, and when the server looks for matching rows, it uses the first match that it finds.

The `tables_priv`, `columns_priv`, and `procs_priv` tables grant table-specific, column-specific, and routine-specific privileges. Values in the scope columns of these tables can take the following forms:

- The wildcard characters `%` and `_` can be used in the `Host` column. These have the same meaning as for pattern-matching operations performed with the `LIKE` operator.
- A `'%'` or blank `Host` value means “any host.”
- The `Db`, `Table_name`, `Column_name`, and `Routine_name` columns cannot contain wildcards or be blank.

The server sorts the `tables_priv`, `columns_priv`, and `procs_priv` tables based on the `Host`, `Db`, and `User` columns. This is similar to `db` table sorting, but simpler because only the `Host` column can contain wildcards.

The server uses the sorted tables to verify each request that it receives. For requests that require administrative privileges such as `SHUTDOWN` or `RELOAD`, the server checks only the `user` and `global_privilege` tables because those are the only tables that specify administrative privileges. The server grants access if a row for the account in those tables permits the requested operation and denies access otherwise. For example, if you want to execute `mysqladmin shutdown` but your `user` table row does not grant the `SHUTDOWN` privilege to you, the server denies access without even checking the `db` table. (The latter table contains no `Shutdown_priv` column, so there is no need to check it.)

For database-related requests (`INSERT`, `UPDATE`, and so on), the server first checks the user's global privileges in the `user` table row (less any privilege restrictions imposed by partial revokes). If the row permits the requested operation, access is granted. If the global privileges in the `user` table are insufficient, the server determines the user's database-specific privileges from the `db` table:

- The server looks in the `db` table for a match on the `Host`, `Db`, and `User` columns.
- The `Host` and `User` columns are matched to the connecting user's host name and MySQL user name.
- The `Db` column is matched to the database that the user wants to access.
- If there is no row for the `Host` and `User`, access is denied.

After determining the database-specific privileges granted by the `db` table rows, the server adds them to the global privileges granted by the `user` table. If the result permits the requested operation, access

is granted. Otherwise, the server successively checks the user's table and column privileges in the `tables_priv` and `columns_priv` tables, adds those to the user's privileges, and permits or denies access based on the result. For stored-routine operations, the server uses the `procs_priv` table rather than `tables_priv` and `columns_priv`.

Expressed in boolean terms, the preceding description of how a user's privileges are calculated may be summarized like this:

```
global privileges
OR database privileges
OR table privileges
OR column privileges
OR routine privileges
```

It may not be apparent why, if the global privileges are initially found to be insufficient for the requested operation, the server adds those privileges to the database, table, and column privileges later. The reason is that a request might require more than one type of privilege. For example, if you execute an `INSERT INTO ... SELECT` statement, you need both the `INSERT` and the `SELECT` privileges. Your privileges might be such that the `user` table row grants one privilege global and the `db` table row grants the other specifically for the relevant database. In this case, you have the necessary privileges to perform the request, but the server cannot tell that from either your global or database privileges alone. It must make an access-control decision based on the combined privileges.

## 8.2.8 Adding Accounts, Assigning Privileges, and Dropping Accounts

To manage MySQL accounts, use the SQL statements intended for that purpose:

- `CREATE USER` and `DROP USER` create and remove accounts.
- `GRANT` and `REVOKE` assign privileges to and revoke privileges from accounts.
- `SHOW GRANTS` displays account privilege assignments.

Account-management statements cause the server to make appropriate modifications to the underlying grant tables, which are discussed in [Section 8.2.3, “Grant Tables”](#).

### Note

Direct modification of grant tables using statements such as `INSERT`, `UPDATE`, or `DELETE` is discouraged and done at your own risk. The server is free to ignore rows that become malformed as a result of such modifications.

For any operation that modifies a grant table, the server checks whether the table has the expected structure and produces an error if not. To update the tables to the expected structure, perform the MySQL upgrade procedure. See [Chapter 3, \*Upgrading MySQL\*](#).

Another option for creating accounts is to use the GUI tool MySQL Workbench. Also, several third-party programs offer capabilities for MySQL account administration. [phpMyAdmin](#) is one such program.

This section discusses the following topics:

- [Creating Accounts and Granting Privileges](#)
- [Checking Account Privileges and Properties](#)
- [Revoking Account Privileges](#)

- [Dropping Accounts](#)

For additional information about the statements discussed here, see [Section 15.7.1, “Account Management Statements”](#).

## Creating Accounts and Granting Privileges

The following examples show how to use the `mysql` client program to set up new accounts. These examples assume that the MySQL `root` account has the `CREATE USER` privilege and all privileges that it grants to other accounts.

At the command line, connect to the server as the MySQL `root` user, supplying the appropriate password at the password prompt:

```
$> mysql -u root -p
Enter password: (enter root password here)
```

After connecting to the server, you can add new accounts. The following example uses `CREATE USER` and `GRANT` statements to set up four accounts (where you see `'password'`, substitute an appropriate password):

```
CREATE USER 'finley'@'localhost'
 IDENTIFIED BY 'password';
GRANT ALL
 ON *.*
 TO 'finley'@'localhost'
 WITH GRANT OPTION;

CREATE USER 'finley'@'%.example.com'
 IDENTIFIED BY 'password';
GRANT ALL
 ON *.*
 TO 'finley'@'%.example.com'
 WITH GRANT OPTION;

CREATE USER 'admin'@'localhost'
 IDENTIFIED BY 'password';
GRANT RELOAD,PROCESS
 ON *.*
 TO 'admin'@'localhost';

CREATE USER 'dummy'@'localhost';
```

The accounts created by those statements have the following properties:

- Two accounts have a user name of `finley`. Both are superuser accounts with full global privileges to do anything. The `'finley'@'localhost'` account can be used only when connecting from the local host. The `'finley'@'%.example.com'` account uses the `'%'` wildcard in the host part, so it can be used to connect from any host in the `example.com` domain.

The `'finley'@'localhost'` account is necessary if there is an anonymous-user account for `localhost`. Without the `'finley'@'localhost'` account, that anonymous-user account takes precedence when `finley` connects from the local host and `finley` is treated as an anonymous user. The reason for this is that the anonymous-user account has a more specific `Host` column value than the `'finley'@'%'` account and thus comes earlier in the `user` table sort order. (For information about `user` table sorting, see [Section 8.2.6, “Access Control, Stage 1: Connection Verification”](#).)

- The `'admin'@'localhost'` account can be used only by `admin` to connect from the local host. It is granted the global `RELOAD` and `PROCESS` administrative privileges. These privileges enable the `admin` user to execute the `mysqladmin reload`, `mysqladmin refresh`, and `mysqladmin flush-xxx`

commands, as well as `mysqladmin processlist`. No privileges are granted for accessing any databases. You could add such privileges using `GRANT` statements.

- The `'dummy'@'localhost'` account has no password (which is insecure and not recommended). This account can be used only to connect from the local host. No privileges are granted. It is assumed that you grant specific privileges to the account using `GRANT` statements.

The previous example grants privileges at the global level. The next example creates three accounts and grants them access at lower levels; that is, to specific databases or objects within databases. Each account has a user name of `custom`, but the host name parts differ:

```
CREATE USER 'custom'@'localhost'
 IDENTIFIED BY 'password';
GRANT ALL
 ON bankaccount.*
 TO 'custom'@'localhost';

CREATE USER 'custom'@'host47.example.com'
 IDENTIFIED BY 'password';
GRANT SELECT,INSERT,UPDATE,DELETE,CREATE,DROP
 ON expenses.*
 TO 'custom'@'host47.example.com';

CREATE USER 'custom'@'%.example.com'
 IDENTIFIED BY 'password';
GRANT SELECT,INSERT,UPDATE,DELETE,CREATE,DROP
 ON customer.addresses
 TO 'custom'@'%.example.com';
```

The three accounts can be used as follows:

- The `'custom'@'localhost'` account has all database-level privileges to access the `bankaccount` database. The account can be used to connect to the server only from the local host.
- The `'custom'@'host47.example.com'` account has specific database-level privileges to access the `expenses` database. The account can be used to connect to the server only from the host `host47.example.com`.
- The `'custom'@'%.example.com'` account has specific table-level privileges to access the `addresses` table in the `customer` database, from any host in the `example.com` domain. The account can be used to connect to the server from all machines in the domain due to use of the `%` wildcard character in the host part of the account name.

## Checking Account Privileges and Properties

To see the privileges for an account, use `SHOW GRANTS`:

```
mysql> SHOW GRANTS FOR 'admin'@'localhost';
+-----+
| Grants for admin@localhost |
+-----+
| GRANT RELOAD, PROCESS ON *.* TO `admin`@`localhost` |
+-----+
```

To see nonprivilege properties for an account, use `SHOW CREATE USER`:

```
mysql> SET print_identified_with_as_hex = ON;
mysql> SHOW CREATE USER 'admin'@'localhost'\G
***** 1. row *****
CREATE USER for admin@localhost: CREATE USER `admin`@`localhost`
IDENTIFIED WITH 'caching_sha2_password'
```

```
AS 0x24412430303524301D0E17054E2241362B1419313C3E44326F294133734B30792F436E77764270373039612E32445250786D4
REQUIRE NONE PASSWORD EXPIRE DEFAULT ACCOUNT UNLOCK
PASSWORD HISTORY DEFAULT
PASSWORD REUSE INTERVAL DEFAULT
PASSWORD REQUIRE CURRENT DEFAULT
```

Enabling the `print_identified_with_as_hex` system variable causes `SHOW CREATE USER` to display hash values that contain unprintable characters as hexadecimal strings rather than as regular string literals.

## Revoking Account Privileges

To revoke account privileges, use the `REVOKE` statement. Privileges can be revoked at different levels, just as they can be granted at different levels.

Revoke global privileges:

```
REVOKE ALL
 ON *.*
 FROM 'finley'@'%.example.com';

REVOKE RELOAD
 ON *.*
 FROM 'admin'@'localhost';
```

Revoke database-level privileges:

```
REVOKE CREATE,DROP
 ON expenses.*
 FROM 'custom'@'host47.example.com';
```

Revoke table-level privileges:

```
REVOKE INSERT,UPDATE,DELETE
 ON customer.addresses
 FROM 'custom'@'%.example.com';
```

To check the effect of privilege revocation, use `SHOW GRANTS`:

```
mysql> SHOW GRANTS FOR 'admin'@'localhost';
+-----+
| Grants for admin@localhost |
+-----+
| GRANT PROCESS ON *.* TO `admin`@`localhost` |
+-----+
```

## Dropping Accounts

To remove an account, use the `DROP USER` statement. For example, to drop some of the accounts created previously:

```
DROP USER 'finley'@'localhost';
DROP USER 'finley'@'%.example.com';
DROP USER 'admin'@'localhost';
DROP USER 'dummy'@'localhost';
```

### 8.2.9 Reserved Accounts

One part of the MySQL installation process is data directory initialization (see [Section 2.9.1, “Initializing the Data Directory”](#)). During data directory initialization, MySQL creates user accounts that should be considered reserved:

- `'root'@'localhost'`: Used for administrative purposes. This account has all privileges, is a system account, and can perform any operation.

Strictly speaking, this account name is not reserved, in the sense that some installations rename the `root` account to something else to avoid exposing a highly privileged account with a well-known name.

- `'mysql.sys'@'localhost'`: Used as the `DEFINER` for `sys` schema objects. Use of the `mysql.sys` account avoids problems that occur if a DBA renames or removes the `root` account. This account is locked so that it cannot be used for client connections.
- `'mysql.session'@'localhost'`: Used internally by plugins to access the server. This account is locked so that it cannot be used for client connections. The account is a system account.
- `'mysql.infoschema'@'localhost'`: Used as the `DEFINER` for `INFORMATION_SCHEMA` views. Use of the `mysql.infoschema` account avoids problems that occur if a DBA renames or removes the `root` account. This account is locked so that it cannot be used for client connections.

## 8.2.10 Using Roles

A MySQL role is a named collection of privileges. Like user accounts, roles can have privileges granted to and revoked from them.

A user account can be granted roles, which grants to the account the privileges associated with each role. This enables assignment of sets of privileges to accounts and provides a convenient alternative to granting individual privileges, both for conceptualizing desired privilege assignments and implementing them.

The following list summarizes role-management capabilities provided by MySQL:

- `CREATE ROLE` and `DROP ROLE` create and remove roles.
- `GRANT` and `REVOKE` assign privileges to revoke privileges from user accounts and roles.
- `SHOW GRANTS` displays privilege and role assignments for user accounts and roles.
- `SET DEFAULT ROLE` specifies which account roles are active by default.
- `SET ROLE` changes the active roles within the current session.
- The `CURRENT_ROLE()` function displays the active roles within the current session.
- The `mandatory_roles` and `activate_all_roles_on_login` system variables enable defining mandatory roles and automatic activation of granted roles when users log in to the server.

For descriptions of individual role-manipulation statements (including the privileges required to use them), see [Section 15.7.1, “Account Management Statements”](#). The following discussion provides examples of role usage. Unless otherwise specified, SQL statements shown here should be executed using a MySQL account with sufficient administrative privileges, such as the `root` account.

- [Creating Roles and Granting Privileges to Them](#)
- [Defining Mandatory Roles](#)
- [Checking Role Privileges](#)
- [Activating Roles](#)
- [Revoking Roles or Role Privileges](#)

- [Dropping Roles](#)
- [User and Role Interchangeability](#)

## Creating Roles and Granting Privileges to Them

Consider this scenario:

- An application uses a database named `app_db`.
- Associated with the application, there can be accounts for developers who create and maintain the application, and for users who interact with it.
- Developers need full access to the database. Some users need only read access, others need read/write access.

To avoid granting privileges individually to possibly many user accounts, create roles as names for the required privilege sets. This makes it easy to grant the required privileges to user accounts, by granting the appropriate roles.

To create the roles, use the `CREATE ROLE` statement:

```
CREATE ROLE 'app_developer', 'app_read', 'app_write';
```

Role names are much like user account names and consist of a user part and host part in `'user_name'@'host_name'` format. The host part, if omitted, defaults to `'%'`. The user and host parts can be unquoted unless they contain special characters such as `-` or `%`. Unlike account names, the user part of role names cannot be blank. For additional information, see [Section 8.2.5, “Specifying Role Names”](#).

To assign privileges to the roles, execute `GRANT` statements using the same syntax as for assigning privileges to user accounts:

```
GRANT ALL ON app_db.* TO 'app_developer';
GRANT SELECT ON app_db.* TO 'app_read';
GRANT INSERT, UPDATE, DELETE ON app_db.* TO 'app_write';
```

Now suppose that initially you require one developer account, two user accounts that need read-only access, and one user account that needs read/write access. Use `CREATE USER` to create the accounts:

```
CREATE USER 'dev1'@'localhost' IDENTIFIED BY 'dev1pass';
CREATE USER 'read_user1'@'localhost' IDENTIFIED BY 'read_user1pass';
CREATE USER 'read_user2'@'localhost' IDENTIFIED BY 'read_user2pass';
CREATE USER 'rw_user1'@'localhost' IDENTIFIED BY 'rw_user1pass';
```

To assign each user account its required privileges, you could use `GRANT` statements of the same form as just shown, but that requires enumerating individual privileges for each user. Instead, use an alternative `GRANT` syntax that permits granting roles rather than privileges:

```
GRANT 'app_developer' TO 'dev1'@'localhost';
GRANT 'app_read' TO 'read_user1'@'localhost', 'read_user2'@'localhost';
GRANT 'app_read', 'app_write' TO 'rw_user1'@'localhost';
```

The `GRANT` statement for the `rw_user1` account grants the read and write roles, which combine to provide the required read and write privileges.

The `GRANT` syntax for granting roles to an account differs from the syntax for granting privileges: There is an `ON` clause to assign privileges, whereas there is no `ON` clause to assign roles. Because the syntaxes are distinct, you cannot mix assigning privileges and roles in the same statement. (It is permitted to assign

both privileges and roles to an account, but you must use separate [GRANT](#) statements, each with syntax appropriate to what is to be granted.) Roles cannot be granted to anonymous users.

A role when created is locked, has no password, and is assigned the default authentication plugin. (These role attributes can be changed later with the [ALTER USER](#) statement, by users who have the global [CREATE USER](#) privilege.)

While locked, a role cannot be used to authenticate to the server. If unlocked, a role can be used to authenticate. This is because roles and users are both authorization identifiers with much in common and little to distinguish them. See also [User and Role Interchangeability](#).

## Defining Mandatory Roles

It is possible to specify roles as mandatory by naming them in the value of the [mandatory\\_roles](#) system variable. The server treats a mandatory role as granted to all users, so that it need not be granted explicitly to any account.

To specify mandatory roles at server startup, define [mandatory\\_roles](#) in your server [my.cnf](#) file:

```
[mysqld]
mandatory_roles='role1,role2@localhost,r3@%.example.com'
```

To set and persist [mandatory\\_roles](#) at runtime, use a statement like this:

```
SET PERSIST mandatory_roles = 'role1,role2@localhost,r3@%.example.com';
```

[SET PERSIST](#) sets a value for the running MySQL instance. It also saves the value, causing it to carry over to subsequent server restarts. To change the value for the running MySQL instance without having it carry over to subsequent restarts, use the [GLOBAL](#) keyword rather than [PERSIST](#). See [Section 15.7.6.1, “SET Syntax for Variable Assignment”](#).

Setting [mandatory\\_roles](#) requires the [ROLE\\_ADMIN](#) privilege, in addition to the [SYSTEM\\_VARIABLES\\_ADMIN](#) privilege (or the deprecated [SUPER](#) privilege) normally required to set a global system variable.

Mandatory roles, like explicitly granted roles, do not take effect until activated (see [Activating Roles](#)). At login time, role activation occurs for all granted roles if the [activate\\_all\\_roles\\_on\\_login](#) system variable is enabled, or for roles that are set as default roles otherwise. At runtime, [SET ROLE](#) activates roles.

Roles named in the value of [mandatory\\_roles](#) cannot be revoked with [REVOKE](#) or dropped with [DROP ROLE](#) or [DROP USER](#).

To prevent sessions from being made system sessions by default, a role that has the [SYSTEM\\_USER](#) privilege cannot be listed in the value of the [mandatory\\_roles](#) system variable:

- If [mandatory\\_roles](#) is assigned a role at startup that has the [SYSTEM\\_USER](#) privilege, the server writes a message to the error log and exits.
- If [mandatory\\_roles](#) is assigned a role at runtime that has the [SYSTEM\\_USER](#) privilege, an error occurs and the [mandatory\\_roles](#) value remains unchanged.

Even with this safeguard, it is better to avoid granting the [SYSTEM\\_USER](#) privilege through a role in order to guard against the possibility of privilege escalation.

If a role named in [mandatory\\_roles](#) is not present in the [mysql.user](#) system table, the role is not granted to users. When the server attempts role activation for a user, it does not treat the nonexistent role

as mandatory and writes a warning to the error log. If the role is created later and thus becomes valid, `FLUSH PRIVILEGES` may be necessary to cause the server to treat it as mandatory.

`SHOW GRANTS` displays mandatory roles according to the rules described in [Section 15.7.7.22, “SHOW GRANTS Statement”](#).

## Checking Role Privileges

To verify the privileges assigned to an account, use `SHOW GRANTS`. For example:

```
mysql> SHOW GRANTS FOR 'dev1'@'localhost';
+-----+
| Grants for dev1@localhost |
+-----+
| GRANT USAGE ON *.* TO `dev1`@`localhost` |
| GRANT `app_developer`@`%` TO `dev1`@`localhost` |
+-----+
```

However, that shows each granted role without “expanding” it to the privileges the role represents. To show role privileges as well, add a `USING` clause naming the granted roles for which to display privileges:

```
mysql> SHOW GRANTS FOR 'dev1'@'localhost' USING 'app_developer';
+-----+
| Grants for dev1@localhost |
+-----+
| GRANT USAGE ON *.* TO `dev1`@`localhost` |
| GRANT ALL PRIVILEGES ON `app_db`.* TO `dev1`@`localhost` |
| GRANT `app_developer`@`%` TO `dev1`@`localhost` |
+-----+
```

Verify each other type of user similarly:

```
mysql> SHOW GRANTS FOR 'read_user1'@'localhost' USING 'app_read';
+-----+
| Grants for read_user1@localhost |
+-----+
| GRANT USAGE ON *.* TO `read_user1`@`localhost` |
| GRANT SELECT ON `app_db`.* TO `read_user1`@`localhost` |
| GRANT `app_read`@`%` TO `read_user1`@`localhost` |
+-----+
mysql> SHOW GRANTS FOR 'rw_user1'@'localhost' USING 'app_read', 'app_write';
+-----+
| Grants for rw_user1@localhost |
+-----+
| GRANT USAGE ON *.* TO `rw_user1`@`localhost` |
| GRANT SELECT, INSERT, UPDATE, DELETE ON `app_db`.* TO `rw_user1`@`localhost` |
| GRANT `app_read`@`%`,`app_write`@`%` TO `rw_user1`@`localhost` |
+-----+
```

`SHOW GRANTS` displays mandatory roles according to the rules described in [Section 15.7.7.22, “SHOW GRANTS Statement”](#).

## Activating Roles

Roles granted to a user account can be active or inactive within account sessions. If a granted role is active within a session, its privileges apply; otherwise, they do not. To determine which roles are active within the current session, use the `CURRENT_ROLE()` function.

By default, granting a role to an account or naming it in the `mandatory_roles` system variable value does not automatically cause the role to become active within account sessions. For example, because thus far in the preceding discussion no `rw_user1` roles have been activated, if you connect to the server as `rw_user1` and invoke the `CURRENT_ROLE()` function, the result is `NONE` (no active roles):

```
mysql> SELECT CURRENT_ROLE();
```

```
+-----+
| CURRENT_ROLE() |
+-----+
| NONE |
+-----+
```

To specify which roles should become active each time a user connects to the server and authenticates, use `SET DEFAULT ROLE`. To set the default to all assigned roles for each account created earlier, use this statement:

```
SET DEFAULT ROLE ALL TO
 'dev1'@'localhost',
 'read_user1'@'localhost',
 'read_user2'@'localhost',
 'rw_user1'@'localhost';
```

Now if you connect as `rw_user1`, the initial value of `CURRENT_ROLE()` reflects the new default role assignments:

```
mysql> SELECT CURRENT_ROLE();
```

```
+-----+
| CURRENT_ROLE() |
+-----+
| `app_read`@`%`,`app_write`@`%` |
+-----+
```

To cause all explicitly granted and mandatory roles to be automatically activated when users connect to the server, enable the `activate_all_roles_on_login` system variable. By default, automatic role activation is disabled.

Within a session, a user can execute `SET ROLE` to change the set of active roles. For example, for `rw_user1`:

```
mysql> SET ROLE NONE; SELECT CURRENT_ROLE();
```

```
+-----+
| CURRENT_ROLE() |
+-----+
| NONE |
+-----+
```

```
mysql> SET ROLE ALL EXCEPT 'app_write'; SELECT CURRENT_ROLE();
```

```
+-----+
| CURRENT_ROLE() |
+-----+
| `app_read`@`%` |
+-----+
```

```
mysql> SET ROLE DEFAULT; SELECT CURRENT_ROLE();
```

```
+-----+
| CURRENT_ROLE() |
+-----+
| `app_read`@`%`,`app_write`@`%` |
+-----+
```

The first `SET ROLE` statement deactivates all roles. The second makes `rw_user1` effectively read only. The third restores the default roles.

The effective user for stored program and view objects is subject to the `DEFINER` and `SQL SECURITY` attributes, which determine whether execution occurs in invoker or definer context (see [Section 27.7](#), “Stored Object Access Control”):

- Stored program and view objects that execute in invoker context execute with the roles that are active within the current session.

- Stored program and view objects that execute in definer context execute with the default roles of the user named in their `DEFINER` attribute. If `activate_all_roles_on_login` is enabled, such objects execute with all roles granted to the `DEFINER` user, including mandatory roles. For stored programs, if execution should occur with roles different from the default, the program body can execute `SET ROLE` to activate the required roles. This must be done with caution since the privileges assigned to roles can be changed.

## Revoking Roles or Role Privileges

Just as roles can be granted to an account, they can be revoked from an account:

```
REVOKE role FROM user;
```

Roles named in the `mandatory_roles` system variable value cannot be revoked.

`REVOKE` can also be applied to a role to modify the privileges granted to it. This affects not only the role itself, but any account granted that role. Suppose that you want to temporarily make all application users read only. To do this, use `REVOKE` to revoke the modification privileges from the `app_write` role:

```
REVOKE INSERT, UPDATE, DELETE ON app_db.* FROM 'app_write';
```

As it happens, that leaves the role with no privileges at all, as can be seen using `SHOW GRANTS` (which demonstrates that this statement can be used with roles, not just users):

```
mysql> SHOW GRANTS FOR 'app_write';
+-----+
| Grants for app_write@% |
+-----+
| GRANT USAGE ON *.* TO `app_write`@`%` |
+-----+
```

Because revoking privileges from a role affects the privileges for any user who is assigned the modified role, `rw_user1` now has no table modification privileges (`INSERT`, `UPDATE`, and `DELETE` are no longer present):

```
mysql> SHOW GRANTS FOR 'rw_user1'@'localhost'
 USING 'app_read', 'app_write';
+-----+
| Grants for rw_user1@localhost |
+-----+
| GRANT USAGE ON *.* TO `rw_user1`@`localhost` |
| GRANT SELECT ON `app_db`.* TO `rw_user1`@`localhost` |
| GRANT `app_read`@`%`,`app_write`@`%` TO `rw_user1`@`localhost` |
+-----+
```

In effect, the `rw_user1` read/write user has become a read-only user. This also occurs for any other accounts that are granted the `app_write` role, illustrating how use of roles makes it unnecessary to modify privileges for individual accounts.

To restore modification privileges to the role, simply re-grant them:

```
GRANT INSERT, UPDATE, DELETE ON app_db.* TO 'app_write';
```

Now `rw_user1` again has modification privileges, as do any other accounts granted the `app_write` role.

## Dropping Roles

To drop roles, use `DROP ROLE`:

```
DROP ROLE 'app_read', 'app_write';
```

Dropping a role revokes it from every account to which it was granted.

Roles named in the `mandatory_roles` system variable value cannot be dropped.

## User and Role Interchangeability

As has been hinted at earlier for `SHOW GRANTS`, which displays grants for user accounts or roles, accounts and roles can be used interchangeably.

One difference between roles and users is that `CREATE ROLE` creates an authorization identifier that is locked by default, whereas `CREATE USER` creates an authorization identifier that is unlocked by default. You should keep in mind that this distinction is not immutable; a user with appropriate privileges can lock or unlock roles or (other) users after they have been created.

If a database administrator has a preference that a specific authorization identifier must be a role, a name scheme can be used to communicate this intention. For example, you could use a `r_` prefix for all authorization identifiers that you intend to be roles and nothing else.

Another difference between roles and users lies in the privileges available for administering them:

- The `CREATE ROLE` and `DROP ROLE` privileges enable only use of the `CREATE ROLE` and `DROP ROLE` statements, respectively.
- The `CREATE USER` privilege enables use of the `ALTER USER`, `CREATE ROLE`, `CREATE USER`, `DROP ROLE`, `DROP USER`, `RENAME USER`, and `REVOKE ALL PRIVILEGES` statements.

Thus, the `CREATE ROLE` and `DROP ROLE` privileges are not as powerful as `CREATE USER` and may be granted to users who should only be permitted to create and drop roles, and not perform more general account manipulation.

With regard to privileges and interchangeability of users and roles, you can treat a user account like a role and grant that account to another user or a role. The effect is to grant the account's privileges and roles to the other user or role.

This set of statements demonstrates that you can grant a user to a user, a role to a user, a user to a role, or a role to a role:

```
CREATE USER 'u1';
CREATE ROLE 'r1';
GRANT SELECT ON db1.* TO 'u1';
GRANT SELECT ON db2.* TO 'r1';
CREATE USER 'u2';
CREATE ROLE 'r2';
GRANT 'u1', 'r1' TO 'u2';
GRANT 'u1', 'r1' TO 'r2';
```

The result in each case is to grant to the grantee object the privileges associated with the granted object. After executing those statements, each of `u2` and `r2` have been granted privileges from a user (`u1`) and a role (`r1`):

```
mysql> SHOW GRANTS FOR 'u2' USING 'u1', 'r1';
+-----+
| Grants for u2@% |
+-----+
| GRANT USAGE ON *.* TO `u2`@`%` |
| GRANT SELECT ON `db1`.* TO `u2`@`%` |
| GRANT SELECT ON `db2`.* TO `u2`@`%` |
| GRANT `u1`@`%`,`r1`@`%` TO `u2`@`%` |
+-----+
```

```
mysql> SHOW GRANTS FOR 'r2' USING 'u1', 'r1';
+-----+
| Grants for r2@% |
+-----+
| GRANT USAGE ON *.* TO `r2`@`%` |
| GRANT SELECT ON `db1`.* TO `r2`@`%` |
| GRANT SELECT ON `db2`.* TO `r2`@`%` |
| GRANT `u1`@`%`,`r1`@`%` TO `r2`@`%` |
+-----+
```

The preceding example is illustrative only, but interchangeability of user accounts and roles has practical application, such as in the following situation: Suppose that a legacy application development project began before the advent of roles in MySQL, so all user accounts associated with the project are granted privileges directly (rather than granted privileges by virtue of being granted roles). One of these accounts is a developer account that was originally granted privileges as follows:

```
CREATE USER 'old_app_dev'@'localhost' IDENTIFIED BY 'old_app_devpass';
GRANT ALL ON old_app.* TO 'old_app_dev'@'localhost';
```

If this developer leaves the project, it becomes necessary to assign the privileges to another user, or perhaps multiple users if development activities have expanded. Here are some ways to deal with the issue:

- Without using roles: Change the account password so the original developer cannot use it, and have a new developer use the account instead:

```
ALTER USER 'old_app_dev'@'localhost' IDENTIFIED BY 'new_password';
```

- Using roles: Lock the account to prevent anyone from using it to connect to the server:

```
ALTER USER 'old_app_dev'@'localhost' ACCOUNT LOCK;
```

Then treat the account as a role. For each developer new to the project, create a new account and grant to it the original developer account:

```
CREATE USER 'new_app_dev1'@'localhost' IDENTIFIED BY 'new_password';
GRANT 'old_app_dev'@'localhost' TO 'new_app_dev1'@'localhost';
```

The effect is to assign the original developer account privileges to the new account.

## 8.2.11 Account Categories

MySQL incorporates the concept of user account categories, based on the `SYSTEM_USER` privilege.

- [System and Regular Accounts](#)
- [Operations Affected by the SYSTEM\\_USER Privilege](#)
- [System and Regular Sessions](#)
- [Protecting System Accounts Against Manipulation by Regular Accounts](#)

### System and Regular Accounts

MySQL incorporates the concept of user account categories, with system and regular users distinguished according to whether they have the `SYSTEM_USER` privilege:

- A user with the `SYSTEM_USER` privilege is a system user.
- A user without the `SYSTEM_USER` privilege is a regular user.

The `SYSTEM_USER` privilege has an effect on the accounts to which a given user can apply its other privileges, as well as whether the user is protected from other accounts:

- A system user can modify both system and regular accounts. That is, a user who has the appropriate privileges to perform a given operation on regular accounts is enabled by possession of `SYSTEM_USER` to also perform the operation on system accounts. A system account can be modified only by system users with appropriate privileges, not by regular users.
- A regular user with appropriate privileges can modify regular accounts, but not system accounts. A regular account can be modified by both system and regular users with appropriate privileges.

If a user has the appropriate privileges to perform a given operation on regular accounts, `SYSTEM_USER` enables the user to also perform the operation on system accounts. `SYSTEM_USER` does not imply any other privilege, so the ability to perform a given account operation remains predicated on possession of any other required privileges. For example, if a user can grant the `SELECT` and `UPDATE` privileges to regular accounts, then with `SYSTEM_USER` the user can also grant `SELECT` and `UPDATE` to system accounts.

The distinction between system and regular accounts enables better control over certain account administration issues by protecting accounts that have the `SYSTEM_USER` privilege from accounts that do not have the privilege. For example, the `CREATE USER` privilege enables not only creation of new accounts, but modification and removal of existing accounts. Without the system user concept, a user who has the `CREATE USER` privilege can modify or drop any existing account, including the `root` account. The concept of system user enables restricting modifications to the `root` account (itself a system account) so they can be made only by system users. Regular users with the `CREATE USER` privilege can still modify or drop existing accounts, but only regular accounts.

## Operations Affected by the `SYSTEM_USER` Privilege

The `SYSTEM_USER` privilege affects these operations:

- Account manipulation.

Account manipulation includes creating and dropping accounts, granting and revoking privileges, changing account authentication characteristics such as credentials or authentication plugin, and changing other account characteristics such as password expiration policy.

The `SYSTEM_USER` privilege is required to manipulate system accounts using account-management statements such as `CREATE USER` and `GRANT`. To prevent an account from modifying system accounts this way, make it a regular account by not granting it the `SYSTEM_USER` privilege. (However, to fully protect system accounts against regular accounts, you must also withhold modification privileges for the `mysql` system schema from regular accounts. See [Protecting System Accounts Against Manipulation by Regular Accounts](#).)

- Killing current sessions and statements executing within them.

To kill a session or statement that is executing with the `SYSTEM_USER` privilege, your own session must have the `SYSTEM_USER` privilege, in addition to any other required privilege (`CONNECTION_ADMIN` or the deprecated `SUPER` privilege).

If the user that puts a server in offline mode does not have the `SYSTEM_USER` privilege, connected client users who have the `SYSTEM_USER` privilege are also not disconnected. However, these users cannot initiate new connections to the server while it is in offline mode, unless they have the `CONNECTION_ADMIN` or `SUPER` privilege as well. It is only their existing connection that is not terminated, because the `SYSTEM_USER` privilege is required to do that.

- Setting the `DEFINER` attribute for stored objects.

To set the `DEFINER` attribute for a stored object to an account that has the `SYSTEM_USER` privilege, you must have the `SYSTEM_USER` privilege, in addition to any other required privilege.

- Specifying mandatory roles.

A role that has the `SYSTEM_USER` privilege cannot be listed in the value of the `mandatory_roles` system variable.

- Overriding “abort” items in MySQL Enterprise Audit’s audit log filter.

Accounts with the `SYSTEM_USER` privilege are automatically assigned the `AUDIT_ABORT_EXEMPT` privilege, so that queries from the account are always executed even if an “abort” item in the audit log filter would block them. Accounts with the `SYSTEM_USER` privilege can therefore be used to regain access to a system following an audit misconfiguration. See [Section 8.4.5, “MySQL Enterprise Audit”](#).

## System and Regular Sessions

Sessions executing within the server are distinguished as system or regular sessions, similar to the distinction between system and regular users:

- A session that possesses the `SYSTEM_USER` privilege is a system session.
- A session that does not possess the `SYSTEM_USER` privilege is a regular session.

A regular session is able to perform only operations permitted to regular users. A system session is additionally able to perform operations permitted only to system users.

The privileges possessed by a session are those granted directly to its underlying account, plus those granted to all roles currently active within the session. Thus, a session may be a system session because its account has been granted the `SYSTEM_USER` privilege directly, or because the session has activated a role that has the `SYSTEM_USER` privilege. Roles granted to an account that are not active within the session do not affect session privileges.

Because activating and deactivating roles can change the privileges possessed by sessions, a session may change from a regular session to a system session or vice versa. If a session activates or deactivates a role that has the `SYSTEM_USER` privilege, the appropriate change between regular and system session takes place immediately, for that session only:

- If a regular session activates a role with the `SYSTEM_USER` privilege, the session becomes a system session.
- If a system session deactivates a role with the `SYSTEM_USER` privilege, the session becomes a regular session, unless some other role with the `SYSTEM_USER` privilege remains active.

These operations have no effect on existing sessions:

- If the `SYSTEM_USER` privilege is granted to or revoked from an account, existing sessions for the account do not change between regular and system sessions. The grant or revoke operation affects only sessions for subsequent connections by the account.
- Statements executed by a stored object invoked within a session execute with the system or regular status of the parent session, even if the object `DEFINER` attribute names a system account.

Because role activation affects only sessions and not accounts, granting a role that has the `SYSTEM_USER` privilege to a regular account does not protect that account against regular users. The role protects only

sessions for the account in which the role has been activated, and protects the session only against being killed by regular sessions.

## Protecting System Accounts Against Manipulation by Regular Accounts

Account manipulation includes creating and dropping accounts, granting and revoking privileges, changing account authentication characteristics such as credentials or authentication plugin, and changing other account characteristics such as password expiration policy.

Account manipulation can be done two ways:

- By using account-management statements such as `CREATE USER` and `GRANT`. This is the preferred method.
- By direct grant-table modification using statements such as `INSERT` and `UPDATE`. This method is discouraged but possible for users with the appropriate privileges on the `mysql` system schema that contains the grant tables.

To fully protect system accounts against modification by a given account, make it a regular account and do not grant it modification privileges for the `mysql` schema:

- The `SYSTEM_USER` privilege is required to manipulate system accounts using account-management statements. To prevent an account from modifying system accounts this way, make it a regular account by not granting `SYSTEM_USER` to it. This includes not granting `SYSTEM_USER` to any roles granted to the account.
- Privileges for the `mysql` schema enable manipulation of system accounts through direct modification of the grant tables, even if the modifying account is a regular account. To restrict unauthorized direct modification of system accounts by a regular account, do not grant modification privileges for the `mysql` schema to the account (or any roles granted to the account). If a regular account must have global privileges that apply to all schemas, `mysql` schema modifications can be prevented using privilege restrictions imposed using partial revokes. See [Section 8.2.12, “Privilege Restriction Using Partial Revokes”](#).

### Note

Unlike withholding the `SYSTEM_USER` privilege, which prevents an account from modifying system accounts but not regular accounts, withholding `mysql` schema privileges prevents an account from modifying system accounts as well as regular accounts. This should not be an issue because, as mentioned, direct grant-table modification is discouraged.

Suppose that you want to create a user `u1` who has all privileges on all schemas, except that `u1` should be a regular user without the ability to modify system accounts. Assuming that the `partial_revokes` system variable is enabled, configure `u1` as follows:

```
CREATE USER u1 IDENTIFIED BY 'password';

GRANT ALL ON *.* TO u1 WITH GRANT OPTION;
-- GRANT ALL includes SYSTEM_USER, so at this point
-- u1 can manipulate system or regular accounts

REVOKE SYSTEM_USER ON *.* FROM u1;
-- Revoking SYSTEM_USER makes u1 a regular user;
-- now u1 can use account-management statements
-- to manipulate only regular accounts

REVOKE ALL ON mysql.* FROM u1;
```

```
-- This partial revoke prevents u1 from directly
-- modifying grant tables to manipulate accounts
```

To prevent all `mysql` system schema access by an account, revoke all its privileges on the `mysql` schema, as just shown. It is also possible to permit partial `mysql` schema access, such as read-only access. The following example creates an account that has `SELECT`, `INSERT`, `UPDATE`, and `DELETE` privileges globally for all schemas, but only `SELECT` for the `mysql` schema:

```
CREATE USER u2 IDENTIFIED BY 'password';
GRANT SELECT, INSERT, UPDATE, DELETE ON *.* TO u2;
REVOKE INSERT, UPDATE, DELETE ON mysql.* FROM u2;
```

Another possibility is to revoke all `mysql` schema privileges but grant access to specific `mysql` tables or columns. This can be done even with a partial revoke on `mysql`. The following statements enable read-only access to `u1` within the `mysql` schema, but only for the `db` table and the `Host` and `User` columns of the `user` table:

```
CREATE USER u3 IDENTIFIED BY 'password';
GRANT ALL ON *.* TO u3;
REVOKE ALL ON mysql.* FROM u3;
GRANT SELECT ON mysql.db TO u3;
GRANT SELECT(Host,User) ON mysql.user TO u3;
```

## 8.2.12 Privilege Restriction Using Partial Revokes

It is possible to grant privileges that apply globally if the `partial_revokes` system variable is enabled. Specifically, for users who have privileges at the global level, `partial_revokes` enables privileges for specific schemas to be revoked while leaving the privileges in place for other schemas. Privilege restrictions thus imposed may be useful for administration of accounts that have global privileges but should not be permitted to access certain schemas. For example, it is possible to permit an account to modify any table except those in the `mysql` system schema.

- [Using Partial Revokes](#)
- [Partial Revokes Versus Explicit Schema Grants](#)
- [Disabling Partial Revokes](#)
- [Partial Revokes and Replication](#)

### Note

For brevity, `CREATE USER` statements shown here do not include passwords. For production use, always assign account passwords.

## Using Partial Revokes

The `partial_revokes` system variable controls whether privilege restrictions can be placed on accounts. By default, `partial_revokes` is disabled and attempts to partially revoke global privileges produce an error:

```
mysql> CREATE USER u1;
mysql> GRANT SELECT, INSERT ON *.* TO u1;
mysql> REVOKE INSERT ON world.* FROM u1;
ERROR 1141 (42000): There is no such grant defined for user 'u1' on host '%'
```

To permit the `REVOKE` operation, enable `partial_revokes`:

```
SET PERSIST partial_revokes = ON;
```

`SET PERSIST` sets a value for the running MySQL instance. It also saves the value, causing it to carry over to subsequent server restarts. To change the value for the running MySQL instance without having it carry over to subsequent restarts, use the `GLOBAL` keyword rather than `PERSIST`. See [Section 15.7.6.1, “SET Syntax for Variable Assignment”](#).

With `partial_revokes` enabled, the partial revoke succeeds:

```
mysql> REVOKE INSERT ON world.* FROM u1;
mysql> SHOW GRANTS FOR u1;
+-----+
| Grants for u1@% |
+-----+
| GRANT SELECT, INSERT ON *.* TO `u1`@`%` |
| REVOKE INSERT ON `world`.`*` FROM `u1`@`%` |
+-----+
```

`SHOW GRANTS` lists partial revokes as `REVOKE` statements in its output. The result indicates that `u1` has global `SELECT` and `INSERT` privileges, except that `INSERT` cannot be exercised for tables in the `world` schema. That is, access by `u1` to `world` tables is read only.

The server records privilege restrictions implemented through partial revokes in the `mysql.user` system table. If an account has partial revokes, its `User_attributes` column value has a `Restrictions` attribute:

```
mysql> SELECT User, Host, User_attributes->>'$.Restrictions'
FROM mysql.user WHERE User_attributes->>'$.Restrictions' <> '';
+-----+
| User | Host | User_attributes->>'$.Restrictions' |
+-----+
| u1 | % | [{"Database": "world", "Privileges": ["INSERT"]}] |
+-----+
```

#### Note

Although partial revokes can be imposed for any schema, privilege restrictions on the `mysql` system schema in particular are useful as part of a strategy for preventing regular accounts from modifying system accounts. See [Protecting System Accounts Against Manipulation by Regular Accounts](#).

Partial revoke operations are subject to these conditions:

- It is possible to use partial revokes to place restrictions on nonexistent schemas, but only if the revoked privilege is granted globally. If a privilege is not granted globally, revoking it for a nonexistent schema produces an error.
- Partial revokes apply at the schema level only. You cannot use partial revokes for privileges that apply only globally (such as `FILE` or `BINLOG_ADMIN`), or for table, column, or routine privileges.
- In privilege assignments, enabling `partial_revokes` causes MySQL to interpret occurrences of unescaped `_` and `%` SQL wildcard characters in schema names as literal characters, just as if they had been escaped as `\_` and `\%`. Because this changes how MySQL interprets privileges, it may be advisable to avoid unescaped wildcard characters in privilege assignments for installations where `partial_revokes` may be enabled.

As mentioned previously, partial revokes of schema-level privileges appear in `SHOW GRANTS` output as `REVOKE` statements. This differs from how `SHOW GRANTS` represents “plain” schema-level privileges:

- When granted, schema-level privileges are represented by their own `GRANT` statements in the output:

```
mysql> CREATE USER u1;
```

```
mysql> GRANT UPDATE ON mysql.* TO u1;
mysql> GRANT DELETE ON world.* TO u1;
mysql> SHOW GRANTS FOR u1;
+-----+
| Grants for u1@% |
+-----+
| GRANT USAGE ON *.* TO `u1`@`%` |
| GRANT UPDATE ON `mysql`.* TO `u1`@`%` |
| GRANT DELETE ON `world`.* TO `u1`@`%` |
+-----+
```

- When revoked, schema-level privileges simply disappear from the output. They do not appear as **REVOKE** statements:

```
mysql> REVOKE UPDATE ON mysql.* FROM u1;
mysql> REVOKE DELETE ON world.* FROM u1;
mysql> SHOW GRANTS FOR u1;
+-----+
| Grants for u1@% |
+-----+
| GRANT USAGE ON *.* TO `u1`@`%` |
+-----+
```

When a user grants a privilege, any restriction the grantor has on the privilege is inherited by the grantee, unless the grantee already has the privilege without the restriction. Consider the following two users, one of whom has the global **SELECT** privilege:

```
CREATE USER u1, u2;
GRANT SELECT ON *.* TO u2;
```

Suppose that an administrative user **admin** has a global but partially revoked **SELECT** privilege:

```
mysql> CREATE USER admin;
mysql> GRANT SELECT ON *.* TO admin WITH GRANT OPTION;
mysql> REVOKE SELECT ON mysql.* FROM admin;
mysql> SHOW GRANTS FOR admin;
+-----+
| Grants for admin@% |
+-----+
| GRANT SELECT ON *.* TO `admin`@`%` WITH GRANT OPTION |
| REVOKE SELECT ON `mysql`.* FROM `admin`@`%` |
+-----+
```

If **admin** grants **SELECT** globally to **u1** and **u2**, the result differs for each user:

- If **admin** grants **SELECT** globally to **u1**, who has no **SELECT** privilege to begin with, **u1** inherits the **admin** privilege restriction:

```
mysql> GRANT SELECT ON *.* TO u1;
mysql> SHOW GRANTS FOR u1;
+-----+
| Grants for u1@% |
+-----+
| GRANT SELECT ON *.* TO `u1`@`%` |
| REVOKE SELECT ON `mysql`.* FROM `u1`@`%` |
+-----+
```

- On the other hand, **u2** already holds a global **SELECT** privilege without restriction. **GRANT** can only add to a grantee's existing privileges, not reduce them, so if **admin** grants **SELECT** globally to **u2**, **u2** does not inherit the **admin** restriction:

```
mysql> GRANT SELECT ON *.* TO u2;
mysql> SHOW GRANTS FOR u2;
+-----+
```

```
| Grants for u2@% |
+-----+
| GRANT SELECT ON *.* TO `u2`@`%` |
+-----+
```

If a `GRANT` statement includes an `AS user` clause, the privilege restrictions applied are those on the user/role combination specified by the clause, rather than those on the user who executes the statement. For information about the `AS` clause, see [Section 15.7.1.6, “GRANT Statement”](#).

Restrictions on new privileges granted to an account are added to any existing restrictions for that account:

```
mysql> CREATE USER u1;
mysql> GRANT SELECT, INSERT, UPDATE, DELETE ON *.* TO u1;
mysql> REVOKE INSERT ON mysql.* FROM u1;
mysql> SHOW GRANTS FOR u1;
+-----+
| Grants for u1@% |
+-----+
| GRANT SELECT, INSERT, UPDATE, DELETE ON *.* TO `u1`@`%` |
| REVOKE INSERT ON `mysql`.* FROM `u1`@`%` |
+-----+
mysql> REVOKE DELETE, UPDATE ON db2.* FROM u1;
mysql> SHOW GRANTS FOR u1;
+-----+
| Grants for u1@% |
+-----+
| GRANT SELECT, INSERT, UPDATE, DELETE ON *.* TO `u1`@`%` |
| REVOKE UPDATE, DELETE ON `db2`.* FROM `u1`@`%` |
| REVOKE INSERT ON `mysql`.* FROM `u1`@`%` |
+-----+
```

Aggregation of privilege restrictions applies both when privileges are partially revoked explicitly (as just shown) and when restrictions are inherited implicitly from the user who executes the statement or the user mentioned in an `AS user` clause.

If an account has a privilege restriction on a schema:

- The account cannot grant to other accounts a privilege on the restricted schema or any object within it.
- Another account that does not have the restriction can grant privileges to the restricted account for the restricted schema or objects within it. Suppose that an unrestricted user executes these statements:

```
CREATE USER u1;
GRANT SELECT, INSERT, UPDATE ON *.* TO u1;
REVOKE SELECT, INSERT, UPDATE ON mysql.* FROM u1;
GRANT SELECT ON mysql.user TO u1; -- grant table privilege
GRANT SELECT(Host,User) ON mysql.db TO u1; -- grant column privileges
```

The resulting account has these privileges, with the ability to perform limited operations within the restricted schema:

```
mysql> SHOW GRANTS FOR u1;
+-----+
| Grants for u1@% |
+-----+
| GRANT SELECT, INSERT, UPDATE ON *.* TO `u1`@`%` |
| REVOKE SELECT, INSERT, UPDATE ON `mysql`.* FROM `u1`@`%` |
| GRANT SELECT (`Host`, `User`) ON `mysql`.`db` TO `u1`@`%` |
| GRANT SELECT ON `mysql`.`user` TO `u1`@`%` |
+-----+
```

If an account has a restriction on a global privilege, the restriction is removed by any of these actions:

- Granting the privilege globally to the account by an account that has no restriction on the privilege.

- Granting the privilege at the schema level.
- Revoking the privilege globally.

Consider a user `u1` who holds several privileges globally, but with restrictions on `INSERT`, `UPDATE` and `DELETE`:

```
mysql> CREATE USER u1;
mysql> GRANT SELECT, INSERT, UPDATE, DELETE ON *.* TO u1;
mysql> REVOKE INSERT, UPDATE, DELETE ON mysql.* FROM u1;
mysql> SHOW GRANTS FOR u1;
+-----+
| Grants for u1@% |
+-----+
| GRANT SELECT, INSERT, UPDATE, DELETE ON *.* TO `u1`@`%` |
| REVOKE INSERT, UPDATE, DELETE ON `mysql`.`.*` FROM `u1`@`%` |
+-----+
```

Granting a privilege globally to `u1` from an account with no restriction removes the privilege restriction. For example, to remove the `INSERT` restriction:

```
mysql> GRANT INSERT ON *.* TO u1;
mysql> SHOW GRANTS FOR u1;
+-----+
| Grants for u1@% |
+-----+
| GRANT SELECT, INSERT, UPDATE, DELETE ON *.* TO `u1`@`%` |
| REVOKE UPDATE, DELETE ON `mysql`.`.*` FROM `u1`@`%` |
+-----+
```

Granting a privilege at the schema level to `u1` removes the privilege restriction. For example, to remove the `UPDATE` restriction:

```
mysql> GRANT UPDATE ON mysql.* TO u1;
mysql> SHOW GRANTS FOR u1;
+-----+
| Grants for u1@% |
+-----+
| GRANT SELECT, INSERT, UPDATE, DELETE ON *.* TO `u1`@`%` |
| REVOKE DELETE ON `mysql`.`.*` FROM `u1`@`%` |
+-----+
```

Revoking a global privilege removes the privilege, including any restrictions on it. For example, to remove the `DELETE` restriction (at the cost of removing all `DELETE` access):

```
mysql> REVOKE DELETE ON *.* FROM u1;
mysql> SHOW GRANTS FOR u1;
+-----+
| Grants for u1@% |
+-----+
| GRANT SELECT, INSERT, UPDATE ON *.* TO `u1`@`%` |
+-----+
```

If an account has a privilege at both the global and schema levels, you must revoke it at the schema level twice to effect a partial revoke. Suppose that `u1` has these privileges, where `INSERT` is held both globally and on the `world` schema:

```
mysql> CREATE USER u1;
mysql> GRANT SELECT, INSERT ON *.* TO u1;
mysql> GRANT INSERT ON world.* TO u1;
mysql> SHOW GRANTS FOR u1;
+-----+
| Grants for u1@% |
+-----+
```

```
| GRANT SELECT, INSERT ON *.* TO 'u1'@'%' |
| GRANT INSERT ON `world`.* TO 'u1'@'%' |
+-----+
```

Revoking `INSERT` on `world` revokes the schema-level privilege (`SHOW GRANTS` no longer displays the schema-level `GRANT` statement):

```
mysql> REVOKE INSERT ON world.* FROM u1;
mysql> SHOW GRANTS FOR u1;
+-----+
| Grants for u1@% |
+-----+
| GRANT SELECT, INSERT ON *.* TO 'u1'@'%' |
+-----+
```

Revoking `INSERT` on `world` again performs a partial revoke of the global privilege (`SHOW GRANTS` now includes a schema-level `REVOKE` statement):

```
mysql> REVOKE INSERT ON world.* FROM u1;
mysql> SHOW GRANTS FOR u1;
+-----+
| Grants for u1@% |
+-----+
| GRANT SELECT, INSERT ON *.* TO 'u1'@'%' |
| REVOKE INSERT ON `world`.* FROM 'u1'@'%' |
+-----+
```

## Partial Revokes Versus Explicit Schema Grants

To provide access to accounts for some schemas but not others, partial revokes provide an alternative to the approach of explicitly granting schema-level access without granting global privileges. The two approaches have different advantages and disadvantages.

Granting schema-level privileges and not global privileges:

- Adding a new schema: The schema is inaccessible to existing accounts by default. For any account to which the schema should be accessible, the DBA must grant schema-level access.
- Adding a new account: The DBA must grant schema-level access for each schema to which the account should have access.

Granting global privileges in conjunction with partial revokes:

- Adding a new schema: The schema is accessible to existing accounts that have global privileges. For any such account to which the schema should be inaccessible, the DBA must add a partial revoke.
- Adding a new account: The DBA must grant the global privileges, plus a partial revoke on each restricted schema.

The approach that uses explicit schema-level grant is more convenient for accounts for which access is limited to a few schemas. The approach that uses partial revokes is more convenient for accounts with broad access to all schemas except a few.

## Disabling Partial Revokes

Once enabled, `partial_revokes` cannot be disabled if any account has privilege restrictions. If any such account exists, disabling `partial_revokes` fails:

- For attempts to disable `partial_revokes` at startup, the server logs an error message and enables `partial_revokes`.

- For attempts to disable `partial_revokes` at runtime, an error occurs and the `partial_revokes` value remains unchanged.

To disable `partial_revokes` when restrictions exist, the restrictions first must be removed:

1. Determine which accounts have partial revokes:

```
SELECT User, Host, User_attributes->>'$.Restrictions'
FROM mysql.user WHERE User_attributes->>'$.Restrictions' <> '';
```

2. For each such account, remove its privilege restrictions. Suppose that the previous step shows account `u1` to have these restrictions:

```
[{"Database": "world", "Privileges": ["INSERT", "DELETE"]}]
```

Restriction removal can be done various ways:

- Grant the privileges globally, without restrictions:

```
GRANT INSERT, DELETE ON *.* TO u1;
```

- Grant the privileges at the schema level:

```
GRANT INSERT, DELETE ON world.* TO u1;
```

- Revoke the privileges globally (assuming that they are no longer needed):

```
REVOKE INSERT, DELETE ON *.* FROM u1;
```

- Remove the account itself (assuming that it is no longer needed):

```
DROP USER u1;
```

After all privilege restrictions are removed, it is possible to disable partial revokes:

```
SET PERSIST partial_revokes = OFF;
```

## Partial Revokes and Replication

In replication scenarios, if `partial_revokes` is enabled on any host, it must be enabled on all hosts. Otherwise, `REVOKE` statements to partially revoke a global privilege do not have the same effect for all hosts on which replication occurs, potentially resulting in replication inconsistencies or errors.

When `partial_revokes` is enabled, an extended syntax is recorded in the binary log for `GRANT` statements, including the current user that issued the statement and their currently active roles. If a user or a role recorded in this way does not exist on the replica, the replication applier thread stops at the `GRANT` statement with an error. Ensure that all user accounts that issue or might issue `GRANT` statements on the replication source server also exist on the replica, and have the same set of roles as they have on the source.

### 8.2.13 When Privilege Changes Take Effect

If the `mysqld` server is started without the `--skip-grant-tables` option, it reads all grant table contents into memory during its startup sequence. The in-memory tables become effective for access control at that point.

If you modify the grant tables indirectly using an account-management statement, the server notices these changes and loads the grant tables into memory again immediately. Account-management statements are

described in [Section 15.7.1, “Account Management Statements”](#). Examples include `GRANT`, `REVOKE`, `SET PASSWORD`, and `RENAME USER`.

If you modify the grant tables directly using statements such as `INSERT`, `UPDATE`, or `DELETE` (which is not recommended), the changes have no effect on privilege checking until you either tell the server to reload the tables or restart it. Thus, if you change the grant tables directly but forget to reload them, the changes have *no effect* until you restart the server. This may leave you wondering why your changes seem to make no difference!

To tell the server to reload the grant tables, perform a flush-privileges operation. This can be done by issuing a `FLUSH PRIVILEGES` statement or by executing a `mysqladmin flush-privileges` or `mysqladmin reload` command.

A grant table reload affects privileges for each existing client session as follows:

- Table and column privilege changes take effect with the client's next request.
- Database privilege changes take effect the next time the client executes a `USE db_name` statement.

**Note**

Client applications may cache the database name; thus, this effect may not be visible to them without actually changing to a different database.

- Static global privileges and passwords are unaffected for a connected client. These changes take effect only in sessions for subsequent connections. Changes to dynamic global privileges apply immediately. For information about the differences between static and dynamic privileges, see [Static Versus Dynamic Privileges](#).)

Changes to the set of active roles within a session take effect immediately, for that session only. The `SET ROLE` statement performs session role activation and deactivation (see [Section 15.7.1.11, “SET ROLE Statement”](#)).

If the server is started with the `--skip-grant-tables` option, it does not read the grant tables or implement any access control. Any user can connect and perform any operation, *which is insecure*. To cause a server thus started to read the tables and enable access checking, flush the privileges.

## 8.2.14 Assigning Account Passwords

Required credentials for clients that connect to the MySQL server can include a password. This section describes how to assign passwords for MySQL accounts.

MySQL stores credentials in the `user` table in the `mysql` system database. Operations that assign or modify passwords are permitted only to users with the `CREATE USER` privilege, or, alternatively, privileges for the `mysql` database (`INSERT` privilege to create new accounts, `UPDATE` privilege to modify existing accounts). If the `read_only` system variable is enabled, use of account-modification statements such as `CREATE USER` or `ALTER USER` additionally requires the `CONNECTION_ADMIN` privilege (or the deprecated `SUPER` privilege).

The discussion here summarizes syntax only for the most common password-assignment statements. For complete details on other possibilities, see [Section 15.7.1.3, “CREATE USER Statement”](#), [Section 15.7.1.1, “ALTER USER Statement”](#), and [Section 15.7.1.10, “SET PASSWORD Statement”](#).

MySQL uses plugins to perform client authentication; see [Section 8.2.17, “Pluggable Authentication”](#). In password-assigning statements, the authentication plugin associated with an account performs any hashing required of a cleartext password specified. This enables MySQL to obfuscate passwords prior to

storing them in the `mysql.user` system table. For the statements described here, MySQL automatically hashes the password specified. There are also syntax for `CREATE USER` and `ALTER USER` that permits hashed values to be specified literally. For details, see the descriptions of those statements.

To assign a password when you create a new account, use `CREATE USER` and include an `IDENTIFIED BY` clause:

```
CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'password';
```

`CREATE USER` also supports syntax for specifying the account authentication plugin. See [Section 15.7.1.3, “CREATE USER Statement”](#).

To assign or change a password for an existing account, use the `ALTER USER` statement with an `IDENTIFIED BY` clause:

```
ALTER USER 'jeffrey'@'localhost' IDENTIFIED BY 'password';
```

If you are not connected as an anonymous user, you can change your own password without naming your own account literally:

```
ALTER USER USER() IDENTIFIED BY 'password';
```

To change an account password from the command line, use the `mysqladmin` command:

```
mysqladmin -u user_name -h host_name password "password"
```

The account for which this command sets the password is the one with a row in the `mysql.user` system table that matches `user_name` in the `User` column and the client host *from which you connect* in the `Host` column.

### Warning

Setting a password using `mysqladmin` should be considered *insecure*. On some systems, your password becomes visible to system status programs such as `ps` that may be invoked by other users to display command lines. MySQL clients typically overwrite the command-line password argument with zeros during their initialization sequence. However, there is still a brief interval during which the value is visible. Also, on some systems this overwriting strategy is ineffective and the password remains visible to `ps`. (SystemV Unix systems and perhaps others are subject to this problem.)

If you are using MySQL Replication, be aware that a password used by a replica as part of `CHANGE REPLICATION SOURCE TO` is effectively limited to 32 characters in length; if the password is longer, any excess characters are truncated. This is not due to any limit imposed by MySQL Server generally, but rather is an issue specific to MySQL Replication.

## 8.2.15 Password Management

MySQL supports these password-management capabilities:

- Password expiration, to require passwords to be changed periodically.
- Password reuse restrictions, to prevent old passwords from being chosen again.
- Password verification, to require that password changes also specify the current password to be replaced.
- Dual passwords, to enable clients to connect using either a primary or secondary password.

- Password strength assessment, to require strong passwords.
- Random password generation, as an alternative to requiring explicit administrator-specified literal passwords.
- Password failure tracking, to enable temporary account locking after too many consecutive incorrect-password login failures.

The following sections describe these capabilities, except password strength assessment, which is implemented using the `validate_password` component and is described in [Section 8.4.3, “The Password Validation Component”](#).

- [Internal Versus External Credentials Storage](#)
- [Password Expiration Policy](#)
- [Password Reuse Policy](#)
- [Password Verification-Required Policy](#)
- [Dual Password Support](#)
- [Random Password Generation](#)
- [Failed-Login Tracking and Temporary Account Locking](#)

**Important**

MySQL implements password-management capabilities using tables in the `mysql` system database. If you upgrade MySQL from an earlier version, your system tables might not be up to date. In that case, the server writes messages similar to these to the error log during the startup process (the exact numbers may vary):

```
[ERROR] Column count of mysql.user is wrong. Expected
49, found 47. The table is probably corrupted
[Warning] ACL table mysql.password_history missing.
Some operations may fail.
```

To correct the issue, perform the MySQL upgrade procedure. See [Chapter 3, \*Upgrading MySQL\*](#). Until this is done, *password changes are not possible*.

## Internal Versus External Credentials Storage

Some authentication plugins store account credentials internally to MySQL, in the `mysql.user` system table:

- `caching_sha2_password`
- `sha256_password` (deprecated)

Most discussion in this section applies to such authentication plugins because most password-management capabilities described here are based on internal credentials storage handled by MySQL itself. Other authentication plugins store account credentials externally to MySQL. For accounts that use plugins that perform authentication against an external credentials system, password management must be handled externally against that system as well.

The exception is that the options for failed-login tracking and temporary account locking apply to all accounts, not just accounts that use internal credentials storage, because MySQL is able to assess the status of login attempts for any account no matter whether it uses internal or external credentials storage.

For information about individual authentication plugins, see [Section 8.4.1, “Authentication Plugins”](#).

## Password Expiration Policy

MySQL enables database administrators to expire account passwords manually, and to establish a policy for automatic password expiration. Expiration policy can be established globally, and individual accounts can be set to either defer to the global policy or override the global policy with specific per-account behavior.

To expire an account password manually, use the `ALTER USER` statement:

```
ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE;
```

This operation marks the password expired in the corresponding row in the `mysql.user` system table.

Password expiration according to policy is automatic and is based on password age, which for a given account is assessed from the date and time of its most recent password change. The `mysql.user` system table indicates for each account when its password was last changed, and the server automatically treats the password as expired at client connection time if its age is greater than its permitted lifetime. This works with no explicit manual password expiration.

To establish automatic password-expiration policy globally, use the `default_password_lifetime` system variable. Its default value is 0, which disables automatic password expiration. If the value of `default_password_lifetime` is a positive integer *N*, it indicates the permitted password lifetime, such that passwords must be changed every *N* days.

Examples:

- To establish a global policy that passwords have a lifetime of approximately six months, start the server with these lines in a server `my.cnf` file:

```
[mysqld]
default_password_lifetime=180
```

- To establish a global policy such that passwords never expire, set `default_password_lifetime` to 0:

```
[mysqld]
default_password_lifetime=0
```

- `default_password_lifetime` can also be set and persisted at runtime:

```
SET PERSIST default_password_lifetime = 180;
SET PERSIST default_password_lifetime = 0;
```

`SET PERSIST` sets a value for the running MySQL instance. It also saves the value to carry over to subsequent server restarts; see [Section 15.7.6.1, “SET Syntax for Variable Assignment”](#). To change the value for the running MySQL instance without having it carry over to subsequent restarts, use the `GLOBAL` keyword rather than `PERSIST`.

The global password-expiration policy applies to all accounts that have not been set to override it. To establish policy for individual accounts, use the `PASSWORD EXPIRE` option of the `CREATE USER` and `ALTER USER` statements. See [Section 15.7.1.3, “CREATE USER Statement”](#), and [Section 15.7.1.1, “ALTER USER Statement”](#).

Example account-specific statements:

- Require the password to be changed every 90 days:

```
CREATE USER 'jeffrey'@'localhost' PASSWORD EXPIRE INTERVAL 90 DAY;
ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE INTERVAL 90 DAY;
```

This expiration option overrides the global policy for all accounts named by the statement.

- Disable password expiration:

```
CREATE USER 'jeffrey'@'localhost' PASSWORD EXPIRE NEVER;
ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE NEVER;
```

This expiration option overrides the global policy for all accounts named by the statement.

- Defer to the global expiration policy for all accounts named by the statement:

```
CREATE USER 'jeffrey'@'localhost' PASSWORD EXPIRE DEFAULT;
ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE DEFAULT;
```

When a client successfully connects, the server determines whether the account password has expired:

- The server checks whether the password has been manually expired.
- Otherwise, the server checks whether the password age is greater than its permitted lifetime according to the automatic password expiration policy. If so, the server considers the password expired.

If the password is expired (whether manually or automatically), the server either disconnects the client or restricts the operations permitted to it (see [Section 8.2.16, “Server Handling of Expired Passwords”](#)). Operations performed by a restricted client result in an error until the user establishes a new account password:

```
mysql> SELECT 1;
ERROR 1820 (HY000): You must reset your password using ALTER USER
statement before executing this statement.

mysql> ALTER USER USER() IDENTIFIED BY 'password';
Query OK, 0 rows affected (0.01 sec)

mysql> SELECT 1;
+----+
| 1 |
+----+
| 1 |
+----+
1 row in set (0.00 sec)
```

After the client resets the password, the server restores normal access for the session, as well as for subsequent connections that use the account. It is also possible for an administrative user to reset the account password, but any existing restricted sessions for that account remain restricted. A client using the account must disconnect and reconnect before statements can be executed successfully.

## Note

Although it is possible to “reset” an expired password by setting it to its current value, it is preferable, as a matter of good policy, to choose a different password. DBAs can enforce non-reuse by establishing an appropriate password-reuse policy. See [Password Reuse Policy](#).

## Password Reuse Policy

MySQL enables restrictions to be placed on reuse of previous passwords. Reuse restrictions can be established based on number of password changes, time elapsed, or both. Reuse policy can be

established globally, and individual accounts can be set to either defer to the global policy or override the global policy with specific per-account behavior.

The password history for an account consists of passwords it has been assigned in the past. MySQL can restrict new passwords from being chosen from this history:

- If an account is restricted on the basis of number of password changes, a new password cannot be chosen from a specified number of the most recent passwords. For example, if the minimum number of password changes is set to 3, a new password cannot be the same as any of the most recent 3 passwords.
- If an account is restricted based on time elapsed, a new password cannot be chosen from passwords in the history that are newer than a specified number of days. For example, if the password reuse interval is set to 60, a new password must not be among those previously chosen within the last 60 days.

#### Note

The empty password does not count in the password history and is subject to reuse at any time.

To establish password-reuse policy globally, use the `password_history` and `password_reuse_interval` system variables.

Examples:

- To prohibit reusing any of the last 6 passwords or passwords newer than 365 days, put these lines in the server `my.cnf` file:

```
[mysqld]
password_history=6
password_reuse_interval=365
```

- To set and persist the variables at runtime, use statements like this:

```
SET PERSIST password_history = 6;
SET PERSIST password_reuse_interval = 365;
```

`SET PERSIST` sets a value for the running MySQL instance. It also saves the value to carry over to subsequent server restarts; see [Section 15.7.6.1, “SET Syntax for Variable Assignment”](#). To change the value for the running MySQL instance without having it carry over to subsequent restarts, use the `GLOBAL` keyword rather than `PERSIST`.

The global password-reuse policy applies to all accounts that have not been set to override it. To establish policy for individual accounts, use the `PASSWORD HISTORY` and `PASSWORD REUSE INTERVAL` options of the `CREATE USER` and `ALTER USER` statements. See [Section 15.7.1.3, “CREATE USER Statement”](#), and [Section 15.7.1.1, “ALTER USER Statement”](#).

Example account-specific statements:

- Require a minimum of 5 password changes before permitting reuse:

```
CREATE USER 'jeffrey'@'localhost' PASSWORD HISTORY 5;
ALTER USER 'jeffrey'@'localhost' PASSWORD HISTORY 5;
```

This history-length option overrides the global policy for all accounts named by the statement.

- Require a minimum of 365 days elapsed before permitting reuse:

```
CREATE USER 'jeffrey'@'localhost' PASSWORD REUSE INTERVAL 365 DAY;
```

```
ALTER USER 'jeffrey'@'localhost' PASSWORD REUSE INTERVAL 365 DAY;
```

This time-elapsed option overrides the global policy for all accounts named by the statement.

- To combine both types of reuse restrictions, use `PASSWORD HISTORY` and `PASSWORD REUSE INTERVAL` together:

```
CREATE USER 'jeffrey'@'localhost'
 PASSWORD HISTORY 5
 PASSWORD REUSE INTERVAL 365 DAY;
ALTER USER 'jeffrey'@'localhost'
 PASSWORD HISTORY 5
 PASSWORD REUSE INTERVAL 365 DAY;
```

These options override both global policy reuse restrictions for all accounts named by the statement.

- Defer to the global policy for both types of reuse restrictions:

```
CREATE USER 'jeffrey'@'localhost'
 PASSWORD HISTORY DEFAULT
 PASSWORD REUSE INTERVAL DEFAULT;
ALTER USER 'jeffrey'@'localhost'
 PASSWORD HISTORY DEFAULT
 PASSWORD REUSE INTERVAL DEFAULT;
```

## Password Verification-Required Policy

It is possible to require that attempts to change an account password be verified by specifying the current password to be replaced. This enables DBAs to prevent users from changing a password without proving that they know the current password. Such changes could otherwise occur, for example, if one user walks away from a terminal session temporarily without logging out, and a malicious user uses the session to change the original user's MySQL password. This can have unfortunate consequences:

- The original user becomes unable to access MySQL until the account password is reset by an administrator.
- Until the password reset occurs, the malicious user can access MySQL with the benign user's changed credentials.

Password-verification policy can be established globally, and individual accounts can be set to either defer to the global policy or override the global policy with specific per-account behavior.

For each account, its `mysql.user` row indicates whether there is an account-specific setting requiring verification of the current password for password change attempts. The setting is established by the `PASSWORD REQUIRE` option of the `CREATE USER` and `ALTER USER` statements:

- If the account setting is `PASSWORD REQUIRE CURRENT`, password changes must specify the current password.
- If the account setting is `PASSWORD REQUIRE CURRENT OPTIONAL`, password changes may but need not specify the current password.
- If the account setting is `PASSWORD REQUIRE CURRENT DEFAULT`, the `password_require_current` system variable determines the verification-required policy for the account:
  - If `password_require_current` is enabled, password changes must specify the current password.
  - If `password_require_current` is disabled, password changes may but need not specify the current password.

In other words, if the account setting is not `PASSWORD REQUIRE CURRENT DEFAULT`, the account setting takes precedence over the global policy established by the `password_require_current` system variable. Otherwise, the account defers to the `password_require_current` setting.

By default, password verification is optional: `password_require_current` is disabled and accounts created with no `PASSWORD REQUIRE` option default to `PASSWORD REQUIRE CURRENT DEFAULT`.

The following table shows how per-account settings interact with `password_require_current` system variable values to determine account password verification-required policy.

**Table 8.10 Password-Verification Policy**

Per-Account Setting	<code>password_require_current</code> System Variable	Password Changes Require Current Password?
<code>PASSWORD REQUIRE CURRENT</code>	<code>OFF</code>	Yes
<code>PASSWORD REQUIRE CURRENT</code>	<code>ON</code>	Yes
<code>PASSWORD REQUIRE CURRENT OPTIONAL</code>	<code>OFF</code>	No
<code>PASSWORD REQUIRE CURRENT OPTIONAL</code>	<code>ON</code>	No
<code>PASSWORD REQUIRE CURRENT DEFAULT</code>	<code>OFF</code>	No
<code>PASSWORD REQUIRE CURRENT DEFAULT</code>	<code>ON</code>	Yes

**Note**

Privileged users can change any account password without specifying the current password, regardless of the verification-required policy. A privileged user is one who has the global `CREATE USER` privilege or the `UPDATE` privilege for the `mysql` system database.

To establish password-verification policy globally, use the `password_require_current` system variable. Its default value is `OFF`, so it is not required that account password changes specify the current password.

Examples:

- To establish a global policy that password changes must specify the current password, start the server with these lines in a server `my.cnf` file:

```
[mysqld]
password_require_current=ON
```

- To set and persist `password_require_current` at runtime, use a statement such as one of these:

```
SET PERSIST password_require_current = ON;
SET PERSIST password_require_current = OFF;
```

`SET PERSIST` sets a value for the running MySQL instance. It also saves the value to carry over to subsequent server restarts; see [Section 15.7.6.1, “SET Syntax for Variable Assignment”](#). To change the value for the running MySQL instance without having it carry over to subsequent restarts, use the `GLOBAL` keyword rather than `PERSIST`.

The global password verification-required policy applies to all accounts that have not been set to override it. To establish policy for individual accounts, use the `PASSWORD REQUIRE` options of the `CREATE USER`

and `ALTER USER` statements. See [Section 15.7.1.3, “CREATE USER Statement”](#), and [Section 15.7.1.1, “ALTER USER Statement”](#).

Example account-specific statements:

- Require that password changes specify the current password:

```
CREATE USER 'jeffrey'@'localhost' PASSWORD REQUIRE CURRENT;
ALTER USER 'jeffrey'@'localhost' PASSWORD REQUIRE CURRENT;
```

This verification option overrides the global policy for all accounts named by the statement.

- Do not require that password changes specify the current password (the current password may but need not be given):

```
CREATE USER 'jeffrey'@'localhost' PASSWORD REQUIRE CURRENT OPTIONAL;
ALTER USER 'jeffrey'@'localhost' PASSWORD REQUIRE CURRENT OPTIONAL;
```

This verification option overrides the global policy for all accounts named by the statement.

- Defer to the global password verification-required policy for all accounts named by the statement:

```
CREATE USER 'jeffrey'@'localhost' PASSWORD REQUIRE CURRENT DEFAULT;
ALTER USER 'jeffrey'@'localhost' PASSWORD REQUIRE CURRENT DEFAULT;
```

Verification of the current password comes into play when a user changes a password using the `ALTER USER` or `SET PASSWORD` statement. The examples use `ALTER USER`, which is preferred over `SET PASSWORD`, but the principles described here are the same for both statements.

In password-change statements, a `REPLACE` clause specifies the current password to be replaced. Examples:

- Change the current user's password:

```
ALTER USER USER() IDENTIFIED BY 'auth_string' REPLACE 'current_auth_string';
```

- Change a named user's password:

```
ALTER USER 'jeffrey'@'localhost'
 IDENTIFIED BY 'auth_string'
 REPLACE 'current_auth_string';
```

- Change a named user's authentication plugin and password:

```
ALTER USER 'jeffrey'@'localhost'
 IDENTIFIED WITH caching_sha2_password BY 'auth_string'
 REPLACE 'current_auth_string';
```

The `REPLACE` clause works like this:

- `REPLACE` must be given if password changes for the account are required to specify the current password, as verification that the user attempting to make the change actually knows the current password.
- `REPLACE` is optional if password changes for the account may but need not specify the current password.
- If `REPLACE` is specified, it must specify the correct current password, or an error occurs. This is true even if `REPLACE` is optional.
- `REPLACE` can be specified only when changing the account password for the current user. (This means that in the examples just shown, the statements that explicitly name the account for `jeffrey` fail

unless the current user is `jeffrey`.) This is true even if the change is attempted for another user by a privileged user; however, such a user can change any password without specifying `REPLACE`.

- `REPLACE` is omitted from the binary log to avoid writing cleartext passwords to it.

## Dual Password Support

User accounts are permitted to have dual passwords, designated as primary and secondary passwords. Dual-password capability makes it possible to seamlessly perform credential changes in scenarios like this:

- A system has a large number of MySQL servers, possibly involving replication.
- Multiple applications connect to different MySQL servers.
- Periodic credential changes must be made to the account or accounts used by the applications to connect to the servers.

Consider how a credential change must be performed in the preceding type of scenario when an account is permitted only a single password. In this case, there must be close cooperation in the timing of when the account password change is made and propagated throughout all servers, and when all applications that use the account are updated to use the new password. This process may involve downtime during which servers or applications are unavailable.

With dual passwords, credential changes can be made more easily, in phases, without requiring close cooperation, and without downtime:

1. For each affected account, establish a new primary password on the servers, retaining the current password as the secondary password. This enables servers to recognize either the primary or secondary password for each account, while applications can continue to connect to the servers using the same password as previously (which is now the secondary password).
2. After the password change has propagated to all servers, modify applications that use any affected account to connect using the account primary password.
3. After all applications have been migrated from the secondary passwords to the primary passwords, the secondary passwords are no longer needed and can be discarded. After this change has propagated to all servers, only the primary password for each account can be used to connect. The credential change is now complete.

MySQL implements dual-password capability with syntax that saves and discards secondary passwords:

- The `RETAIN CURRENT PASSWORD` clause for the `ALTER USER` and `SET PASSWORD` statements saves an account current password as its secondary password when you assign a new primary password.
- The `DISCARD OLD PASSWORD` clause for `ALTER USER` discards an account secondary password, leaving only the primary password.

Suppose that, for the previously described credential-change scenario, an account named `'appuser1'@'host1.example.com'` is used by applications to connect to servers, and that the account password is to be changed from `'password_a'` to `'password_b'`.

To perform this change of credentials, use `ALTER USER` as follows:

1. On each server that is not a replica, establish `'password_b'` as the new `appuser1` primary password, retaining the current password as the secondary password:

```
ALTER USER 'appuser1'@'host1.example.com'
```

```
IDENTIFIED BY 'password_b'
RETAIN CURRENT PASSWORD;
```

2. Wait for the password change to replicate throughout the system to all replicas.
3. Modify each application that uses the `appuser1` account so that it connects to the servers using a password of `'password_b'` rather than `'password_a'`.
4. At this point, the secondary password is no longer needed. On each server that is not a replica, discard the secondary password:

```
ALTER USER 'appuser1'@'host1.example.com'
DISCARD OLD PASSWORD;
```

5. After the discard-password change has replicated to all replicas, the credential change is complete.

The `RETAIN CURRENT PASSWORD` and `DISCARD OLD PASSWORD` clauses have the following effects:

- `RETAIN CURRENT PASSWORD` retains an account current password as its secondary password, replacing any existing secondary password. The new password becomes the primary password, but clients can use the account to connect to the server using either the primary or secondary password. (Exception: If the new password specified by the `ALTER USER` or `SET PASSWORD` statement is empty, the secondary password becomes empty as well, even if `RETAIN CURRENT PASSWORD` is given.)
- If you specify `RETAIN CURRENT PASSWORD` for an account that has an empty primary password, the statement fails.
- If an account has a secondary password and you change its primary password without specifying `RETAIN CURRENT PASSWORD`, the secondary password remains unchanged.
- For `ALTER USER`, if you change the authentication plugin assigned to the account, the secondary password is discarded. If you change the authentication plugin and also specify `RETAIN CURRENT PASSWORD`, the statement fails.
- For `ALTER USER`, `DISCARD OLD PASSWORD` discards the secondary password, if one exists. The account retains only its primary password, and clients can use the account to connect to the server only with the primary password.

Statements that modify secondary passwords require these privileges:

- The `APPLICATION_PASSWORD_ADMIN` privilege is required to use the `RETAIN CURRENT PASSWORD` or `DISCARD OLD PASSWORD` clause for `ALTER USER` and `SET PASSWORD` statements that apply to your own account. The privilege is required to manipulate your own secondary password because most users require only one password.
- If an account is to be permitted to manipulate secondary passwords for all accounts, it should be granted the `CREATE USER` privilege rather than `APPLICATION_PASSWORD_ADMIN`.

## Random Password Generation

The `CREATE USER`, `ALTER USER`, and `SET PASSWORD` statements have the capability of generating random passwords for user accounts, as an alternative to requiring explicit administrator-specified literal passwords. See the description of each statement for details about the syntax. This section describes the characteristics common to generated random passwords.

By default, generated random passwords have a length of 20 characters. This length is controlled by the `generated_random_password_length` system variable, which has a range from 5 to 255.

For each account for which a statement generates a random password, the statement stores the password in the `mysql.user` system table, hashed appropriately for the account authentication plugin. The statement also returns the cleartext password in a row of a result set to make it available to the user or application executing the statement. The result set columns are named `user`, `host`, `generated password`, and `auth_factor` indicating the user name and host name values that identify the affected row in the `mysql.user` system table, the cleartext generated password, and the authentication factor the displayed password value applies to.

```
mysql> CREATE USER
 'u1'@'localhost' IDENTIFIED BY RANDOM PASSWORD,
 'u2'@'%.example.com' IDENTIFIED BY RANDOM PASSWORD,
 'u3'@'%.org' IDENTIFIED BY RANDOM PASSWORD;
```

user	host	generated password	auth_factor
u1	localhost	iOeqf>Mh9:;XD&qn(Hl}	1
u2	%.example.com	sXTSAEvw3St-R+_-C3Vb	1
u3	%.org	nEVe%Ctw/U/*Md)Exc7&	1

```
mysql> ALTER USER
 'u1'@'localhost' IDENTIFIED BY RANDOM PASSWORD,
 'u2'@'%.example.com' IDENTIFIED BY RANDOM PASSWORD;
```

user	host	generated password	auth_factor
u1	localhost	Seiei:&cw}8]@30A64vh	1
u2	%.example.com	j@&diTX80l8}(NiHXSae	1

```
mysql> SET PASSWORD FOR 'u3'@'%.org' TO RANDOM;
```

user	host	generated password	auth_factor
u3	%.org	n&cz2xF;P3!U)+]Vw52H	1

A `CREATE USER`, `ALTER USER`, or `SET PASSWORD` statement that generates a random password for an account is written to the binary log as a `CREATE USER` or `ALTER USER` statement with an `IDENTIFIED WITH auth_plugin AS 'auth_string'` clause, where `auth_plugin` is the account authentication plugin and `'auth_string'` is the account hashed password value.

If the `validate_password` component is installed, the policy that it implements has no effect on generated passwords. (The purpose of password validation is to help humans create better passwords.)

## Failed-Login Tracking and Temporary Account Locking

Administrators can configure user accounts such that too many consecutive login failures cause temporary account locking.

“Login failure” in this context means failure of the client to provide a correct password during a connection attempt. It does not include failure to connect for reasons such as unknown user or network issues. For accounts that have dual passwords (see [Dual Password Support](#)), either account password counts as correct.

The required number of login failures and the lock time are configurable per account, using the `FAILED_LOGIN_ATTEMPTS` and `PASSWORD_LOCK_TIME` options of the `CREATE USER` and `ALTER USER` statements. Examples:

```
CREATE USER 'u1'@'localhost' IDENTIFIED BY 'password'
 FAILED_LOGIN_ATTEMPTS 3 PASSWORD_LOCK_TIME 3;

ALTER USER 'u2'@'localhost'
```

```
FAILED_LOGIN_ATTEMPTS 4 PASSWORD_LOCK_TIME UNBOUNDED;
```

When too many consecutive login failures occur, the client receives an error that looks like this:

```
ERROR 3957 (HY000): Access denied for user user.
Account is blocked for D day(s) (R day(s) remaining)
due to N consecutive failed logins.
```

Use the options as follows:

- `FAILED_LOGIN_ATTEMPTS N`

This option indicates whether to track account login attempts that specify an incorrect password. The number *N* specifies how many consecutive incorrect passwords cause temporary account locking.

- `PASSWORD_LOCK_TIME {N | UNBOUNDED}`

This option indicates how long to lock the account after too many consecutive login attempts provide an incorrect password. The value is a number *N* to specify the number of days the account remains locked, or `UNBOUNDED` to specify that when an account enters the temporarily locked state, the duration of that state is unbounded and does not end until the account is unlocked. The conditions under which unlocking occurs are described later.

Permitted values of *N* for each option are in the range from 0 to 32767. A value of 0 disables the option.

Failed-login tracking and temporary account locking have these characteristics:

- For failed-login tracking and temporary locking to occur for an account, its `FAILED_LOGIN_ATTEMPTS` and `PASSWORD_LOCK_TIME` options both must be nonzero.
- For `CREATE USER`, if `FAILED_LOGIN_ATTEMPTS` or `PASSWORD_LOCK_TIME` is not specified, its implicit default value is 0 for all accounts named by the statement. This means that failed-login tracking and temporary account locking are disabled.
- For `ALTER USER`, if `FAILED_LOGIN_ATTEMPTS` or `PASSWORD_LOCK_TIME` is not specified, its value remains unchanged for all accounts named by the statement.
- For temporary account locking to occur, password failures must be consecutive. Any successful login that occurs prior to reaching the `FAILED_LOGIN_ATTEMPTS` value for failed logins causes failure counting to reset. For example, if `FAILED_LOGIN_ATTEMPTS` is 4 and three consecutive password failures have occurred, one more failure is necessary for locking to begin. But if the next login succeeds, failed-login counting for the account is reset so that four consecutive failures are again required for locking.
- Once temporary locking begins, successful login cannot occur even with the correct password until either the lock duration has passed or the account is unlocked by one of the account-reset methods listed in the following discussion.

When the server reads the grant tables, it initializes state information for each account regarding whether failed-login tracking is enabled, whether the account is currently temporarily locked and when locking began if so, and the number of failures before temporary locking occurs if the account is not locked.

An account's state information can be reset, which means that failed-login counting is reset, and the account is unlocked if currently temporarily locked. Account resets can be global for all accounts or per account:

- A global reset of all accounts occurs for any of these conditions:
  - A server restart.

- Execution of `FLUSH PRIVILEGES`. (Starting the server with `--skip-grant-tables` causes the grant tables not to be read, which disables failed-login tracking. In this case, the first execution of `FLUSH PRIVILEGES` causes the server to read the grant tables and enable failed-login tracking, in addition to resetting all accounts.)
- A per-account reset occurs for any of these conditions:
  - Successful login for the account.
  - The lock duration passes. In this case, failed-login counting resets at the time of the next login attempt.
  - Execution of an `ALTER USER` statement for the account that sets either `FAILED_LOGIN_ATTEMPTS` or `PASSWORD_LOCK_TIME` (or both) to any value (including the current option value), or execution of an `ALTER USER ... UNLOCK` statement for the account.

Other `ALTER USER` statements for the account have no effect on its current failed-login count or its locking state.

Failed-login tracking is tied to the login account that is used to check credentials. If user proxying is in use, tracking occurs for the proxy user, not the proxied user. That is, tracking is tied to the account indicated by `USER()`, not the account indicated by `CURRENT_USER()`. For information about the distinction between proxy and proxied users, see [Section 8.2.19, “Proxy Users”](#).

## 8.2.16 Server Handling of Expired Passwords

MySQL provides password-expiration capability, which enables database administrators to require that users reset their password. Passwords can be expired manually, and on the basis of a policy for automatic expiration (see [Section 8.2.15, “Password Management”](#)).

The `ALTER USER` statement enables account password expiration. For example:

```
ALTER USER 'myuser'@'localhost' PASSWORD EXPIRE;
```

For each connection that uses an account with an expired password, the server either disconnects the client or restricts the client to “sandbox mode,” in which the server permits the client to perform only those operations necessary to reset the expired password. Which action is taken by the server depends on both client and server settings, as discussed later.

If the server disconnects the client, it returns an `ER_MUST_CHANGE_PASSWORD_LOGIN` error:

```
$> mysql -u myuser -p
Password: *****
ERROR 1862 (HY000): Your password has expired. To log in you must
change it using a client that supports expired passwords.
```

If the server restricts the client to sandbox mode, these operations are permitted within the client session:

- The client can reset the account password with `ALTER USER` or `SET PASSWORD`. After that has been done, the server restores normal access for the session, as well as for subsequent connections that use the account.

### Note

Although it is possible to “reset” an expired password by setting it to its current value, it is preferable, as a matter of good policy, to choose a different password. DBAs can enforce non-reuse by establishing an appropriate password-reuse policy. See [Password Reuse Policy](#).

For any operation not permitted within the session, the server returns an `ER_MUST_CHANGE_PASSWORD` error:

```
mysql> USE performance_schema;
ERROR 1820 (HY000): You must reset your password using ALTER USER
statement before executing this statement.

mysql> SELECT 1;
ERROR 1820 (HY000): You must reset your password using ALTER USER
statement before executing this statement.
```

That is what normally happens for interactive invocations of the `mysql` client because by default such invocations are put in sandbox mode. To resume normal functioning, select a new password.

For noninteractive invocations of the `mysql` client (for example, in batch mode), the server normally disconnects the client if the password is expired. To permit noninteractive `mysql` invocations to stay connected so that the password can be changed (using the statements permitted in sandbox mode), add the `--connect-expired-password` option to the `mysql` command.

As mentioned previously, whether the server disconnects an expired-password client or restricts it to sandbox mode depends on a combination of client and server settings. The following discussion describes the relevant settings and how they interact.

#### Note

This discussion applies only for accounts with expired passwords. If a client connects using a nonexpired password, the server handles the client normally.

On the client side, a given client indicates whether it can handle sandbox mode for expired passwords. For clients that use the C client library, there are two ways to do this:

- Pass the `MYSQL_OPT_CAN_HANDLE_EXPIRED_PASSWORDS` flag to `mysql_options()` prior to connecting:

```
bool arg = 1;
mysql_options(mysql,
 MYSQL_OPT_CAN_HANDLE_EXPIRED_PASSWORDS,
 &arg);
```

This is the technique used within the `mysql` client, which enables `MYSQL_OPT_CAN_HANDLE_EXPIRED_PASSWORDS` if invoked interactively or with the `--connect-expired-password` option.

- Pass the `CLIENT_CAN_HANDLE_EXPIRED_PASSWORDS` flag to `mysql_real_connect()` at connect time:

```
MYSQL mysql;
mysql_init(&mysql);
if (!mysql_real_connect(&mysql,
 host, user, password, db,
 port, unix_socket,
 CLIENT_CAN_HANDLE_EXPIRED_PASSWORDS))
{
 ... handle error ...
}
```

Other MySQL Connectors have their own conventions for indicating readiness to handle sandbox mode. See the documentation for the Connector in which you are interested.

On the server side, if a client indicates that it can handle expired passwords, the server puts it in sandbox mode.

If a client does not indicate that it can handle expired passwords (or uses an older version of the client library that cannot so indicate), the server action depends on the value of the `disconnect_on_expired_password` system variable:

- If `disconnect_on_expired_password` is enabled (the default), the server disconnects the client with an `ER_MUST_CHANGE_PASSWORD_LOGIN` error.
- If `disconnect_on_expired_password` is disabled, the server puts the client in sandbox mode.

## 8.2.17 Pluggable Authentication

When a client connects to the MySQL server, the server uses the user name provided by the client and the client host to select the appropriate account row from the `mysql.user` system table. The server then authenticates the client, determining from the account row which authentication plugin applies to the client:

- If the server cannot find the plugin, an error occurs and the connection attempt is rejected.
- Otherwise, the server invokes that plugin to authenticate the user, and the plugin returns a status to the server indicating whether the user provided the correct password and is permitted to connect.

Pluggable authentication enables these important capabilities:

- **Choice of authentication methods.** Pluggable authentication makes it easy for DBAs to choose and change the authentication method used for individual MySQL accounts.
- **External authentication.** Pluggable authentication makes it possible for clients to connect to the MySQL server with credentials appropriate for authentication methods that store credentials elsewhere than in the `mysql.user` system table. For example, plugins can be created to use external authentication methods such as PAM, Windows login IDs, LDAP, or Kerberos.
- **Proxy users:** If a user is permitted to connect, an authentication plugin can return to the server a user name different from the name of the connecting user, to indicate that the connecting user is a proxy for another user (the proxied user). While the connection lasts, the proxy user is treated, for purposes of access control, as having the privileges of the proxied user. In effect, one user impersonates another. For more information, see [Section 8.2.19, “Proxy Users”](#).

### Note

If you start the server with the `--skip-grant-tables` option, authentication plugins are not used even if loaded because the server performs no client authentication and permits any client to connect. Because this is insecure, if the server is started with the `--skip-grant-tables` option, it also disables remote connections by enabling `skip_networking`.

- [Available Authentication Plugins](#)
- [The Default Authentication Plugin](#)
- [Authentication Plugin Usage](#)
- [Authentication Plugin Client/Server Compatibility](#)
- [Authentication Plugin Connector-Writing Considerations](#)
- [Restrictions on Pluggable Authentication](#)

## Available Authentication Plugins

MySQL 9.1 provides these authentication plugins:

- Plugins that perform authentication using SHA-256 password hashing. This is stronger encryption than that available with native authentication. See [Section 8.4.1.1, “Caching SHA-2 Pluggable Authentication”](#), and [Section 8.4.1.2, “SHA-256 Pluggable Authentication”](#).
- A client-side plugin that sends the password to the server without hashing or encryption. This plugin is used in conjunction with server-side plugins that require access to the password exactly as provided by the client user. See [Section 8.4.1.3, “Client-Side Cleartext Pluggable Authentication”](#).
- A plugin that performs external authentication using PAM (Pluggable Authentication Modules), enabling MySQL Server to use PAM to authenticate MySQL users. This plugin supports proxy users as well. See [Section 8.4.1.4, “PAM Pluggable Authentication”](#).
- A plugin that performs external authentication on Windows, enabling MySQL Server to use native Windows services to authenticate client connections. Users who have logged in to Windows can connect from MySQL client programs to the server based on the information in their environment without specifying an additional password. This plugin supports proxy users as well. See [Section 8.4.1.5, “Windows Pluggable Authentication”](#).
- Plugins that perform authentication using LDAP (Lightweight Directory Access Protocol) to authenticate MySQL users by accessing directory services such as X.500. These plugins support proxy users as well. See [Section 8.4.1.6, “LDAP Pluggable Authentication”](#).
- A plugin that performs authentication using Kerberos to authenticate MySQL users that correspond to Kerberos principals. See [Section 8.4.1.7, “Kerberos Pluggable Authentication”](#).
- A plugin that performs authentication using OpenID Connect to authenticate MySQL users. See [Section 8.4.1.9, “OpenID Connect Pluggable Authentication”](#).
- A plugin that prevents all client connections to any account that uses it. Use cases for this plugin include proxied accounts that should never permit direct login but are accessed only through proxy accounts and accounts that must be able to execute stored programs and views with elevated privileges without exposing those privileges to ordinary users. See [Section 8.4.1.8, “No-Login Pluggable Authentication”](#).
- A plugin that authenticates clients that connect from the local host through the Unix socket file. See [Section 8.4.1.10, “Socket Peer-Credential Pluggable Authentication”](#).
- A plugin that authenticates users to MySQL Server using WebAuthn format with a FIDO/FIDO2 device. See [Section 8.4.1.11, “WebAuthn Pluggable Authentication”](#).
- A test plugin that checks account credentials and logs success or failure to the server error log. This plugin is intended for testing and development purposes, and as an example of how to write an authentication plugin. See [Section 8.4.1.12, “Test Pluggable Authentication”](#).

**Note**

For information about current restrictions on the use of pluggable authentication, including which connectors support which plugins, see [Restrictions on Pluggable Authentication](#).

Third-party connector developers should read that section to determine the extent to which a connector can take advantage of pluggable authentication capabilities and what steps to take to become more compliant.

If you are interested in writing your own authentication plugins, see [Writing Authentication Plugins](#).

## The Default Authentication Plugin

The `CREATE USER` and `ALTER USER` statements have syntax for specifying how an account authenticates. Some forms of this syntax do not explicitly name an authentication plugin (there is no `IDENTIFIED WITH` clause). For example:

```
CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'password';
```

In such cases, the server assigns the default authentication plugin to the account. MySQL 9.1 supports multifactor authentication and up to three clauses that specify how an account authenticates. The rules that determine the default authentication plugin for authentication methods that name no plugin are factor-specific:

- Factor 1: If `authentication_policy` element 1 names an authentication plugin, that plugin is the default. If `authentication_policy` element 1 is `*`, `caching_sha2_password` is the default.

Given the rules above, the following statement creates a two-factor authentication account, with the first factor authentication method determined by `authentication_policy`, as shown here:

```
CREATE USER 'wei'@'localhost' IDENTIFIED BY 'password'
AND IDENTIFIED WITH authentication_ldap_simple;
```

In the same way, this example creates a three-factor authentication account:

```
CREATE USER 'mateo'@'localhost' IDENTIFIED BY 'password'
AND IDENTIFIED WITH authentication_ldap_simple
AND IDENTIFIED WITH authentication_fido;
```

You can use `SHOW CREATE USER` to view the applied authentication methods.

- Factor 2 or 3: If the corresponding `authentication_policy` element names an authentication plugin, that plugin is the default. If the `authentication_policy` element is `*` or empty, there is no default; attempting to define an account authentication method for the factor without naming a plugin is an error, as in the following examples:

```
mysql> CREATE USER 'sofia'@'localhost' IDENTIFIED WITH authentication_ldap_simple
AND IDENTIFIED BY 'abc';
ERROR 1524 (HY000): Plugin '' is not loaded

mysql> CREATE USER 'sofia'@'localhost' IDENTIFIED WITH authentication_ldap_simple
AND IDENTIFIED BY 'abc';
ERROR 1524 (HY000): Plugin '*' is not loaded
```

## Authentication Plugin Usage

This section provides general instructions for installing and using authentication plugins. For instructions specific to a given plugin, see the section that describes that plugin under [Section 8.4.1, “Authentication Plugins”](#).

In general, pluggable authentication uses a pair of corresponding plugins on the server and client sides, so you use a given authentication method like this:

- If necessary, install the plugin library or libraries containing the appropriate plugins. On the server host, install the library containing the server-side plugin, so that the server can use it to authenticate client connections. Similarly, on each client host, install the library containing the client-side plugin for use by client programs. Authentication plugins that are built in need not be installed.
- For each MySQL account that you create, specify the appropriate server-side plugin to use for authentication. If the account is to use the default authentication plugin, the account-creation statement need not specify the plugin explicitly. The server assigns the default authentication plugin, determined as described in [The Default Authentication Plugin](#).

- When a client connects, the server-side plugin tells the client program which client-side plugin to use for authentication.

In the case that an account uses an authentication method that is the default for both the server and the client program, the server need not communicate to the client which client-side plugin to use, and a round trip in client/server negotiation can be avoided.

For standard MySQL clients such as `mysql` and `mysqladmin`, the `--default-auth=plugin_name` option can be specified on the command line as a hint about which client-side plugin the program can expect to use, although the server overrides this if the server-side plugin associated with the user account requires a different client-side plugin.

If the client program does not find the client-side plugin library file, specify a `--plugin-dir=dir_name` option to indicate the plugin library directory location.

## Authentication Plugin Client/Server Compatibility

Pluggable authentication enables flexibility in the choice of authentication methods for MySQL accounts, but in some cases client connections cannot be established due to authentication plugin incompatibility between the client and server.

The general compatibility principle for a successful client connection to a given account on a given server is that the client and server both must support the authentication *method* required by the account. Because authentication methods are implemented by authentication plugins, the client and server both must support the authentication *plugin* required by the account.

Authentication plugin incompatibilities can arise in various ways. Examples:

- Connect using a MySQL 5.7 client from 5.7.22 or lower to a MySQL 9.1 server account that authenticates with `caching_sha2_password`. This fails because the 5.7 client does not recognize the plugin. (This issue is addressed in MySQL 5.7 as of 5.7.23, when `caching_sha2_password` client-side support was added to the MySQL client library and client programs.)
- Connect using a MySQL 5.7 client to a pre-5.7 server account that authenticates with `mysql_old_password`. This fails for multiple reasons. First, such a connection requires `--secure-auth=0`, which is no longer a supported option. Even were it supported, the 5.7 client does not recognize the plugin because it was removed in MySQL 5.7.
- Connect using a MySQL 5.7 client from a Community distribution to a MySQL 5.7 Enterprise server account that authenticates using one of the Enterprise-only LDAP authentication plugins. This fails because the Community client does not have access to the Enterprise plugin.

In general, these compatibility issues do not arise when connections are made between a client and server from the same MySQL distribution. When connections are made between a client and server from different MySQL series, issues can arise. These issues are inherent in the development process when MySQL introduces new authentication plugins or removes old ones. To minimize the potential for incompatibilities, regularly upgrade the server, clients, and connectors on a timely basis.

## Authentication Plugin Connector-Writing Considerations

Various implementations of the MySQL client/server protocol exist. The `libmysqlclient` C API client library is one implementation. Some MySQL connectors (typically those not written in C) provide their own implementation. However, not all protocol implementations handle plugin authentication the same way. This section describes an authentication issue that protocol implementors should take into account.

In the client/server protocol, the server tells connecting clients which authentication plugin it considers the default. If the protocol implementation used by the client tries to load the default plugin and that plugin does

not exist on the client side, the load operation fails. This is an unnecessary failure if the default plugin is not the plugin actually required by the account to which the client is trying to connect.

If a client/server protocol implementation does not have its own notion of default authentication plugin and always tries to load the default plugin specified by the server, it fails with an error if that plugin is not available.

To avoid this problem, the protocol implementation used by the client should have its own default plugin and should use it as its first choice (or, alternatively, fall back to this default in case of failure to load the default plugin specified by the server). Example:

- In MySQL 5.7, `libmysqlclient` uses as its default choice either `mysql_native_password` or the plugin specified through the `MYSQL_DEFAULT_AUTH` option for `mysql_options()`.
- When a 5.7 client tries to connect to an 9.1 server, the server specifies `caching_sha2_password` as its default authentication plugin, but the client still sends credential details per either `mysql_native_password` or whatever is specified through `MYSQL_DEFAULT_AUTH`.
- The only time the client loads the plugin specified by the server is for a change-plugin request, but in that case it can be any plugin depending on the user account. In this case, the client must try to load the plugin, and if that plugin is not available, an error is not optional.

## Restrictions on Pluggable Authentication

The first part of this section describes general restrictions on the applicability of the pluggable authentication framework described at [Section 8.2.17, “Pluggable Authentication”](#). The second part describes how third-party connector developers can determine the extent to which a connector can take advantage of pluggable authentication capabilities and what steps to take to become more compliant.

The term “native authentication” used here refers to authentication against passwords stored in the `mysql.user` system table. This is the same authentication method provided by older MySQL servers, before pluggable authentication was implemented. “Windows native authentication” refers to authentication using the credentials of a user who has already logged in to Windows, as implemented by the Windows Native Authentication plugin (“Windows plugin” for short).

- [General Pluggable Authentication Restrictions](#)
- [Pluggable Authentication and Third-Party Connectors](#)

## General Pluggable Authentication Restrictions

- **Connector/C++:** Clients that use this connector can connect to the server only through accounts that use native authentication.

Exception: A connector supports pluggable authentication if it was built to link to `libmysqlclient` dynamically (rather than statically) and it loads the current version of `libmysqlclient` if that version is installed, or if the connector is recompiled from source to link against the current `libmysqlclient`.

For information about writing connectors to handle information from the server about the default server-side authentication plugin, see [Authentication Plugin Connector-Writing Considerations](#).

- **Connector/NET:** Clients that use Connector/NET can connect to the server through accounts that use native authentication or Windows native authentication.
- **Connector/PHP:** Clients that use this connector can connect to the server only through accounts that use native authentication, when compiled using the MySQL native driver for PHP (`mysqlnd`).

- **Windows native authentication:** Connecting through an account that uses the Windows plugin requires Windows Domain setup. Without it, NTLM authentication is used and then only local connections are possible; that is, the client and server must run on the same computer.
- **Proxy users:** Proxy user support is available to the extent that clients can connect through accounts authenticated with plugins that implement proxy user capability (that is, plugins that can return a user name different from that of the connecting user). For example, the PAM and Windows plugins support proxy users. The `sha256_password` authentication plugin does not support proxy users by default, but can be configured to do so; see [Server Support for Proxy User Mapping](#).
- **Replication:** Replicas can not only employ replication user accounts using native authentication, but can also connect through replication user accounts that use nonnative authentication if the required client-side plugin is available. If the plugin is built into `libmysqlclient`, it is available by default. Otherwise, the plugin must be installed on the replica side in the directory named by the replica's `plugin_dir` system variable.
- **FEDERATED tables:** A `FEDERATED` table can access the remote table only through accounts on the remote server that use native authentication.

## Pluggable Authentication and Third-Party Connectors

Third-party connector developers can use the following guidelines to determine readiness of a connector to take advantage of pluggable authentication capabilities and what steps to take to become more compliant:

- An existing connector to which no changes have been made uses native authentication and clients that use the connector can connect to the server only through accounts that use native authentication. *However, you should test the connector against a recent version of the server to verify that such connections still work without problem.*

Exception: A connector might work with pluggable authentication without any changes if it links to `libmysqlclient` dynamically (rather than statically) and it loads the current version of `libmysqlclient` if that version is installed.

- To take advantage of pluggable authentication capabilities, a connector that is `libmysqlclient`-based should be relinked against the current version of `libmysqlclient`. This enables the connector to support connections through accounts that require client-side plugins now built into `libmysqlclient` (such as the cleartext plugin needed for PAM authentication and the Windows plugin needed for Windows native authentication). Linking with a current `libmysqlclient` also enables the connector to access client-side plugins installed in the default MySQL plugin directory (typically the directory named by the default value of the local server's `plugin_dir` system variable).

If a connector links to `libmysqlclient` dynamically, it must be ensured that the newer version of `libmysqlclient` is installed on the client host and that the connector loads it at runtime.

- Another way for a connector to support a given authentication method is to implement it directly in the client/server protocol. Connector/NET uses this approach to provide support for Windows native authentication.
- If a connector should be able to load client-side plugins from a directory different from the default plugin directory, it must implement some means for client users to specify the directory. Possibilities for this include a command-line option or environment variable from which the connector can obtain the directory name. Standard MySQL client programs such as `mysql` and `mysqladmin` implement a `--plugin-dir` option. See also [C API Client Plugin Interface](#).
- Proxy user support by a connector depends, as described earlier in this section, on whether the authentication methods that it supports permit proxy users.

## 8.2.18 Multifactor Authentication

Authentication involves one party establishing its identity to the satisfaction of a second party. Multifactor authentication (MFA) is the use of multiple authentication values (or “factors”) during the authentication process. MFA provides greater security than one-factor/single-factor authentication (1FA/SFA), which uses only one authentication method such as a password. MFA enables additional authentication methods, such as authentication using multiple passwords, or authentication using devices like smart cards, security keys, and biometric readers.

MySQL includes support for multifactor authentication. This capability includes forms of MFA that require up to three authentication values. That is, MySQL account management supports accounts that use 2FA or 3FA, in addition to the existing 1FA support.

When a client attempts a connection to the MySQL server using a single-factor account, the server invokes the authentication plugin indicated by the account definition and accepts or rejects the connection depending on whether the plugin reports success or failure.

For an account that has multiple authentication factors, the process is similar. The server invokes authentication plugins in the order listed in the account definition. If a plugin reports success, the server either accepts the connection if the plugin is the last one, or proceeds to invoke the next plugin if any remain. If any plugin reports failure, the server rejects the connection.

The following sections cover multifactor authentication in MySQL in more detail.

- [Elements of Multifactor Authentication Support](#)
- [Configuring the Multifactor Authentication Policy](#)
- [Getting Started with Multifactor Authentication](#)

### Elements of Multifactor Authentication Support

Authentication factors commonly include these types of information:

- Something you know, such as a secret password or passphrase.
- Something you have, such as a security key or smart card.
- Something you are; that is, a biometric characteristic such as a fingerprint or facial scan.

The “something you know” factor type relies on information that is kept secret on both sides of the authentication process. Unfortunately, secrets may be subject to compromise: Someone might see you enter your password or fool you with a phishing attack, a password stored on the server side might be exposed by a security breach, and so forth. Security can be improved by using multiple passwords, but each may still be subject to compromise. Use of the other factor types enables improved security with less risk of compromise.

Implementation of multifactor authentication in MySQL comprises these elements:

- The `authentication_policy` system variable controls how many authentication factors can be used and the types of authentication permitted for each factor. That is, it places constraints on `CREATE USER` and `ALTER USER` statements with respect to multifactor authentication.
- `CREATE USER` and `ALTER USER` have syntax enabling multiple authentication methods to be specified for new accounts, and for adding, modifying, or dropping authentication methods for existing accounts. If an account uses 2FA or 3FA, the `mysql.user` system table stores information about the additional authentication factors in the `User_attributes` column.

- To enable authentication to the MySQL server using accounts that require multiple passwords, client programs have `--password1`, `--password2`, and `--password3` options that permit up to three passwords to be specified. For applications that use the C API, the `MYSQL_OPT_USER_PASSWORD` option for the `mysql_options4()` C API function enables the same capability.
- The server-side `authentication_webauthn` plugin enables authentication using devices. This server-side, device-based authentication plugin is included only in MySQL Enterprise Edition distributions. It is not included in MySQL community distributions. However, the client-side `authentication_webauthn_client` plugin is included in all distributions, including community distributions. This enables clients from any distribution to connect to accounts that use `authentication_webauthn` to authenticate on a server that has that plugin loaded. See [Section 8.4.1.11, “WebAuthn Pluggable Authentication”](#).
- `authentication_webauthn` also enables passwordless authentication, if it is the only authentication plugin used by an account. See [WebAuthn Passwordless Authentication](#).
- Multifactor authentication can use non-WebAuthn MySQL authentication methods, the WebAuthn authentication method, or a combination of both.
- These privileges enable users to perform certain restricted multifactor authentication-related operations:
  - A user who has the `AUTHENTICATION_POLICY_ADMIN` privilege is not subject to the constraints imposed by the `authentication_policy` system variable. (A warning does occur for statements that otherwise would not be permitted.)
  - The `PASSWORDLESS_USER_ADMIN` privilege enables creation of passwordless-authentication accounts and replication of operations on them.

## Configuring the Multifactor Authentication Policy

The `authentication_policy` system variable defines the multifactor authentication policy. Specifically, it defines how many authentication factors accounts may have (or are required to have) and the authentication methods that can be used for each factor.

The value of `authentication_policy` is a list of 1, 2, or 3 comma-separated elements. Each element in the list corresponds to an authentication factor and can be an authentication plugin name, an asterisk (\*), empty, or missing. (Exception: Element 1 cannot be empty or missing.) The entire list is enclosed in single quotes. For example, the following `authentication_policy` value includes an asterisk, an authentication plugin name, and an empty element:

```
authentication_policy = '*,authentication_webauthn,'
```

An asterisk (\*) indicates that an authentication method is required but any method is permitted. An empty element indicates that an authentication method is optional and any method is permitted. A missing element (no asterisk, empty element, or authentication plugin name) indicates that an authentication method is not permitted. When a plugin name is specified, that authentication method is required for the respective factor when creating or modifying an account.

The default `authentication_policy` value is `'*,,'` (an asterisk and two empty elements), which requires a first factor, and optionally permits second and third factors. The default `authentication_policy` value is thus backward compatible with existing 1FA accounts, but also permits creation or modification of accounts to use 2FA or 3FA.

A user who has the `AUTHENTICATION_POLICY_ADMIN` privilege is not subject to the constraints imposed by the `authentication_policy` setting. (A warning occurs for statements that otherwise would not be permitted.)

`authentication_policy` values can be defined in an option file or specified using a `SET GLOBAL` statement:

```
SET GLOBAL authentication_policy='*,*,*';
```

There are several rules that govern how the `authentication_policy` value can be defined. Refer to the `authentication_policy` system variable description for a complete account of those rules. The following table provides several `authentication_policy` example values and the policy established by each.

**Table 8.11 Example authentication\_policy Values**

authentication_policy Value	Effective Policy
'*'	Permit only creating or altering accounts with one factor.
'*,*'	Permit only creating or altering accounts with two factors.
'*,*,*'	Permit only creating or altering accounts with three factors.
'*, '	Permit creating or altering accounts with one or two factors.
'*, , '	Permit creating or altering accounts with one, two, or three factors.
'*,*, '	Permit creating or altering accounts with two or three factors.
'*,auth_plugin'	Permit creating or altering accounts with two factors, where the first factor can be any authentication method, and the second factor must be the named plugin.
'auth_plugin*, '	Permit creating or altering accounts with two or three factors, where the first factor must be the named plugin.
'auth_plugin, '	Permit creating or altering accounts with one or two factors, where the first factor must be the named plugin.
'auth_plugin,auth_plugin,auth_plugin'	Permits creating or altering accounts with three factors, where the factors must use the named plugins.

## Getting Started with Multifactor Authentication

By default, MySQL uses a multifactor authentication policy that permits any authentication plugin for the first factor, and optionally permits second and third authentication factors. This policy is configurable; for details, see [Configuring the Multifactor Authentication Policy](#).

### Note

It is not permitted to use any internal credential storage plugins (such as `caching_sha2_password`) for factor 2 or 3.

Suppose that you want an account to authenticate first using the `caching_sha2_password` plugin, then using the `authentication_ldap_sasl` SASL LDAP plugin. (This assumes that LDAP authentication is

already set up as described in [Section 8.4.1.6, “LDAP Pluggable Authentication”](#), and that the user has an entry in the LDAP directory corresponding to the authentication string shown in the example.) Create the account using a statement like this:

```
CREATE USER 'alice'@'localhost'
 IDENTIFIED WITH caching_sha2_password
 BY 'sha2_password'
 AND IDENTIFIED WITH authentication_ldap_sasl
 AS 'uid=u1_ldap,ou=People,dc=example,dc=com';
```

To connect, the user must supply two passwords. To enable authentication to the MySQL server using accounts that require multiple passwords, client programs have `--password1`, `--password2`, and `--password3` options that permit up to three passwords to be specified. These options are similar to the `--password` option in that they can take a password value following the option on the command line (which is insecure) or if given without a password value cause the user to be prompted for one. For the account just created, factors 1 and 2 take passwords, so invoke the `mysql` client with the `--password1` and `--password2` options. `mysql` prompts for each password in turn:

```
$> mysql --user=alice --password1 --password2
Enter password: (enter factor 1 password)
Enter password: (enter factor 2 password)
```

Suppose you want to add a third authentication factor. This can be achieved by dropping and recreating the user with a third factor or by using `ALTER USER user ADD factor` syntax. Both methods are shown below:

```
DROP USER 'alice'@'localhost';

CREATE USER 'alice'@'localhost'
 IDENTIFIED WITH caching_sha2_password
 BY 'sha2_password'
 AND IDENTIFIED WITH authentication_ldap_sasl
 AS 'uid=u1_ldap,ou=People,dc=example,dc=com'
 AND IDENTIFIED WITH authentication_webauthn;
```

`ADD factor` syntax includes the factor number and `FACTOR` keyword:

```
ALTER USER 'alice'@'localhost' ADD 3 FACTOR IDENTIFIED WITH authentication_webauthn;
```

`ALTER USER user DROP factor` syntax permits dropping a factor. The following example drops the third factor (`authentication_webauthn`) that was added in the previous example:

```
ALTER USER 'alice'@'localhost' DROP 3 FACTOR;
```

`ALTER USER user MODIFY factor` syntax permits changing the plugin or authentication string for a particular factor, provided that the factor exists. The following example modifies the second factor, changing the authentication method from `authentication_ldap_sasl` to `authentication_webauthn`:

```
ALTER USER 'alice'@'localhost' MODIFY 2 FACTOR IDENTIFIED WITH authentication_webauthn;
```

Use `SHOW CREATE USER` to view the authentication methods defined for an account:

```
SHOW CREATE USER 'u1'@'localhost'\G
***** 1. row *****
CREATE USER for u1@localhost: CREATE USER `u1`@`localhost`
IDENTIFIED WITH 'caching_sha2_password' AS 'sha2_password'
AND IDENTIFIED WITH 'authentication_authn' REQUIRE NONE
PASSWORD EXPIRE DEFAULT ACCOUNT UNLOCK PASSWORD HISTORY
DEFAULT PASSWORD REUSE INTERVAL DEFAULT PASSWORD REQUIRE
```

## 8.2.19 Proxy Users

The MySQL server authenticates client connections using authentication plugins. The plugin that authenticates a given connection may request that the connecting (external) user be treated as a different user for privilege-checking purposes. This enables the external user to be a proxy for the second user; that is, to assume the privileges of the second user:

- The external user is a “proxy user” (a user who can impersonate or become known as another user).
- The second user is a “proxied user” (a user whose identity and privileges can be assumed by a proxy user).

This section describes how the proxy user capability works. For general information about authentication plugins, see [Section 8.2.17, “Pluggable Authentication”](#). For information about specific plugins, see [Section 8.4.1, “Authentication Plugins”](#). For information about writing authentication plugins that support proxy users, see [Implementing Proxy User Support in Authentication Plugins](#).

- [Requirements for Proxy User Support](#)
- [Simple Proxy User Example](#)
- [Preventing Direct Login to Proxied Accounts](#)
- [Granting and Revoking the PROXY Privilege](#)
- [Default Proxy Users](#)
- [Default Proxy User and Anonymous User Conflicts](#)
- [Server Support for Proxy User Mapping](#)
- [Proxy User System Variables](#)

### Note

One administrative benefit to be gained by proxying is that the DBA can set up a single account with a set of privileges and then enable multiple proxy users to have those privileges without having to assign the privileges individually to each of those users. As an alternative to proxy users, DBAs may find that roles provide a suitable way to map users onto specific sets of named privileges. Each user can be granted a given single role to, in effect, be granted the appropriate set of privileges. See [Section 8.2.10, “Using Roles”](#).

## Requirements for Proxy User Support

For proxying to occur for a given authentication plugin, these conditions must be satisfied:

- Proxying must be supported, either by the plugin itself, or by the MySQL server on behalf of the plugin. In the latter case, server support may need to be enabled explicitly; see [Server Support for Proxy User Mapping](#).
- The account for the external proxy user must be set up to be authenticated by the plugin. Use the `CREATE USER` statement to associate an account with an authentication plugin, or `ALTER USER` to change its plugin.

- The account for the proxied user must exist and be granted the privileges to be assumed by the proxy user. Use the `CREATE USER` and `GRANT` statements for this.
- Normally, the proxied user is configured so that it can be used only in proxying scenarios and not for direct logins.
- The proxy user account must have the `PROXY` privilege for the proxied account. Use the `GRANT` statement for this.
- For a client connecting to the proxy account to be treated as a proxy user, the authentication plugin must return a user name different from the client user name, to indicate the user name of the proxied account that defines the privileges to be assumed by the proxy user.

Alternatively, for plugins that are provided proxy mapping by the server, the proxied user is determined from the `PROXY` privilege held by the proxy user.

The proxy mechanism permits mapping only the external client user name to the proxied user name. There is no provision for mapping host names:

- When a client connects to the server, the server determines the proper account based on the user name passed by the client program and the host from which the client connects.
- If that account is a proxy account, the server attempts to determine the appropriate proxied account by finding a match for a proxied account using the user name returned by the authentication plugin and the host name of the proxy account. The host name in the proxied account is ignored.

## Simple Proxy User Example

Consider the following account definitions:

```
-- create proxy account
CREATE USER 'employee_ext'@'localhost'
 IDENTIFIED WITH my_auth_plugin
 AS 'my_auth_string';

-- create proxied account and grant its privileges;
-- use mysql_no_login plugin to prevent direct login
CREATE USER 'employee'@'localhost'
 IDENTIFIED WITH mysql_no_login;
GRANT ALL
 ON employees.*
 TO 'employee'@'localhost';

-- grant to proxy account the
-- PROXY privilege for proxied account
GRANT PROXY
 ON 'employee'@'localhost'
 TO 'employee_ext'@'localhost';
```

When a client connects as `employee_ext` from the local host, MySQL uses the plugin named `my_auth_plugin` to perform authentication. Suppose that `my_auth_plugin` returns a user name of `employee` to the server, based on the content of `'my_auth_string'` and perhaps by consulting some external authentication system. The name `employee` differs from `employee_ext`, so returning `employee` serves as a request to the server to treat the `employee_ext` external user, for purposes of privilege checking, as the `employee` local user.

In this case, `employee_ext` is the proxy user and `employee` is the proxied user.

The server verifies that proxy authentication for `employee` is possible for the `employee_ext` user by checking whether `employee_ext` (the proxy user) has the `PROXY` privilege for `employee` (the proxied

user). If this privilege has not been granted, an error occurs. Otherwise, `employee_ext` assumes the privileges of `employee`. The server checks statements executed during the client session by `employee_ext` against the privileges granted to `employee`. In this case, `employee_ext` can access tables in the `employees` database.

The proxied account, `employee`, uses the `mysql_no_login` authentication plugin to prevent clients from using the account to log in directly. (This assumes that the plugin is installed. For instructions, see [Section 8.4.1.8, “No-Login Pluggable Authentication”](#).) For alternative methods of protecting proxied accounts against direct use, see [Preventing Direct Login to Proxied Accounts](#).

When proxying occurs, the `USER()` and `CURRENT_USER()` functions can be used to see the difference between the connecting user (the proxy user) and the account whose privileges apply during the current session (the proxied user). For the example just described, those functions return these values:

```
mysql> SELECT USER(), CURRENT_USER();
+-----+-----+
| USER() | CURRENT_USER() |
+-----+-----+
| employee_ext@localhost | employee@localhost |
+-----+-----+
```

In the `CREATE USER` statement that creates the proxy user account, the `IDENTIFIED WITH` clause that names the proxy-supporting authentication plugin is optionally followed by an `AS 'auth_string'` clause specifying a string that the server passes to the plugin when the user connects. If present, the string provides information that helps the plugin determine how to map the proxy (external) client user name to a proxied user name. It is up to each plugin whether it requires the `AS` clause. If so, the format of the authentication string depends on how the plugin intends to use it. Consult the documentation for a given plugin for information about the authentication string values it accepts.

## Preventing Direct Login to Proxied Accounts

Proxied accounts generally are intended to be used only by means of proxy accounts. That is, clients connect using a proxy account, then are mapped onto and assume the privileges of the appropriate proxied user.

There are multiple ways to ensure that a proxied account cannot be used directly:

- Associate the account with the `mysql_no_login` authentication plugin. In this case, the account cannot be used for direct logins under any circumstances. This assumes that the plugin is installed. For instructions, see [Section 8.4.1.8, “No-Login Pluggable Authentication”](#).
- Include the `ACCOUNT LOCK` option when you create the account. See [Section 15.7.1.3, “CREATE USER Statement”](#). With this method, also include a password so that if the account is unlocked later, it cannot be accessed with no password. (If the `validate_password` component is enabled, creating an account without a password is not permitted, even if the account is locked. See [Section 8.4.3, “The Password Validation Component”](#).)
- Create the account with a password but do not tell anyone else the password. If you do not let anyone know the password for the account, clients cannot use it to connect directly to the MySQL server.

## Granting and Revoking the PROXY Privilege

The `PROXY` privilege is needed to enable an external user to connect as and have the privileges of another user. To grant this privilege, use the `GRANT` statement. For example:

```
GRANT PROXY ON 'proxied_user' TO 'proxy_user';
```

The statement creates a row in the `mysql.proxies_priv` grant table.

At connect time, `proxy_user` must represent a valid externally authenticated MySQL user, and `proxied_user` must represent a valid locally authenticated user. Otherwise, the connection attempt fails.

The corresponding `REVOKE` syntax is:

```
REVOKE PROXY ON 'proxied_user' FROM 'proxy_user';
```

MySQL `GRANT` and `REVOKE` syntax extensions work as usual. Examples:

```
-- grant PROXY to multiple accounts
GRANT PROXY ON 'a' TO 'b', 'c', 'd';

-- revoke PROXY from multiple accounts
REVOKE PROXY ON 'a' FROM 'b', 'c', 'd';

-- grant PROXY to an account and enable the account to grant
-- PROXY to the proxied account
GRANT PROXY ON 'a' TO 'd' WITH GRANT OPTION;

-- grant PROXY to default proxy account
GRANT PROXY ON 'a' TO '@';
```

The `PROXY` privilege can be granted in these cases:

- By a user that has `GRANT PROXY ... WITH GRANT OPTION` for `proxied_user`.
- By `proxied_user` for itself: The value of `USER()` must exactly match `CURRENT_USER()` and `proxied_user`, for both the user name and host name parts of the account name.

The initial `root` account created during MySQL installation has the `PROXY ... WITH GRANT OPTION` privilege for `'@'`, that is, for all users and all hosts. This enables `root` to set up proxy users, as well as to delegate to other accounts the authority to set up proxy users. For example, `root` can do this:

```
CREATE USER 'admin'@'localhost'
 IDENTIFIED BY 'admin_password';
GRANT PROXY
 ON '@'
 TO 'admin'@'localhost'
 WITH GRANT OPTION;
```

Those statements create an `admin` user that can manage all `GRANT PROXY` mappings. For example, `admin` can do this:

```
GRANT PROXY ON sally TO joe;
```

## Default Proxy Users

To specify that some or all users should connect using a given authentication plugin, create a “blank” MySQL account with an empty user name and host name (`'@'`), associate it with that plugin, and let the plugin return the real authenticated user name (if different from the blank user). Suppose that there exists a plugin named `ldap_auth` that implements LDAP authentication and maps connecting users onto either a developer or manager account. To set up proxying of users onto these accounts, use the following statements:

```
-- create default proxy account
CREATE USER '@'
 IDENTIFIED WITH ldap_auth
```

```

AS 'O=Oracle, OU=MySQL';

-- create proxied accounts; use
-- mysql_no_login plugin to prevent direct login
CREATE USER 'developer'@'localhost'
 IDENTIFIED WITH mysql_no_login;
CREATE USER 'manager'@'localhost'
 IDENTIFIED WITH mysql_no_login;

-- grant to default proxy account the
-- PROXY privilege for proxied accounts
GRANT PROXY
 ON 'manager'@'localhost'
 TO '@';
GRANT PROXY
 ON 'developer'@'localhost'
 TO '@';

```

Now assume that a client connects as follows:

```

$> mysql --user=myuser --password ...
Enter password: myuser_password

```

The server does not find `myuser` defined as a MySQL user, but because there is a blank user account ( `'@'` ) that matches the client user name and host name, the server authenticates the client against that account. The server invokes the `ldap_auth` authentication plugin and passes `myuser` and `myuser_password` to it as the user name and password.

If the `ldap_auth` plugin finds in the LDAP directory that `myuser_password` is not the correct password for `myuser`, authentication fails and the server rejects the connection.

If the password is correct and `ldap_auth` finds that `myuser` is a developer, it returns the user name `developer` to the MySQL server, rather than `myuser`. Returning a user name different from the client user name of `myuser` signals to the server that it should treat `myuser` as a proxy. The server verifies that `'@'` can authenticate as `developer` (because `'@'` has the `PROXY` privilege to do so) and accepts the connection. The session proceeds with `myuser` having the privileges of the `developer` proxied user. (These privileges should be set up by the DBA using `GRANT` statements, not shown.) The `USER()` and `CURRENT_USER()` functions return these values:

```

mysql> SELECT USER(), CURRENT_USER();
+-----+-----+
| USER() | CURRENT_USER() |
+-----+-----+
| myuser@localhost | developer@localhost |
+-----+-----+

```

If the plugin instead finds in the LDAP directory that `myuser` is a manager, it returns `manager` as the user name and the session proceeds with `myuser` having the privileges of the `manager` proxied user.

```

mysql> SELECT USER(), CURRENT_USER();
+-----+-----+
| USER() | CURRENT_USER() |
+-----+-----+
| myuser@localhost | manager@localhost |
+-----+-----+

```

For simplicity, external authentication cannot be multilevel: Neither the credentials for `developer` nor those for `manager` are taken into account in the preceding example. However, they are still used if a client tries to connect and authenticate directly as the `developer` or `manager` account, which is why those proxied accounts should be protected against direct login (see [Preventing Direct Login to Proxied Accounts](#)).

## Default Proxy User and Anonymous User Conflicts

If you intend to create a default proxy user, check for other existing “match any user” accounts that take precedence over the default proxy user because they can prevent that user from working as intended.

In the preceding discussion, the default proxy user account has `' '` in the host part, which matches any host. If you set up a default proxy user, take care to also check whether nonproxy accounts exist with the same user part and `' % '` in the host part, because `' % '` also matches any host, but has precedence over `' '` by the rules that the server uses to sort account rows internally (see [Section 8.2.6, “Access Control, Stage 1: Connection Verification”](#)).

Suppose that a MySQL installation includes these two accounts:

```
-- create default proxy account
CREATE USER ''@'
 IDENTIFIED WITH some_plugin
 AS 'some_auth_string';
-- create anonymous account
CREATE USER ''@'%'
 IDENTIFIED BY 'anon_user_password';
```

The first account (`' '@'`) is intended as the default proxy user, used to authenticate connections for users who do not otherwise match a more-specific account. The second account (`' '@' % '`) is an anonymous-user account, which might have been created, for example, to enable users without their own account to connect anonymously.

Both accounts have the same user part (`' '`), which matches any user. And each account has a host part that matches any host. Nevertheless, there is a priority in account matching for connection attempts because the matching rules sort a host of `' % '` ahead of `' '`. For accounts that do not match any more-specific account, the server attempts to authenticate them against `' '@' % '` (the anonymous user) rather than `' '@'` (the default proxy user). As a result, the default proxy account is never used.

To avoid this problem, use one of the following strategies:

- Remove the anonymous account so that it does not conflict with the default proxy user.
- Use a more-specific default proxy user that matches ahead of the anonymous user. For example, to permit only `localhost` proxy connections, use `' '@'localhost'`:

```
CREATE USER ''@'localhost'
 IDENTIFIED WITH some_plugin
 AS 'some_auth_string';
```

In addition, modify any `GRANT PROXY` statements to name `' '@'localhost'` rather than `' '@'` as the proxy user.

Be aware that this strategy prevents anonymous-user connections from `localhost`.

- Use a named default account rather than an anonymous default account. For an example of this technique, consult the instructions for using the `authentication_windows` plugin. See [Section 8.4.1.5, “Windows Pluggable Authentication”](#).
- Create multiple proxy users, one for local connections and one for “everything else” (remote connections). This can be useful particularly when local users should have different privileges from remote users.

Create the proxy users:

```
-- create proxy user for local connections
```

```
CREATE USER '@'localhost'
 IDENTIFIED WITH some_plugin
 AS 'some_auth_string';
-- create proxy user for remote connections
CREATE USER '@'%'
 IDENTIFIED WITH some_plugin
 AS 'some_auth_string';
```

Create the proxied users:

```
-- create proxied user for local connections
CREATE USER 'developer'@'localhost'
 IDENTIFIED WITH mysql_no_login;
-- create proxied user for remote connections
CREATE USER 'developer'@'%'
 IDENTIFIED WITH mysql_no_login;
```

Grant to each proxy account the [PROXY](#) privilege for the corresponding proxied account:

```
GRANT PROXY
 ON 'developer'@'localhost'
 TO '@'localhost';
GRANT PROXY
 ON 'developer'@'%'
 TO '@'%';
```

Finally, grant appropriate privileges to the local and remote proxied users (not shown).

Assume that the [some\\_plugin](#)/[some\\_auth\\_string](#)' combination causes [some\\_plugin](#) to map the client user name to [developer](#). Local connections match the '@'localhost' proxy user, which maps to the 'developer'@'localhost' proxied user. Remote connections match the '@'%' proxy user, which maps to the 'developer'@'%' proxied user.

## Server Support for Proxy User Mapping

Some authentication plugins implement proxy user mapping for themselves (for example, the PAM and Windows authentication plugins). Other authentication plugins do not support proxy users by default. [sha256\\_password](#) can request that the MySQL server itself map proxy users according to granted proxy privileges. If the [check\\_proxy\\_users](#) system variable is enabled, the server performs proxy user mapping for any authentication plugins that make such a request:

- By default, [check\\_proxy\\_users](#) is disabled, so the server performs no proxy user mapping even for authentication plugins that request server support for proxy users.
- If [check\\_proxy\\_users](#) is enabled, it may also be necessary to enable a plugin-specific system variable to take advantage of server proxy user mapping support. For the [sha256\\_password](#) plugin, enable [sha256\\_password\\_proxy\\_users](#).

For example, to enable all the preceding capabilities, start the server with these lines in the [my.cnf](#) file:

```
[mysqld]
check_proxy_users=ON
sha256_password_proxy_users=ON
```

Assuming that the relevant system variables have been enabled, create the proxy user as usual using [CREATE USER](#), then grant it the [PROXY](#) privilege to a single other account to be treated as the proxied user. When the server receives a successful connection request for the proxy user, it finds that the user has the [PROXY](#) privilege and uses it to determine the proper proxied user.

```
-- create proxy account
CREATE USER 'proxy_user'@'localhost'
```

```

IDENTIFIED WITH sha256_password
BY 'password';

-- create proxied account and grant its privileges;
-- use mysql_no_login plugin to prevent direct login
CREATE USER 'proxied_user'@'localhost'
 IDENTIFIED WITH mysql_no_login;
-- grant privileges to proxied account
GRANT ...
 ON ...
 TO 'proxied_user'@'localhost';

-- grant to proxy account the
-- PROXY privilege for proxied account
GRANT PROXY
 ON 'proxied_user'@'localhost'
 TO 'proxy_user'@'localhost';

```

To use the proxy account, connect to the server using its name and password:

```

$> mysql -u proxy_user -p
Enter password: (enter proxy_user password here)

```

Authentication succeeds, the server finds that `proxy_user` has the `PROXY` privilege for `proxied_user`, and the session proceeds with `proxy_user` having the privileges of `proxied_user`.

Proxy user mapping performed by the server is subject to these restrictions:

- The server does not proxy to or from an anonymous user, even if the associated `PROXY` privilege is granted.
- When a single account has been granted proxy privileges for more than one proxied account, server proxy user mapping is nondeterministic. Therefore, granting to a single account proxy privileges for multiple proxied accounts is discouraged.

## Proxy User System Variables

Two system variables help trace the proxy login process:

- `proxy_user`: This value is `NULL` if proxying is not used. Otherwise, it indicates the proxy user account. For example, if a client authenticates through the `'@'` proxy account, this variable is set as follows:

```

mysql> SELECT @@proxy_user;
+-----+
| @@proxy_user |
+-----+
| '@' |
+-----+

```

- `external_user`: Sometimes the authentication plugin may use an external user to authenticate to the MySQL server. For example, when using Windows native authentication, a plugin that authenticates using the windows API does not need the login ID passed to it. However, it still uses a Windows user ID to authenticate. The plugin may return this external user ID (or the first 512 UTF-8 bytes of it) to the server using the `external_user` read-only session variable. If the plugin does not set this variable, its value is `NULL`.

### 8.2.20 Account Locking

MySQL supports locking and unlocking user accounts using the `ACCOUNT LOCK` and `ACCOUNT UNLOCK` clauses for the `CREATE USER` and `ALTER USER` statements:

- When used with `CREATE USER`, these clauses specify the initial locking state for a new account. In the absence of either clause, the account is created in an unlocked state.

If the `validate_password` component is enabled, creating an account without a password is not permitted, even if the account is locked. See [Section 8.4.3, “The Password Validation Component”](#).

- When used with `ALTER USER`, these clauses specify the new locking state for an existing account. In the absence of either clause, the account locking state remains unchanged.

`ALTER USER ... UNLOCK` unlocks any account named by the statement that is temporarily locked due to too many failed logins. See [Section 8.2.15, “Password Management”](#).

Account locking state is recorded in the `account_locked` column of the `mysql.user` system table. The output from `SHOW CREATE USER` indicates whether an account is locked or unlocked.

If a client attempts to connect to a locked account, the attempt fails. The server increments the `Locked_connects` status variable that indicates the number of attempts to connect to a locked account, returns an `ER_ACCOUNT_HAS_BEEN_LOCKED` error, and writes a message to the error log:

```
Access denied for user 'user_name'@'host_name'.
Account is locked.
```

Locking an account does not affect being able to connect using a proxy user that assumes the identity of the locked account. It also does not affect the ability to execute stored programs or views that have a `DEFINER` attribute naming the locked account. That is, the ability to use a proxied account or stored programs or views is not affected by locking the account.

The account-locking capability depends on the presence of the `account_locked` column in the `mysql.user` system table. For upgrades from MySQL versions older than 5.7.6, perform the MySQL upgrade procedure to ensure that this column exists. See [Chapter 3, Upgrading MySQL](#). For nonupgraded installations that have no `account_locked` column, the server treats all accounts as unlocked, and using the `ACCOUNT LOCK` or `ACCOUNT UNLOCK` clauses produces an error.

## 8.2.21 Setting Account Resource Limits

One means of restricting client use of MySQL server resources is to set the global `max_user_connections` system variable to a nonzero value. This limits the number of simultaneous connections that can be made by any given account, but places no limits on what a client can do once connected. In addition, setting `max_user_connections` does not enable management of individual accounts. Both types of control are of interest to MySQL administrators.

To address such concerns, MySQL permits limits for individual accounts on use of these server resources:

- The number of queries an account can issue per hour
- The number of updates an account can issue per hour
- The number of times an account can connect to the server per hour
- The number of simultaneous connections to the server by an account

Any statement that a client can issue counts against the query limit. Only statements that modify databases or tables count against the update limit.

An “account” in this context corresponds to a row in the `mysql.user` system table. That is, a connection is assessed against the `User` and `Host` values in the `user` table row that applies to the connection. For example, an account `'usera'@'%.example.com'` corresponds to a row in the `user` table that has

User and Host values of `usera` and `%.example.com`, to permit `usera` to connect from any host in the `example.com` domain. In this case, the server applies resource limits in this row collectively to all connections by `usera` from any host in the `example.com` domain because all such connections use the same account.

To establish resource limits for an account at account-creation time, use the `CREATE USER` statement. To modify the limits for an existing account, use `ALTER USER`. Provide a `WITH` clause that names each resource to be limited. The default value for each limit is zero (no limit). For example, to create a new account that can access the `customer` database, but only in a limited fashion, issue these statements:

```
mysql> CREATE USER 'francis'@'localhost' IDENTIFIED BY 'frank'
-> WITH MAX_QUERIES_PER_HOUR 20
-> MAX_UPDATES_PER_HOUR 10
-> MAX_CONNECTIONS_PER_HOUR 5
-> MAX_USER_CONNECTIONS 2;
```

The limit types need not all be named in the `WITH` clause, but those named can be present in any order. The value for each per-hour limit should be an integer representing a count per hour. For `MAX_USER_CONNECTIONS`, the limit is an integer representing the maximum number of simultaneous connections by the account. If this limit is set to zero, the global `max_user_connections` system variable value determines the number of simultaneous connections. If `max_user_connections` is also zero, there is no limit for the account.

To modify limits for an existing account, use an `ALTER USER` statement. The following statement changes the query limit for `francis` to 100:

```
mysql> ALTER USER 'francis'@'localhost' WITH MAX_QUERIES_PER_HOUR 100;
```

The statement modifies only the limit value specified and leaves the account otherwise unchanged.

To remove a limit, set its value to zero. For example, to remove the limit on how many times per hour `francis` can connect, use this statement:

```
mysql> ALTER USER 'francis'@'localhost' WITH MAX_CONNECTIONS_PER_HOUR 0;
```

As mentioned previously, the simultaneous-connection limit for an account is determined from the `MAX_USER_CONNECTIONS` limit and the `max_user_connections` system variable. Suppose that the global `max_user_connections` value is 10 and three accounts have individual resource limits specified as follows:

```
ALTER USER 'user1'@'localhost' WITH MAX_USER_CONNECTIONS 0;
ALTER USER 'user2'@'localhost' WITH MAX_USER_CONNECTIONS 5;
ALTER USER 'user3'@'localhost' WITH MAX_USER_CONNECTIONS 20;
```

`user1` has a connection limit of 10 (the global `max_user_connections` value) because it has a `MAX_USER_CONNECTIONS` limit of zero. `user2` and `user3` have connection limits of 5 and 20, respectively, because they have nonzero `MAX_USER_CONNECTIONS` limits.

The server stores resource limits for an account in the `user` table row corresponding to the account. The `max_questions`, `max_updates`, and `max_connections` columns store the per-hour limits, and the `max_user_connections` column stores the `MAX_USER_CONNECTIONS` limit. (See [Section 8.2.3, “Grant Tables”](#).)

Resource-use counting takes place when any account has a nonzero limit placed on its use of any of the resources.

As the server runs, it counts the number of times each account uses resources. If an account reaches its limit on number of connections within the last hour, the server rejects further connections for the

account until that hour is up. Similarly, if the account reaches its limit on the number of queries or updates, the server rejects further queries or updates until the hour is up. In all such cases, the server issues appropriate error messages.

Resource counting occurs per account, not per client. For example, if your account has a query limit of 50, you cannot increase your limit to 100 by making two simultaneous client connections to the server. Queries issued on both connections are counted together.

The current per-hour resource-use counts can be reset globally for all accounts, or individually for a given account:

- To reset the current counts to zero for all accounts, issue a `FLUSH USER_RESOURCES` statement. The counts also can be reset by reloading the grant tables (for example, with a `FLUSH PRIVILEGES` statement or a `mysqladmin reload` command).
- The counts for an individual account can be reset to zero by setting any of its limits again. Specify a limit value equal to the value currently assigned to the account.

Per-hour counter resets do not affect the `MAX_USER_CONNECTIONS` limit.

All counts begin at zero when the server starts. Counts do not carry over through server restarts.

For the `MAX_USER_CONNECTIONS` limit, an edge case can occur if the account currently has open the maximum number of connections permitted to it: A disconnect followed quickly by a connect can result in an error (`ER_TOO_MANY_USER_CONNECTIONS` or `ER_USER_LIMIT_REACHED`) if the server has not fully processed the disconnect by the time the connect occurs. When the server finishes disconnect processing, another connection is once more permitted.

## 8.2.22 Troubleshooting Problems Connecting to MySQL

If you encounter problems when you try to connect to the MySQL server, the following items describe some courses of action you can take to correct the problem.

- Make sure that the server is running. If it is not, clients cannot connect to it. For example, if an attempt to connect to the server fails with a message such as one of those following, one cause might be that the server is not running:

```
$> mysql
ERROR 2003: Can't connect to MySQL server on 'host_name' (111)
$> mysql
ERROR 2002: Can't connect to local MySQL server through socket
'/tmp/mysql.sock' (111)
```

- It might be that the server is running, but you are trying to connect using a TCP/IP port, named pipe, or Unix socket file different from the one on which the server is listening. To correct this when you invoke a client program, specify a `--port` option to indicate the proper port number, or a `--socket` option to indicate the proper named pipe or Unix socket file. To find out where the socket file is, you can use this command:

```
$> netstat -ln | grep mysql
```

- Make sure that the server has not been configured to ignore network connections or (if you are attempting to connect remotely) that it has not been configured to listen only locally on its network interfaces. If the server was started with the `skip_networking` system variable enabled, no TCP/IP connections are accepted. If the server was started with the `bind_address` system variable set to `127.0.0.1`, it listens for TCP/IP connections only locally on the loopback interface and does not accept remote connections.

- Check to make sure that there is no firewall blocking access to MySQL. Your firewall may be configured on the basis of the application being executed, or the port number used by MySQL for communication (3306 by default). Under Linux or Unix, check your IP tables (or similar) configuration to ensure that the port has not been blocked. Under Windows, applications such as ZoneAlarm or Windows Firewall may need to be configured not to block the MySQL port.
- The grant tables must be properly set up so that the server can use them for access control. For some distribution types (such as binary distributions on Windows, or RPM and DEB distributions on Linux), the installation process initializes the MySQL data directory, including the `mysql` system database containing the grant tables. For distributions that do not do this, you must initialize the data directory manually. For details, see [Section 2.9, “Postinstallation Setup and Testing”](#).

To determine whether you need to initialize the grant tables, look for a `mysql` directory under the data directory. (The data directory normally is named `data` or `var` and is located under your MySQL installation directory.) Make sure that you have a file named `user.MYD` in the `mysql` database directory. If not, initialize the data directory. After doing so and starting the server, you should be able to connect to the server.

- After a fresh installation, if you try to log on to the server as `root` without using a password, you might get the following error message.

```
$> mysql -u root
ERROR 1045 (28000): Access denied for user 'root'@'localhost' (using password: NO)
```

It means a root password has already been assigned during installation and it has to be supplied. See [Section 2.9.4, “Securing the Initial MySQL Account”](#) on the different ways the password could have been assigned and, in some cases, how to find it. If you need to reset the root password, see instructions in [Section B.3.3.2, “How to Reset the Root Password”](#). After you have found or reset your password, log on again as `root` using the `--password` (or `-p`) option:

```
$> mysql -u root -p
Enter password:
```

However, the server is going to let you connect as `root` without using a password if you have initialized MySQL using `mysqld --initialize-insecure` (see [Section 2.9.1, “Initializing the Data Directory”](#) for details). That is a security risk, so you should set a password for the `root` account; see [Section 2.9.4, “Securing the Initial MySQL Account”](#) for instructions.

- If you have updated an existing MySQL installation to a newer version, did you perform the MySQL upgrade procedure? If not, do so. The structure of the grant tables changes occasionally when new capabilities are added, so after an upgrade you should always make sure that your tables have the current structure. For instructions, see [Chapter 3, \*Upgrading MySQL\*](#).
- If a client program receives the following error message when it tries to connect, it means that the server expects passwords in a newer format than the client is capable of generating:

```
$> mysql
Client does not support authentication protocol requested
by server; consider upgrading MySQL client
```

- Remember that client programs use connection parameters specified in option files or environment variables. If a client program seems to be sending incorrect default connection parameters when you have not specified them on the command line, check any applicable option files and your environment. For example, if you get `Access denied` when you run a client without any options, make sure that you have not specified an old password in any of your option files!

You can suppress the use of option files by a client program by invoking it with the `--no-defaults` option. For example:

```
$> mysqladmin --no-defaults -u root version
```

The option files that clients use are listed in [Section 6.2.2.2, “Using Option Files”](#). Environment variables are listed in [Section 6.9, “Environment Variables”](#).

- If you get the following error, it means that you are using an incorrect `root` password:

```
$> mysqladmin -u root -pxxxx ver
Access denied for user 'root'@'localhost' (using password: YES)
```

If the preceding error occurs even when you have not specified a password, it means that you have an incorrect password listed in some option file. Try the `--no-defaults` option as described in the previous item.

For information on changing passwords, see [Section 8.2.14, “Assigning Account Passwords”](#).

If you have lost or forgotten the `root` password, see [Section B.3.3.2, “How to Reset the Root Password”](#).

- `localhost` is a synonym for your local host name, and is also the default host to which clients try to connect if you specify no host explicitly.

You can use a `--host=127.0.0.1` option to name the server host explicitly. This causes a TCP/IP connection to the local `mysqld` server. You can also use TCP/IP by specifying a `--host` option that uses the actual host name of the local host. In this case, the host name must be specified in a `user` table row on the server host, even though you are running the client program on the same host as the server.

- The `Access denied` error message tells you who you are trying to log in as, the client host from which you are trying to connect, and whether you were using a password. Normally, you should have one row in the `user` table that exactly matches the host name and user name that were given in the error message. For example, if you get an error message that contains `using password: NO`, it means that you tried to log in without a password.
- If you get an `Access denied` error when trying to connect to the database with `mysql -u user_name`, you may have a problem with the `user` table. Check this by executing `mysql -u root mysql` and issuing this SQL statement:

```
SELECT * FROM user;
```

The result should include a row with the `Host` and `User` columns matching your client's host name and your MySQL user name.

- If the following error occurs when you try to connect from a host other than the one on which the MySQL server is running, it means that there is no row in the `user` table with a `Host` value that matches the client host:

```
Host ... is not allowed to connect to this MySQL server
```

You can fix this by setting up an account for the combination of client host name and user name that you are using when trying to connect.

If you do not know the IP address or host name of the machine from which you are connecting, you should put a row with `'%'` as the `Host` column value in the `user` table. After trying to connect from the client machine, use a `SELECT USER()` query to see how you really did connect. Then change the `'%'` in the `user` table row to the actual host name that shows up in the log. Otherwise, your system is left insecure because it permits connections from any host for the given user name.

On Linux, another reason that this error might occur is that you are using a binary MySQL version that is compiled with a different version of the `glibc` library than the one you are using. In this case, you should either upgrade your operating system or `glibc`, or download a source distribution of MySQL version and compile it yourself. A source RPM is normally trivial to compile and install, so this is not a big problem.

- If you specify a host name when trying to connect, but get an error message where the host name is not shown or is an IP address, it means that the MySQL server got an error when trying to resolve the IP address of the client host to a name:

```
$> mysqladmin -u root -pXXXX -h some_hostname ver
Access denied for user 'root'@'' (using password: YES)
```

If you try to connect as `root` and get the following error, it means that you do not have a row in the `user` table with a `User` column value of `'root'` and that `mysqld` cannot resolve the host name for your client:

```
Access denied for user ''@'unknown'
```

These errors indicate a DNS problem. To fix it, execute `mysqladmin flush-hosts` to reset the internal DNS host cache. See [Section 7.1.12.3, “DNS Lookups and the Host Cache”](#).

Some permanent solutions are:

- Determine what is wrong with your DNS server and fix it.
- Specify IP addresses rather than host names in the MySQL grant tables.
- Put an entry for the client machine name in `/etc/hosts` on Unix or `\windows\hosts` on Windows.
- Start `mysqld` with the `skip_name_resolve` system variable enabled.
- Start `mysqld` with `--host-cache-size=0`.
- On Unix, if you are running the server and the client on the same machine, connect to `localhost`. For connections to `localhost`, MySQL programs attempt to connect to the local server by using a Unix socket file, unless there are connection parameters specified to ensure that the client makes a TCP/IP connection. For more information, see [Section 6.2.4, “Connecting to the MySQL Server Using Command Options”](#).
- On Windows, if you are running the server and the client on the same machine and the server supports named pipe connections, connect to the host name `.` (period). Connections to `.` use a named pipe rather than TCP/IP.
- If `mysql -u root` works but `mysql -h your_hostname -u root` results in `Access denied` (where `your_hostname` is the actual host name of the local host), you may not have the correct name for your host in the `user` table. A common problem here is that the `Host` value in the `user` table row specifies an unqualified host name, but your system's name resolution routines return a fully qualified domain name (or vice versa). For example, if you have a row with host `'pluto'` in the `user` table, but your DNS tells MySQL that your host name is `'pluto.example.com'`, the row does not work. Try adding a row to the `user` table that contains the IP address of your host as the `Host` column value. (Alternatively, you could add a row to the `user` table with a `Host` value that contains a wildcard (for example, `'pluto.%'`). However, use of `Host` values ending with `%` is *insecure* and is *not* recommended!)

- If `mysql -u user_name` works but `mysql -u user_name some_db` does not, you have not granted access to the given user for the database named `some_db`.
- If `mysql -u user_name` works when executed on the server host, but `mysql -h host_name -u user_name` does not work when executed on a remote client host, you have not enabled access to the server for the given user name from the remote host.
- If you cannot figure out why you get `Access denied`, remove from the `user` table all rows that have `Host` values containing wildcards (rows that contain `'%'` or `'_'` characters). A very common error is to insert a new row with `Host='%'` and `User='some_user'`, thinking that this enables you to specify `localhost` to connect from the same machine. The reason that this does not work is that the default privileges include a row with `Host='localhost'` and `User=''`. Because that row has a `Host` value `'localhost'` that is more specific than `'%'`, it is used in preference to the new row when connecting from `localhost`! The correct procedure is to insert a second row with `Host='localhost'` and `User='some_user'`, or to delete the row with `Host='localhost'` and `User=''`. After deleting the row, remember to issue a `FLUSH PRIVILEGES` statement to reload the grant tables. See also [Section 8.2.6, “Access Control, Stage 1: Connection Verification”](#).
- If you are able to connect to the MySQL server, but get an `Access denied` message whenever you issue a `SELECT ... INTO OUTFILE` or `LOAD DATA` statement, your row in the `user` table does not have the `FILE` privilege enabled.
- If you change the grant tables directly (for example, by using `INSERT`, `UPDATE`, or `DELETE` statements) and your changes seem to be ignored, remember that you must execute a `FLUSH PRIVILEGES` statement or a `mysqladmin flush-privileges` command to cause the server to reload the privilege tables. Otherwise, your changes have no effect until the next time the server is restarted. Remember that after you change the `root` password with an `UPDATE` statement, you do not need to specify the new password until after you flush the privileges, because the server does not know until then that you have changed the password.
- If your privileges seem to have changed in the middle of a session, it may be that a MySQL administrator has changed them. Reloading the grant tables affects new client connections, but it also affects existing connections as indicated in [Section 8.2.13, “When Privilege Changes Take Effect”](#).
- If you have access problems with a Perl, PHP, Python, or ODBC program, try to connect to the server with `mysql -u user_name db_name` or `mysql -u user_name -ppassword db_name`. If you are able to connect using the `mysql` client, the problem lies with your program, not with the access privileges. (There is no space between `-p` and the password; you can also use the `--password=password` syntax to specify the password. If you use the `-p` or `--password` option with no password value, MySQL prompts you for the password.)
- For testing purposes, start the `mysqld` server with the `--skip-grant-tables` option. Then you can change the MySQL grant tables and use the `SHOW GRANTS` statement to check whether your modifications have the desired effect. When you are satisfied with your changes, execute `mysqladmin flush-privileges` to tell the `mysqld` server to reload the privileges. This enables you to begin using the new grant table contents without stopping and restarting the server.
- If everything else fails, start the `mysqld` server with a debugging option (for example, `--debug=d,general,query`). This prints host and user information about attempted connections, as well as information about each command issued. See [Section 7.9.4, “The DEBUG Package”](#).
- If you have any other problems with the MySQL grant tables and ask on the [MySQL Community Slack](#), always provide a dump of the MySQL grant tables. You can dump the tables with the `mysqldump mysql` command. To file a bug report, see the instructions at [Section 1.6, “How to Report Bugs or Problems”](#). In some cases, you may need to restart `mysqld` with `--skip-grant-tables` to run `mysqldump`.

## 8.2.23 SQL-Based Account Activity Auditing

Applications can use the following guidelines to perform SQL-based auditing that ties database activity to MySQL accounts.

MySQL accounts correspond to rows in the `mysql.user` system table. When a client connects successfully, the server authenticates the client to a particular row in this table. The `User` and `Host` column values in this row uniquely identify the account and correspond to the `'user_name'@'host_name'` format in which account names are written in SQL statements.

The account used to authenticate a client determines which privileges the client has. Normally, the `CURRENT_USER()` function can be invoked to determine which account this is for the client user. Its value is constructed from the `User` and `Host` columns of the `user` table row for the account.

However, there are circumstances under which the `CURRENT_USER()` value corresponds not to the client user but to a different account. This occurs in contexts when privilege checking is not based the client's account:

- Stored routines (procedures and functions) defined with the `SQL SECURITY DEFINER` characteristic
- Views defined with the `SQL SECURITY DEFINER` characteristic
- Triggers and events

In those contexts, privilege checking is done against the `DEFINER` account and `CURRENT_USER()` refers to that account, not to the account for the client who invoked the stored routine or view or who caused the trigger to activate. To determine the invoking user, you can call the `USER()` function, which returns a value indicating the actual user name provided by the client and the host from which the client connected. However, this value does not necessarily correspond directly to an account in the `user` table, because the `USER()` value never contains wildcards, whereas account values (as returned by `CURRENT_USER()`) may contain user name and host name wildcards.

For example, a blank user name matches any user, so an account of `'@'localhost` enables clients to connect as an anonymous user from the local host with any user name. In this case, if a client connects as `user1` from the local host, `USER()` and `CURRENT_USER()` return different values:

```
mysql> SELECT USER(), CURRENT_USER();
+-----+-----+
| USER() | CURRENT_USER() |
+-----+-----+
| user1@localhost | @localhost |
+-----+-----+
```

The host name part of an account can also contain wildcards. If the host name contains a `'%'` or `'_'` pattern character or uses netmask notation, the account can be used for clients connecting from multiple hosts and the `CURRENT_USER()` value does not indicate which one. For example, the account `'user2'@'%.example.com'` can be used by `user2` to connect from any host in the `example.com` domain. If `user2` connects from `remote.example.com`, `USER()` and `CURRENT_USER()` return different values:

```
mysql> SELECT USER(), CURRENT_USER();
+-----+-----+
| USER() | CURRENT_USER() |
+-----+-----+
| user2@remote.example.com | user2@%.example.com |
+-----+-----+
```

If an application must invoke `USER()` for user auditing (for example, if it does auditing from within triggers) but must also be able to associate the `USER()` value with an account in the `user` table, it is necessary

to avoid accounts that contain wildcards in the `User` or `Host` column. Specifically, do not permit `User` to be empty (which creates an anonymous-user account), and do not permit pattern characters or netmask notation in `Host` values. All accounts must have a nonempty `User` value and literal `Host` value.

With respect to the previous examples, the `'@'localhost'` and `'user2'@'%.example.com'` accounts should be changed not to use wildcards:

```
RENAME USER '@'localhost' TO 'user1'@'localhost';
RENAME USER 'user2'@'%.example.com' TO 'user2'@'remote.example.com';
```

If `user2` must be able to connect from several hosts in the `example.com` domain, there should be a separate account for each host.

To extract the user name or host name part from a `CURRENT_USER()` or `USER()` value, use the `SUBSTRING_INDEX()` function:

```
mysql> SELECT SUBSTRING_INDEX(CURRENT_USER(), '@', 1);
+-----+
| SUBSTRING_INDEX(CURRENT_USER(), '@', 1) |
+-----+
| user1 |
+-----+

mysql> SELECT SUBSTRING_INDEX(CURRENT_USER(), '@', -1);
+-----+
| SUBSTRING_INDEX(CURRENT_USER(), '@', -1) |
+-----+
| localhost |
+-----+
```

## 8.3 Using Encrypted Connections

With an unencrypted connection between the MySQL client and the server, someone with access to the network could watch all your traffic and inspect the data being sent or received between client and server.

When you must move information over a network in a secure fashion, an unencrypted connection is unacceptable. To make any kind of data unreadable, use encryption. Encryption algorithms must include security elements to resist many kinds of known attacks such as changing the order of encrypted messages or replaying data twice.

MySQL supports encrypted connections between clients and the server using the TLS (Transport Layer Security) protocol. TLS is sometimes referred to as SSL (Secure Sockets Layer) but MySQL does not actually use the SSL protocol for encrypted connections because its encryption is weak (see [Section 8.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#)).

TLS uses encryption algorithms to ensure that data received over a public network can be trusted. It has mechanisms to detect data change, loss, or replay. TLS also incorporates algorithms that provide identity verification using the X.509 standard.

X.509 makes it possible to identify someone on the Internet. In basic terms, there should be some entity called a “Certificate Authority” (or CA) that assigns electronic certificates to anyone who needs them. Certificates rely on asymmetric encryption algorithms that have two encryption keys (a public key and a secret key). A certificate owner can present the certificate to another party as proof of identity. A certificate consists of its owner's public key. Any data encrypted using this public key can be decrypted only using the corresponding secret key, which is held by the owner of the certificate.

Support for encrypted connections in MySQL is provided using OpenSSL. For information about the encryption protocols and ciphers that OpenSSL supports, see [Section 8.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#).

By default, MySQL instances link to an available installed OpenSSL library at runtime for support of encrypted connections and other encryption-related operations. You may compile MySQL from source and use the `WITH_SSL CMake` option to specify the path to a particular installed OpenSSL version or an alternative OpenSSL system package. In that case, MySQL selects that version. For instructions to do this, see [Section 2.8.6, “Configuring SSL Library Support”](#).

You can check what version of the OpenSSL library is in use at runtime using the `Tls_library_version` system status variable.

If you compile MySQL with one version of OpenSSL and want to change to a different version without recompiling, you may do this by editing the dynamic library loader path (`LD_LIBRARY_PATH` on Unix systems or `PATH` on Windows systems). Remove the path to the compiled version of OpenSSL, and add the path to the replacement version, placing it before any other OpenSSL libraries on the path. At startup, when MySQL cannot find the version of OpenSSL specified with `WITH_SSL` on the path, it uses the first version specified on the path instead.

By default, MySQL programs attempt to connect using encryption if the server supports encrypted connections, falling back to an unencrypted connection if an encrypted connection cannot be established. For information about options that affect use of encrypted connections, see [Section 8.3.1, “Configuring MySQL to Use Encrypted Connections”](#) and [Command Options for Encrypted Connections](#).

MySQL performs encryption on a per-connection basis, and use of encryption for a given user can be optional or mandatory. This enables you to choose an encrypted or unencrypted connection according to the requirements of individual applications. For information on how to require users to use encrypted connections, see the discussion of the `REQUIRE` clause of the `CREATE USER` statement in [Section 15.7.1.3, “CREATE USER Statement”](#). See also the description of the `require_secure_transport` system variable at [Section 7.1.8, “Server System Variables”](#)

Encrypted connections can be used between source and replica servers. See [Section 19.3.1, “Setting Up Replication to Use Encrypted Connections”](#).

For information about using encrypted connections from the MySQL C API, see [Support for Encrypted Connections](#).

It is also possible to connect using encryption from within an SSH connection to the MySQL server host. For an example, see [Section 8.3.4, “Connecting to MySQL Remotely from Windows with SSH”](#).

## 8.3.1 Configuring MySQL to Use Encrypted Connections

Several configuration parameters are available to indicate whether to use encrypted connections, and to specify the appropriate certificate and key files. This section provides general guidance about configuring the server and clients for encrypted connections:

- [Server-Side Startup Configuration for Encrypted Connections](#)
- [Server-Side Runtime Configuration and Monitoring for Encrypted Connections](#)
- [Client-Side Configuration for Encrypted Connections](#)
- [Configuring Certificate Validation Enforcement](#)
- [Configuring Encrypted Connections as Mandatory](#)

Encrypted connections also can be used in other contexts, as discussed in these additional sections:

- Between source and replica replication servers. See [Section 19.3.1, “Setting Up Replication to Use Encrypted Connections”](#).

- Among Group Replication servers. See [Section 20.6.2, “Securing Group Communication Connections with Secure Socket Layer \(SSL\)”](#).
- By client programs that are based on the MySQL C API. See [Support for Encrypted Connections](#).

Instructions for creating any required certificate and key files are available in [Section 8.3.3, “Creating SSL and RSA Certificates and Keys”](#).

## Server-Side Startup Configuration for Encrypted Connections

To require that clients connect using encrypted connections, enable the `require_secure_transport` system variable. See [Configuring Encrypted Connections as Mandatory](#).

These system variables on the server side specify the certificate and key files the server uses when permitting clients to establish encrypted connections:

- `ssl_ca`: The path name of the Certificate Authority (CA) certificate file. (`ssl_capath` is similar but specifies the path name of a directory of CA certificate files.)
- `ssl_cert`: The path name of the server public key certificate file. This certificate can be sent to the client and authenticated against the CA certificate that it has.
- `ssl_key`: The path name of the server private key file.

For example, to enable the server for encrypted connections, start it with these lines in the `my.cnf` file, changing the file names as necessary:

```
[mysqld]
ssl_ca=ca.pem
ssl_cert=server-cert.pem
ssl_key=server-key.pem
```

To specify in addition that clients are required to use encrypted connections, enable the `require_secure_transport` system variable:

```
[mysqld]
ssl_ca=ca.pem
ssl_cert=server-cert.pem
ssl_key=server-key.pem
require_secure_transport=ON
```

Each certificate and key system variable names a file in PEM format. Should you need to create the required certificate and key files, see [Section 8.3.3, “Creating SSL and RSA Certificates and Keys”](#). MySQL servers compiled using OpenSSL can generate missing certificate and key files automatically at startup. See [Section 8.3.3.1, “Creating SSL and RSA Certificates and Keys using MySQL”](#). Alternatively, if you have a MySQL source distribution, you can test your setup using the demonstration certificate and key files in its `mysql-test/std_data` directory.

The server performs certificate and key file autodiscovery. If no explicit encrypted-connection options are given to configure encrypted connections, the server attempts to enable encrypted-connection support automatically at startup:

- If the server discovers valid certificate and key files named `ca.pem`, `server-cert.pem`, and `server-key.pem` in the data directory, it enables support for encrypted connections by clients. (The files need not have been generated automatically; what matters is that they have those names and are valid.)
- If the server does not find valid certificate and key files in the data directory, it continues executing but without support for encrypted connections.

If the server automatically enables encrypted connection support, it writes a note to the error log. If the server discovers that the CA certificate is self-signed, it writes a warning to the error log. (The certificate is self-signed if created automatically by the server.)

MySQL also provides these system variables for server-side encrypted-connection control:

- `ssl_cipher`: The list of permissible ciphers for connection encryption.
- `ssl_crl`: The path name of the file containing certificate revocation lists. (`ssl_crlpath` is similar but specifies the path name of a directory of certificate revocation-list files.)
- `tls_version`, `tls_ciphersuites`: Which encryption protocols and ciphersuites the server permits for encrypted connections; see [Section 8.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#). For example, you can configure `tls_version` to prevent clients from using less-secure protocols.

If the server cannot create a valid TLS context from the system variables for server-side encrypted-connection control, the server executes without support for encrypted connections.

## Server-Side Runtime Configuration and Monitoring for Encrypted Connections

The `tls_xxx` and `ssl_xxx` system variables are dynamic and can be set at runtime, not just at startup. If changed with `SET GLOBAL`, the new values apply only until server restart. If changed with `SET PERSIST`, the new values also carry over to subsequent server restarts. See [Section 15.7.6.1, “SET Syntax for Variable Assignment”](#). However, runtime changes to these variables do not immediately affect the TLS context for new connections, as explained later in this section.

Along with the change that enables runtime changes to the TLS context-related system variables, the server enables runtime updates to the actual TLS context used for new connections. This capability may be useful, for example, to avoid restarting a MySQL server that has been running so long that its SSL certificate has expired.

To create the initial TLS context, the server uses the values that the context-related system variables have at startup. To expose the context values, the server also initializes a set of corresponding status variables. The following table shows the system variables that define the TLS context and the corresponding status variables that expose the currently active context values.

**Table 8.12 System and Status Variables for Server Main Connection Interface TLS Context**

System Variable Name	Corresponding Status Variable Name
<code>ssl_ca</code>	<code>Current_tls_ca</code>
<code>ssl_capath</code>	<code>Current_tls_capath</code>
<code>ssl_cert</code>	<code>Current_tls_cert</code>
<code>ssl_cipher</code>	<code>Current_tls_cipher</code>
<code>ssl_crl</code>	<code>Current_tls_crl</code>
<code>ssl_crlpath</code>	<code>Current_tls_crlpath</code>
<code>ssl_key</code>	<code>Current_tls_key</code>
<code>tls_ciphersuites</code>	<code>Current_tls_ciphersuites</code>
<code>tls_version</code>	<code>Current_tls_version</code>

Those active TLS context values are also exposed as properties in the Performance Schema `tls_channel_status` table, along with the properties for any other active TLS contexts.

To reconfigure the TLS context at runtime, use this procedure:

1. Set each TLS context-related system variable that should be changed to its new value.

2. Execute `ALTER INSTANCE RELOAD TLS`. This statement reconfigures the active TLS context from the current values of the TLS context-related system variables. It also sets the context-related status variables to reflect the new active context values. The statement requires the `CONNECTION_ADMIN` privilege.
3. New connections established after execution of `ALTER INSTANCE RELOAD TLS` use the new TLS context. Existing connections remain unaffected. If existing connections should be terminated, use the `KILL` statement.

The members of each pair of system and status variables may have different values temporarily due to the way the reconfiguration procedure works:

- Changes to the system variables prior to `ALTER INSTANCE RELOAD TLS` do not change the TLS context. At this point, those changes have no effect on new connections, and corresponding context-related system and status variables may have different values. This enables you to make any changes required to individual system variables, then update the active TLS context atomically with `ALTER INSTANCE RELOAD TLS` after all system variable changes have been made.
- After `ALTER INSTANCE RELOAD TLS`, corresponding system and status variables have the same values. This remains true until the next change to the system variables.

In some cases, `ALTER INSTANCE RELOAD TLS` by itself may suffice to reconfigure the TLS context, without changing any system variables. Suppose that the certificate in the file named by `ssl_cert` has expired. It is sufficient to replace the existing file contents with a nonexpired certificate and execute `ALTER INSTANCE RELOAD TLS` to cause the new file contents to be read and used for new connections.

The server implements independent connection-encryption configuration for the administrative connection interface. See [Administrative Interface Support for Encrypted Connections](#). In addition, `ALTER INSTANCE RELOAD TLS` is extended with a `FOR CHANNEL` clause that enables specifying the channel (interface) for which to reload the TLS context. See [Section 15.1.5, “ALTER INSTANCE Statement”](#). There are no status variables to expose the administrative interface TLS context, but the Performance Schema `tls_channel_status` table exposes TLS properties for both the main and administrative interfaces. See [Section 29.12.22.10, “The tls\\_channel\\_status Table”](#).

Updating the main interface TLS context has these effects:

- The update changes the TLS context used for new connections on the main connection interface.
- The update also changes the TLS context used for new connections on the administrative interface unless some nondefault TLS parameter value is configured for that interface.
- The update does not affect the TLS context used by other enabled server plugins or components such as Group Replication or X Plugin:
  - To apply the main interface reconfiguration to Group Replication's group communication connections, which take their settings from the server's TLS context-related system variables, you must execute `STOP GROUP_REPLICATION` followed by `START GROUP_REPLICATION` to stop and restart Group Replication.
  - X Plugin initializes its TLS context at plugin initialization as described at [Section 22.5.3, “Using Encrypted Connections with X Plugin”](#). This context does not change thereafter.

By default, the `RELOAD TLS` action rolls back with an error and has no effect if the configuration values do not permit creation of the new TLS context. The previous context values continue to be used for new connections. If the optional `NO ROLLBACK ON ERROR` clause is given and the new context cannot be created, rollback does not occur. Instead, a warning is generated and encryption is disabled for new connections on the interface to which the statement applies.

Options that enable or disable encrypted connections on a connection interface have an effect only at startup. For example, the `--tls-version` and `--admin-tls-version` options affect only at startup whether the main and administrative interfaces support those TLS versions. Such options are ignored and have no effect on the operation of `ALTER INSTANCE RELOAD TLS` at runtime. For example, you can set `tls_version=''` to start the server with encrypted connections disabled on the main interface, then reconfigure TLS and execute `ALTER INSTANCE RELOAD TLS` to enable encrypted connections at runtime.

## Client-Side Configuration for Encrypted Connections

For a complete list of client options related to establishment of encrypted connections, see [Command Options for Encrypted Connections](#).

By default, MySQL client programs attempt to establish an encrypted connection if the server supports encrypted connections, with further control available through the `--ssl-mode` option:

- In the absence of an `--ssl-mode` option, clients attempt to connect using encryption, falling back to an unencrypted connection if an encrypted connection cannot be established. This is also the behavior with an explicit `--ssl-mode=PREFERRED` option.
- With `--ssl-mode=REQUIRED`, clients require an encrypted connection and fail if one cannot be established.
- With `--ssl-mode=DISABLED`, clients use an unencrypted connection.
- With `--ssl-mode=VERIFY_CA` or `--ssl-mode=VERIFY_IDENTITY`, clients require an encrypted connection, and also perform verification against the server CA certificate and (with `VERIFY_IDENTITY`) against the server host name in its certificate.

### Important

The default setting, `--ssl-mode=PREFERRED`, produces an encrypted connection if the other default settings are unchanged. However, to help prevent sophisticated man-in-the-middle attacks, it is important for the client to verify the server's identity. The settings `--ssl-mode=VERIFY_CA` and `--ssl-mode=VERIFY_IDENTITY` are a better choice than the default setting to help prevent this type of attack. `VERIFY_CA` makes the client check that the server's certificate is valid. `VERIFY_IDENTITY` makes the client check that the server's certificate is valid, and also makes the client check that the host name the client is using matches the identity in the server's certificate. To implement one of these settings, you must first ensure that the CA certificate for the server is reliably available to all the clients that use it in your environment, otherwise availability issues will result. For this reason, they are not the default setting.

Attempts to establish an unencrypted connection fail if the `require_secure_transport` system variable is enabled on the server side to cause the server to require encrypted connections. See [Configuring Encrypted Connections as Mandatory](#).

The following options on the client side identify the certificate and key files clients use when establishing encrypted connections to the server. They are similar to the `ssl_ca`, `ssl_cert`, and `ssl_key` system variables used on the server side, but `--ssl-cert` and `--ssl-key` identify the client public and private key:

- `--ssl-ca`: The path name of the Certificate Authority (CA) certificate file. This option, if used, must specify the same certificate used by the server. (`--ssl-capath` is similar but specifies the path name of a directory of CA certificate files.)

- `--ssl-cert`: The path name of the client public key certificate file.
- `--ssl-key`: The path name of the client private key file.

For additional security relative to that provided by the default encryption, clients can supply a CA certificate matching the one used by the server and enable host name identity verification. In this way, the server and client place their trust in the same CA certificate and the client verifies that the host to which it connected is the one intended:

- To specify the CA certificate, use `--ssl-ca` (or `--ssl-capath`), and specify `--ssl-mode=VERIFY_CA`.
- To enable host name identity verification as well, use `--ssl-mode=VERIFY_IDENTITY` rather than `--ssl-mode=VERIFY_CA`.

**Note**

Host name identity verification with `VERIFY_IDENTITY` does not work with self-signed certificates that are created automatically by the server (see [Section 8.3.3.1, “Creating SSL and RSA Certificates and Keys using MySQL”](#)). Such self-signed certificates do not contain the server name as the Common Name value.

MySQL also provides these options for client-side encrypted-connection control:

- `--ssl-cipher`: The list of permissible ciphers for connection encryption.
- `--ssl-crl`: The path name of the file containing certificate revocation lists. (`--ssl-crlpath` is similar but specifies the path name of a directory of certificate revocation-list files.)
- `--tls-version`, `--tls-ciphersuites`: The permitted encryption protocols and ciphersuites; see [Section 8.3.2, “Encrypted Connection TLS Protocols and Ciphers”](#).

Depending on the encryption requirements of the MySQL account used by a client, the client may be required to specify certain options to connect using encryption to the MySQL server.

Suppose that you want to connect using an account that has no special encryption requirements or that was created using a `CREATE USER` statement that included the `REQUIRE SSL` clause. Assuming that the server supports encrypted connections, a client can connect using encryption with no `--ssl-mode` option or with an explicit `--ssl-mode=PREFERRED` option:

```
mysql
```

Or:

```
mysql --ssl-mode=PREFERRED
```

For an account created with a `REQUIRE SSL` clause, the connection attempt fails if an encrypted connection cannot be established. For an account with no special encryption requirements, the attempt falls back to an unencrypted connection if an encrypted connection cannot be established. To prevent fallback and fail if an encrypted connection cannot be obtained, connect like this:

```
mysql --ssl-mode=REQUIRED
```

If the account has more stringent security requirements, other options must be specified to establish an encrypted connection:

- For accounts created with a `REQUIRE X509` clause, clients must specify at least `--ssl-cert` and `--ssl-key`. In addition, `--ssl-ca` (or `--ssl-capath`) is recommended so that the public certificate provided by the server can be verified. For example (enter the command on a single line):

```
mysql --ssl-ca=ca.pem
```

```
--ssl-cert=client-cert.pem
--ssl-key=client-key.pem
```

- For accounts created with a [REQUIRE ISSUER](#) or [REQUIRE SUBJECT](#) clause, the encryption requirements are the same as for [REQUIRE X509](#), but the certificate must match the issue or subject, respectively, specified in the account definition.

For additional information about the [REQUIRE](#) clause, see [Section 15.7.1.3, “CREATE USER Statement”](#).

MySQL servers can generate client certificate and key files that clients can use to connect to MySQL server instances. See [Section 8.3.3, “Creating SSL and RSA Certificates and Keys”](#).

### Important

If a client connecting to a MySQL server instance uses an SSL certificate with the [extendedKeyUsage](#) extension (an X.509 v3 extension), the extended key usage must include client authentication ([clientAuth](#)). If the SSL certificate is only specified for server authentication ([serverAuth](#)) and other non-client certificate purposes, certificate verification fails and the client connection to the MySQL server instance fails. There is no [extendedKeyUsage](#) extension in SSL certificates generated by MySQL Server (as described in [Section 8.3.3.1, “Creating SSL and RSA Certificates and Keys using MySQL”](#)), and SSL certificates created using the [openssl](#) command following the instructions in [Section 8.3.3.2, “Creating SSL Certificates and Keys Using openssl”](#). If you use your own client certificate created in another way, ensure any [extendedKeyUsage](#) extension includes client authentication.

To prevent use of encryption and override other [--ssl-xxx](#) options, invoke the client program with [--ssl-mode=DISABLED](#):

```
mysql --ssl-mode=DISABLED
```

To determine whether the current connection with the server uses encryption, check the session value of the [Ssl\\_cipher](#) status variable. If the value is empty, the connection is not encrypted. Otherwise, the connection is encrypted and the value indicates the encryption cipher. For example:

```
mysql> SHOW SESSION STATUS LIKE 'Ssl_cipher';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Ssl_cipher | DHE-RSA-AES128-GCM-SHA256 |
+-----+-----+
```

For the [mysql](#) client, an alternative is to use the [STATUS](#) or [\s](#) command and check the [SSL](#) line:

```
mysql> \s
...
SSL: Not in use
...
```

Or:

```
mysql> \s
...
SSL: Cipher in use is DHE-RSA-AES128-GCM-SHA256
...
```

## Configuring Certificate Validation Enforcement

The [--tls-certificates-enforced-validation](#) option enables validation of the server public key certificate file, Certificate Authority (CA) certificate files, and certificate revocation-list files at server startup:

```
mysqld --tls-certificates-enforced-validation
```

If set to `ON`, the server stops execution of the startup in case of invalid certificates. The server informs DBAs by providing valid debug messages, error messages, or both depending on the status of the certificates. This capability may be useful, for example, to avoid restarting a MySQL server that has been running so long that its SSL certificate has expired.

Similarly, when you execute the `ALTER INSTANCE RELOAD TLS` statement to change the TLS context at runtime, the new server and CA certificate files are not used if validation fails. The server continues to use the old certificates in this case. For more information about changing the TLS context dynamically, see [Server-Side Runtime Configuration and Monitoring for Encrypted Connections](#).

### Validating CA Certificates

For a connection using the server main interface:

- If `--ssl_ca` is specified, then the server validates the respective CA certificate and gives the DBA an appropriate warning message.
- If `--ssl_capath` is specified, then the server validates all the CA certificates in the respective folder and gives the DBA an appropriate warning message.
- If SSL parameters are not specified, by default the server validates the CA certificate present in the data directory and gives the DBA an appropriate warning message.

For a connection using the server administrative interface:

- If `--admin_ssl_ca` is specified, then the server validates the respective CA certificate and gives the DBA an appropriate warning message.
- If `--admin_ssl_capath` is specified, then the server validates all of the CA certificates in the respective folder and gives the DBA an appropriate warning message.
- If administrative SSL parameters are not specified, by default the server validates the CA certificate present in the data directory and gives the DBA an appropriate warning message.

### Validating the Server Certificate

For a connection using the server main interface:

- If `--ssl_cert` is not specified, then the server validates the server certificate in default data directory.
- If `--ssl_cert` is given, then the server validates the server certificate, taking into consideration `--ssl_crl`, if specified.
- If a DBA sets the command-line option to validate certificates, then the server stops in case of invalid certificates and an appropriate error message is displayed to the DBA. Otherwise, the server emits warning messages to the DBA and the server starts.

For a connection using the server administrative interface:

- If `--admin_ssl_cert` is not specified, then the server validates the server certificate in default data directory.
- If `--admin_ssl_cert` is given, then the server validates the server certificate, taking into consideration `--admin_ssl_crl`, if specified.
- If a DBA sets the command-line option to validate certificates, then the server stops in case of invalid certificates and an appropriate error message is displayed to the DBA. Otherwise, the server emits warning messages to the DBA and the server starts.

## Configuring Encrypted Connections as Mandatory

For some MySQL deployments it may be not only desirable but mandatory to use encrypted connections (for example, to satisfy regulatory requirements). This section discusses configuration settings that enable you to do this. These levels of control are available:

- You can configure the server to require that clients connect using encrypted connections.
- You can invoke individual client programs to require an encrypted connection, even if the server permits but does not require encryption.
- You can configure individual MySQL accounts to be usable only over encrypted connections.

To require that clients connect using encrypted connections, enable the `require_secure_transport` system variable. For example, put these lines in the server `my.cnf` file:

```
[mysqld]
require_secure_transport=ON
```

Alternatively, to set and persist the value at runtime, use this statement:

```
SET PERSIST require_secure_transport=ON;
```

`SET PERSIST` sets a value for the running MySQL instance. It also saves the value, causing it to be used for subsequent server restarts. See [Section 15.7.6.1, “SET Syntax for Variable Assignment”](#).

With `require_secure_transport` enabled, client connections to the server are required to use some form of secure transport, and the server permits only TCP/IP connections that use SSL, or connections that use a socket file (on Unix) or shared memory (on Windows). The server rejects nonsecure connection attempts, which fail with an `ER_SECURE_TRANSPORT_REQUIRED` error.

To invoke a client program such that it requires an encrypted connection whether or not the server requires encryption, use an `--ssl-mode` option value of `REQUIRED`, `VERIFY_CA`, or `VERIFY_IDENTITY`. For example:

```
mysql --ssl-mode=REQUIRED
mysqldump --ssl-mode=VERIFY_CA
mysqladmin --ssl-mode=VERIFY_IDENTITY
```

To configure a MySQL account to be usable only over encrypted connections, include a `REQUIRE` clause in the `CREATE USER` statement that creates the account, specifying in that clause the encryption characteristics you require. For example, to require an encrypted connection and the use of a valid X.509 certificate, use `REQUIRE X509`:

```
CREATE USER 'jeffrey'@'localhost' REQUIRE X509;
```

For additional information about the `REQUIRE` clause, see [Section 15.7.1.3, “CREATE USER Statement”](#).

To modify existing accounts that have no encryption requirements, use the `ALTER USER` statement.

### 8.3.2 Encrypted Connection TLS Protocols and Ciphers

MySQL supports multiple TLS protocols and ciphers, and enables configuring which protocols and ciphers to permit for encrypted connections. It is also possible to determine which protocol and cipher the current session uses.

- [Supported TLS Protocols](#)
- [Connection TLS Protocol Configuration](#)
- [Connection Cipher Configuration](#)

- [Connection TLS Protocol Negotiation](#)
- [Monitoring Current Client Session TLS Protocol and Cipher](#)

## Supported TLS Protocols

MySQL 9.1 supports the TLSv1.2 and TLSv1.3 protocols for connections. To use TLSv1.3, both the MySQL server and the client application must be compiled using OpenSSL 1.1.1 or higher. The Group Replication component supports TLSv1.3 from MySQL 8.0.18 (for details, see [Section 20.6.2, “Securing Group Communication Connections with Secure Socket Layer \(SSL\)”](#)).

MySQL 9.1 does not support the old TLSv1 and TLSv1.1 protocols.

Permitted TLS protocols can be configured on both the server side and client side to include only a subset of the supported TLS protocols. The configuration on both sides must include at least one protocol in common or connection attempts cannot negotiate a protocol to use. For details, see [Connection TLS Protocol Negotiation](#).

The host system may permit only certain TLS protocols, which means that MySQL connections cannot use protocols not allowed by the host even if MySQL itself permits them. Possible workarounds for this issue include the following:

- Change the system-wide host configuration to permit additional TLS protocols. Consult your operating system documentation for instructions. For example, your system may have an `/etc/ssl/openssl.cnf` file that contains these lines to restrict TLS protocols to TLSv1.3 or higher:

```
[system_default_sect]
MinProtocol = TLSv1.3
```

Changing the value to a lower protocol version or `None` makes the system more permissive. This workaround has the disadvantage that permitting lower (less secure) protocols may have adverse security consequences.

- If you cannot or prefer not to change the host system TLS configuration, change MySQL applications to use higher (more secure) TLS protocols that are permitted by the host system. This may not be possible for older versions of MySQL that support only lower protocol versions. For example, TLSv1 is the only supported protocol prior to MySQL 5.6.46, so attempts to connect to a pre-5.6.46 server fail even if the client is from a newer MySQL version that supports higher protocol versions. In such cases, an upgrade to a version of MySQL that supports additional TLS versions may be required.

- |                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| System-wide host configuration | <ul style="list-style-type: none"><li>• If the MySQL configuration permits TLSv1.2, and your host system configuration permits only connections that use TLSv1.2 or higher, you can establish MySQL connections using TLSv1.2 only.</li><li>• Suppose the MySQL configuration permits TLSv1.2, but your host system configuration permits only connections that use TLSv1.3 or higher. If this is the case, you cannot establish MySQL connections at all, because no protocol permitted by MySQL is permitted by the host system.</li></ul> |
|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Connection TLS Protocol Configuration

On the server side, the value of the `tls_version` system variable determines which TLS protocols a MySQL server permits for encrypted connections. The `tls_version` value applies to connections from clients, regular source/replica replication connections where this server instance is the source, Group Replication group communication connections, and Group Replication distributed recovery connections where this server instance is the donor. The administrative connection interface is configured similarly,

but uses the `admin_tls_version` system variable (see [Section 7.1.12.2, “Administrative Connection Management”](#)). This discussion applies to `admin_tls_version` as well.

The `tls_version` value is a list of one or more comma-separated TLS protocol versions, which is not case-sensitive. By default, this variable lists all protocols that are supported by the SSL library used to compile MySQL and by the MySQL Server release. The default settings are therefore as shown in [MySQL Server TLS Protocol Default Settings](#).

To determine the value of `tls_version` at runtime, use this statement:

```
mysql> SHOW GLOBAL VARIABLES LIKE 'tls_version';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| tls_version | TLSv1.2,TLSv1.3 |
+-----+-----+
```

To change the value of `tls_version`, set it at server startup. For example, to permit connections that use the TLSv1.2 or TLSv1.3 protocol, but prohibit connections that use any other protocol, use these lines in the server `my.cnf` file:

```
[mysqld]
tls_version=TLSv1.2,TLSv1.3
```

To be even more restrictive and permit only TLSv1.3 connections, set `tls_version` like this:

```
[mysqld]
tls_version=TLSv1.3
```

`tls_version` can be changed at runtime. See [Server-Side Runtime Configuration and Monitoring for Encrypted Connections](#).

On the client side, the `--tls-version` option specifies which TLS protocols a client program permits for connections to the server. The format of the option value is the same as for the `tls_version` system variable described previously (a list of one or more comma-separated protocol versions).

For source/replica replication connections where this server instance is the replica, the `SOURCE_TLS_VERSION` option for the `CHANGE REPLICATION SOURCE TO` statement specifies which TLS protocols the replica permits for connections to the source. The format of the option value is the same as for the `tls_version` system variable described previously. See [Section 19.3.1, “Setting Up Replication to Use Encrypted Connections”](#).

The protocols that can be specified for `SOURCE_TLS_VERSION` depend on the SSL library. This option is independent of and not affected by the server `tls_version` value. For example, a server that acts as a replica can be configured with `tls_version` set to TLSv1.3 to permit only incoming connections that use TLSv1.3, but also configured with `SOURCE_TLS_VERSION` set to TLSv1.2 to permit only TLSv1.2 for outgoing replica connections to the source.

For Group Replication distributed recovery connections where this server instance is the joining member that initiates distributed recovery (that is, the client), the `group_replication_recovery_tls_version` system variable specifies which protocols are permitted by the client. Again, this option is independent of and not affected by the server `tls_version` value, which applies when this server instance is the donor. A Group Replication server generally participates in distributed recovery both as a donor and as a joining member over the course of its group membership, so both these system variables should be set. See [Section 20.6.2, “Securing Group Communication Connections with Secure Socket Layer \(SSL\)”](#).

TLS protocol configuration affects which protocol a given connection uses, as described in [Connection TLS Protocol Negotiation](#).

Permitted protocols should be chosen such as not to leave “holes” in the list. For example, these server configuration values do not have holes:

```
tls_version=TLSv1.2,TLSv1.3
tls_version=TLSv1.3
```

The prohibition on holes also applies in other configuration contexts, such as for clients or replicas.

Unless you intend to disable encrypted connections, the list of permitted protocols should not be empty. If you set a TLS version parameter to the empty string, encrypted connections cannot be established:

- `tls_version`: The server does not permit encrypted incoming connections.
- `--tls-version`: The client does not permit encrypted outgoing connections to the server.
- `SOURCE_TLS_VERSION`: The replica does not permit encrypted outgoing connections to the source.
- `group_replication_recovery_tls_version`: The joining member does not permit encrypted connections to the distributed recovery connection.

## Connection Cipher Configuration

A default set of ciphers applies to encrypted connections, which can be overridden by explicitly configuring the permitted ciphers. During connection establishment, both sides of a connection must permit some cipher in common or the connection fails. Of the permitted ciphers common to both sides, the SSL library chooses the one supported by the provided certificate that has the highest priority.

To specify a cipher or ciphers applicable for encrypted connections that use TLSv1.2:

- Set the `ssl_cipher` system variable on the server side, and use the `--ssl-cipher` option for client programs.
- For regular source/replica replication connections, where this server instance is the source, set the `ssl_cipher` system variable. Where this server instance is the replica, use the `SOURCE_SSL_CIPHER` option for the `CHANGE REPLICATION SOURCE TO` statement. See [Section 19.3.1, “Setting Up Replication to Use Encrypted Connections”](#).
- For a Group Replication group member, for Group Replication group communication connections and also for Group Replication distributed recovery connections where this server instance is the donor, set the `ssl_cipher` system variable. For Group Replication distributed recovery connections where this server instance is the joining member, use the `group_replication_recovery_ssl_cipher` system variable. See [Section 20.6.2, “Securing Group Communication Connections with Secure Socket Layer \(SSL\)”](#).

For encrypted connections that use TLSv1.3, OpenSSL 1.1.1 and higher supports the following ciphersuites, all of which are enabled by default for use with server system variables `--tls-ciphersuites` or `--admin-tls-ciphersuites`:

```
TLS_AES_128_GCM_SHA256
TLS_AES_256_GCM_SHA384
TLS_CHACHA20_POLY1305_SHA256
TLS_AES_128_CCM_SHA256
```

### Note

In MySQL 9.1, use of `TLS_AES_128_CCM_8_SHA256` with server system variables `--tls-ciphersuites` or `--admin-tls-ciphersuites` generates a deprecation warning.

To configure the permitted TLSv1.3 ciphersuites explicitly, set the following parameters. In each case, the configuration value is a list of zero or more colon-separated ciphersuite names.

- On the server side, use the `tls_ciphersuites` system variable. If this variable is not set, its default value is `NULL`, which means that the server permits the default set of ciphersuites. If the variable is set to the empty string, no ciphersuites are enabled and encrypted connections cannot be established.
- On the client side, use the `--tls-ciphersuites` option. If this option is not set, the client permits the default set of ciphersuites. If the option is set to the empty string, no ciphersuites are enabled and encrypted connections cannot be established.
- For regular source/replica replication connections, where this server instance is the source, use the `tls_ciphersuites` system variable. Where this server instance is the replica, use the `SOURCE_TLS_CIPHERSUITES` option for the `CHANGE REPLICATION SOURCE TO` statement. See [Section 19.3.1, “Setting Up Replication to Use Encrypted Connections”](#).
- For a Group Replication group member, for Group Replication group communication connections and also for Group Replication distributed recovery connections where this server instance is the donor, use the `tls_ciphersuites` system variable. For Group Replication distributed recovery connections where this server instance is the joining member, use the `group_replication_recovery_tls_ciphersuites` system variable. See [Section 20.6.2, “Securing Group Communication Connections with Secure Socket Layer \(SSL\)”](#).

Ciphersuite support requires that both the MySQL server and the client application be compiled using OpenSSL 1.1.1 or higher.

A given cipher may work only with particular TLS protocols, which affects the TLS protocol negotiation process. See [Connection TLS Protocol Negotiation](#).

To determine which ciphers a given server supports, check the session value of the `Ssl_cipher_list` status variable:

```
SHOW SESSION STATUS LIKE 'Ssl_cipher_list';
```

The `Ssl_cipher_list` status variable lists the possible SSL ciphers (empty for non-SSL connections). If MySQL supports TLSv1.3, the value includes the possible TLSv1.3 ciphersuites.

#### Note

ECDSA ciphers only work in combination with an SSL certificate that uses ECDSA for the digital signature, and they do not work with certificates that use RSA. MySQL Server’s automatic generation process for SSL certificates does not generate ECDSA signed certificates, it generates only RSA signed certificates. Do not select ECDSA ciphers unless you have an ECDSA certificate available to you.

For encrypted connections that use TLS.v1.3, MySQL uses the SSL library default ciphersuite list.

For encrypted connections that use TLSv1.2, MySQL passes the following default cipher list to the SSL library when used with the server system variables `--ssl-cipher` and `--admin-ssl-cipher`.

```
ECDHE-ECDSA-AES128-GCM-SHA256
ECDHE-ECDSA-AES256-GCM-SHA384
ECDHE-RSA-AES128-GCM-SHA256
ECDHE-RSA-AES256-GCM-SHA384
ECDHE-ECDSA-CHACHA20-POLY1305
ECDHE-RSA-CHACHA20-POLY1305
ECDHE-ECDSA-AES256-CCM
ECDHE-ECDSA-AES128-CCM
DHE-RSA-AES128-GCM-SHA256
```

```
DHE-RSA-AES256-GCM-SHA384
DHE-RSA-AES256-CCM
DHE-RSA-AES128-CCM
DHE-RSA-CHACHA20-POLY1305
```

These cipher restrictions are in place:

- The following ciphers are deprecated and produce a warning when used with the server system variables `--ssl-cipher` and `--admin-ssl-cipher`:

```
ECDHE-ECDSA-AES128-SHA256
ECDHE-RSA-AES128-SHA256
ECDHE-ECDSA-AES256-SHA384
ECDHE-RSA-AES256-SHA384
DHE-DSS-AES128-GCM-SHA256
DHE-RSA-AES128-SHA256
DHE-DSS-AES128-SHA256
DHE-DSS-AES256-GCM-SHA384
DHE-RSA-AES256-SHA256
DHE-DSS-AES256-SHA256
ECDHE-RSA-AES128-SHA
ECDHE-ECDSA-AES128-SHA
ECDHE-RSA-AES256-SHA
ECDHE-ECDSA-AES256-SHA
DHE-DSS-AES128-SHA
DHE-RSA-AES128-SHA
TLS_DHE_DSS_WITH_AES_256_CBC_SHA
DHE-RSA-AES256-SHA
AES128-GCM-SHA256
DH-DSS-AES128-GCM-SHA256
ECDH-ECDSA-AES128-GCM-SHA256
AES256-GCM-SHA384
DH-DSS-AES256-GCM-SHA384
ECDH-ECDSA-AES256-GCM-SHA384
AES128-SHA256
DH-DSS-AES128-SHA256
ECDH-ECDSA-AES128-SHA256
AES256-SHA256
DH-DSS-AES256-SHA256
ECDH-ECDSA-AES256-SHA384
AES128-SHA
DH-DSS-AES128-SHA
ECDH-ECDSA-AES128-SHA
AES256-SHA
DH-DSS-AES256-SHA
ECDH-ECDSA-AES256-SHA
DH-RSA-AES128-GCM-SHA256
ECDH-RSA-AES128-GCM-SHA256
DH-RSA-AES256-GCM-SHA384
ECDH-RSA-AES256-GCM-SHA384
DH-RSA-AES128-SHA256
ECDH-RSA-AES128-SHA256
DH-RSA-AES256-SHA256
ECDH-RSA-AES256-SHA384
ECDHE-RSA-AES128-SHA
ECDHE-ECDSA-AES128-SHA
ECDHE-RSA-AES256-SHA
ECDHE-ECDSA-AES256-SHA
DHE-DSS-AES128-SHA
DHE-RSA-AES128-SHA
TLS_DHE_DSS_WITH_AES_256_CBC_SHA
DHE-RSA-AES256-SHA
AES128-SHA
DH-DSS-AES128-SHA
ECDH-ECDSA-AES128-SHA
AES256-SHA
DH-DSS-AES256-SHA
```

```

ECDH-ECDH-AES256-SHA
DH-RSA-AES128-SHA
ECDH-RSA-AES128-SHA
DH-RSA-AES256-SHA
ECDH-RSA-AES256-SHA
DES-CBC3-SHA

```

- The following ciphers are permanently restricted:

```

!DHE-DSS-DES-CBC3-SHA
!DHE-RSA-DES-CBC3-SHA
!ECDH-RSA-DES-CBC3-SHA
!ECDH-ECDH-DES-CBC3-SHA
!ECDHE-RSA-DES-CBC3-SHA
!ECDHE-ECDH-DES-CBC3-SHA

```

- The following categories of ciphers are permanently restricted:

```

!aNULL
!eNULL
!EXPORT
!LOW
!MD5
!DES
!RC2
!RC4
!PSK
!SSLv3

```

If the server is started with the `ssl_cert` system variable set to a certificate that uses any of the preceding restricted ciphers or cipher categories, the server starts with support for encrypted connections disabled.

## Connection TLS Protocol Negotiation

Connection attempts in MySQL negotiate use of the highest TLS protocol version available on both sides for which a protocol-compatible encryption cipher is available on both sides. The negotiation process depends on factors such as the SSL library used to compile the server and client, the TLS protocol and encryption cipher configuration, and which key size is used:

- For a connection attempt to succeed, the server and client TLS protocol configuration must permit some protocol in common.
- Similarly, the server and client encryption cipher configuration must permit some cipher in common. A given cipher may work only with particular TLS protocols, so a protocol available to the negotiation process is not chosen unless there is also a compatible cipher.
- If TLSv1.3 is available, it is used if possible. (This means that server and client configuration both must permit TLSv1.3, and both must also permit some TLSv1.3-compatible encryption cipher.) Otherwise, MySQL continues through the list of available protocols, using TLSv1.2 if possible, and so forth. Negotiation proceeds from more secure protocols to less secure. Negotiation order is independent of the order in which protocols are configured. For example, negotiation order is the same regardless of whether `tls_version` has a value of `TLSv1.2`, `TLSv1.3` or `TLSv1.3`, `TLSv1.2`.
- For better security, use a certificate with an RSA key size of at least 2048 bits.

If the server and client do not have a permitted protocol in common, and a protocol-compatible cipher in common, the server terminates the connection request.

MySQL permits specifying a list of protocols to support. This list is passed directly down to the underlying SSL library and is ultimately up to that library what protocols it actually enables from the supplied list.

Please refer to the MySQL source code and the OpenSSL [SSL\\_CTX\\_new\(\)](#) documentation for information about how the SSL library handles this.

## Monitoring Current Client Session TLS Protocol and Cipher

To determine which encryption TLS protocol and cipher the current client session uses, check the session values of the [Ssl\\_version](#) and [Ssl\\_cipher](#) status variables:

```
mysql> SELECT * FROM performance_schema.session_status
 WHERE VARIABLE_NAME IN ('Ssl_version','Ssl_cipher');
+-----+-----+
| VARIABLE_NAME | VARIABLE_VALUE |
+-----+-----+
| Ssl_cipher | DHE-RSA-AES128-GCM-SHA256 |
| Ssl_version | TLSv1.2 |
+-----+-----+
```

If the connection is not encrypted, both variables have an empty value.

## 8.3.3 Creating SSL and RSA Certificates and Keys

The following discussion describes how to create the files required for SSL and RSA support in MySQL. File creation can be performed using facilities provided by MySQL itself, or by invoking the [openssl](#) command directly.

SSL certificate and key files enable MySQL to support encrypted connections using SSL. See [Section 8.3.1, “Configuring MySQL to Use Encrypted Connections”](#).

RSA key files enable MySQL to support secure password exchange over unencrypted connections for accounts authenticated by the [sha256\\_password](#) (deprecated) or [caching\\_sha2\\_password](#) plugin. See [Section 8.4.1.2, “SHA-256 Pluggable Authentication”](#), and [Section 8.4.1.1, “Caching SHA-2 Pluggable Authentication”](#).

### 8.3.3.1 Creating SSL and RSA Certificates and Keys using MySQL

MySQL provides these ways to create the SSL certificate and key files and RSA key-pair files required to support encrypted connections using SSL and secure password exchange using RSA over unencrypted connections, if those files are missing:

- The server can autogenerate these files at startup, for MySQL distributions.

#### Important

Server autogeneration helps lower the barrier to using SSL by making it easier to generate the required files. However, certificates generated by this method are self-signed, which may not be very secure. After you gain experience using these, consider obtaining certificate and key material from a registered certificate authority.

#### Important

If a client connecting to a MySQL server instance uses an SSL certificate with the [extendedKeyUsage](#) extension (an X.509 v3 extension), the extended key usage must include client authentication ([clientAuth](#)). If the SSL certificate is only specified for server authentication ([serverAuth](#)) and other non-client certificate purposes, certificate verification fails and the client connection to the MySQL server instance fails. There is no [extendedKeyUsage](#) extension in SSL certificates generated by MySQL Server. If you use your own client certificate

created in another way, ensure any `extendedKeyUsage` extension includes client authentication.

- [Automatic SSL and RSA File Generation](#)
- [SSL and RSA File Characteristics](#)

## Automatic SSL and RSA File Generation

For MySQL distributions compiled using OpenSSL, the MySQL server has the capability of automatically generating missing SSL and RSA files at startup. The `auto_generate_certs`, `sha256_password_auto_generate_rsa_keys`, and `caching_sha2_password_auto_generate_rsa_keys` system variables control automatic generation of these files. These variables are enabled by default. They can be enabled at startup and inspected but not set at runtime.

At startup, the server automatically generates server-side and client-side SSL certificate and key files in the data directory if the `auto_generate_certs` system variable is enabled, no SSL options are specified, and the server-side SSL files are missing from the data directory. These files enable encrypted client connections using SSL; see [Section 8.3.1, “Configuring MySQL to Use Encrypted Connections”](#).

1. The server checks the data directory for SSL files with the following names:

```
ca.pem
server-cert.pem
server-key.pem
```

2. If any of those files are present, the server creates no SSL files. Otherwise, it creates them, plus some additional files:

ca.pem	Self-signed CA certificate
ca-key.pem	CA private key
server-cert.pem	Server certificate
server-key.pem	Server private key
client-cert.pem	Client certificate
client-key.pem	Client private key

3. If the server autogenerates SSL files, it uses the names of the `ca.pem`, `server-cert.pem`, and `server-key.pem` files to set the corresponding system variables (`ssl_ca`, `ssl_cert`, `ssl_key`).

At startup, the server automatically generates RSA private/public key-pair files in the data directory if all of these conditions are true: The `sha256_password_auto_generate_rsa_keys` or `caching_sha2_password_auto_generate_rsa_keys` system variable is enabled; no RSA options are specified; the RSA files are missing from the data directory. These key-pair files enable secure password exchange using RSA over unencrypted connections for accounts authenticated by the `sha256_password` (deprecated) or `caching_sha2_password` plugin; see [Section 8.4.1.2, “SHA-256 Pluggable Authentication”](#), and [Section 8.4.1.1, “Caching SHA-2 Pluggable Authentication”](#).

1. The server checks the data directory for RSA files with the following names:

private_key.pem	Private member of private/public key pair
public_key.pem	Public member of private/public key pair

2. If any of these files are present, the server creates no RSA files. Otherwise, it creates them.
3. If the server autogenerates the RSA files, it uses their names to set the corresponding system variables (`sha256_password_private_key_path` and `sha256_password_public_key_path`; `caching_sha2_password_private_key_path` and `caching_sha2_password_public_key_path`).

## SSL and RSA File Characteristics

SSL and RSA files created automatically by the server have these characteristics:

- SSL and RSA keys have a size of 2048 bits.
- The SSL CA certificate is self signed.
- The SSL server and client certificates are signed with the CA certificate and key, using the `sha256WithRSAEncryption` signature algorithm.
- SSL certificates use these Common Name (CN) values, with the appropriate certificate type (CA, Server, Client):

```
ca.pem: MySQL_Server_suffix_Auto_Generated_CA_Certificate
server-cert.pm: MySQL_Server_suffix_Auto_Generated_Server_Certificate
client-cert.pm: MySQL_Server_suffix_Auto_Generated_Client_Certificate
```

The *suffix* value is based on the MySQL version number.

For files generated by the server, if the resulting CN values exceed 64 characters, the *\_suffix* portion of the name is omitted.

- SSL files have blank values for Country (C), State or Province (ST), Organization (O), Organization Unit Name (OU) and email address.
- SSL files created by the server are valid for ten years from the time of generation.
- RSA files do not expire.
- SSL files have different serial numbers for each certificate/key pair (1 for CA, 2 for Server, 3 for Client).
- Files created automatically by the server are owned by the account that runs the server.
- On Unix and Unix-like systems, the file access mode is 644 for certificate files (that is, world readable) and 600 for key files (that is, accessible only by the account that runs the server).

To see the contents of an SSL certificate (for example, to check the range of dates over which it is valid), invoke `openssl` directly:

```
openssl x509 -text -in ca.pem
openssl x509 -text -in server-cert.pem
openssl x509 -text -in client-cert.pem
```

It is also possible to check SSL certificate expiration information using this SQL statement:

```
mysql> SHOW STATUS LIKE 'Ssl_server_not%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Ssl_server_not_after | Apr 28 14:16:39 2027 GMT |
| Ssl_server_not_before | May 1 14:16:39 2017 GMT |
+-----+-----+
```

### 8.3.3.2 Creating SSL Certificates and Keys Using openssl

This section describes how to use the `openssl` command to set up SSL certificate and key files for use by MySQL servers and clients. The first example shows a simplified procedure such as you might use from the command line. The second shows a script that contains more detail. The first two examples are intended for use on Unix and both use the `openssl` command that is part of OpenSSL. The third example describes how to set up SSL files on Windows.

**Note**

An easier alternative to generating the files required for SSL than the procedure described here is to let the server autogenerate them; see [Section 8.3.3.1, “Creating SSL and RSA Certificates and Keys using MySQL”](#).

**Important**

Whatever method you use to generate the certificate and key files, the Common Name value used for the server and client certificates/keys must each differ from the Common Name value used for the CA certificate. Otherwise, the certificate and key files do not work for servers compiled using OpenSSL. A typical error in this case is:

```
ERROR 2026 (HY000): SSL connection error:
error:00000001:lib(0):func(0):reason(1)
```

**Important**

If a client connecting to a MySQL server instance uses an SSL certificate with the `extendedKeyUsage` extension (an X.509 v3 extension), the extended key usage must include client authentication (`clientAuth`). If the SSL certificate is only specified for server authentication (`serverAuth`) and other non-client certificate purposes, certificate verification fails and the client connection to the MySQL server instance fails. There is no `extendedKeyUsage` extension in SSL certificates created using the `openssl` command following the instructions in this topic. If you use your own client certificate created in another way, ensure any `extendedKeyUsage` extension includes client authentication.

- [Example 1: Creating SSL Files from the Command Line on Unix](#)
- [Example 2: Creating SSL Files Using a Script on Unix](#)
- [Example 3: Creating SSL Files on Windows](#)

**Example 1: Creating SSL Files from the Command Line on Unix**

The following example shows a set of commands to create MySQL server and client certificate and key files. You must respond to several prompts by the `openssl` commands. To generate test files, you can press Enter to all prompts. To generate files for production use, you should provide nonempty responses.

```
Create clean environment
rm -rf newcerts
mkdir newcerts && cd newcerts

Create CA certificate
openssl genrsa 2048 > ca-key.pem
openssl req -new -x509 -nodes -days 3600 \
 -key ca-key.pem -out ca.pem

Create server certificate, remove passphrase, and sign it
server-cert.pem = public key, server-key.pem = private key
openssl req -newkey rsa:2048 -days 3600 \
 -nodes -keyout server-key.pem -out server-req.pem
openssl rsa -in server-key.pem -out server-key.pem
openssl x509 -req -in server-req.pem -days 3600 \
 -CA ca.pem -CAkey ca-key.pem -set_serial 01 -out server-cert.pem

Create client certificate, remove passphrase, and sign it
client-cert.pem = public key, client-key.pem = private key
openssl req -newkey rsa:2048 -days 3600 \
```

```
-nodes -keyout client-key.pem -out client-req.pem
openssl rsa -in client-key.pem -out client-key.pem
openssl x509 -req -in client-req.pem -days 3600 \
 -CA ca.pem -CAkey ca-key.pem -set_serial 01 -out client-cert.pem
```

After generating the certificates, verify them:

```
openssl verify -CAfile ca.pem server-cert.pem client-cert.pem
```

You should see a response like this:

```
server-cert.pem: OK
client-cert.pem: OK
```

To see the contents of a certificate (for example, to check the range of dates over which a certificate is valid), invoke `openssl` like this:

```
openssl x509 -text -in ca.pem
openssl x509 -text -in server-cert.pem
openssl x509 -text -in client-cert.pem
```

Now you have a set of files that can be used as follows:

- `ca.pem`: Use this to set the `ssl_ca` system variable on the server side and the `--ssl-ca` option on the client side. (The CA certificate, if used, must be the same on both sides.)
- `server-cert.pem`, `server-key.pem`: Use these to set the `ssl_cert` and `ssl_key` system variables on the server side.
- `client-cert.pem`, `client-key.pem`: Use these as the arguments to the `--ssl-cert` and `--ssl-key` options on the client side.

For additional usage instructions, see [Section 8.3.1, “Configuring MySQL to Use Encrypted Connections”](#).

## Example 2: Creating SSL Files Using a Script on Unix

Here is an example script that shows how to set up SSL certificate and key files for MySQL. After executing the script, use the files for SSL connections as described in [Section 8.3.1, “Configuring MySQL to Use Encrypted Connections”](#).

```
DIR=`pwd`/openssl
PRIV=$DIR/private

mkdir $DIR $PRIV $DIR/newcerts
cp /usr/share/ssl/openssl.cnf $DIR
replace ./demoCA $DIR -- $DIR/openssl.cnf

Create necessary files: $database, $serial and $new_certs_dir
directory (optional)

touch $DIR/index.txt
echo "01" > $DIR/serial

#
Generation of Certificate Authority(CA)
#

openssl req -new -x509 -keyout $PRIV/cakey.pem -out $DIR/ca.pem \
 -days 3600 -config $DIR/openssl.cnf

Sample output:
Using configuration from /home/jones/openssl/openssl.cnf
Generating a 1024 bit RSA private key
.....++++++
.....++++++
```

```
writing new private key to '/home/jones/openssl/private/cakey.pem'
Enter PEM pass phrase:
Verifying password - Enter PEM pass phrase:

You are about to be asked to enter information to be
incorporated into your certificate request.
What you are about to enter is what is called a Distinguished Name
or a DN.

```

## Example 3: Creating SSL Files on Windows

Download OpenSSL for Windows if it is not installed on your system. An overview of available packages can be seen here:

<http://www.slproweb.com/products/Win32OpenSSL.html>

Choose the Win32 OpenSSL Light or Win64 OpenSSL Light package, depending on your architecture (32-bit or 64-bit). The default installation location is `C:\OpenSSL-Win32` or `C:\OpenSSL-Win64`, depending on which package you downloaded. The following instructions assume a default location of `C:\OpenSSL-Win32`. Modify this as necessary if you are using the 64-bit package.

If a message occurs during setup indicating '`...critical component is missing: Microsoft Visual C++ 2019 Redistributables`', cancel the setup and download one of the following packages as well, again depending on your architecture (32-bit or 64-bit):

- Visual C++ 2008 Redistributables (x86), available at:

<http://www.microsoft.com/downloads/details.aspx?familyid=9B2DA534-3E03-4391-8A4D-074B9F2BC1BF>

- Visual C++ 2008 Redistributables (x64), available at:

<http://www.microsoft.com/downloads/details.aspx?familyid=bd2a6171-e2d6-4230-b809-9a8d7548c1b6>

After installing the additional package, restart the OpenSSL setup procedure.

During installation, leave the default `C:\OpenSSL-Win32` as the install path, and also leave the default option '`Copy OpenSSL DLL files to the Windows system directory`' selected.

When the installation has finished, add `C:\OpenSSL-Win32\bin` to the Windows System Path variable of your server (depending on your version of Windows, the following path-setting instructions might differ slightly):

1. On the Windows desktop, right-click the **My Computer** icon, and select **Properties**.
2. Select the **Advanced** tab from the **System Properties** menu that appears, and click the **Environment Variables** button.
3. Under **System Variables**, select **Path**, then click the **Edit** button. The **Edit System Variable** dialogue should appear.
4. Add `';C:\OpenSSL-Win32\bin'` to the end (notice the semicolon).
5. Press OK 3 times.
6. Check that OpenSSL was correctly integrated into the Path variable by opening a new command console (`Start>Run>cmd.exe`) and verifying that OpenSSL is available:

```
Microsoft Windows [Version ...]
Copyright (c) 2006 Microsoft Corporation. All rights reserved.

C:\Windows\system32>cd \

C:\>openssl
OpenSSL> exit <<< If you see the OpenSSL prompt, installation was successful.

C:\>
```

After OpenSSL has been installed, use instructions similar to those from Example 1 (shown earlier in this section), with the following changes:

- Change the following Unix commands:

```
Create clean environment
rm -rf newcerts
mkdir newcerts && cd newcerts
```

On Windows, use these commands instead:

```
Create clean environment
md c:\newcerts
cd c:\newcerts
```

- When a `'\'` character is shown at the end of a command line, this `'\'` character must be removed and the command lines entered all on a single line.

After generating the certificate and key files, to use them for SSL connections, see [Section 8.3.1, “Configuring MySQL to Use Encrypted Connections”](#).

### 8.3.3.3 Creating RSA Keys Using openssl

This section describes how to use the `openssl` command to set up the RSA key files that enable MySQL to support secure password exchange over unencrypted connections for accounts authenticated by the `sha256_password` (deprecated) and `caching_sha2_password` plugins.

#### Note

An easier alternative to generating the files required for SSL than the procedure described here is to let the server autogenerate them; see [Section 8.3.3.1, “Creating SSL and RSA Certificates and Keys using MySQL”](#).

To create the RSA private and public key-pair files, run these commands while logged into the system account used to run the MySQL server so that the files are owned by that account:

```
openssl genrsa -out private_key.pem 2048
openssl rsa -in private_key.pem -pubout -out public_key.pem
```

Those commands create 2,048-bit keys. To create stronger keys, use a larger value.

Then set the access modes for the key files. The private key should be readable only by the server, whereas the public key can be freely distributed to client users:

```
chmod 400 private_key.pem
chmod 444 public_key.pem
```

### 8.3.4 Connecting to MySQL Remotely from Windows with SSH

This section describes how to get an encrypted connection to a remote MySQL server with SSH. The information was provided by David Carlson <[dcarlson@mplcomm.com](mailto:dcarlson@mplcomm.com)>.

1. Install an SSH client on your Windows machine. For a comparison of SSH clients, see [http://en.wikipedia.org/wiki/Comparison\\_of\\_SSH\\_clients](http://en.wikipedia.org/wiki/Comparison_of_SSH_clients).
2. Start your Windows SSH client. Set `Host_Name` = `yourmysqlserver_URL_or_IP`. Set `userid=your_userid` to log in to your server. This `userid` value might not be the same as the user name of your MySQL account.
3. Set up port forwarding. Either do a remote forward (Set `local_port`: 3306, `remote_host`: `yourmysqlservername_or_ip`, `remote_port`: 3306 ) or a local forward (Set `port`: 3306, `host`: `localhost`, `remote port`: 3306).
4. Save everything, otherwise you must redo it the next time.
5. Log in to your server with the SSH session you just created.
6. On your Windows machine, start some ODBC application (such as Access).
7. Create a new file in Windows and link to MySQL using the ODBC driver the same way you normally do, except type in `localhost` for the MySQL host server, not `yourmysqlservername`.

At this point, you should have an ODBC connection to MySQL, encrypted using SSH.

### 8.3.5 Reusing SSL Sessions

MySQL client programs may elect to resume a prior SSL session, provided that the server has the session in its runtime cache. This section describes the conditions that are favorable for SSL session reuse, the server variables used for managing and monitoring the session cache, and the client command-line options for storing and reusing session data.

- [Server-Side Runtime Configuration and Monitoring for SSL Session Reuse](#)
- [Client-Side Configuration for SSL Session Reuse](#)

Each full TLS exchange can be costly both in terms of computation and network overhead, less costly if TLSv1.3 is used. By extracting a session ticket from an established session and then submitting that ticket while establishing the next connection, the overall cost is reduced if the session can be reused. For example, consider the benefit of having web pages that can open multiple connections and generate faster.

In general, the following conditions must be satisfied before SSL sessions can be reused:

- The server must keep its session cache in memory.
- The server-side session cache timeout must not have expired.
- Each client has to maintain a cache of active sessions and keep it secure.

C applications can use the C API capabilities to enable session reuse for encrypted connections (see [SSL Session Reuse](#)).

## Server-Side Runtime Configuration and Monitoring for SSL Session Reuse

To create the initial TLS context, the server uses the values that the context-related system variables have at startup. To expose the context values, the server also initializes a set of corresponding status variables. The following table shows the system variables that define the server's runtime session cache and the corresponding status variables that expose the currently active session-cache values.

**Table 8.13 System and Status Variables for Session Reuse**

System Variable Name	Corresponding Status Variable Name
<code>ssl_session_cache_mode</code>	<code>Ssl_session_cache_mode</code>
<code>ssl_session_cache_timeout</code>	<code>Ssl_session_cache_timeout</code>

### Note

When the value of the `ssl_session_cache_mode` server variable is `ON`, which is the default mode, the value of the `Ssl_session_cache_mode` status variable is `SERVER`.

SSL session cache variables apply to both the `mysql_main` and `mysql_admin` TLS channels. Their values are also exposed as properties in the Performance Schema `tls_channel_status` table, along with the properties for any other active TLS contexts.

To reconfigure the SSL session cache at runtime, use this procedure:

1. Set each cache-related system variable that should be changed to its new value. For example, change the cache timeout value from the default (300 seconds) to 600 seconds:

```
mysql> SET GLOBAL ssl_session_cache_timeout = 600;
```

The members of each pair of system and status variables may have different values temporarily due to the way the reconfiguration procedure works.

```
mysql> SHOW VARIABLES LIKE 'ssl_session_cache_timeout';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| ssl_session_cache_timeout | 600 |
+-----+-----+
1 row in set (0.00 sec)

mysql> SHOW STATUS LIKE 'Ssl_session_cache_timeout';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Ssl_session_cache_timeout | 300 |
+-----+-----+
1 row in set (0.00 sec)
```

For additional information about setting variable values, see [System Variable Assignment](#).

2. Execute `ALTER INSTANCE RELOAD TLS`. This statement reconfigures the active TLS context from the current values of the cache-related system variables. It also sets the cache-related status variables to reflect the new active cache values. The statement requires the `CONNECTION_ADMIN` privilege.

```
mysql> ALTER INSTANCE RELOAD TLS;
Query OK, 0 rows affected (0.01 sec)

mysql> SHOW VARIABLES LIKE 'ssl_session_cache_timeout';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| ssl_session_cache_timeout | 600 |
+-----+-----+
1 row in set (0.00 sec)

mysql> SHOW STATUS LIKE 'Ssl_session_cache_timeout';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Ssl_session_cache_timeout | 600 |
+-----+-----+
1 row in set (0.00 sec)
```

New connections established after execution of `ALTER INSTANCE RELOAD TLS` use the new TLS context. Existing connections remain unaffected.

## Client-Side Configuration for SSL Session Reuse

All MySQL client programs are capable of reusing a prior session for new encrypted connections made to the same server, provided that you stored the session data while the original connection was still active. Session data are stored to a file and you specify this file when you invoke the client again.

To store and reuse SSL session data, use this procedure:

1. Invoke `mysql` to establish an encrypted connection to a server running MySQL 9.1.
2. Use the `ssl_session_data_print` command to specify the path to a file where you can store the currently active session data securely. For example:

```
mysql> ssl_session_data_print ~/private-dir/session.txt
```

Session data are obtained in the form of a null-terminated, PEM encoded ANSI string. If you omit the path and file name, the string prints to standard output.

3. From the prompt of your command interpreter, invoke any MySQL client program to establish a new encrypted connection to the same server. To reuse the session data, specify the `--ssl-session-data` command-line option and the file argument.

For example, establish a new connection using `mysql`:

```
mysql -u admin -p --ssl-session-data=~/private-dir/session.txt
```

and then `mysqlshow` client:

```
mysqlshow -u admin -p --ssl-session-data=~/private-dir/session.txt
Enter password: *****
+-----+
| Databases |
+-----+
```

```

| information_schema |
| mysql |
| performance_schema |
| sys |
| world |
+-----+

```

In each example, the client attempts to resume the original session while it establishes a new connection to the same server.

To confirm whether `mysql` reused a session, see the output from the `status` command. If the currently active `mysql` connection did resume the session, the status information includes `SSL session reused: true`.

In addition to `mysql` and `mysqlshow`, SSL session reuse applies to `mysqladmin`, `mysqlbinlog`, `mysqlcheck`, `mysqldump`, `mysqlimport`, `mysqlslap`, `mysqltest`, `mysql_migrate_keyring`, and `mysql_secure_installation`.

Several conditions may prevent the successful retrieval of session data. For instance, if the session is not fully connected, it is not an SSL session, the server has not yet sent the session data, or the SSL session is simply not reusable. Even with properly stored session data, the server's session cache can time out. Regardless of the cause, an error is returned by default if you specify `--ssl-session-data` but the session cannot be reused. For example:

```

mysqlshow -u admin -p --ssl-session-data=~/.private-dir/session.txt
Enter password: *****
ERROR:
--ssl-session-data specified but the session was not reused.

```

To suppress the error message, and to establish the connection by silently creating a new session instead, specify `--ssl-session-data-continue-on-failed-reuse` on the command line, along with `--ssl-session-data`. If the server's cache timeout has expired, you can store the session data again to the same file. The default server cache timeout can be extended (see [Server-Side Runtime Configuration and Monitoring for SSL Session Reuse](#)).

## 8.4 Security Components and Plugins

MySQL includes several components and plugins that implement security features:

- Plugins for authenticating attempts by clients to connect to MySQL Server. Plugins are available for several authentication protocols. For general discussion of the authentication process, see [Section 8.2.17, “Pluggable Authentication”](#). For characteristics of specific authentication plugins, see [Section 8.4.1, “Authentication Plugins”](#).
- A password-validation component for implementing password strength policies and assessing the strength of potential passwords. See [Section 8.4.3, “The Password Validation Component”](#).
- Keyring components and plugins that provide secure storage for sensitive information. See [Section 8.4.4, “The MySQL Keyring”](#).
- (MySQL Enterprise Edition only) MySQL Enterprise Audit, implemented using a server plugin, uses the open MySQL Audit API to enable standard, policy-based monitoring and logging of connection and query activity executed on specific MySQL servers. Designed to meet the Oracle audit specification, MySQL Enterprise Audit provides an out of box, easy to use auditing and compliance solution for applications that are governed by both internal and external regulatory guidelines. See [Section 8.4.5, “MySQL Enterprise Audit”](#).
- A function enables applications to add their own message events to the audit log. See [Section 8.4.6, “The Audit Message Component”](#).

- (MySQL Enterprise Edition only) MySQL Enterprise Firewall, an application-level firewall that enables database administrators to permit or deny SQL statement execution based on matching against lists of accepted statement patterns. This helps harden MySQL Server against attacks such as SQL injection or attempts to exploit applications by using them outside of their legitimate query workload characteristics. See [Section 8.4.7, “MySQL Enterprise Firewall”](#).
- (MySQL Enterprise Edition only) MySQL Enterprise Data Masking and De-Identification, implemented as a plugin library containing a plugin and a set of functions. Data masking hides sensitive information by replacing real values with substitutes. MySQL Enterprise Data Masking and De-Identification functions enable masking existing data using several methods such as obfuscation (removing identifying characteristics), generation of formatted random data, and data replacement or substitution. See [Section 8.5, “MySQL Enterprise Data Masking and De-Identification”](#).

## 8.4.1 Authentication Plugins

### Note

If you are looking for information about the `authentication_oci` plugin, it is HeatWave Service only. See [authentication\\_oci plugin](#), in the *HeatWave Service* manual.

The following sections describe pluggable authentication methods available in MySQL and the plugins that implement these methods. For general discussion of the authentication process, see [Section 8.2.17, “Pluggable Authentication”](#).

The default authentication plugin is determined as described in [The Default Authentication Plugin](#).

### 8.4.1.1 Caching SHA-2 Pluggable Authentication

MySQL provides two authentication plugins that implement SHA-256 hashing for user account passwords:

- `caching_sha2_password`: Implements SHA-256 authentication (like `sha256_password`), but uses caching on the server side for better performance and has additional features for wider applicability.
- `sha256_password`: Implements basic SHA-256 authentication. This is deprecated and subject to removal, do not use this authentication plugin.

This section describes the caching SHA-2 authentication plugin. For information about the original basic (noncaching) deprecated plugin, see [Section 8.4.1.2, “SHA-256 Pluggable Authentication”](#).

### Important

In MySQL 9.1, `caching_sha2_password` is the default authentication plugin; `mysql_native_password` is no longer available. For information about the implications of this change for server operation and compatibility of the server with clients and connectors, see [caching\\_sha2\\_password as the Preferred Authentication Plugin](#).

### Important

To connect to the server using an account that authenticates with the `caching_sha2_password` plugin, you must use either a secure connection or an unencrypted connection that supports password exchange using an RSA key pair, as described later in this section. Either way, the `caching_sha2_password` plugin uses MySQL's encryption capabilities. See [Section 8.3, “Using Encrypted Connections”](#).

**Note**

In the name `sha256_password`, “sha256” refers to the 256-bit digest length the plugin uses for encryption. In the name `caching_sha2_password`, “sha2” refers more generally to the SHA-2 class of encryption algorithms, of which 256-bit encryption is one instance. The latter name choice leaves room for future expansion of possible digest lengths without changing the plugin name.

The `caching_sha2_password` plugin has these advantages, compared to `sha256_password`:

- On the server side, an in-memory cache enables faster reauthentication of users who have connected previously when they connect again.
- RSA-based password exchange is available regardless of the SSL library against which MySQL is linked.
- Support is provided for client connections that use the Unix socket-file and shared-memory protocols.

The following table shows the plugin names on the server and client sides.

**Table 8.14 Plugin and Library Names for SHA-2 Authentication**

Plugin or File	Plugin or File Name
Server-side plugin	<code>caching_sha2_password</code>
Client-side plugin	<code>caching_sha2_password</code>
Library file	None (plugins are built in)

The following sections provide installation and usage information specific to caching SHA-2 pluggable authentication:

- [Installing SHA-2 Pluggable Authentication](#)
- [Using SHA-2 Pluggable Authentication](#)
- [Cache Operation for SHA-2 Pluggable Authentication](#)

For general information about pluggable authentication in MySQL, see [Section 8.2.17, “Pluggable Authentication”](#).

## Installing SHA-2 Pluggable Authentication

The `caching_sha2_password` plugin exists in server and client forms:

- The server-side plugin is built into the server, need not be loaded explicitly, and cannot be disabled by unloading it.
- The client-side plugin is built into the `libmysqlclient` client library and is available to any program linked against `libmysqlclient`.

The server-side plugin uses the `sha2_cache_cleaner` audit plugin as a helper to perform password cache management. `sha2_cache_cleaner`, like `caching_sha2_password`, is built in and need not be installed.

## Using SHA-2 Pluggable Authentication

To set up an account that uses the `caching_sha2_password` plugin for SHA-256 password hashing, use the following statement, where `password` is the desired account password:

```
CREATE USER 'sha2user'@'localhost'
IDENTIFIED WITH caching_sha2_password BY 'password';
```

The server assigns the `caching_sha2_password` plugin to the account and uses it to encrypt the password using SHA-256, storing those values in the `plugin` and `authentication_string` columns of the `mysql.user` system table.

The preceding instructions do not assume that `caching_sha2_password` is the default authentication plugin. If `caching_sha2_password` is the default authentication plugin, a simpler `CREATE USER` syntax can be used:

```
CREATE USER 'sha2user'@'localhost' IDENTIFIED BY 'password';
```

The default plugin is determined by the value of the `authentication_policy` system variable; the default is to use `caching_sha2_password`.

To use a different plugin, you must specify it using `IDENTIFIED WITH`. For example, to specify the deprecated `sha256_password` plugin, use this statement:

```
CREATE USER 'nativeuser'@'localhost'
IDENTIFIED WITH sha256_password BY 'password';
```

`caching_sha2_password` supports connections over secure transport. If you follow the RSA configuration procedure given later in this section, it also supports encrypted password exchange using RSA over unencrypted connections. RSA support has these characteristics:

- On the server side, two system variables name the RSA private and public key-pair files: `caching_sha2_password_private_key_path` and `caching_sha2_password_public_key_path`. The database administrator must set these variables at server startup if the key files to use have names that differ from the system variable default values.
- The server uses the `caching_sha2_password_auto_generate_rsa_keys` system variable to determine whether to automatically generate the RSA key-pair files. See [Section 8.3.3, “Creating SSL and RSA Certificates and Keys”](#).
- The `Caching_sha2_password_rsa_public_key` status variable displays the RSA public key value used by the `caching_sha2_password` authentication plugin.
- Clients that are in possession of the RSA public key can perform RSA key pair-based password exchange with the server during the connection process, as described later.
- For connections by accounts that authenticate with `caching_sha2_password` and RSA key pair-based password exchange, the server does not send the RSA public key to clients by default. Clients can use a client-side copy of the required public key, or request the public key from the server.

Use of a trusted local copy of the public key enables the client to avoid a round trip in the client/server protocol, and is more secure than requesting the public key from the server. On the other hand, requesting the public key from the server is more convenient (it requires no management of a client-side file) and may be acceptable in secure network environments.

- For command-line clients, use the `--server-public-key-path` option to specify the RSA public key file. Use the `--get-server-public-key` option to request the public key from the server. The following programs support the two options: `mysql`, `mysqlsh`, `mysqladmin`, `mysqlbinlog`, `mysqlcheck`, `mysqldump`, `mysqlimport`, `mysqlshow`, `mysqlslap`, `mysqltest`.
- For programs that use the C API, call `mysql_options()` to specify the RSA public key file by passing the `MYSQL_SERVER_PUBLIC_KEY` option and the name of the file, or request the public key from the server by passing the `MYSQL_OPT_GET_SERVER_PUBLIC_KEY` option.

- For replicas, use the `CHANGE REPLICATION SOURCE TO` statement with the `SOURCE_PUBLIC_KEY_PATH` option to specify the RSA public key file, or the `GET_SOURCE_PUBLIC_KEY` option to request the public key from the source. For Group Replication, the `group_replication_recovery_public_key_path` and `group_replication_recovery_get_public_key` system variables serve the same purpose.

In all cases, if the option is given to specify a valid public key file, it takes precedence over the option to request the public key from the server.

For clients that use the `caching_sha2_password` plugin, passwords are never exposed as cleartext when connecting to the server. How password transmission occurs depends on whether a secure connection or RSA encryption is used:

- If the connection is secure, an RSA key pair is unnecessary and is not used. This applies to TCP connections encrypted using TLS, as well as Unix socket-file and shared-memory connections. The password is sent as cleartext but cannot be snooped because the connection is secure.
- If the connection is not secure, an RSA key pair is used. This applies to TCP connections not encrypted using TLS and named-pipe connections. RSA is used only for password exchange between client and server, to prevent password snooping. When the server receives the encrypted password, it decrypts it. A scramble is used in the encryption to prevent repeat attacks.

To enable use of an RSA key pair for password exchange during the client connection process, use the following procedure:

1. Create the RSA private and public key-pair files using the instructions in [Section 8.3.3, “Creating SSL and RSA Certificates and Keys”](#).
2. If the private and public key files are located in the data directory and are named `private_key.pem` and `public_key.pem` (the default values of the `caching_sha2_password_private_key_path` and `caching_sha2_password_public_key_path` system variables), the server uses them automatically at startup.

Otherwise, to name the key files explicitly, set the system variables to the key file names in the server option file. If the files are located in the server data directory, you need not specify their full path names:

```
[mysqld]
caching_sha2_password_private_key_path=myprivkey.pem
caching_sha2_password_public_key_path=myspubkey.pem
```

If the key files are not located in the data directory, or to make their locations explicit in the system variable values, use full path names:

```
[mysqld]
caching_sha2_password_private_key_path=/usr/local/mysql/myprivkey.pem
caching_sha2_password_public_key_path=/usr/local/mysql/mypubkey.pem
```

3. If you want to change the number of hash rounds used by `caching_sha2_password` during password generation, set the `caching_sha2_password_digest_rounds` system variable. For example:

```
[mysqld]
caching_sha2_password_digest_rounds=10000
```

4. Restart the server, then connect to it and check the `Caching_sha2_password_rsa_public_key` status variable value. The value actually displayed differs from that shown here, but should be nonempty:

```
mysql> SHOW STATUS LIKE 'Caching_sha2_password_rsa_public_key'\G
***** 1. row *****
Variable_name: Caching_sha2_password_rsa_public_key
Value: -----BEGIN PUBLIC KEY-----
MIGfMA0GCSqGSIb3DQEBAQUAA4GNADCBiQKBgQDO9nRUDd+KvSZgY7cNBZMNpwX6
MvE1PbJFXO7u18nJ9lw99Du/E7lw6CVXw7VKrXPehbVQUzGyUNkf45Nz/ckaaJa
aLgJOBCIDmNVnyU540T/1lcs2xiyfaDMe8fCJ64ZwTnKbY2gkt1IMjUAB5Ogd5kJ
g8aV7EtKwyhHb0c30QIDAQAB
-----END PUBLIC KEY-----
```

If the value is empty, the server found some problem with the key files. Check the error log for diagnostic information.

After the server has been configured with the RSA key files, accounts that authenticate with the `caching_sha2_password` plugin have the option of using those key files to connect to the server. As mentioned previously, such accounts can use either a secure connection (in which case RSA is not used) or an unencrypted connection that performs password exchange using RSA. Suppose that an unencrypted connection is used. For example:

```
$> mysql --ssl-mode=DISABLED -u sha2user -p
Enter password: password
```

For this connection attempt by `sha2user`, the server determines that `caching_sha2_password` is the appropriate authentication plugin and invokes it (because that was the plugin specified at `CREATE USER` time). The plugin finds that the connection is not encrypted and thus requires the password to be transmitted using RSA encryption. However, the server does not send the public key to the client, and the client provided no public key, so it cannot encrypt the password and the connection fails:

```
ERROR 2061 (HY000): Authentication plugin 'caching_sha2_password'
reported error: Authentication requires secure connection.
```

To request the RSA public key from the server, specify the `--get-server-public-key` option:

```
$> mysql --ssl-mode=DISABLED -u sha2user -p --get-server-public-key
Enter password: password
```

In this case, the server sends the RSA public key to the client, which uses it to encrypt the password and returns the result to the server. The plugin uses the RSA private key on the server side to decrypt the password and accepts or rejects the connection based on whether the password is correct.

Alternatively, if the client has a file containing a local copy of the RSA public key required by the server, it can specify the file using the `--server-public-key-path` option:

```
$> mysql --ssl-mode=DISABLED -u sha2user -p --server-public-key-path=file_name
Enter password: password
```

In this case, the client uses the public key to encrypt the password and returns the result to the server. The plugin uses the RSA private key on the server side to decrypt the password and accepts or rejects the connection based on whether the password is correct.

The public key value in the file named by the `--server-public-key-path` option should be the same as the key value in the server-side file named by the `caching_sha2_password_public_key_path` system variable. If the key file contains a valid public key value but the value is incorrect, an access-denied error occurs. If the key file does not contain a valid public key, the client program cannot use it.

Client users can obtain the RSA public key two ways:

- The database administrator can provide a copy of the public key file.
- A client user who can connect to the server some other way can use a `SHOW STATUS LIKE 'Caching_sha2_password_rsa_public_key'` statement and save the returned key value in a file.

## Cache Operation for SHA-2 Pluggable Authentication

On the server side, the `caching_sha2_password` plugin uses an in-memory cache for faster authentication of clients who have connected previously. Entries consist of account-name/password-hash pairs. The cache works like this:

1. When a client connects, `caching_sha2_password` checks whether the client and password match some cache entry. If so, authentication succeeds.
2. If there is no matching cache entry, the plugin attempts to verify the client against the credentials in the `mysql.user` system table. If this succeeds, `caching_sha2_password` adds an entry for the client to the hash. Otherwise, authentication fails and the connection is rejected.

In this way, when a client first connects, authentication against the `mysql.user` system table occurs. When the client connects subsequently, faster authentication against the cache occurs.

Password cache operations other than adding entries are handled by the `sha2_cache_cleaner` audit plugin, which performs these actions on behalf of `caching_sha2_password`:

- It clears the cache entry for any account that is renamed or dropped, or any account for which the credentials or authentication plugin are changed.
- It empties the cache when the `FLUSH PRIVILEGES` statement is executed.
- It empties the cache at server shutdown. (This means the cache is not persistent across server restarts.)

Cache clearing operations affect the authentication requirements for subsequent client connections. For each user account, the first client connection for the user after any of the following operations must use a secure connection (made using TCP using TLS credentials, a Unix socket file, or shared memory) or RSA key pair-based password exchange:

- After account creation.
- After a password change for the account.
- After `RENAME USER` for the account.
- After `FLUSH PRIVILEGES`.

`FLUSH PRIVILEGES` clears the entire cache and affects all accounts that use the `caching_sha2_password` plugin. The other operations clear specific cache entries and affect only accounts that are part of the operation.

Once the user authenticates successfully, the account is entered into the cache and subsequent connections do not require a secure connection or the RSA key pair, until another cache clearing event occurs that affects the account. (When the cache can be used, the server uses a challenge-response mechanism that does not use cleartext password transmission and does not require a secure connection.)

### 8.4.1.2 SHA-256 Pluggable Authentication

MySQL provides two authentication plugins that implement SHA-256 hashing for user account passwords:

- `sha256_password`: Implements basic SHA-256 authentication.
- `caching_sha2_password`: Implements SHA-256 authentication (like `sha256_password`), but uses caching on the server side for better performance and has additional features for wider applicability.

This section describes the original noncaching SHA-2 authentication plugin. For information about the caching plugin, see [Section 8.4.1.1, “Caching SHA-2 Pluggable Authentication”](#).

**Important**

In MySQL 9.1, `caching_sha2_password` is the default authentication plugin; `mysql_native_password` is no longer available. For information about the implications of this change for server operation and compatibility of the server with clients and connectors, see [caching\\_sha2\\_password as the Preferred Authentication Plugin](#).

Because `caching_sha2_password` is the default authentication plugin in MySQL 9.1 and provides a superset of the capabilities of the `sha256_password` authentication plugin, `sha256_password` is deprecated; expect it to be removed in a future version of MySQL. MySQL accounts that authenticate using `sha256_password` should be migrated to use `caching_sha2_password` instead.

**Important**

To connect to the server using an account that authenticates with the `sha256_password` plugin, you must use either a TLS connection or an unencrypted connection that supports password exchange using an RSA key pair, as described later in this section. Either way, the `sha256_password` plugin uses MySQL's encryption capabilities. See [Section 8.3, “Using Encrypted Connections”](#).

**Note**

In the name `sha256_password`, “sha256” refers to the 256-bit digest length the plugin uses for encryption. In the name `caching_sha2_password`, “sha2” refers more generally to the SHA-2 class of encryption algorithms, of which 256-bit encryption is one instance. The latter name choice leaves room for future expansion of possible digest lengths without changing the plugin name.

The following table shows the plugin names on the server and client sides.

**Table 8.15 Plugin and Library Names for SHA-256 Authentication**

Plugin or File	Plugin or File Name
Server-side plugin	<code>sha256_password</code>
Client-side plugin	<code>sha256_password</code>
Library file	None (plugins are built in)

The following sections provide installation and usage information specific to SHA-256 pluggable authentication:

- [Installing SHA-256 Pluggable Authentication](#)
- [Using SHA-256 Pluggable Authentication](#)

For general information about pluggable authentication in MySQL, see [Section 8.2.17, “Pluggable Authentication”](#).

## Installing SHA-256 Pluggable Authentication

The `sha256_password` plugin exists in server and client forms:

- The server-side plugin is built into the server, need not be loaded explicitly, and cannot be disabled by unloading it.

- The client-side plugin is built into the `libmysqlclient` client library and is available to any program linked against `libmysqlclient`.

## Using SHA-256 Pluggable Authentication

To set up an account that uses the `sha256_password` plugin for SHA-256 password hashing, use the following statement, where `password` is the desired account password:

```
CREATE USER 'sha256user'@'localhost'
IDENTIFIED WITH sha256_password BY 'password';
```

The server assigns the `sha256_password` plugin to the account and uses it to encrypt the password using SHA-256, storing those values in the `plugin` and `authentication_string` columns of the `mysql.user` system table.

(The `IDENTIFIED WITH` clause is not needed if `sha256_password` is the default plugin; this can be specified using `authentication_policy`.)

`sha256_password` supports connections over secure transport. `sha256_password` also supports encrypted password exchange using RSA over unencrypted connections if MySQL is compiled using OpenSSL, and the MySQL server to which you wish to connect is configured to support RSA (using the RSA configuration procedure given later in this section).

RSA support has these characteristics:

- On the server side, two system variables name the RSA private and public key-pair files: `sha256_password_private_key_path` and `sha256_password_public_key_path`. The database administrator must set these variables at server startup if the key files to use have names that differ from the system variable default values.
- The server uses the `sha256_password_auto_generate_rsa_keys` system variable to determine whether to automatically generate the RSA key-pair files. See [Section 8.3.3, “Creating SSL and RSA Certificates and Keys”](#).
- The `Rsa_public_key` status variable displays the RSA public key value used by the `sha256_password` authentication plugin.
- Clients that are in possession of the RSA public key can perform RSA key pair-based password exchange with the server during the connection process, as described later.
- For connections by accounts that authenticate with `sha256_password` and RSA public key pair-based password exchange, the server sends the RSA public key to the client as needed. However, if a copy of the public key is available on the client host, the client can use it to save a round trip in the client/server protocol:
  - For these command-line clients, use the `--server-public-key-path` option to specify the RSA public key file: `mysql`, `mysqladmin`, `mysqlbinlog`, `mysqlcheck`, `mysqldump`, `mysqlimport`, `mysqlshow`, `mysqlslap`, `mysqltest`.
  - For programs that use the C API, call `mysql_options()` to specify the RSA public key file by passing the `MYSQL_SERVER_PUBLIC_KEY` option and the name of the file.
  - For replicas, use the `CHANGE REPLICATION SOURCE TO` statement with the `SOURCE_PUBLIC_KEY_PATH` option to specify the RSA public key file. For Group Replication, the `group_replication_recovery_get_public_key` system variable serves the same purpose.

For clients that use the `sha256_password` plugin, passwords are never exposed as cleartext when connecting to the server. How password transmission occurs depends on whether a secure connection or RSA encryption is used:

- If the connection is secure, an RSA key pair is unnecessary and is not used. This applies to connections encrypted using TLS. The password is sent as cleartext but cannot be snooped because the connection is secure.

**Note**

Unlike `caching_sha2_password`, the `sha256_password` plugin does not treat shared-memory connections as secure, even though share-memory transport is secure by default.

- If the connection is not secure, and an RSA key pair is available, the connection remains unencrypted. This applies to connections not encrypted using TLS. RSA is used only for password exchange between client and server, to prevent password snooping. When the server receives the encrypted password, it decrypts it. A scramble is used in the encryption to prevent repeat attacks.
- If a secure connection is not used and RSA encryption is not available, the connection attempt fails because the password cannot be sent without being exposed as cleartext.

**Note**

To use RSA password encryption with `sha256_password`, the client and server both must be compiled using OpenSSL, not just one of them.

Assuming that MySQL has been compiled using OpenSSL, use the following procedure to enable use of an RSA key pair for password exchange during the client connection process:

1. Create the RSA private and public key-pair files using the instructions in [Section 8.3.3, “Creating SSL and RSA Certificates and Keys”](#).
2. If the private and public key files are located in the data directory and are named `private_key.pem` and `public_key.pem` (the default values of the `sha256_password_private_key_path` and `sha256_password_public_key_path` system variables), the server uses them automatically at startup.

Otherwise, to name the key files explicitly, set the system variables to the key file names in the server option file. If the files are located in the server data directory, you need not specify their full path names:

```
[mysqld]
sha256_password_private_key_path=myprivkey.pem
sha256_password_public_key_path=myspubkey.pem
```

If the key files are not located in the data directory, or to make their locations explicit in the system variable values, use full path names:

```
[mysqld]
sha256_password_private_key_path=/usr/local/mysql/myprivkey.pem
sha256_password_public_key_path=/usr/local/mysql/mypubkey.pem
```

3. Restart the server, then connect to it and check the `Rsa_public_key` status variable value. The value actually displayed differs from that shown here, but should be nonempty:

```
mysql> SHOW STATUS LIKE 'Rsa_public_key'\G
***** 1. row *****
Variable_name: Rsa_public_key
Value: -----BEGIN PUBLIC KEY-----
MIGfMA0GCsGSIb3DQEBAQUAA4GNADCBiQKBgQDO9nRUDd+KvSZgY7cNBZMNpwX6
MvE1PbJFXO7u18nJ9lwc99Du/E7lw6CVXw7VKrXPehbVQUzGyUNkf45Nz/ckaaJa
aLgJOBcIDmNVnyU540T/1lcs2xiyfaDMe8fCJ64ZwTnKbY2gkt1IMjUAB5Ogd5kJ
g8aV7EtKwyhHb0c30QIDAQAB
-----END PUBLIC KEY-----
```

If the value is empty, the server found some problem with the key files. Check the error log for diagnostic information.

After the server has been configured with the RSA key files, accounts that authenticate with the `sha256_password` plugin have the option of using those key files to connect to the server. As mentioned previously, such accounts can use either a secure connection (in which case RSA is not used) or an unencrypted connection that performs password exchange using RSA. Suppose that an unencrypted connection is used. For example:

```
$> mysql --ssl-mode=DISABLED -u sha256user -p
Enter password: password
```

For this connection attempt by `sha256user`, the server determines that `sha256_password` is the appropriate authentication plugin and invokes it (because that was the plugin specified at `CREATE USER` time). The plugin finds that the connection is not encrypted and thus requires the password to be transmitted using RSA encryption. In this case, the plugin sends the RSA public key to the client, which uses it to encrypt the password and returns the result to the server. The plugin uses the RSA private key on the server side to decrypt the password and accepts or rejects the connection based on whether the password is correct.

The server sends the RSA public key to the client as needed. However, if the client has a file containing a local copy of the RSA public key required by the server, it can specify the file using the `--server-public-key-path` option:

```
$> mysql --ssl-mode=DISABLED -u sha256user -p --server-public-key-path=file_name
Enter password: password
```

The public key value in the file named by the `--server-public-key-path` option should be the same as the key value in the server-side file named by the `sha256_password_public_key_path` system variable. If the key file contains a valid public key value but the value is incorrect, an access-denied error occurs. If the key file does not contain a valid public key, the client program cannot use it. In this case, the `sha256_password` plugin sends the public key to the client as if no `--server-public-key-path` option had been specified.

Client users can obtain the RSA public key two ways:

- The database administrator can provide a copy of the public key file.
- A client user who can connect to the server some other way can use a `SHOW STATUS LIKE 'Rsa_public_key'` statement and save the returned key value in a file.

### 8.4.1.3 Client-Side Cleartext Pluggable Authentication

A client-side authentication plugin is available that enables clients to send passwords to the server as cleartext, without hashing or encryption. This plugin is built into the MySQL client library.

The following table shows the plugin name.

**Table 8.16 Plugin and Library Names for Cleartext Authentication**

Plugin or File	Plugin or File Name
Server-side plugin	None, see discussion
Client-side plugin	<code>mysql_clear_password</code>
Library file	None (plugin is built in)

Many client-side authentication plugins perform hashing or encryption of a password before the client sends it to the server. This enables clients to avoid sending passwords as cleartext.

Hashing or encryption cannot be done for authentication schemes that require the server to receive the password as entered on the client side. In such cases, the client-side `mysql_clear_password` plugin is used, which enables the client to send the password to the server as cleartext. There is no corresponding server-side plugin. Rather, `mysql_clear_password` can be used on the client side in concert with any server-side plugin that needs a cleartext password. (Examples are the PAM and simple LDAP authentication plugins; see [Section 8.4.1.4, “PAM Pluggable Authentication”](#), and [Section 8.4.1.6, “LDAP Pluggable Authentication”](#).)

The following discussion provides usage information specific to cleartext pluggable authentication. For general information about pluggable authentication in MySQL, see [Section 8.2.17, “Pluggable Authentication”](#).

**Note**

Sending passwords as cleartext may be a security problem in some configurations. To avoid problems if there is any possibility that the password would be intercepted, clients should connect to MySQL Server using a method that protects the password. Possibilities include SSL (see [Section 8.3, “Using Encrypted Connections”](#)), IPsec, or a private network.

To make inadvertent use of the `mysql_clear_password` plugin less likely, MySQL clients must explicitly enable it. This can be done in several ways:

- Set the `LIBMYSQL_ENABLE_CLEARTEXT_PLUGIN` environment variable to a value that begins with `1`, `y`, or `Y`. This enables the plugin for all client connections.
- The `mysql`, `mysqladmin`, `mysqlcheck`, `mysqldump`, `mysqlshow`, and `mysqlslap` client programs support an `--enable-cleartext-plugin` option that enables the plugin on a per-invocation basis.
- The `mysql_options()` C API function supports a `MYSQL_ENABLE_CLEARTEXT_PLUGIN` option that enables the plugin on a per-connection basis. Also, any program that uses `libmysqlclient` and reads option files can enable the plugin by including an `enable-cleartext-plugin` option in an option group read by the client library.

#### 8.4.1.4 PAM Pluggable Authentication

**Note**

PAM pluggable authentication is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see <https://www.mysql.com/products/>.

MySQL Enterprise Edition supports an authentication method that enables MySQL Server to use PAM (Pluggable Authentication Modules) to authenticate MySQL users. PAM enables a system to use a standard interface to access various kinds of authentication methods, such as traditional Unix passwords or an LDAP directory.

PAM pluggable authentication provides these capabilities:

- External authentication: PAM authentication enables MySQL Server to accept connections from users defined outside the MySQL grant tables and that authenticate using methods supported by PAM.
- Proxy user support: PAM authentication can return to MySQL a user name different from the external user name passed by the client program, based on the PAM groups the external user is a member of and the authentication string provided. This means that the plugin can return the MySQL user that defines the privileges the external PAM-authenticated user should have. For example, an operating system user named `joe` can connect and have the privileges of a MySQL user named `developer`.

PAM pluggable authentication has been tested on Linux and macOS; note that Windows does not support PAM.

The following table shows the plugin and library file names. The file name suffix might differ on your system. The file must be located in the directory named by the `plugin_dir` system variable. For installation information, see [Installing PAM Pluggable Authentication](#).

**Table 8.17 Plugin and Library Names for PAM Authentication**

Plugin or File	Plugin or File Name
Server-side plugin	<code>authentication_pam</code>
Client-side plugin	<code>mysql_clear_password</code>
Library file	<code>authentication_pam.so</code>

The client-side `mysql_clear_password` cleartext plugin that communicates with the server-side PAM plugin is built into the `libmysqlclient` client library and is included in all distributions, including community distributions. Inclusion of the client-side cleartext plugin in all MySQL distributions enables clients from any distribution to connect to a server that has the server-side PAM plugin loaded.

The following sections provide installation and usage information specific to PAM pluggable authentication:

- [How PAM Authentication of MySQL Users Works](#)
- [Installing PAM Pluggable Authentication](#)
- [Uninstalling PAM Pluggable Authentication](#)
- [Using PAM Pluggable Authentication](#)
- [PAM Unix Password Authentication without Proxy Users](#)
- [PAM LDAP Authentication without Proxy Users](#)
- [PAM Unix Password Authentication with Proxy Users and Group Mapping](#)
- [PAM Authentication Access to Unix Password Store](#)
- [PAM Authentication Debugging](#)

For general information about pluggable authentication in MySQL, see [Section 8.2.17, “Pluggable Authentication”](#). For information about the `mysql_clear_password` plugin, see [Section 8.4.1.3, “Client-Side Cleartext Pluggable Authentication”](#). For proxy user information, see [Section 8.2.19, “Proxy Users”](#).

## How PAM Authentication of MySQL Users Works

This section provides an overview of how MySQL and PAM work together to authenticate MySQL users. For examples showing how to set up MySQL accounts to use specific PAM services, see [Using PAM Pluggable Authentication](#).

1. The client program and the server communicate, with the client sending to the server the client user name (the operating system user name by default) and password:
  - The client user name is the external user name.
  - For accounts that use the PAM server-side authentication plugin, the corresponding client-side plugin is `mysql_clear_password`. This client-side plugin performs no password hashing, with the result that the client sends the password to the server as cleartext.

2. The server finds a matching MySQL account based on the external user name and the host from which the client connects. The PAM plugin uses the information passed to it by MySQL Server (such as user name, host name, password, and authentication string). When you define a MySQL account that authenticates using PAM, the authentication string contains:
  - A PAM service name, which is a name that the system administrator can use to refer to an authentication method for a particular application. There can be multiple applications associated with a single database server instance, so the choice of service name is left to the SQL application developer.
  - Optionally, if proxying is to be used, a mapping from PAM groups to MySQL user names.
3. The plugin uses the PAM service named in the authentication string to check the user credentials and returns 'Authentication succeeded, Username is *user\_name*' or 'Authentication failed'. The password must be appropriate for the password store used by the PAM service. Examples:
  - For traditional Unix passwords, the service looks up passwords stored in the `/etc/shadow` file.
  - For LDAP, the service looks up passwords stored in an LDAP directory.If the credentials check fails, the server refuses the connection.
4. Otherwise, the authentication string indicates whether proxying occurs. If the string contains no PAM group mapping, proxying does not occur. In this case, the MySQL user name is the same as the external user name.
5. Otherwise, proxying is indicated based on the PAM group mapping, with the MySQL user name determined based on the first matching group in the mapping list. The meaning of “PAM group” depends on the PAM service. Examples:
  - For traditional Unix passwords, groups are Unix groups defined in the `/etc/group` file, possibly supplemented with additional PAM information in a file such as `/etc/security/group.conf`.
  - For LDAP, groups are LDAP groups defined in an LDAP directory.

If the proxy user (the external user) has the `PROXY` privilege for the proxied MySQL user name, proxying occurs, with the proxy user assuming the privileges of the proxied user.

## Installing PAM Pluggable Authentication

This section describes how to install the server-side PAM authentication plugin. For general information about installing plugins, see [Section 7.6.1, “Installing and Uninstalling Plugins”](#).

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

The plugin library file base name is `authentication_pam`, and is typically compiled with the `.so` suffix.

To load the plugin at server startup, use the `--plugin-load-add` option to name the library file that contains it. With this plugin-loading method, the option must be given each time the server starts. For example, put these lines in the server `my.cnf` file:

```
[mysqld]
plugin-load-add=authentication_pam.so
```

After modifying `my.cnf`, restart the server to cause the new settings to take effect.

Alternatively, to load the plugin at runtime, use this statement, adjusting the `.so` suffix as necessary:

```
INSTALL PLUGIN authentication_pam SONAME 'authentication_pam.so';
```

`INSTALL PLUGIN` loads the plugin immediately, and also registers it in the `mysql.plugins` system table to cause the server to load it for each subsequent normal startup without the need for `--plugin-load-add`.

To verify plugin installation, examine the Information Schema `PLUGINS` table or use the `SHOW PLUGINS` statement (see [Section 7.6.2, “Obtaining Server Plugin Information”](#)). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
 FROM INFORMATION_SCHEMA.PLUGINS
 WHERE PLUGIN_NAME LIKE '%pam%';
+-----+-----+
| PLUGIN_NAME | PLUGIN_STATUS |
+-----+-----+
| authentication_pam | ACTIVE |
+-----+-----+
```

If the plugin fails to initialize, check the server error log for diagnostic messages.

To associate MySQL accounts with the PAM plugin, see [Using PAM Pluggable Authentication](#).

## Uninstalling PAM Pluggable Authentication

The method used to uninstall the PAM authentication plugin depends on how you installed it:

- If you installed the plugin at server startup using a `--plugin-load-add` option, restart the server without the option.
- If you installed the plugin at runtime using an `INSTALL PLUGIN` statement, it remains installed across server restarts. To uninstall it, use `UNINSTALL PLUGIN`:

```
UNINSTALL PLUGIN authentication_pam;
```

## Using PAM Pluggable Authentication

This section describes in general terms how to use the PAM authentication plugin to connect from MySQL client programs to the server. The following sections provide instructions for using PAM authentication in specific ways. It is assumed that the server is running with the server-side PAM plugin enabled, as described in [Installing PAM Pluggable Authentication](#).

To refer to the PAM authentication plugin in the `IDENTIFIED WITH` clause of a `CREATE USER` statement, use the name `authentication_pam`. For example:

```
CREATE USER user
 IDENTIFIED WITH authentication_pam
 AS 'auth_string';
```

The authentication string specifies the following types of information:

- The PAM service name (see [How PAM Authentication of MySQL Users Works](#)). Examples in the following discussion use a service name of `mysql-unix` for authentication using traditional Unix passwords, and `mysql-ldap` for authentication using LDAP.
- For proxy support, PAM provides a way for a PAM module to return to the server a MySQL user name other than the external user name passed by the client program when it connects to the server. Use the authentication string to control the mapping from external user names to MySQL user names. If you want to take advantage of proxy user capabilities, the authentication string must include this kind of mapping.

For example, if an account uses the `mysql-unix` PAM service name and should map operating system users in the `root` and `users` PAM groups to the `developer` and `data_entry` MySQL users, respectively, use a statement like this:

```
CREATE USER user
 IDENTIFIED WITH authentication_pam
 AS 'mysql-unix, root=developer, users=data_entry';
```

Authentication string syntax for the PAM authentication plugin follows these rules:

- The string consists of a PAM service name, optionally followed by a PAM group mapping list consisting of one or more keyword/value pairs each specifying a PAM group name and a MySQL user name:

```
pam_service_name[,pam_group_name=mysql_user_name]...
```

The plugin parses the authentication string for each connection attempt that uses the account. To minimize overhead, keep the string as short as possible.

- Each `pam_group_name=mysql_user_name` pair must be preceded by a comma.
- Leading and trailing spaces not inside double quotation marks are ignored.
- Unquoted `pam_service_name`, `pam_group_name`, and `mysql_user_name` values can contain anything except equal sign, comma, or space.
- If a `pam_service_name`, `pam_group_name`, or `mysql_user_name` value is quoted with double quotation marks, everything between the quotation marks is part of the value. This is necessary, for example, if the value contains space characters. All characters are legal except double quotation mark and backslash (`\`). To include either character, escape it with a backslash.

If the plugin successfully authenticates the external user name (the name passed by the client), it looks for a PAM group mapping list in the authentication string and, if present, uses it to return a different MySQL user name to the MySQL server based on which PAM groups the external user is a member of:

- If the authentication string contains no PAM group mapping list, the plugin returns the external name.
- If the authentication string does contain a PAM group mapping list, the plugin examines each `pam_group_name=mysql_user_name` pair in the list from left to right and tries to find a match for the `pam_group_name` value in a non-MySQL directory of the groups assigned to the authenticated user and returns `mysql_user_name` for the first match it finds. If the plugin finds no match for any PAM group, it returns the external name. If the plugin is not capable of looking up a group in a directory, it ignores the PAM group mapping list and returns the external name.

The following sections describe how to set up several authentication scenarios that use the PAM authentication plugin:

- No proxy users. This uses PAM only to check login names and passwords. Every external user permitted to connect to MySQL Server should have a matching MySQL account that is defined to use PAM authentication. (For a MySQL account of '`user_name`'@'`host_name`' to match the external user, `user_name` must be the external user name and `host_name` must match the host from which the client connects.) Authentication can be performed by various PAM-supported methods. Later discussion shows how to authenticate client credentials using traditional Unix passwords, and passwords in LDAP.

PAM authentication, when not done through proxy users or PAM groups, requires the MySQL user name to be same as the operating system user name. MySQL user names are limited to 32 characters (see [Section 8.2.3, “Grant Tables”](#)), which limits PAM nonproxy authentication to Unix accounts with names of at most 32 characters.

- Proxy users only, with PAM group mapping. For this scenario, create one or more MySQL accounts that define different sets of privileges. (Ideally, nobody should connect using those accounts directly.) Then define a default user authenticating through PAM that uses some mapping scheme (usually based on the external PAM groups the users are members of) to map all the external user names to the few MySQL accounts holding the privilege sets. Any client who connects and specifies an external user name as the client user name is mapped to one of the MySQL accounts and uses its privileges. The discussion shows how to set this up using traditional Unix passwords, but other PAM methods such as LDAP could be used instead.

Variations on these scenarios are possible:

- You can permit some users to log in directly (without proxying) but require others to connect through proxy accounts.
- You can use one PAM authentication method for some users, and another method for other users, by using differing PAM service names among your PAM-authenticated accounts. For example, you can use the `mysql-unix` PAM service for some users, and `mysql-ldap` for others.

The examples make the following assumptions. You might need to make some adjustments if your system is set up differently.

- The login name and password are `antonio` and `antonio_password`, respectively. Change these to correspond to the user you want to authenticate.
- The PAM configuration directory is `/etc/pam.d`.
- The PAM service name corresponds to the authentication method (`mysql-unix` or `mysql-ldap` in this discussion). To use a given PAM service, you must set up a PAM file with the same name in the PAM configuration directory (creating the file if it does not exist). In addition, you must name the PAM service in the authentication string of the `CREATE USER` statement for any account that authenticates using that PAM service.

The PAM authentication plugin checks at initialization time whether the `AUTHENTICATION_PAM_LOG` environment value is set in the server's startup environment. If so, the plugin enables logging of diagnostic messages to the standard output. Depending on how your server is started, the message might appear on the console or in the error log. These messages can be helpful for debugging PAM-related issues that occur when the plugin performs authentication. For more information, see [PAM Authentication Debugging](#).

## PAM Unix Password Authentication without Proxy Users

This authentication scenario uses PAM to check external users defined in terms of operating system user names and Unix passwords, without proxying. Every such external user permitted to connect to MySQL Server should have a matching MySQL account that is defined to use PAM authentication through traditional Unix password store.

### Note

Traditional Unix passwords are checked using the `/etc/shadow` file. For information regarding possible issues related to this file, see [PAM Authentication Access to Unix Password Store](#).

1. Verify that Unix authentication permits logins to the operating system with the user name `antonio` and password `antonio_password`.
2. Set up PAM to authenticate MySQL connections using traditional Unix passwords by creating a `mysql-unix` PAM service file named `/etc/pam.d/mysql-unix`. The file contents are system dependent, so check existing login-related files in the `/etc/pam.d` directory to see what they look like. On Linux, the `mysql-unix` file might look like this:

```
#%PAM-1.0
auth include password-auth
account include password-auth
```

For macOS, use `login` rather than `password-auth`.

The PAM file format might differ on some systems. For example, on Ubuntu and other Debian-based systems, use these file contents instead:

```
@include common-auth
@include common-account
@include common-session-noninteractive
```

3. Create a MySQL account with the same user name as the operating system user name and define it to authenticate using the PAM plugin and the `mysql-unix` PAM service:

```
CREATE USER 'antonio'@'localhost'
 IDENTIFIED WITH authentication_pam
 AS 'mysql-unix';
GRANT ALL PRIVILEGES
 ON mydb.*
 TO 'antonio'@'localhost';
```

Here, the authentication string contains only the PAM service name, `mysql-unix`, which authenticates Unix passwords.

4. Use the `mysql` command-line client to connect to the MySQL server as `antonio`. For example:

```
$> mysql --user=antonio --password --enable-cleartext-plugin
Enter password: antonio_password
```

The server should permit the connection and the following query returns output as shown:

```
mysql> SELECT USER(), CURRENT_USER(), @@proxy_user;
+-----+-----+-----+
| USER() | CURRENT_USER() | @@proxy_user |
+-----+-----+-----+
| antonio@localhost | antonio@localhost | NULL |
+-----+-----+-----+
```

This demonstrates that the `antonio` operating system user is authenticated to have the privileges granted to the `antonio` MySQL user, and that no proxying has occurred.

#### Note

The client-side `mysql_clear_password` authentication plugin leaves the password untouched, so client programs send it to the MySQL server as cleartext. This enables the password to be passed as is to PAM. A cleartext password is necessary to use the server-side PAM library, but may be a security problem in some configurations. These measures minimize the risk:

- To make inadvertent use of the `mysql_clear_password` plugin less likely, MySQL clients must explicitly enable it (for example, with the `--enable-cleartext-plugin` option). See [Section 8.4.1.3, “Client-Side Cleartext Pluggable Authentication”](#).
- To avoid password exposure with the `mysql_clear_password` plugin enabled, MySQL clients should connect to the MySQL server using an encrypted connection. See [Section 8.3.1, “Configuring MySQL to Use Encrypted Connections”](#).

## PAM LDAP Authentication without Proxy Users

This authentication scenario uses PAM to check external users defined in terms of operating system user names and LDAP passwords, without proxying. Every such external user permitted to connect to MySQL Server should have a matching MySQL account that is defined to use PAM authentication through LDAP.

To use PAM LDAP pluggable authentication for MySQL, these prerequisites must be satisfied:

- An LDAP server must be available for the PAM LDAP service to communicate with.
- Each LDAP user to be authenticated by MySQL must be present in the directory managed by the LDAP server.

### Note

Another way to use LDAP for MySQL user authentication is to use the LDAP-specific authentication plugins. See [Section 8.4.1.6, “LDAP Pluggable Authentication”](#).

Configure MySQL for PAM LDAP authentication as follows:

1. Verify that Unix authentication permits logins to the operating system with the user name `antonio` and password `antonio_password`.
2. Set up PAM to authenticate MySQL connections using LDAP by creating a `mysql-ldap` PAM service file named `/etc/pam.d/mysql-ldap`. The file contents are system dependent, so check existing login-related files in the `/etc/pam.d` directory to see what they look like. On Linux, the `mysql-ldap` file might look like this:

```
#%PAM-1.0
auth required pam_ldap.so
account required pam_ldap.so
```

If PAM object files have a suffix different from `.so` on your system, substitute the correct suffix.

The PAM file format might differ on some systems.

3. Create a MySQL account with the same user name as the operating system user name and define it to authenticate using the PAM plugin and the `mysql-ldap` PAM service:

```
CREATE USER 'antonio'@'localhost'
 IDENTIFIED WITH authentication_pam
 AS 'mysql-ldap';
GRANT ALL PRIVILEGES
 ON mydb.*
 TO 'antonio'@'localhost';
```

Here, the authentication string contains only the PAM service name, `mysql-ldap`, which authenticates using LDAP.

4. Connecting to the server is the same as described in [PAM Unix Password Authentication without Proxy Users](#).

## PAM Unix Password Authentication with Proxy Users and Group Mapping

The authentication scheme described here uses proxying and PAM group mapping to map connecting MySQL users who authenticate using PAM onto other MySQL accounts that define different sets of privileges. Users do not connect directly through the accounts that define the privileges. Instead, they connect through a default proxy account authenticated using PAM, such that all the external users are mapped to the MySQL accounts that hold the privileges. Any user who connects using the proxy account

is mapped to one of those MySQL accounts, the privileges for which determine the database operations permitted to the external user.

The procedure shown here uses Unix password authentication. To use LDAP instead, see the early steps of [PAM LDAP Authentication without Proxy Users](#).

#### Note

Traditional Unix passwords are checked using the `/etc/shadow` file. For information regarding possible issues related to this file, see [PAM Authentication Access to Unix Password Store](#).

1. Verify that Unix authentication permits logins to the operating system with the user name `antonio` and password `antonio_password`.
2. Verify that `antonio` is a member of the `root` or `users` PAM group.
3. Set up PAM to authenticate the `mysql-unix` PAM service through operating system users by creating a file named `/etc/pam.d/mysql-unix`. The file contents are system dependent, so check existing login-related files in the `/etc/pam.d` directory to see what they look like. On Linux, the `mysql-unix` file might look like this:

```
#%PAM-1.0
auth include password-auth
account include password-auth
```

For macOS, use `login` rather than `password-auth`.

The PAM file format might differ on some systems. For example, on Ubuntu and other Debian-based systems, use these file contents instead:

```
@include common-auth
@include common-account
@include common-session-noninteractive
```

4. Create a default proxy user (`' '@'`) that maps external PAM users to the proxied accounts:

```
CREATE USER ' '@'
 IDENTIFIED WITH authentication_pam
 AS 'mysql-unix, root=developer, users=data_entry';
```

Here, the authentication string contains the PAM service name, `mysql-unix`, which authenticates Unix passwords. The authentication string also maps external users in the `root` and `users` PAM groups to the `developer` and `data_entry` MySQL user names, respectively.

The PAM group mapping list following the PAM service name is required when you set up proxy users. Otherwise, the plugin cannot tell how to perform mapping from external user names to the proper proxied MySQL user names.

#### Note

If your MySQL installation has anonymous users, they might conflict with the default proxy user. For more information about this issue, and ways of dealing with it, see [Default Proxy User and Anonymous User Conflicts](#).

5. Create the proxied accounts and grant to each one the privileges it should have:

```
CREATE USER 'developer'@'localhost'
 IDENTIFIED WITH mysql_no_login;
CREATE USER 'data_entry'@'localhost'
```

```

IDENTIFIED WITH mysql_no_login;

GRANT ALL PRIVILEGES
 ON mydevdb.*
 TO 'developer'@'localhost';
GRANT ALL PRIVILEGES
 ON mydb.*
 TO 'data_entry'@'localhost';

```

The proxied accounts use the `mysql_no_login` authentication plugin to prevent clients from using the accounts to log in directly to the MySQL server. Instead, users who authenticate using PAM are expected to use the `developer` or `data_entry` account by proxy based on their PAM group. (This assumes that the plugin is installed. For instructions, see [Section 8.4.1.8, “No-Login Pluggable Authentication”](#).) For alternative methods of protecting proxied accounts against direct use, see [Preventing Direct Login to Proxied Accounts](#).

6. Grant to the proxy account the `PROXY` privilege for each proxied account:

```

GRANT PROXY
 ON 'developer'@'localhost'
 TO '@';
GRANT PROXY
 ON 'data_entry'@'localhost'
 TO '@';

```

7. Use the `mysql` command-line client to connect to the MySQL server as `antonio`.

```

$> mysql --user=antonio --password --enable-cleartext-plugin
Enter password: antonio_password

```

The server authenticates the connection using the default `'@'` proxy account. The resulting privileges for `antonio` depend on which PAM groups `antonio` is a member of. If `antonio` is a member of the `root` PAM group, the PAM plugin maps `root` to the `developer` MySQL user name and returns that name to the server. The server verifies that `'@'` has the `PROXY` privilege for `developer` and permits the connection. The following query returns output as shown:

```

mysql> SELECT USER(), CURRENT_USER(), @@proxy_user;
+-----+-----+-----+
| USER() | CURRENT_USER() | @@proxy_user |
+-----+-----+-----+
| antonio@localhost | developer@localhost | '@' |
+-----+-----+-----+

```

This demonstrates that the `antonio` operating system user is authenticated to have the privileges granted to the `developer` MySQL user, and that proxying occurs through the default proxy account.

If `antonio` is not a member of the `root` PAM group but is a member of the `users` PAM group, a similar process occurs, but the plugin maps `user` PAM group membership to the `data_entry` MySQL user name and returns that name to the server:

```

mysql> SELECT USER(), CURRENT_USER(), @@proxy_user;
+-----+-----+-----+
| USER() | CURRENT_USER() | @@proxy_user |
+-----+-----+-----+
| antonio@localhost | data_entry@localhost | '@' |
+-----+-----+-----+

```

This demonstrates that the `antonio` operating system user is authenticated to have the privileges of the `data_entry` MySQL user, and that proxying occurs through the default proxy account.

**Note**

The client-side `mysql_clear_password` authentication plugin leaves the password untouched, so client programs send it to the MySQL server as cleartext. This enables the password to be passed as is to PAM. A cleartext password is necessary to use the server-side PAM library, but may be a security problem in some configurations. These measures minimize the risk:

- To make inadvertent use of the `mysql_clear_password` plugin less likely, MySQL clients must explicitly enable it (for example, with the `--enable-cleartext-plugin` option). See [Section 8.4.1.3, “Client-Side Cleartext Pluggable Authentication”](#).
- To avoid password exposure with the `mysql_clear_password` plugin enabled, MySQL clients should connect to the MySQL server using an encrypted connection. See [Section 8.3.1, “Configuring MySQL to Use Encrypted Connections”](#).

## PAM Authentication Access to Unix Password Store

On some systems, Unix authentication uses a password store such as `/etc/shadow`, a file that typically has restricted access permissions. This can cause MySQL PAM-based authentication to fail. Unfortunately, the PAM implementation does not permit distinguishing “password could not be checked” (due, for example, to inability to read `/etc/shadow`) from “password does not match.” If you are using Unix password store for PAM authentication, you may be able to enable access to it from MySQL using one of the following methods:

- Assuming that the MySQL server is run from the `mysql` operating system account, put that account in the `shadow` group that has `/etc/shadow` access:

1. Create a `shadow` group in `/etc/group`.
2. Add the `mysql` operating system user to the `shadow` group in `/etc/group`.
3. Assign `/etc/group` to the `shadow` group and enable the group read permission:

```
chgrp shadow /etc/shadow
chmod g+r /etc/shadow
```

4. Restart the MySQL server.

- If you are using the `pam_unix` module and the `unix_chkpwd` utility, enable password store access as follows:

```
chmod u-s /usr/sbin/unix_chkpwd
setcap cap_dac_read_search+ep /usr/sbin/unix_chkpwd
```

Adjust the path to `unix_chkpwd` as necessary for your platform.

## PAM Authentication Debugging

The PAM authentication plugin checks at initialization time whether the `AUTHENTICATION_PAM_LOG` environment value is set. If so, the plugin enables logging of diagnostic messages to the standard output. These messages may be helpful for debugging PAM-related issues that occur when the plugin performs authentication.

Setting `AUTHENTICATION_PAM_LOG=1` (or some other arbitrary value) does *not* include any passwords. If you wish to include passwords in these messages, set `AUTHENTICATION_PAM_LOG=PAM_LOG_WITH_SECRET_INFO`.

Some messages include reference to PAM plugin source files and line numbers, which enables plugin actions to be tied more closely to the location in the code where they occur.

Another technique for debugging connection failures and determining what is happening during connection attempts is to configure PAM authentication to permit all connections, then check the system log files. This technique should be used only on a *temporary* basis, and not on a production server.

Configure a PAM service file named `/etc/pam.d/mysql-any-password` with these contents (the format may differ on some systems):

```
#%PAM-1.0
auth required pam_permit.so
account required pam_permit.so
```

Create an account that uses the PAM plugin and names the `mysql-any-password` PAM service:

```
CREATE USER 'testuser'@'localhost'
 IDENTIFIED WITH authentication_pam
 AS 'mysql-any-password';
```

The `mysql-any-password` service file causes any authentication attempt to return true, even for incorrect passwords. If an authentication attempt fails, that tells you the configuration problem is on the MySQL side. Otherwise, the problem is on the operating system/PAM side. To see what might be happening, check system log files such as `/var/log/secure`, `/var/log/audit.log`, `/var/log/syslog`, or `/var/log/messages`.

After determining what the problem is, remove the `mysql-any-password` PAM service file to disable any-password access.

### 8.4.1.5 Windows Pluggable Authentication

#### Note

Windows pluggable authentication is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see <https://www.mysql.com/products/>.

MySQL Enterprise Edition for Windows supports an authentication method that performs external authentication on Windows, enabling MySQL Server to use native Windows services to authenticate client connections. Users who have logged in to Windows can connect from MySQL client programs to the server based on the information in their environment without specifying an additional password.

The client and server exchange data packets in the authentication handshake. As a result of this exchange, the server creates a security context object that represents the identity of the client in the Windows OS. This identity includes the name of the client account. Windows pluggable authentication uses the identity of the client to check whether it is a given account or a member of a group. By default, negotiation uses Kerberos to authenticate, then NTLM if Kerberos is unavailable.

Windows pluggable authentication provides these capabilities:

- **External authentication:** Windows authentication enables MySQL Server to accept connections from users defined outside the MySQL grant tables who have logged in to Windows.

- Proxy user support: Windows authentication can return to MySQL a user name different from the external user name passed by the client program. This means that the plugin can return the MySQL user that defines the privileges the external Windows-authenticated user should have. For example, a Windows user named `joe` can connect and have the privileges of a MySQL user named `developer`.

The following table shows the plugin and library file names. The file must be located in the directory named by the `plugin_dir` system variable.

**Table 8.18 Plugin and Library Names for Windows Authentication**

Plugin or File	Plugin or File Name
Server-side plugin	<code>authentication_windows</code>
Client-side plugin	<code>authentication_windows_client</code>
Library file	<code>authentication_windows.dll</code>

The library file includes only the server-side plugin. The client-side plugin is built into the `libmysqlclient` client library.

The server-side Windows authentication plugin is included only in MySQL Enterprise Edition. It is not included in MySQL community distributions. The client-side plugin is included in all distributions, including community distributions. This enables clients from any distribution to connect to a server that has the server-side plugin loaded.

The following sections provide installation and usage information specific to Windows pluggable authentication:

- [Installing Windows Pluggable Authentication](#)
- [Uninstalling Windows Pluggable Authentication](#)
- [Using Windows Pluggable Authentication](#)

For general information about pluggable authentication in MySQL, see [Section 8.2.17, “Pluggable Authentication”](#). For proxy user information, see [Section 8.2.19, “Proxy Users”](#).

## Installing Windows Pluggable Authentication

This section describes how to install the server-side Windows authentication plugin. For general information about installing plugins, see [Section 7.6.1, “Installing and Uninstalling Plugins”](#).

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

To load the plugin at server startup, use the `--plugin-load-add` option to name the library file that contains it. With this plugin-loading method, the option must be given each time the server starts. For example, put these lines in the server `my.cnf` file:

```
[mysqld]
plugin-load-add=authentication_windows.dll
```

After modifying `my.cnf`, restart the server to cause the new settings to take effect.

Alternatively, to load the plugin at runtime, use this statement:

```
INSTALL PLUGIN authentication_windows SONAME 'authentication_windows.dll';
```

`INSTALL PLUGIN` loads the plugin immediately, and also registers it in the `mysql.plugins` system table to cause the server to load it for each subsequent normal startup without the need for `--plugin-load-add`.

To verify plugin installation, examine the Information Schema `PLUGINS` table or use the `SHOW PLUGINS` statement (see [Section 7.6.2, “Obtaining Server Plugin Information”](#)). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
 FROM INFORMATION_SCHEMA.PLUGINS
 WHERE PLUGIN_NAME LIKE '%windows%';
+-----+-----+
| PLUGIN_NAME | PLUGIN_STATUS |
+-----+-----+
| authentication_windows | ACTIVE |
+-----+-----+
```

If the plugin fails to initialize, check the server error log for diagnostic messages.

To associate MySQL accounts with the Windows authentication plugin, see [Using Windows Pluggable Authentication](#). Additional plugin control is provided by the `authentication_windows_use_principal_name` and `authentication_windows_log_level` system variables. See [Section 7.1.8, “Server System Variables”](#).

## Uninstalling Windows Pluggable Authentication

The method used to uninstall the Windows authentication plugin depends on how you installed it:

- If you installed the plugin at server startup using a `--plugin-load-add` option, restart the server without the option.
- If you installed the plugin at runtime using an `INSTALL PLUGIN` statement, it remains installed across server restarts. To uninstall it, use `UNINSTALL PLUGIN`:

```
UNINSTALL PLUGIN authentication_windows;
```

In addition, remove any startup options that set Windows plugin-related system variables.

## Using Windows Pluggable Authentication

The Windows authentication plugin supports the use of MySQL accounts such that users who have logged in to Windows can connect to the MySQL server without having to specify an additional password. It is assumed that the server is running with the server-side plugin enabled, as described in [Installing Windows Pluggable Authentication](#). Once the DBA has enabled the server-side plugin and set up accounts to use it, clients can connect using those accounts with no other setup required on their part.

To refer to the Windows authentication plugin in the `IDENTIFIED WITH` clause of a `CREATE USER` statement, use the name `authentication_windows`. Suppose that the Windows users `Rafal` and `Tasha` should be permitted to connect to MySQL, as well as any users in the `Administrators` or `Power Users` group. To set this up, create a MySQL account named `sql_admin` that uses the Windows plugin for authentication:

```
CREATE USER sql_admin
 IDENTIFIED WITH authentication_windows
 AS 'Rafal, Tasha, Administrators, "Power Users"';
```

The plugin name is `authentication_windows`. The string following the `AS` keyword is the authentication string. It specifies that the Windows users named `Rafal` or `Tasha` are permitted to authenticate to the server as the MySQL user `sql_admin`, as are any Windows users in the

`Administrators` or `Power Users` group. The latter group name contains a space, so it must be quoted with double quote characters.

After you create the `sql_admin` account, a user who has logged in to Windows can attempt to connect to the server using that account:

```
C:\> mysql --user=sql_admin
```

No password is required here. The `authentication_windows` plugin uses the Windows security API to check which Windows user is connecting. If that user is named `Rafal` or `Tasha`, or is a member of the `Administrators` or `Power Users` group, the server grants access and the client is authenticated as `sql_admin` and has whatever privileges are granted to the `sql_admin` account. Otherwise, the server denies access.

Authentication string syntax for the Windows authentication plugin follows these rules:

- The string consists of one or more user mappings separated by commas.
- Each user mapping associates a Windows user or group name with a MySQL user name:

```
win_user_or_group_name=mysql_user_name
win_user_or_group_name
```

For the latter syntax, with no `mysql_user_name` value given, the implicit value is the MySQL user created by the `CREATE USER` statement. Thus, these statements are equivalent:

```
CREATE USER sql_admin
 IDENTIFIED WITH authentication_windows
 AS 'Rafal, Tasha, Administrators, "Power Users"';

CREATE USER sql_admin
 IDENTIFIED WITH authentication_windows
 AS 'Rafal=sql_admin, Tasha=sql_admin, Administrators=sql_admin,
 "Power Users"=sql_admin';
```

- Each backslash character (`\`) in a value must be doubled because backslash is the escape character in MySQL strings.
- Leading and trailing spaces not inside double quotation marks are ignored.
- Unquoted `win_user_or_group_name` and `mysql_user_name` values can contain anything except equal sign, comma, or space.
- If a `win_user_or_group_name` and or `mysql_user_name` value is quoted with double quotation marks, everything between the quotation marks is part of the value. This is necessary, for example, if the name contains space characters. All characters within double quotes are legal except double quotation mark and backslash. To include either character, escape it with a backslash.
- `win_user_or_group_name` values use conventional syntax for Windows principals, either local or in a domain. Examples (note the doubling of backslashes):

```
domain\\user
.\\user
domain\\group
.\\group
BUILTIN\\WellKnownGroup
```

When invoked by the server to authenticate a client, the plugin scans the authentication string left to right for a user or group match to the Windows user. If there is a match, the plugin returns the corresponding `mysql_user_name` to the MySQL server. If there is no match, authentication fails.

A user name match takes preference over a group name match. Suppose that the Windows user named `win_user` is a member of `win_group` and the authentication string looks like this:

```
'win_group = sql_user1, win_user = sql_user2'
```

When `win_user` connects to the MySQL server, there is a match both to `win_group` and to `win_user`. The plugin authenticates the user as `sql_user2` because the more-specific user match takes precedence over the group match, even though the group is listed first in the authentication string.

Windows authentication always works for connections from the same computer on which the server is running. For cross-computer connections, both computers must be registered with Microsoft Active Directory. If they are in the same Windows domain, it is unnecessary to specify a domain name. It is also possible to permit connections from a different domain, as in this example:

```
CREATE USER sql_accounting
 IDENTIFIED WITH authentication_windows
 AS 'SomeDomain\\Accounting';
```

Here `SomeDomain` is the name of the other domain. The backslash character is doubled because it is the MySQL escape character within strings.

MySQL supports the concept of proxy users whereby a client can connect and authenticate to the MySQL server using one account but while connected has the privileges of another account (see [Section 8.2.19, “Proxy Users”](#)). Suppose that you want Windows users to connect using a single user name but be mapped based on their Windows user and group names onto specific MySQL accounts as follows:

- The `local_user` and `MyDomain\domain_user` local and domain Windows users should map to the `local_wlad` MySQL account.
- Users in the `MyDomain\Developers` domain group should map to the `local_dev` MySQL account.
- Local machine administrators should map to the `local_admin` MySQL account.

To set this up, create a proxy account for Windows users to connect to, and configure this account so that users and groups map to the appropriate MySQL accounts (`local_wlad`, `local_dev`, `local_admin`). In addition, grant the MySQL accounts the privileges appropriate to the operations they need to perform. The following instructions use `win_proxy` as the proxy account, and `local_wlad`, `local_dev`, and `local_admin` as the proxied accounts.

1. Create the proxy MySQL account:

```
CREATE USER win_proxy
 IDENTIFIED WITH authentication_windows
 AS 'local_user = local_wlad,
 MyDomain\\domain_user = local_wlad,
 MyDomain\\Developers = local_dev,
 BUILTIN\\Administrators = local_admin';
```

2. For proxying to work, the proxied accounts must exist, so create them:

```
CREATE USER local_wlad
 IDENTIFIED WITH mysql_no_login;
CREATE USER local_dev
 IDENTIFIED WITH mysql_no_login;
CREATE USER local_admin
 IDENTIFIED WITH mysql_no_login;
```

The proxied accounts use the `mysql_no_login` authentication plugin to prevent clients from using the accounts to log in directly to the MySQL server. Instead, users who authenticate using Windows are expected to use the `win_proxy` proxy account. (This assumes that the plugin is installed. For

instructions, see [Section 8.4.1.8, “No-Login Pluggable Authentication”](#).) For alternative methods of protecting proxied accounts against direct use, see [Preventing Direct Login to Proxied Accounts](#).

You should also execute `GRANT` statements (not shown) that grant each proxied account the privileges required for MySQL access.

3. Grant to the proxy account the `PROXY` privilege for each proxied account:

```
GRANT PROXY ON local_wlad TO win_proxy;
GRANT PROXY ON local_dev TO win_proxy;
GRANT PROXY ON local_admin TO win_proxy;
```

Now the Windows users `local_user` and `MyDomain\domain_user` can connect to the MySQL server as `win_proxy` and when authenticated have the privileges of the account given in the authentication string (in this case, `local_wlad`). A user in the `MyDomain\Developers` group who connects as `win_proxy` has the privileges of the `local_dev` account. A user in the `BUILTIN\Administrators` group has the privileges of the `local_admin` account.

To configure authentication so that all Windows users who do not have their own MySQL account go through a proxy account, substitute the default proxy account (`'@'`) for `win_proxy` in the preceding instructions. For information about default proxy accounts, see [Section 8.2.19, “Proxy Users”](#).

**Note**

If your MySQL installation has anonymous users, they might conflict with the default proxy user. For more information about this issue, and ways of dealing with it, see [Default Proxy User and Anonymous User Conflicts](#).

To use the Windows authentication plugin with Connector/NET connection strings in Connector/NET 9.1 and higher, see [Connector/NET Authentication](#).

### 8.4.1.6 LDAP Pluggable Authentication

**Note**

LDAP pluggable authentication is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see <https://www.mysql.com/products/>.

MySQL Enterprise Edition supports an authentication method that enables MySQL Server to use LDAP (Lightweight Directory Access Protocol) to authenticate MySQL users by accessing directory services such as X.500. MySQL uses LDAP to fetch user, credential, and group information.

LDAP pluggable authentication provides these capabilities:

- External authentication: LDAP authentication enables MySQL Server to accept connections from users defined outside the MySQL grant tables in LDAP directories.
- Proxy user support: LDAP authentication can return to MySQL a user name different from the external user name passed by the client program, based on the LDAP groups the external user is a member of. This means that an LDAP plugin can return the MySQL user that defines the privileges the external LDAP-authenticated user should have. For example, an LDAP user named `joe` can connect and have the privileges of a MySQL user named `developer`, if the LDAP group for `joe` is `developer`.
- Security: Using TLS, connections to the LDAP server can be secure.

Server and client plugins are available for simple and SASL-based LDAP authentication. On Microsoft Windows, the server plugin for SASL-based LDAP authentication is not supported, but the client plugin is.

The following tables show the plugin and library file names for simple and SASL-based LDAP authentication. The file name suffix might differ on your system. The files must be located in the directory named by the `plugin_dir` system variable.

**Table 8.19 Plugin and Library Names for Simple LDAP Authentication**

Plugin or File	Plugin or File Name
Server-side plugin name	<code>authentication_ldap_simple</code>
Client-side plugin name	<code>mysql_clear_password</code>
Library file name	<code>authentication_ldap_simple.so</code>

**Table 8.20 Plugin and Library Names for SASL-Based LDAP Authentication**

Plugin or File	Plugin or File Name
Server-side plugin name	<code>authentication_ldap_sasl</code>
Client-side plugin name	<code>authentication_ldap_sasl_client</code>
Library file names	<code>authentication_ldap_sasl.so</code> , <code>authentication_ldap_sasl_client.so</code>

The library files include only the `authentication_ldap_XXX` authentication plugins. The client-side `mysql_clear_password` plugin is built into the `libmysqlclient` client library.

Each server-side LDAP plugin works with a specific client-side plugin:

- The server-side `authentication_ldap_simple` plugin performs simple LDAP authentication. For connections by accounts that use this plugin, client programs use the client-side `mysql_clear_password` plugin, which sends the password to the server as cleartext. No password hashing or encryption is used, so a secure connection between the MySQL client and server is recommended to prevent password exposure.
- The server-side `authentication_ldap_sasl` plugin performs SASL-based LDAP authentication. For connections by accounts that use this plugin, client programs use the client-side `authentication_ldap_sasl_client` plugin. The client-side and server-side SASL LDAP plugins use SASL messages for secure transmission of credentials within the LDAP protocol, to avoid sending the cleartext password between the MySQL client and server.

On Microsoft Windows platforms, both the server plugin and the client plugin are supported for SASL-based LDAP authentication.

The server-side LDAP authentication plugins are included only in MySQL Enterprise Edition. They are not included in MySQL community distributions. The client-side SASL LDAP plugin is included in all distributions, including community distributions, and, as mentioned previously, the client-side `mysql_clear_password` plugin is built into the `libmysqlclient` client library, which also is included in all distributions. This enables clients from any distribution to connect to a server that has the appropriate server-side plugin loaded.

The following sections provide installation and usage information specific to LDAP pluggable authentication:

- [Prerequisites for LDAP Pluggable Authentication](#)
- [How LDAP Authentication of MySQL Users Works](#)

- [Uninstalling LDAP Pluggable Authentication](#)
- [LDAP Pluggable Authentication and ldap.conf](#)
- [Setting Timeouts for LDAP Pluggable Authentication](#)
- [Using LDAP Pluggable Authentication](#)
- [Simple LDAP Authentication \(Without Proxying\)](#)
- [SASL-Based LDAP Authentication \(Without Proxying\)](#)
- [LDAP Authentication with Proxying](#)
- [LDAP Authentication Group Preference and Mapping Specification](#)
- [LDAP Authentication User DN Suffixes](#)
- [LDAP Authentication Methods](#)
- [The GSSAPI/Kerberos Authentication Method](#)
- [LDAP Search Referral](#)

For general information about pluggable authentication in MySQL, see [Section 8.2.17, “Pluggable Authentication”](#). For information about the `mysql_clear_password` plugin, see [Section 8.4.1.3, “Client-Side Cleartext Pluggable Authentication”](#). For proxy user information, see [Section 8.2.19, “Proxy Users”](#).

**Note**

If your system supports PAM and permits LDAP as a PAM authentication method, another way to use LDAP for MySQL user authentication is to use the server-side `authentication_pam` plugin. See [Section 8.4.1.4, “PAM Pluggable Authentication”](#).

## Prerequisites for LDAP Pluggable Authentication

To use LDAP pluggable authentication for MySQL, these prerequisites must be satisfied:

- An LDAP server must be available for the LDAP authentication plugins to communicate with.
- LDAP users to be authenticated by MySQL must be present in the directory managed by the LDAP server.
- An LDAP client library must be available on systems where the server-side `authentication_ldap_sasl` or `authentication_ldap_simple` plugin is used. Currently, supported libraries are the Windows native LDAP library, or the OpenLDAP library on non-Windows systems.
- To use SASL-based LDAP authentication:
  - The LDAP server must be configured to communicate with a SASL server.
  - A SASL client library must be available on systems where the client-side `authentication_ldap_sasl_client` plugin is used. Currently, the only supported library is the Cyrus SASL library.

- To use a particular SASL authentication method, any other services required by that method must be available. For example, to use GSSAPI/Kerberos, a GSSAPI library and Kerberos services must be available.

## How LDAP Authentication of MySQL Users Works

This section provides an overview of how MySQL and LDAP work together to authenticate MySQL users. For examples showing how to set up MySQL accounts to use specific LDAP authentication plugins, see [Using LDAP Pluggable Authentication](#). For information about authentication methods available to the LDAP plugins, see [LDAP Authentication Methods](#).

The client connects to the MySQL server, providing the MySQL client user name and a password:

- For simple LDAP authentication, the client-side and server-side plugins communicate the password as cleartext. A secure connection between the MySQL client and server is recommended to prevent password exposure.
- For SASL-based LDAP authentication, the client-side and server-side plugins avoid sending the cleartext password between the MySQL client and server. For example, the plugins might use SASL messages for secure transmission of credentials within the LDAP protocol. For the GSSAPI authentication method, the client-side and server-side plugins communicate securely using Kerberos without using LDAP messages directly.

If the client user name and host name match no MySQL account, the connection is rejected.

If there is a matching MySQL account, authentication against LDAP occurs. The LDAP server looks for an entry matching the user and authenticates the entry against the LDAP password:

- If the MySQL account names an LDAP user distinguished name (DN), LDAP authentication uses that value and the LDAP password provided by the client. (To associate an LDAP user DN with a MySQL account, include a `BY` clause that specifies an authentication string in the `CREATE USER` statement that creates the account.)
- If the MySQL account names no LDAP user DN, LDAP authentication uses the user name and LDAP password provided by the client. In this case, the authentication plugin first binds to the LDAP server using the root DN and password as credentials to find the user DN based on the client user name, then authenticates that user DN against the LDAP password. This bind using the root credentials fails if the root DN and password are set to incorrect values, or are empty (not set) and the LDAP server does not permit anonymous connections.

If the LDAP server finds no match or multiple matches, authentication fails and the client connection is rejected.

If the LDAP server finds a single match, LDAP authentication succeeds (assuming that the password is correct), the LDAP server returns the LDAP entry, and the authentication plugin determines the name of the authenticated user based on that entry:

- If the LDAP entry has a group attribute (by default, the `cn` attribute), the plugin returns its value as the authenticated user name.
- If the LDAP entry has no group attribute, the authentication plugin returns the client user name as the authenticated user name.

The MySQL server compares the client user name with the authenticated user name to determine whether proxying occurs for the client session:

- If the names are the same, no proxying occurs: The MySQL account matching the client user name is used for privilege checking.
- If the names differ, proxying occurs: MySQL looks for an account matching the authenticated user name. That account becomes the proxied user, which is used for privilege checking. The MySQL account that matched the client user name is treated as the external proxy user.

## Installing LDAP Pluggable Authentication

This section describes how to install the server-side LDAP authentication plugins. For general information about installing plugins, see [Section 7.6.1, “Installing and Uninstalling Plugins”](#).

To be usable by the server, the plugin library files must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

The server-side plugin library file base names are `authentication_ldap_simple` and `authentication_ldap_sasl`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

### Note

On Microsoft Windows, the server plugin for SASL-based LDAP authentication is not supported, but the client plugin is supported. On other platforms, both the server and client plugins are supported.

To load the plugins at server startup, use `--plugin-load-add` options to name the library files that contain them. With this plugin-loading method, the options must be given each time the server starts. Also, specify values for any plugin-provided system variables you wish to configure.

Each server-side LDAP plugin exposes a set of system variables that enable its operation to be configured. Setting most of these is optional, but you must set the variables that specify the LDAP server host (so the plugin knows where to connect) and base distinguished name for LDAP bind operations (to limit the scope of searches and obtain faster searches). For details about all LDAP system variables, see [Section 8.4.1.13, “Pluggable Authentication System Variables”](#).

To load the plugins and set the LDAP server host and base distinguished name for LDAP bind operations, put lines such as these in your `my.cnf` file, adjusting the `.so` suffix for your platform as necessary:

```
[mysqld]
plugin-load-add=authentication_ldap_simple.so
authentication_ldap_simple_server_host=127.0.0.1
authentication_ldap_simple_bind_base_dn="dc=example,dc=com"
plugin-load-add=authentication_ldap_sasl.so
authentication_ldap_sasl_server_host=127.0.0.1
authentication_ldap_sasl_bind_base_dn="dc=example,dc=com"
```

After modifying `my.cnf`, restart the server to cause the new settings to take effect.

Alternatively, to load the plugins at runtime, use these statements, adjusting the `.so` suffix for your platform as necessary:

```
INSTALL PLUGIN authentication_ldap_simple
 SONAME 'authentication_ldap_simple.so';
INSTALL PLUGIN authentication_ldap_sasl
 SONAME 'authentication_ldap_sasl.so';
```

`INSTALL PLUGIN` loads the plugin immediately, and also registers it in the `mysql.plugins` system table to cause the server to load it for each subsequent normal startup without the need for `--plugin-load-add`.

After installing the plugins at runtime, the system variables that they expose become available and you can add settings for them to your `my.cnf` file to configure the plugins for subsequent restarts. For example:

```
[mysqld]
authentication_ldap_simple_server_host=127.0.0.1
authentication_ldap_simple_bind_base_dn="dc=example,dc=com"
authentication_ldap_sasl_server_host=127.0.0.1
authentication_ldap_sasl_bind_base_dn="dc=example,dc=com"
```

After modifying `my.cnf`, restart the server to cause the new settings to take effect.

To set and persist each value at runtime rather than at startup, use these statements:

```
SET PERSIST authentication_ldap_simple_server_host='127.0.0.1';
SET PERSIST authentication_ldap_simple_bind_base_dn='dc=example,dc=com';
SET PERSIST authentication_ldap_sasl_server_host='127.0.0.1';
SET PERSIST authentication_ldap_sasl_bind_base_dn='dc=example,dc=com';
```

`SET PERSIST` sets a value for the running MySQL instance. It also saves the value, causing it to carry over to subsequent server restarts. To change a value for the running MySQL instance without having it carry over to subsequent restarts, use the `GLOBAL` keyword rather than `PERSIST`. See [Section 15.7.6.1, “SET Syntax for Variable Assignment”](#).

To verify plugin installation, examine the Information Schema `PLUGINS` table or use the `SHOW PLUGINS` statement (see [Section 7.6.2, “Obtaining Server Plugin Information”](#)). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
 FROM INFORMATION_SCHEMA.PLUGINS
 WHERE PLUGIN_NAME LIKE '%ldap%';
```

PLUGIN_NAME	PLUGIN_STATUS
authentication_ldap_sasl	ACTIVE
authentication_ldap_simple	ACTIVE

If a plugin fails to initialize, check the server error log for diagnostic messages.

To associate MySQL accounts with an LDAP plugin, see [Using LDAP Pluggable Authentication](#).

### Additional Notes for SELinux

On systems running EL6 or EL that have SELinux enabled, changes to the SELinux policy are required to enable the MySQL LDAP plugins to communicate with the LDAP service:

1. Create a file `mysqlldap.te` with these contents:

```
module mysqlldap 1.0;

require {
 type ldap_port_t;
 type mysqld_t;
 class tcp_socket name_connect;
}

#===== mysqld_t =====

allow mysqld_t ldap_port_t:tcp_socket name_connect;
```

2. Compile the security policy module into a binary representation:

```
checkmodule -M -m mysqlldap.te -o mysqlldap.mod
```

3. Create an SELinux policy module package:

```
semodule_package -m mysqlldap.mod -o mysqlldap.pp
```

4. Install the module package:

```
semodule -i mysqlldap.pp
```

5. When the SELinux policy changes have been made, restart the MySQL server:

```
service mysqld restart
```

## Uninstalling LDAP Pluggable Authentication

The method used to uninstall the LDAP authentication plugins depends on how you installed them:

- If you installed the plugins at server startup using `--plugin-load-add` options, restart the server without those options.
- If you installed the plugins at runtime using `INSTALL PLUGIN`, they remain installed across server restarts. To uninstall them, use `UNINSTALL PLUGIN`:

```
UNINSTALL PLUGIN authentication_ldap_simple;
UNINSTALL PLUGIN authentication_ldap_sasl;
```

In addition, remove from your `my.cnf` file any startup options that set LDAP plugin-related system variables. If you used `SET PERSIST` to persist LDAP system variables, use `RESET PERSIST` to remove the settings.

## LDAP Pluggable Authentication and `ldap.conf`

For installations that use OpenLDAP, the `ldap.conf` file provides global defaults for LDAP clients. Options can be set in this file to affect LDAP clients, including the LDAP authentication plugins. OpenLDAP uses configuration options in this order of precedence:

- Configuration specified by the LDAP client.
- Configuration specified in the `ldap.conf` file. To disable use of this file, set the `LDAPNOINIT` environment variable.
- OpenLDAP library built-in defaults.

If the library defaults or `ldap.conf` values do not yield appropriate option values, an LDAP authentication plugin may be able to set related variables to affect the LDAP configuration directly. For example, LDAP plugins can override `ldap.conf` for parameters such as these:

- TLS configuration: System variables are available to enable TLS and control CA configuration, such as `authentication_ldap_simple_tls` and `authentication_ldap_simple_ca_path` for simple LDAP authentication, and `authentication_ldap_sasl_tls` and `authentication_ldap_sasl_ca_path` for SASL LDAP authentication.
- LDAP referral. See [LDAP Search Referral](#).

For more information about `ldap.conf` consult the `ldap.conf(5)` man page.

## Setting Timeouts for LDAP Pluggable Authentication

For MySQL accounts to connect to a MySQL server using LDAP pluggable authentication, the LDAP server must be available and operational. The interaction between the MySQL and LDAP servers involves

two steps. First, the MySQL server establishes a connection to the LDAP server over TCP. Second, the MySQL server sends an LDAP binding request over the connection to the LDAP server and waits for a reply before authenticating the account. If either step fails, the MySQL account cannot connect to the MySQL server.

Short-duration timeouts that supersede a host system's timeout values are applied to both the connection and response steps by default. In all cases, the account user receives notification that their attempt to connect to MySQL is denied if the timeout expires. Client-side and server-side logging can provide additional information. On the client side, set the following environmental variable to elevate the detail level and then restart MySQL client:

```
AUTHENTICATION_LDAP_CLIENT_LOG=5
export AUTHENTICATION_LDAP_CLIENT_LOG
```

The following system variables support default timeouts for SASL-based and simple LDAP authentication on Linux platforms only.

**Table 8.21 System variables for SASL-based and simple LDAP Authentication**

System Variable Name	Default Timeout Value
<code>authentication_ldap_sasl_connect_timeout</code>	30 seconds
<code>authentication_ldap_sasl_response_timeout</code>	30 seconds
<code>authentication_ldap_simple_connect_timeout</code>	30 seconds
<code>authentication_ldap_simple_response_timeout</code>	30 seconds

Timeout values for LDAP authentication are adjustable at server startup and at runtime. If you set a timeout to zero using one of these variables, you effectively disengage it and MySQL server reverts to using the host system's default timeout.

#### Note

Under the following combination of conditions, the actual wait time of the `authentication_ldap_sasl_connect_timeout` setting doubles because (internally) the server must invoke the TCP connection twice:

- The LDAP server is offline.
- `authentication_ldap_sasl_connect_timeout` has a value greater than zero.
- Connection pooling is in use (specifically, the `authentication_ldap_sasl_max_pool_size` system variable has a value greater than zero, which enables pooling).

## Using LDAP Pluggable Authentication

This section describes how to enable MySQL accounts to connect to the MySQL server using LDAP pluggable authentication. It is assumed that the server is running with the appropriate server-side plugins enabled, as described in [Installing LDAP Pluggable Authentication](#), and that the appropriate client-side plugins are available on the client host.

This section does not describe LDAP configuration or administration. You are assumed to be familiar with those topics.

The two server-side LDAP plugins each work with a specific client-side plugin:

- The server-side `authentication_ldap_simple` plugin performs simple LDAP authentication. For connections by accounts that use this plugin, client programs use the client-side `mysql_clear_password` plugin, which sends the password to the server as cleartext. No password hashing or encryption is used, so a secure connection between the MySQL client and server is recommended to prevent password exposure.
- The server-side `authentication_ldap_sasl` plugin performs SASL-based LDAP authentication. For connections by accounts that use this plugin, client programs use the client-side `authentication_ldap_sasl_client` plugin. The client-side and server-side SASL LDAP plugins use SASL messages for secure transmission of credentials within the LDAP protocol, to avoid sending the cleartext password between the MySQL client and server.

Overall requirements for LDAP authentication of MySQL users:

- There must be an LDAP directory entry for each user to be authenticated.
- There must be a MySQL user account that specifies a server-side LDAP authentication plugin and optionally names the associated LDAP user distinguished name (DN). (To associate an LDAP user DN with a MySQL account, include a `BY` clause in the `CREATE USER` statement that creates the account.) If an account names no LDAP string, LDAP authentication uses the user name specified by the client to find the LDAP entry.
- Client programs connect using the connection method appropriate for the server-side authentication plugin the MySQL account uses. For LDAP authentication, connections require the MySQL user name and LDAP password. In addition, for accounts that use the server-side `authentication_ldap_simple` plugin, invoke client programs with the `--enable-cleartext-plugin` option to enable the client-side `mysql_clear_password` plugin.

The instructions here assume the following scenario:

- MySQL users `betsy` and `boris` authenticate to the LDAP entries for `betsy_ldap` and `boris_ldap`, respectively. (It is not necessary that the MySQL and LDAP user names differ. The use of different names in this discussion helps clarify whether an operation context is MySQL or LDAP.)
- LDAP entries use the `uid` attribute to specify user names. This may vary depending on LDAP server. Some LDAP servers use the `cn` attribute for user names rather than `uid`. To change the attribute, modify the `authentication_ldap_simple_user_search_attr` or `authentication_ldap_sasl_user_search_attr` system variable appropriately.
- These LDAP entries are available in the directory managed by the LDAP server, to provide distinguished name values that uniquely identify each user:

```
uid=betsy_ldap,ou=People,dc=example,dc=com
uid=boris_ldap,ou=People,dc=example,dc=com
```

- `CREATE USER` statements that create MySQL accounts name an LDAP user in the `BY` clause, to indicate which LDAP entry the MySQL account authenticates against.

The instructions for setting up an account that uses LDAP authentication depend on which server-side LDAP plugin is used. The following sections describe several usage scenarios.

## Simple LDAP Authentication (Without Proxying)

The procedure outlined in this section requires that `authentication_ldap_simple_group_search_attr` be set to an empty string, like this:

```
SET GLOBAL.authentication_ldap_simple_group_search_attr='';
```

Otherwise, proxying is used by default.

To set up a MySQL account for simple LDAP authentication, use a `CREATE USER` statement to specify the `authentication_ldap_simple` plugin, optionally including the LDAP user distinguished name (DN), as shown here:

```
CREATE USER user
 IDENTIFIED WITH authentication_ldap_simple
 [BY 'LDAP user DN'];
```

Suppose that MySQL user `betsy` has this entry in the LDAP directory:

```
uid=betsy_ldap,ou=People,dc=example,dc=com
```

Then the statement to create the MySQL account for `betsy` looks like this:

```
CREATE USER 'betsy'@'localhost'
 IDENTIFIED WITH authentication_ldap_simple
 AS 'uid=betsy_ldap,ou=People,dc=example,dc=com';
```

The authentication string specified in the `BY` clause does not include the LDAP password. That must be provided by the client user at connect time.

Clients connect to the MySQL server by providing the MySQL user name and LDAP password, and by enabling the client-side `mysql_clear_password` plugin:

```
$> mysql --user=betsy --password --enable-cleartext-plugin
Enter password: betsy_ldap_password
```

#### Note

The client-side `mysql_clear_password` authentication plugin leaves the password untouched, so client programs send it to the MySQL server as cleartext. This enables the password to be passed as is to the LDAP server. A cleartext password is necessary to use the server-side LDAP library without SASL, but may be a security problem in some configurations. These measures minimize the risk:

- To make inadvertent use of the `mysql_clear_password` plugin less likely, MySQL clients must explicitly enable it (for example, with the `--enable-cleartext-plugin` option). See [Section 8.4.1.3, “Client-Side Cleartext Pluggable Authentication”](#).
- To avoid password exposure with the `mysql_clear_password` plugin enabled, MySQL clients should connect to the MySQL server using an encrypted connection. See [Section 8.3.1, “Configuring MySQL to Use Encrypted Connections”](#).

The authentication process occurs as follows:

1. The client-side plugin sends `betsy` and `betsy_password` as the client user name and LDAP password to the MySQL server.
2. The connection attempt matches the `'betsy'@'localhost'` account. The server-side LDAP plugin finds that this account has an authentication string of `'uid=betsy_ldap,ou=People,dc=example,dc=com'` to name the LDAP user DN. The plugin sends this string and the LDAP password to the LDAP server.
3. The LDAP server finds the LDAP entry for `betsy_ldap` and the password matches, so LDAP authentication succeeds.

4. The LDAP entry has no group attribute, so the server-side plugin returns the client user name (`betsy`) as the authenticated user. This is the same user name supplied by the client, so no proxying occurs and the client session uses the '`betsy`'@'`localhost`' account for privilege checking.

Had the `CREATE USER` statement contained no `BY` clause to specify the `betsy_ldap` LDAP distinguished name, authentication attempts would use the user name provided by the client (in this case, `betsy`). In the absence of an LDAP entry for `betsy`, authentication would fail.

## SASL-Based LDAP Authentication (Without Proxying)

The procedure outlined in this section requires that `authentication_ldap_sasl_group_search_attr` be set to an empty string, like this:

```
SET GLOBAL.authentication_ldap_sasl_group_search_attr='';
```

Otherwise, proxying is used by default.

To set up a MySQL account for SASL LDAP authentication, use a `CREATE USER` statement to specify the `authentication_ldap_sasl` plugin, optionally including the LDAP user distinguished name (DN), as shown here:

```
CREATE USER user
 IDENTIFIED WITH authentication_ldap_sasl
 [BY 'LDAP user DN'];
```

Suppose that MySQL user `boris` has this entry in the LDAP directory:

```
uid=boris_ldap,ou=People,dc=example,dc=com
```

Then the statement to create the MySQL account for `boris` looks like this:

```
CREATE USER 'boris'@'localhost'
 IDENTIFIED WITH authentication_ldap_sasl
 AS 'uid=boris_ldap,ou=People,dc=example,dc=com';
```

The authentication string specified in the `BY` clause does not include the LDAP password. That must be provided by the client user at connect time.

Clients connect to the MySQL server by providing the MySQL user name and LDAP password:

```
$> mysql --user=boris --password
Enter password: boris_ldap_password
```

For the server-side `authentication_ldap_sasl` plugin, clients use the client-side `authentication_ldap_sasl_client` plugin. If a client program does not find the client-side plugin, specify a `--plugin-dir` option that names the directory where the plugin library file is installed.

The authentication process for `boris` is similar to that previously described for `betsy` with simple LDAP authentication, except that the client-side and server-side SASL LDAP plugins use SASL messages for secure transmission of credentials within the LDAP protocol, to avoid sending the cleartext password between the MySQL client and server.

## LDAP Authentication with Proxying

LDAP authentication plugins support proxying, enabling a user to connect to the MySQL server as one user but assume the privileges of a different user. This section describes basic LDAP plugin proxy support. The LDAP plugins also support specification of group preference and proxy user mapping; see [LDAP Authentication Group Preference and Mapping Specification](#).

The proxying implementation described here is based on use of LDAP group attribute values to map connecting MySQL users who authenticate using LDAP onto other MySQL accounts that define different sets of privileges. Users do not connect directly through the accounts that define the privileges. Instead, they connect through a default proxy account authenticated with LDAP, such that all external logins are mapped to the proxied MySQL accounts that hold the privileges. Any user who connects using the proxy account is mapped to one of those proxied MySQL accounts, the privileges for which determine the database operations permitted to the external user.

The instructions here assume the following scenario:

- LDAP entries use the `uid` and `cn` attributes to specify user name and group values, respectively. To use different user and group attribute names, set the appropriate plugin-specific system variables:
  - For the `authentication_ldap_simple` plugin: Set `authentication_ldap_simple_user_search_attr` and `authentication_ldap_simple_group_search_attr`.
  - For the `authentication_ldap_sasl` plugin: Set `authentication_ldap_sasl_user_search_attr` and `authentication_ldap_sasl_group_search_attr`.
- These LDAP entries are available in the directory managed by the LDAP server, to provide distinguished name values that uniquely identify each user:

```
uid=basha,ou=People,dc=example,dc=com,cn=accounting
uid=basil,ou=People,dc=example,dc=com,cn=front_office
```

At connect time, the group attribute values become the authenticated user names, so they name the `accounting` and `front_office` proxied accounts.

- The examples assume use of SASL LDAP authentication. Make the appropriate adjustments for simple LDAP authentication.

Create the default proxy MySQL account:

```
CREATE USER ''@'%'
 IDENTIFIED WITH authentication_ldap_sasl;
```

The proxy account definition has no `AS 'auth_string'` clause to name an LDAP user DN. Thus:

- When a client connects, the client user name becomes the LDAP user name to search for.
- The matching LDAP entry is expected to include a group attribute naming the proxied MySQL account that defines the privileges the client should have.

#### Note

If your MySQL installation has anonymous users, they might conflict with the default proxy user. For more information about this issue, and ways of dealing with it, see [Default Proxy User and Anonymous User Conflicts](#).

Create the proxied accounts and grant to each one the privileges it should have:

```
CREATE USER 'accounting'@'localhost'
 IDENTIFIED WITH mysql_no_login;
CREATE USER 'front_office'@'localhost'
 IDENTIFIED WITH mysql_no_login;

GRANT ALL PRIVILEGES
```

```
ON accountingdb.*
TO 'accounting'@'localhost';
GRANT ALL PRIVILEGES
ON frontdb.*
TO 'front_office'@'localhost';
```

The proxied accounts use the `mysql_no_login` authentication plugin to prevent clients from using the accounts to log in directly to the MySQL server. Instead, users who authenticate using LDAP are expected to use the default `' '@' % '` proxy account. (This assumes that the `mysql_no_login` plugin is installed. For instructions, see [Section 8.4.1.8, “No-Login Pluggable Authentication”](#).) For alternative methods of protecting proxied accounts against direct use, see [Preventing Direct Login to Proxied Accounts](#).

Grant to the proxy account the `PROXY` privilege for each proxied account:

```
GRANT PROXY
ON 'accounting'@'localhost'
TO ' '@' % ';
GRANT PROXY
ON 'front_office'@'localhost'
TO ' '@' % ';
```

Use the `mysql` command-line client to connect to the MySQL server as `basha`.

```
$> mysql --user=basha --password
Enter password: basha_password (basha LDAP password)
```

Authentication occurs as follows:

1. The server authenticates the connection using the default `' '@' % '` proxy account, for client user `basha`.
2. The matching LDAP entry is:

```
uid=basha,ou=People,dc=example,dc=com,cn=accounting
```

3. The matching LDAP entry has group attribute `cn=accounting`, so `accounting` becomes the authenticated proxied user.
4. The authenticated user differs from the client user name `basha`, with the result that `basha` is treated as a proxy for `accounting`, and `basha` assumes the privileges of the proxied `accounting` account. The following query returns output as shown:

```
mysql> SELECT USER(), CURRENT_USER(), @@proxy_user;
+-----+-----+-----+
| USER() | CURRENT_USER() | @@proxy_user |
+-----+-----+-----+
| basha@localhost | accounting@localhost | ' '@' % ' |
+-----+-----+-----+
```

This demonstrates that `basha` uses the privileges granted to the proxied `accounting` MySQL account, and that proxying occurs through the default proxy user account.

Now connect as `basil` instead:

```
$> mysql --user=basil --password
Enter password: basil_password (basil LDAP password)
```

The authentication process for `basil` is similar to that previously described for `basha`:

1. The server authenticates the connection using the default `' '@' % '` proxy account, for client user `basil`.

- The matching LDAP entry is:

```
uid=basil,ou=People,dc=example,dc=com,cn=front_office
```

- The matching LDAP entry has group attribute `cn=front_office`, so `front_office` becomes the authenticated proxied user.
- The authenticated user differs from the client user name `basil`, with the result that `basil` is treated as a proxy for `front_office`, and `basil` assumes the privileges of the proxied `front_office` account. The following query returns output as shown:

```
mysql> SELECT USER(), CURRENT_USER(), @@proxy_user;
+-----+-----+-----+
| USER() | CURRENT_USER() | @@proxy_user |
+-----+-----+-----+
| basil@localhost | front_office@localhost | '@'%' |
+-----+-----+-----+
```

This demonstrates that `basil` uses the privileges granted to the proxied `front_office` MySQL account, and that proxying occurs through the default proxy user account.

## LDAP Authentication Group Preference and Mapping Specification

As described in [LDAP Authentication with Proxying](#), basic LDAP authentication proxying works by the principle that the plugin uses the first group name returned by the LDAP server as the MySQL proxied user account name. This simple capability does not enable specifying any preference about which group name to use if the LDAP server returns multiple group names, or specifying any name other than the group name as the proxied user name.

For MySQL accounts that use LDAP authentication, the authentication string can specify the following information to enable greater proxying flexibility:

- A list of groups in preference order, such that the plugin uses the first group name in the list that matches a group returned by the LDAP server.
- A mapping from group names to proxied user names, such that a group name when matched can provide a specified name to use as the proxied user. This provides an alternative to using the group name as the proxied user.

Consider the following MySQL proxy account definition:

```
CREATE USER '@'%'
 IDENTIFIED WITH authentication_ldap_sasl
 AS '+ou=People,dc=example,dc=com#grp1=usera,grp2,grp3=userc';
```

The authentication string has a user DN suffix `ou=People,dc=example,dc=com` prefixed by the `+` character. Thus, as described in [LDAP Authentication User DN Suffixes](#), the full user DN is constructed from the user DN suffix as specified, plus the client user name as the `uid` attribute.

The remaining part of the authentication string begins with `#`, which signifies the beginning of group preference and mapping information. This part of the authentication string lists group names in the order `grp1`, `grp2`, `grp3`. The LDAP plugin compares that list with the set of group names returned by the LDAP server, looking in list order for a match against the returned names. The plugin uses the first match, or if there is no match, authentication fails.

Suppose that the LDAP server returns groups `grp3`, `grp2`, and `grp7`. The LDAP plugin uses `grp2` because it is the first group in the authentication string that matches, even though it is not the first group returned by the LDAP server. If the LDAP server returns `grp4`, `grp2`, and `grp1`, the plugin uses `grp1`

even though `grp2` also matches. `grp1` has a precedence higher than `grp2` because it is listed earlier in the authentication string.

Assuming that the plugin finds a group name match, it performs mapping from that group name to the MySQL proxied user name, if there is one. For the example proxy account, mapping occurs as follows:

- If the matching group name is `grp1` or `grp3`, those are associated in the authentication string with user names `usera` and `userc`, respectively. The plugin uses the corresponding associated user name as the proxied user name.
- If the matching group name is `grp2`, there is no associated user name in the authentication string. The plugin uses `grp2` as the proxied user name.

If the LDAP server returns a group in DN format, the LDAP plugin parses the group DN to extract the group name from it.

To specify LDAP group preference and mapping information, these principles apply:

- Begin the group preference and mapping part of the authentication string with a `#` prefix character.
- The group preference and mapping specification is a list of one or more items, separated by commas. Each item has the form `group_name=user_name` or `group_name`. Items should be listed in group name preference order. For a group name selected by the plugin as a match from set of group names returned by the LDAP server, the two syntaxes differ in effect as follows:
  - For an item specified as `group_name=user_name` (with a user name), the group name maps to the user name, which is used as the MySQL proxied user name.
  - For an item specified as `group_name` (with no user name), the group name is used as the MySQL proxied user name.
- To quote a group or user name that contains special characters such as space, surround it by double quote (") characters. For example, if an item has group and user names of `my group name` and `my user name`, it must be written in a group mapping using quotes:

```
"my group name"="my user name"
```

If an item has group and user names of `my_group_name` and `my_user_name` (which contain no special characters), it may but need not be written using quotes. Any of the following are valid:

```
my_group_name=my_user_name
my_group_name="my_user_name"
"my_group_name"=my_user_name
"my_group_name"="my_user_name"
```

- To escape a character, precede it by a backslash (`\`). This is useful particularly to include a literal double quote or backslash, which are otherwise not included literally.
- A user DN need not be present in the authentication string, but if present, it must precede the group preference and mapping part. A user DN can be given as a full user DN, or as a user DN suffix with a `+` prefix character. (See [LDAP Authentication User DN Suffixes](#).)

## LDAP Authentication User DN Suffixes

LDAP authentication plugins permit the authentication string that provides user DN information to begin with a `+` prefix character:

- In the absence of a `+` character, the authentication string value is treated as is without modification.

- If the authentication string begins with `+`, the plugin constructs the full user DN value from the user name sent by the client, together with the DN specified in the authentication string (with the `+` removed). In the constructed DN, the client user name becomes the value of the attribute that specifies LDAP user names. This is `uid` by default; to change the attribute, modify the appropriate system variable (`authentication_ldap_simple_user_search_attr` or `authentication_ldap_sasl_user_search_attr`). The authentication string is stored as given in the `mysql.user` system table, with the full user DN constructed on the fly before authentication.

This account authentication string does not have `+` at the beginning, so it is taken as the full user DN:

```
CREATE USER 'baldwin'
 IDENTIFIED WITH authentication_ldap_simple
 AS 'uid=admin,ou=People,dc=example,dc=com';
```

The client connects with the user name specified in the account (`baldwin`). In this case, that name is not used because the authentication string has no prefix and thus fully specifies the user DN.

This account authentication string does have `+` at the beginning, so it is taken as just part of the user DN:

```
CREATE USER 'accounting'
 IDENTIFIED WITH authentication_ldap_simple
 AS '+ou=People,dc=example,dc=com';
```

The client connects with the user name specified in the account (`accounting`), which in this case is used as the `uid` attribute together with the authentication string to construct the user DN:  
`uid=accounting,ou=People,dc=example,dc=com`

The accounts in the preceding examples have a nonempty user name, so the client always connects to the MySQL server using the same name as specified in the account definition. If an account has an empty user name, such as the default anonymous `'@'%'` proxy account described in [LDAP Authentication with Proxying](#), clients might connect to the MySQL server with varying user names. But the principle is the same: If the authentication string begins with `+`, the plugin uses the user name sent by the client together with the authentication string to construct the user DN.

## LDAP Authentication Methods

The LDAP authentication plugins use a configurable authentication method. The appropriate system variable and available method choices are plugin-specific:

- For the `authentication_ldap_simple` plugin: Set the `authentication_ldap_simple_auth_method_name` system variable to configure the method. The permitted choices are `SIMPLE` and `AD-FOREST`.
- For the `authentication_ldap_sasl` plugin: Set the `authentication_ldap_sasl_auth_method_name` system variable to configure the method. The permitted choices are `SCRAM-SHA-1`, `SCRAM-SHA-256`, and `GSSAPI`. (To determine which SASL LDAP methods are actually available on the host system, check the value of the `Authentication_ldap_sasl_supported_methods` status variable.)

See the system variable descriptions for information about each permitted method. Also, depending on the method, additional configuration may be needed, as described in the following sections.

## The GSSAPI/Kerberos Authentication Method

Generic Security Service Application Program Interface (GSSAPI) is a security abstraction interface. Kerberos is an instance of a specific security protocol that can be used through that abstract interface.

Using GSSAPI, applications authenticate to Kerberos to obtain service credentials, then use those credentials in turn to enable secure access to other services.

One such service is LDAP, which is used by the client-side and server-side SASL LDAP authentication plugins. When the `authentication_ldap_sasl_auth_method_name` system variable is set to `GSSAPI`, these plugins use the GSSAPI/Kerberos authentication method. In this case, the plugins communicate securely using Kerberos without using LDAP messages directly. The server-side plugin then communicates with the LDAP server to interpret LDAP authentication messages and retrieve LDAP groups.

GSSAPI/Kerberos is supported as an LDAP authentication method for MySQL servers and clients on Linux. It is useful in Linux environments where applications have access to LDAP through Microsoft Active Directory, which has Kerberos enabled by default.

The following discussion provides information about the configuration requirements for using the GSSAPI method. Familiarity is assumed with Kerberos concepts and operation. The following list briefly defines several common Kerberos terms. You may also find the Glossary section of [RFC 4120](#) helpful.

- **Principal**: A named entity, such as a user or server.
- **KDC**: The key distribution center, comprising the AS and TGS:
  - **AS**: The authentication server; provides the initial ticket-granting ticket needed to obtain additional tickets.
  - **TGS**: The ticket-granting server; provides additional tickets to Kerberos clients that possess a valid TGT.
- **TGT**: The ticket-granting ticket; presented to the TGS to obtain service tickets for service access.

LDAP authentication using Kerberos requires both a KDC server and an LDAP server. This requirement can be satisfied in different ways:

- Active Directory includes both servers, with Kerberos authentication enabled by default in the Active Directory LDAP server.
- OpenLDAP provides an LDAP server, but a separate KDC server may be needed, with additional Kerberos setup required.

Kerberos must also be available on the client host. A client contacts the AS using a password to obtain a TGT. The client then uses the TGT to obtain access from the TGS to other services, such as LDAP.

The following sections discuss the configuration steps to use GSSAPI/Kerberos for SASL LDAP authentication in MySQL:

- [Verify Kerberos and LDAP Availability](#)
- [Configure the Server-Side SASL LDAP Authentication Plugin for GSSAPI/Kerberos](#)
- [Create a MySQL Account That Uses GSSAPI/Kerberos for LDAP Authentication](#)
- [Use the MySQL Account to Connect to the MySQL Server](#)
- [Client Configuration Parameters for LDAP Authentication](#)

### Verify Kerberos and LDAP Availability

The following example shows how to test availability of Kerberos in Active Directory. The example makes these assumptions:

- Active Directory is running on the host named `ldap_auth.example.com` with IP address `198.51.100.10`.
- MySQL-related Kerberos authentication and LDAP lookups use the `MYSQL.LOCAL` domain.
- A principal named `bredon@MYSQL.LOCAL` is registered with the KDC. (In later discussion, this principal name is also associated with the MySQL account that authenticates to the MySQL server using GSSAPI/Kerberos.)

With those assumptions satisfied, follow this procedure:

1. Verify that the Kerberos library is installed and configured correctly in the operating system. For example, to configure a `MYSQL.LOCAL` domain for use during MySQL authentication, the `/etc/krb5.conf` Kerberos configuration file should contain something like this:

```
[realms]
 MYSQL.LOCAL = {
 kdc = ldap_auth.example.com
 admin_server = ldap_auth.example.com
 default_domain = MYSQL.LOCAL
 }
```

2. You may need to add an entry to `/etc/hosts` for the server host:

```
198.51.100.10 ldap_auth ldap_auth.example.com
```

3. Check whether Kerberos authentication works correctly:

- a. Use `kinit` to authenticate to Kerberos:

```
$> kinit bredon@MYSQL.LOCAL
Password for bredon@MYSQL.LOCAL: (enter password here)
```

The command authenticates for the Kerberos principal named `bredon@MYSQL.LOCAL`. Enter the principal's password when the command prompts for it. The KDC returns a TGT that is cached on the client side for use by other Kerberos-aware applications.

- b. Use `klist` to check whether the TGT was obtained correctly. The output should be similar to this:

```
$> klist
Ticket cache: FILE:/tmp/krb5cc_244306
Default principal: bredon@MYSQL.LOCAL

Valid starting Expires Service principal
03/23/2021 08:18:33 03/23/2021 18:18:33 krbtgt/MYSQL.LOCAL@MYSQL.LOCAL
```

4. Check whether `ldapsearch` works with the Kerberos TGT using this command, which searches for users in the `MYSQL.LOCAL` domain:

```
ldapsearch -h 198.51.100.10 -Y GSSAPI -b "dc=MYSQL,dc=LOCAL"
```

## Configure the Server-Side SASL LDAP Authentication Plugin for GSSAPI/Kerberos

Assuming that the LDAP server is accessible through Kerberos as just described, configure the server-side SASL LDAP authentication plugin to use the GSSAPI/Kerberos authentication method. (For general LDAP plugin installation information, see [Installing LDAP Pluggable Authentication](#).) Here is an example of plugin-related settings the server `my.cnf` file might contain:

```
[mysqld]
plugin-load-add=authentication_ldap_sasl.so
authentication_ldap_sasl_auth_method_name="GSSAPI"
authentication_ldap_sasl_server_host=198.51.100.10
```

```
authentication_ldap_sasl_server_port=389
authentication_ldap_sasl_bind_root_dn="cn=admin,cn=users,dc=MYSQL,dc=LOCAL"
authentication_ldap_sasl_bind_root_pwd="password"
authentication_ldap_sasl_bind_base_dn="cn=users,dc=MYSQL,dc=LOCAL"
authentication_ldap_sasl_user_search_attr="sAMAccountName"
```

Those option file settings configure the SASL LDAP plugin as follows:

- The `--plugin-load-add` option loads the plugin (adjust the `.so` suffix for your platform as necessary). If you loaded the plugin previously using an `INSTALL PLUGIN` statement, this option is unnecessary.
- `authentication_ldap_sasl_auth_method_name` must be set to `GSSAPI` to use GSSAPI/Kerberos as the SASL LDAP authentication method.
- `authentication_ldap_sasl_server_host` and `authentication_ldap_sasl_server_port` indicate the IP address and port number of the Active Directory server host for authentication.
- `authentication_ldap_sasl_bind_root_dn` and `authentication_ldap_sasl_bind_root_pwd` configure the root DN and password for group search capability. This capability is required, but users may not have privileges to search. In such cases, it is necessary to provide root DN information:
  - In the DN option value, `admin` should be the name of an administrative LDAP account that has privileges to perform user searches.
  - In the password option value, `password` should be the `admin` account password.
- `authentication_ldap_sasl_bind_base_dn` indicates the user DN base path, so that searches look for users in the `MYSQL.LOCAL` domain.
- `authentication_ldap_sasl_user_search_attr` specifies a standard Active Directory search attribute, `sAMAccountName`. This attribute is used in searches to match logon names; attribute values are not the same as the user DN values.

## Create a MySQL Account That Uses GSSAPI/Kerberos for LDAP Authentication

MySQL authentication using the SASL LDAP authentication plugin with the GSSAPI/Kerberos method is based on a user that is a Kerberos principal. The following discussion uses a principal named `bredon@MYSQL.LOCAL` as this user, which must be registered in several places:

- The Kerberos administrator should register the user name as a Kerberos principal. This name should include a domain name. Clients use the principal name and password to authenticate with Kerberos and obtain a TGT.
- The LDAP administrator should register the user name in an LDAP entry. For example:

```
uid=bredon,dc=MYSQL,dc=LOCAL
```

### Note

In Active Directory (which uses Kerberos as the default authentication method), creating a user creates both the Kerberos principal and the LDAP entry.

- The MySQL DBA should create an account that has the Kerberos principal name as the user name and that authenticates using the SASL LDAP plugin.

Assume that the Kerberos principal and LDAP entry have been registered by the appropriate service administrators, and that, as previously described in [Installing LDAP Pluggable Authentication](#), and

[Configure the Server-Side SASL LDAP Authentication Plugin for GSSAPI/Kerberos](#), the MySQL server has been started with appropriate configuration settings for the server-side SASL LDAP plugin. The MySQL DBA then creates a MySQL account that corresponds to the Kerberos principal name, including the domain name.

#### Note

The SASL LDAP plugin uses a constant user DN for Kerberos authentication and ignores any user DN configured from MySQL. This has certain implications:

- For any MySQL account that uses GSSAPI/Kerberos authentication, the authentication string in `CREATE USER` or `ALTER USER` statements should contain no user DN because it has no effect.
- Because the authentication string contains no user DN, it should contain group mapping information, to enable the user to be handled as a proxy user that is mapped onto the desired proxied user. For information about proxying with the LDAP authentication plugin, see [LDAP Authentication with Proxying](#).

The following statements create a proxy user named `bredon@MYSQL.LOCAL` that assumes the privileges of the proxied user named `proxied_krb_usr`. Other GSSAPI/Kerberos users that should have the same privileges can similarly be created as proxy users for the same proxied user.

```
-- create proxy account
CREATE USER 'bredon@MYSQL.LOCAL'
 IDENTIFIED WITH authentication_ldap_sasl
 BY '#krb_grp=proxied_krb_user';

-- create proxied account and grant its privileges;
-- use mysql_no_login plugin to prevent direct login
CREATE USER 'proxied_krb_user'
 IDENTIFIED WITH mysql_no_login;
GRANT ALL
 ON krb_user_db.*
 TO 'proxied_krb_user';

-- grant to proxy account the
-- PROXY privilege for proxied account
GRANT PROXY
 ON 'proxied_krb_user'
 TO 'bredon@MYSQL.LOCAL';
```

Observe closely the quoting for the proxy account name in the first `CREATE USER` statement and the `GRANT PROXY` statement:

- For most MySQL accounts, the user and host are separate parts of the account name, and thus are quoted separately as `'user_name'@'host_name'`.
- For LDAP Kerberos authentication, the user part of the account name includes the principal domain, so `'bredon@MYSQL.LOCAL'` is quoted as a single value. Because no host part is given, the full MySQL account name uses the default of `'%'` as the host part: `'bredon@MYSQL.LOCAL'@' % '`

#### Note

When creating an account that authenticates using the `authentication_ldap_sasl` SASL LDAP authentication plugin with the GSSAPI/Kerberos authentication method, the `CREATE USER` statement includes the realm as part of the user name. This differs from creating accounts that use the `authentication_kerberos` Kerberos plugin. For such accounts, the `CREATE`

`USER` statement does not include the realm as part of the user name. Instead, specify the realm as the authentication string in the `BY` clause. See [Create a MySQL Account That Uses Kerberos Authentication](#).

The proxied account uses the `mysql_no_login` authentication plugin to prevent clients from using the account to log in directly to the MySQL server. Instead, it is expected that users who authenticate using LDAP use the `bredon@MYSQL.LOCAL` proxy account. (This assumes that the `mysql_no_login` plugin is installed. For instructions, see [Section 8.4.1.8, “No-Login Pluggable Authentication”](#).) For alternative methods of protecting proxied accounts against direct use, see [Preventing Direct Login to Proxied Accounts](#).

## Use the MySQL Account to Connect to the MySQL Server

After a MySQL account that authenticates using GSSAPI/Kerberos has been set up, clients can use it to connect to the MySQL server. Kerberos authentication can take place either prior to or at the time of MySQL client program invocation:

- Prior to invoking the MySQL client program, the client user can obtain a TGT from the KDC independently of MySQL. For example, the client user can use `kinit` to authenticate to Kerberos by providing a Kerberos principal name and the principal password:

```
$> kinit bredon@MYSQL.LOCAL
Password for bredon@MYSQL.LOCAL: (enter password here)
```

The resulting TGT is cached and becomes available for use by other Kerberos-aware applications, such as programs that use the client-side SASL LDAP authentication plugin. In this case, the MySQL client program authenticates to the MySQL server using the TGT, so invoke the client without specifying a user name or password:

```
mysql --default-auth=authentication_ldap_sasl_client
```

As just described, when the TGT is cached, user-name and password options are not needed in the client command. If the command includes them anyway, they are handled as follows:

- If the command includes a user name, authentication fails if that name does not match the principal name in the TGT.
- If the command includes a password, the client-side plugin ignores it. Because authentication is based on the TGT, it can succeed *even if the user-provided password is incorrect*. For this reason, the plugin produces a warning if a valid TGT is found that causes a password to be ignored.
- If the Kerberos cache contains no TGT, the client-side SASL LDAP authentication plugin itself can obtain the TGT from the KDC. Invoke the client with options for the name and password of the Kerberos principal associated with the MySQL account (enter the command on a single line, then enter the principal password when prompted):

```
mysql --default-auth=authentication_ldap_sasl_client
--user=bredon@MYSQL.LOCAL
--password
```

- If the Kerberos cache contains no TGT and the client command specifies no principal name as the user name, authentication fails.

If you are uncertain whether a TGT exists, you can use `klist` to check.

Authentication occurs as follows:

1. The client uses the TGT to authenticate using Kerberos.

2. The server finds the LDAP entry for the principal and uses it to authenticate the connection for the `bredon@MYSQL.LOCAL` MySQL proxy account.
3. The group mapping information in the proxy account authentication string (`'#krb_grp=proxied_krb_user'`) indicates that the authenticated proxied user should be `proxied_krb_user`.
4. `bredon@MYSQL.LOCAL` is treated as a proxy for `proxied_krb_user`, and the following query returns output as shown:

```
mysql> SELECT USER(), CURRENT_USER(), @@proxy_user;
+-----+-----+-----+
| USER() | CURRENT_USER() | @@proxy_user |
+-----+-----+-----+
| bredon@MYSQL.LOCAL@localhost | proxied_krb_user@% | 'bredon@MYSQL.LOCAL'@'%' |
+-----+-----+-----+
```

The `USER()` value indicates the user name used for the client command (`bredon@MYSQL.LOCAL`) and the host from which the client connected (`localhost`).

The `CURRENT_USER()` value is the full name of the proxied user account, which consists of the `proxied_krb_user` user part and the `%` host part.

The `@@proxy_user` value indicates the full name of the account used to make the connection to the MySQL server, which consists of the `bredon@MYSQL.LOCAL` user part and the `%` host part.

This demonstrates that proxying occurs through the `bredon@MYSQL.LOCAL` proxy user account, and that `bredon@MYSQL.LOCAL` assumes the privileges granted to the `proxied_krb_user` proxied user account.

A TGT once obtained is cached on the client side and can be used until it expires without specifying the password again. However the TGT is obtained, the client-side plugin uses it to acquire service tickets and communicate with the server-side plugin.

#### Note

When the client-side authentication plugin itself obtains the TGT, the client user may not want the TGT to be reused. As described in [Client Configuration Parameters for LDAP Authentication](#), the local `/etc/krb5.conf` file can be used to cause the client-side plugin to destroy the TGT when done with it.

The server-side plugin has no access to the TGT itself or the Kerberos password used to obtain it.

The LDAP authentication plugins have no control over the caching mechanism (storage in a local file, in memory, and so forth), but Kerberos utilities such as `kswitch` may be available for this purpose.

### Client Configuration Parameters for LDAP Authentication

The `authentication_ldap_sasl_client` client-side SASL LDAP plugin reads the local `/etc/krb5.conf` file. If this file is missing or inaccessible, an error occurs. Assuming that the file is accessible, it can include an optional `[appdefaults]` section to provide information used by the plugin. Place the information within the `mysql` part of the section. For example:

```
[appdefaults]
mysql = {
 ldap_server_host = "ldap_host.example.com"
 ldap_destroy_tgt = true
}
```

The client-side plugin recognizes these parameters in the `mysql` section:

- The `ldap_server_host` value specifies the LDAP server host and can be useful when that host differs from the KDC server host specified in the `[realms]` section. By default, the plugin uses the KDC server host as the LDAP server host.
- The `ldap_destroy_tgt` value indicates whether the client-side plugin destroys the TGT after obtaining and using it. By default, `ldap_destroy_tgt` is `false`, but can be set to `true` to avoid TGT reuse. (This setting applies only to TGTs created by the client-side plugin, not TGTs created by other plugins or externally to MySQL.)

## LDAP Search Referral

An LDAP server can be configured to delegate LDAP searches to another LDAP server, a functionality known as LDAP referral. Suppose that the server `a.example.com` holds a `"dc=example,dc=com"` root DN and wishes to delegate searches to another server `b.example.com`. To enable this, `a.example.com` would be configured with a named referral object having these attributes:

```
dn: dc=subtree,dc=example,dc=com
objectClass: referral
objectClass: extensibleObject
dc: subtree
ref: ldap://b.example.com/dc=subtree,dc=example,dc=com
```

An issue with enabling LDAP referral is that searches can fail with LDAP operation errors when the search base DN is the root DN, and referral objects are not set. A MySQL DBA might wish to avoid such referral errors for the LDAP authentication plugins, even though LDAP referral might be set globally in the `ldap.conf` configuration file. To configure on a plugin-specific basis whether the LDAP server should use LDAP referral when communicating with each plugin, set the `authentication_ldap_simple_referral` and `authentication_ldap_sasl_referral` system variables. Setting either variable to `ON` or `OFF` causes the corresponding LDAP authentication plugin to tell the LDAP server whether to use referral during MySQL authentication. Each variable has a plugin-specific effect and does not affect other applications that communicate with the LDAP server. Both variables are `OFF` by default.

### 8.4.1.7 Kerberos Pluggable Authentication

#### Note

Kerberos pluggable authentication is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see <https://www.mysql.com/products/>.

MySQL Enterprise Edition supports an authentication method that enables users to authenticate to MySQL Server using Kerberos, provided that appropriate Kerberos tickets are available or can be obtained.

This authentication method is available in MySQL 9.1 for MySQL servers and clients on Linux. It is useful in Linux environments where applications have access to Microsoft Active Directory, which has Kerberos enabled by default. The client-side plugin is supported on Windows as well. The server-side plugin is still supported only on Linux.

Kerberos pluggable authentication provides these capabilities:

- External authentication: Kerberos authentication enables MySQL Server to accept connections from users defined outside the MySQL grant tables who have obtained the proper Kerberos tickets.
- Security: Kerberos uses tickets together with symmetric-key cryptography, enabling authentication without sending passwords over the network. Kerberos authentication supports userless and passwordless scenarios.

The following table shows the plugin and library file names. The file name suffix might differ on your system. The file must be located in the directory named by the `plugin_dir` system variable. For installation information, see [Installing Kerberos Pluggable Authentication](#).

**Table 8.22 Plugin and Library Names for Kerberos Authentication**

Plugin or File	Plugin or File Name
Server-side plugin	<code>authentication_kerberos</code>
Client-side plugin	<code>authentication_kerberos_client</code>
Library file	<code>authentication_kerberos.so</code> , <code>authentication_kerberos_client.so</code>

The server-side Kerberos authentication plugin is included only in MySQL Enterprise Edition. It is not included in MySQL community distributions. The client-side plugin is included in all distributions, including community distributions. This enables clients from any distribution to connect to a server that has the server-side plugin loaded.

The following sections provide installation and usage information specific to Kerberos pluggable authentication:

- [Prerequisites for Kerberos Pluggable Authentication](#)
- [How Kerberos Authentication of MySQL Users Works](#)
- [Installing Kerberos Pluggable Authentication](#)
- [Using Kerberos Pluggable Authentication](#)
- [Kerberos Authentication Debugging](#)

For general information about pluggable authentication in MySQL, see [Section 8.2.17, “Pluggable Authentication”](#).

## Prerequisites for Kerberos Pluggable Authentication

To use Kerberos pluggable authentication for MySQL, these prerequisites must be satisfied:

- A Kerberos service must be available for the Kerberos authentication plugins to communicate with.
- Each Kerberos user (principal) to be authenticated by MySQL must be present in the database managed by the KDC server.
- A Kerberos client library must be available on systems where either the server-side or client-side Kerberos authentication plugin is used. In addition, GSSAPI is used as the interface for accessing Kerberos authentication, so a GSSAPI library must be available.

## How Kerberos Authentication of MySQL Users Works

This section provides an overview of how MySQL and Kerberos work together to authenticate MySQL users. For examples showing how to set up MySQL accounts to use the Kerberos authentication plugins, see [Using Kerberos Pluggable Authentication](#).

Familiarity is assumed here with Kerberos concepts and operation. The following list briefly defines several common Kerberos terms. You may also find the Glossary section of [RFC 4120](#) helpful.

- **Principal**: A named entity, such as a user or server. In this discussion, certain principal-related terms occur frequently:
  - **SPN**: Service principal name; the name of a principal that represents a service.
  - **UPN**: User principal name; the name of a principal that represents a user.
- **KDC**: The key distribution center, comprising the AS and TGS:
  - **AS**: The authentication server; provides the initial ticket-granting ticket needed to obtain additional tickets.
  - **TGS**: The ticket-granting server; provides additional tickets to Kerberos clients that possess a valid TGT.
- **TGT**: The ticket-granting ticket; presented to the TGS to obtain service tickets for service access.
- **ST**: A service ticket; provides access to a service such as that offered by a MySQL server.

Authentication using Kerberos requires a KDC server, for example, as provided by Microsoft Active Directory.

Kerberos authentication in MySQL uses Generic Security Service Application Program Interface (GSSAPI), which is a security abstraction interface. Kerberos is an instance of a specific security protocol that can be used through that abstract interface. Using GSSAPI, applications authenticate to Kerberos to obtain service credentials, then use those credentials in turn to enable secure access to other services.

On Windows, the `authentication_kerberos_client` authentication plugin supports two modes, which the client user can set at runtime or specify in an option file:

- **SSPI** mode: Security Support Provider Interface (SSPI) implements GSSAPI (see [Commands for Windows Clients in SSPI Mode](#)). SSPI, while being compatible with GSSAPI at the wire level, only supports the Windows single sign-on scenario and specifically refers to the logged-on user. SSPI is the default mode on most Windows clients.
- **GSSAPI** mode: Supports GSSAPI through the MIT Kerberos library on Windows (see [Commands for Windows Clients in GSSAPI Mode](#)).

With the Kerberos authentication plugins, applications and MySQL servers are able to use the Kerberos authentication protocol to mutually authenticate users and MySQL services. This way both the user and the server are able to verify each other's identity. No passwords are sent over the network and Kerberos protocol messages are protected against eavesdropping and replay attacks.

Kerberos authentication follows these steps, where the server-side and client-side parts are performed using the `authentication_kerberos` and `authentication_kerberos_client` authentication plugins, respectively:

1. The MySQL server sends to the client application its service principal name. This SPN must be registered in the Kerberos system, and is configured on the server side using the `authentication_kerberos_service_principal` system variable.
2. Using GSSAPI, the client application creates a Kerberos client-side authentication session and exchanges Kerberos messages with the Kerberos KDC:
  - The client obtains a ticket-granting ticket from the authentication server.
  - Using the TGT, the client obtains a service ticket for MySQL from the ticket-granting service.

This step can be skipped or partially skipped if the TGT, ST, or both are already cached locally. The client optionally may use a client keytab file to obtain a TGT and ST without supplying a password.

3. Using GSSAPI, the client application presents the MySQL ST to the MySQL server.
4. Using GSSAPI, the MySQL server creates a Kerberos server-side authentication session. The server validates the user identity and the validity of the user request. It authenticates the ST using the service key configured in its service keytab file to determine whether authentication succeeds or fails, and returns the authentication result to the client.

Applications are able to authenticate using a provided user name and password, or using a locally cached TGT or ST (for example, created using `kinit` or similar). This design therefore covers use cases ranging from completely useless and passwordless connections, where Kerberos service tickets are obtained from a locally stored Kerberos cache, to connections where both user name and password are provided and used to obtain a valid Kerberos service ticket from a KDC, to send to the MySQL server.

As indicated in the preceding description, MySQL Kerberos authentication uses two kinds of keytab files:

- On the client host, a client keytab file may be used to obtain a TGT and ST without supplying a password. See [Client Configuration Parameters for Kerberos Authentication](#).
- On the MySQL server host, a server-side service keytab file is used to verify service tickets received by the MySQL server from clients. The keytab file name is configured using the `authentication_kerberos_service_key_tab` system variable.

For information about keytab files, see [https://web.mit.edu/kerberos/krb5-latest/doc/basic/keytab\\_def.html](https://web.mit.edu/kerberos/krb5-latest/doc/basic/keytab_def.html).

## Installing Kerberos Pluggable Authentication

This section describes how to install the server-side Kerberos authentication plugin. For general information about installing plugins, see [Section 7.6.1, “Installing and Uninstalling Plugins”](#).

### Note

The server-side plugin is supported only on Linux systems. On Windows systems, only the client-side plugin is supported, which can be used on a Windows system to connect to a Linux server that uses Kerberos authentication.

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

The server-side plugin library file base name is `authentication_kerberos`. The file name suffix for Unix and Unix-like systems is `.so`.

To load the plugin at server startup, use the `--plugin-load-add` option to name the library file that contains it. With this plugin-loading method, the option must be given each time the server starts. Also, specify values for any plugin-provided system variables you wish to configure. The plugin exposes these system variables, enabling its operation to be configured:

- `authentication_kerberos_service_principal`: The MySQL service principal name (SPN). This name is sent to clients that attempt to authenticate using Kerberos. The SPN must be present in the database managed by the KDC server. The default is `mysql/host_name@realm_name`.
- `authentication_kerberos_service_key_tab`: The keytab file for authenticating tickets received from clients. This file must exist and contain a valid key for the SPN or authentication of clients will fail. The default is `mysql.keytab` in the data directory.

For details about all Kerberos authentication system variables, see [Section 8.4.1.13, “Pluggable Authentication System Variables”](#).

To load the plugin and configure it, put lines such as these in your `my.cnf` file, using values for the system variables that are appropriate for your installation:

```
[mysqld]
plugin-load-add=authentication_kerberos.so
authentication_kerberos_service_principal=mysql/krbauth.example.com@MYSQL.LOCAL
authentication_kerberos_service_key_tab=/var/mysql/data/mysql.keytab
```

After modifying `my.cnf`, restart the server to cause the new settings to take effect.

Alternatively, to load the plugin at runtime, use this statement:

```
INSTALL PLUGIN authentication_kerberos
 SONAME 'authentication_kerberos.so';
```

`INSTALL PLUGIN` loads the plugin immediately, and also registers it in the `mysql.plugins` system table to cause the server to load it for each subsequent normal startup without the need for `--plugin-load-add`.

When you install the plugin at runtime without configuring its system variables in the `my.cnf` file, the system variable `authentication_kerberos_service_key_tab` is set to the default value of `mysql.keytab` in the data directory. The value of this system variable cannot be changed at runtime, so if you need to specify a different file, you need to add the setting to your `my.cnf` file then restart the MySQL server. For example:

```
[mysqld]
authentication_kerberos_service_key_tab=/var/mysql/data/mysql.keytab
```

If the keytab file is not in the correct place or does not contain a valid SPN key, the MySQL server does not validate this, but clients return authentication errors until you fix the issue.

The `authentication_kerberos_service_principal` system variable can be set and persisted at runtime without restarting the server, by using a `SET PERSIST` statement:

```
SET PERSIST authentication_kerberos_service_principal='mysql/krbauth.example.com@MYSQL.LOCAL';
```

`SET PERSIST` sets a value for the running MySQL instance. It also saves the value, causing it to carry over to subsequent server restarts. To change a value for the running MySQL instance without having it carry over to subsequent restarts, use the `GLOBAL` keyword rather than `PERSIST`. See [Section 15.7.6.1, “SET Syntax for Variable Assignment”](#).

To verify plugin installation, examine the Information Schema `PLUGINS` table or use the `SHOW PLUGINS` statement (see [Section 7.6.2, “Obtaining Server Plugin Information”](#)). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
 FROM INFORMATION_SCHEMA.PLUGINS
 WHERE PLUGIN_NAME = 'authentication_kerberos';
+-----+-----+
| PLUGIN_NAME | PLUGIN_STATUS |
+-----+-----+
| authentication_kerberos | ACTIVE |
+-----+-----+
```

If a plugin fails to initialize, check the server error log for diagnostic messages.

To associate MySQL accounts with the Kerberos plugin, see [Using Kerberos Pluggable Authentication](#).

## Using Kerberos Pluggable Authentication

This section describes how to enable MySQL accounts to connect to the MySQL server using Kerberos pluggable authentication. It is assumed that the server is running with the server-side plugin enabled, as described in [Installing Kerberos Pluggable Authentication](#), and that the client-side plugin is available on the client host.

- [Verify Kerberos Availability](#)
- [Create a MySQL Account That Uses Kerberos Authentication](#)
- [Use the MySQL Account to Connect to the MySQL Server](#)
- [Client Configuration Parameters for Kerberos Authentication](#)

### Verify Kerberos Availability

The following example shows how to test availability of Kerberos in Active Directory. The example makes these assumptions:

- Active Directory is running on the host named `krbauth.example.com` with IP address `198.51.100.11`.
- MySQL-related Kerberos authentication uses the `MYSQL.LOCAL` domain, and also uses `MYSQL.LOCAL` as the realm name.
- A principal named `karl@MYSQL.LOCAL` is registered with the KDC. (In later discussion, this principal name is associated with the MySQL account that authenticates to the MySQL server using Kerberos.)

With those assumptions satisfied, follow this procedure:

1. Verify that the Kerberos library is installed and configured correctly in the operating system. For example, to configure a `MYSQL.LOCAL` domain and realm for use during MySQL authentication, the `/etc/krb5.conf` Kerberos configuration file should contain something like this:

```
[realms]
MYSQL.LOCAL = {
 kdc = krbauth.example.com
 admin_server = krbauth.example.com
 default_domain = MYSQL.LOCAL
}
```

2. You may need to add an entry to `/etc/hosts` for the server host:

```
198.51.100.11 krbauth krbauth.example.com
```

3. Check whether Kerberos authentication works correctly:

- a. Use `kinit` to authenticate to Kerberos:

```
$> kinit karl@MYSQL.LOCAL
Password for karl@MYSQL.LOCAL: (enter password here)
```

The command authenticates for the Kerberos principal named `karl@MYSQL.LOCAL`. Enter the principal's password when the command prompts for it. The KDC returns a TGT that is cached on the client side for use by other Kerberos-aware applications.

- b. Use `klist` to check whether the TGT was obtained correctly. The output should be similar to this:

```
$> klist
```

```
Ticket cache: FILE:/tmp/krb5cc_244306
Default principal: karl@MYSQL.LOCAL

Valid starting Expires Service principal
03/23/2021 08:18:33 03/23/2021 18:18:33 krbtgt/MYSQL.LOCAL@MYSQL.LOCAL
```

## Create a MySQL Account That Uses Kerberos Authentication

MySQL authentication using the `authentication_kerberos` authentication plugin is based on a Kerberos user principal name (UPN). The instructions here assume that a MySQL user named `karl` authenticates to MySQL using Kerberos, that the Kerberos realm is named `MYSQL.LOCAL`, and that the user principal name is `karl@MYSQL.LOCAL`. This UPN must be registered in several places:

- The Kerberos administrator should register the user name as a Kerberos principal. This name includes a realm name. Clients use the principal name and password to authenticate with Kerberos and obtain a ticket-granting ticket (TGT).
- The MySQL DBA should create an account that corresponds to the Kerberos principal name and that authenticates using the Kerberos plugin.

Assume that the Kerberos user principal name has been registered by the appropriate service administrator, and that, as previously described in [Installing Kerberos Pluggable Authentication](#), the MySQL server has been started with appropriate configuration settings for the server-side Kerberos plugin. To create a MySQL account that corresponds to a Kerberos UPN of `user@realm_name`, the MySQL DBA uses a statement like this:

```
CREATE USER user
 IDENTIFIED WITH authentication_kerberos
 BY 'realm_name';
```

The account named by `user` can include or omit the host name part. If the host name is omitted, it defaults to `%` as usual. The `realm_name` is stored as the `authentication_string` value for the account in the `mysql.user` system table.

To create a MySQL account that corresponds to the UPN `karl@MYSQL.LOCAL`, use this statement:

```
CREATE USER 'karl'
 IDENTIFIED WITH authentication_kerberos
 BY 'MYSQL.LOCAL';
```

If MySQL must construct the UPN for this account, for example, to obtain or validate tickets (TGTs or STs), it does so by combining the account name (ignoring any host name part) and the realm name. For example, the full account name resulting from the preceding `CREATE USER` statement is `'karl'@'%'`. MySQL constructs the UPN from the user name part `karl` (ignoring the host name part) and the realm name `MYSQL.LOCAL` to produce `karl@MYSQL.LOCAL`.

### Note

Observe that when creating an account that authenticates using `authentication_kerberos`, the `CREATE USER` statement does not include the UPN realm as part of the user name. Instead, specify the realm (`MYSQL.LOCAL` in this case) as the authentication string in the `BY` clause. This differs from creating accounts that use the `authentication_ldap_sasl` SASL LDAP authentication plugin with the GSSAPI/Kerberos authentication method. For such accounts, the `CREATE USER` statement does include the UPN realm as part of the user name. See [Create a MySQL Account That Uses GSSAPI/Kerberos for LDAP Authentication](#).

With the account set up, clients can use it to connect to the MySQL server. The procedure depends on whether the client host runs Linux or Windows, as indicated in the following discussion.

Use of `authentication_kerberos` is subject to the restriction that UPNs with the same user part but a different realm part are not supported. For example, you cannot create MySQL accounts that correspond to both these UPNs:

```
kate@MYSQL.LOCAL
kate@EXAMPLE.COM
```

Both UPNs have a user part of `kate` but differ in the realm part (`MYSQL.LOCAL` versus `EXAMPLE.COM`). This is disallowed.

## Use the MySQL Account to Connect to the MySQL Server

After a MySQL account that authenticates using Kerberos has been set up, clients can use it to connect to the MySQL server as follows:

1. Authenticate to Kerberos with the user principal name (UPN) and its password to obtain a ticket-granting ticket (TGT).
2. Use the TGT to obtain a service ticket (ST) for MySQL.
3. Authenticate to the MySQL server by presenting the MySQL ST.

The first step (authenticating to Kerberos) can be performed various ways:

- Prior to connecting to MySQL:
  - On Linux or on Windows in `GSSAPI` mode, invoke `kinit` to obtain the TGT and save it in the Kerberos credentials cache.
  - On Windows in `SSPI` mode, authentication may already have been done at login time, which saves the TGT for the logged-in user in the Windows in-memory cache. `kinit` is not used and there is no Kerberos cache.
- When connecting to MySQL, the client program itself can obtain the TGT, if it can determine the required Kerberos UPN and password:
  - That information can come from sources such as command options or the operating system.
  - On Linux, clients also can use a keytab file or the `/etc/krb5.conf` configuration file. Windows clients in `GSSAPI` mode use a configuration file. Windows clients in `SSPI` mode use neither.

Details of the client commands for connecting to the MySQL server differ for Linux and Windows, so each host type is discussed separately, but these command properties apply regardless of host type:

- Each command shown includes the following options, but each one may be omitted under certain conditions:
  - The `--default-auth` option specifies the name of the client-side authentication plugin (`authentication_kerberos_client`). This option may be omitted when the `--user` option is specified because in that case MySQL can determine the plugin from the user account information sent by MySQL server.
  - The `--plugin-dir` option indicates to the client program the location of the `authentication_kerberos_client` plugin. This option may be omitted if the plugin is installed in the default (compiled-in) location.

- Commands should also include any other options such as `--host` or `--port` that are required to specify which MySQL server to connect to.
- Enter each command on a single line. If the command includes a `--password` option to solicit a password, enter the password of the Kerberos UPN associated with the MySQL user when prompted.

### Connection Commands for Linux Clients

On Linux, the appropriate client command for connecting to the MySQL server varies depending on whether the command authenticates using a TGT from the Kerberos cache, or based on command options for the MySQL user name and the UPN password:

- Prior to invoking the MySQL client program, the client user can obtain a TGT from the KDC independently of MySQL. For example, the client user can use `kinit` to authenticate to Kerberos by providing a Kerberos user principal name and the principal password:

```
$> kinit karl@MYSQL.LOCAL
Password for karl@MYSQL.LOCAL: (enter password here)
```

The resulting TGT for the UPN is cached and becomes available for use by other Kerberos-aware applications, such as programs that use the client-side Kerberos authentication plugin. In this case, invoke the client without specifying a user-name or password option:

```
mysql
--default-auth=authentication_kerberos_client
--plugin-dir=path/to/plugin/directory
```

The client-side plugin finds the TGT in the cache, uses it to obtain a MySQL ST, and uses the ST to authenticate to the MySQL server.

As just described, when the TGT for the UPN is cached, user-name and password options are not needed in the client command. If the command includes them anyway, they are handled as follows:

- This command includes a user-name option:

```
mysql
--default-auth=authentication_kerberos_client
--plugin-dir=path/to/plugin/directory
--user=karl
```

In this case, authentication fails if the user name specified by the option does not match the user name part of the UPN in the TGT.

- This command includes a password option, which you enter when prompted:

```
mysql
--default-auth=authentication_kerberos_client
--plugin-dir=path/to/plugin/directory
--password
```

In this case, the client-side plugin ignores the password. Because authentication is based on the TGT, it can succeed *even if the user-provided password is incorrect*. For this reason, the plugin produces a warning if a valid TGT is found that causes a password to be ignored.

- If the Kerberos cache contains no TGT, the client-side Kerberos authentication plugin itself can obtain the TGT from the KDC. Invoke the client with options for the MySQL user name and the password, then enter the UPN password when prompted:

```
mysql --default-auth=authentication_kerberos_client
--plugin-dir=path/to/plugin/directory
```

```
--user=karl
--password
```

The client-side Kerberos authentication plugin combines the user name (`karl`) and the realm specified in the user account (`MYSQL.LOCAL`) to construct the UPN (`karl@MYSQL.LOCAL`). The client-side plugin uses the UPN and password to obtain a TGT, uses the TGT to obtain a MySQL ST, and uses the ST to authenticate to the MySQL server.

Or, suppose that the Kerberos cache contains no TGT and the command specifies a password option but no user-name option:

```
mysql --default-auth=authentication_kerberos_client
--plugin-dir=path/to/plugin/directory
--password
```

The client-side Kerberos authentication plugin uses the operating system login name as the MySQL user name. It combines that user name and the realm in the user's MySQL account to construct the UPN. The client-side plugin uses the UPN and the password to obtain a TGT, uses the TGT to obtain a MySQL ST, and uses the ST to authenticate to the MySQL server.

If you are uncertain whether a TGT exists, you can use `klist` to check.

**Note**

When the client-side Kerberos authentication plugin itself obtains the TGT, the client user may not want the TGT to be reused. As described in [Client Configuration Parameters for Kerberos Authentication](#), the local `/etc/krb5.conf` file can be used to cause the client-side plugin to destroy the TGT when done with it.

**Connection Commands for Windows Clients in SSPI Mode**

On Windows, using the default client-side plugin option (SSPI), the appropriate client command for connecting to the MySQL server varies depending on whether the command authenticates based on command options for the MySQL user name and the UPN password, or instead uses a TGT from the Windows in-memory cache. For details about GSSAPI mode on Windows, see [Commands for Windows Clients in GSSAPI Mode](#).

A command can explicitly specify options for the MySQL user name and the UPN password, or the command can omit those options:

- This command includes options for the MySQL user name and UPN password:

```
mysql --default-auth=authentication_kerberos_client
--plugin-dir=path/to/plugin/directory
--user=karl
--password
```

The client-side Kerberos authentication plugin combines the user name (`karl`) and the realm specified in the user account (`MYSQL.LOCAL`) to construct the UPN (`karl@MYSQL.LOCAL`). The client-side plugin uses the UPN and password to obtain a TGT, uses the TGT to obtain a MySQL ST, and uses the ST to authenticate to the MySQL server.

Any information in the Windows in-memory cache is ignored; the user-name and password option values take precedence.

- This command includes an option for the UPN password but not for the MySQL user name:

```
mysql
--default-auth=authentication_kerberos_client
```

```
--plugin-dir=path/to/plugin/directory
--password
```

The client-side Kerberos authentication plugin uses the logged-in user name as the MySQL user name and combines that user name and the realm in the user's MySQL account to construct the UPN. The client-side plugin uses the UPN and the password to obtain a TGT, uses the TGT to obtain a MySQL ST, and uses the ST to authenticate to the MySQL server.

- This command includes no options for the MySQL user name or UPN password:

```
mysql
--default-auth=authentication_kerberos_client
--plugin-dir=path/to/plugin/directory
```

The client-side plugin obtains the TGT from the Windows in-memory cache, uses the TGT to obtain a MySQL ST, and uses the ST to authenticate to the MySQL server.

This approach requires the client host to be part of the Windows Server Active Directory (AD) domain. If that is not the case, help the MySQL client discover the IP address for the AD domain by manually entering the AD server and realm as the DNS server and prefix:

1. Start `console.exe` and select **Network and Sharing Center**.
  2. From the sidebar of the Network and Sharing Center window, select **Change adapter settings**.
  3. In the Network Connections window, right-click the network or VPN connection to configure and select **Properties**.
  4. From the **Network** tab, locate and click **Internet Protocol Version 4 (TCP/IPv4)**, and then click **Properties**.
  5. Click **Advanced** in the Internet Protocol Version 4 (TCP/IPv4) Properties dialog. The Advanced TCP/IP Settings dialog opens.
  6. From the **DNS** tab, add the Active Directory server and realm as a DNS server and prefix.
- This command includes an option for the MySQL user name but not for the UPN password:

```
mysql
--default-auth=authentication_kerberos_client
--plugin-dir=path/to/plugin/directory
--user=karl
```

The client-side Kerberos authentication plugin compares the name specified by the user-name option against the logged-in user name. If the names are the same, the plugin uses the logged-in user TGT for authentication. If the names differ, authentication fails.

### Connection Commands for Windows Clients in GSSAPI Mode

On Windows, the client user must specify `GSSAPI` mode explicitly using the `plugin_authentication_kerberos_client_mode` plugin option to enable support through the MIT Kerberos library. The default mode is `SSPI` (see [Commands for Windows Clients in SSPI Mode](#)).

It is possible to specify `GSSAPI` mode:

- Prior to invoking the MySQL client program in an option file. The plugin variable name is valid using either underscores or dashes:

```
[mysql]
plugin_authentication_kerberos_client_mode=GSSAPI
```

Or:

```
[mysql]
plugin-authentication-kerberos-client-mode=GSSAPI
```

- At runtime from the command line using the `mysql` or `mysqldump` client programs. For example, the following commands (with underscores or dashes) causes `mysql` to connect to the server through the MIT Kerberos library on Windows.

```
mysql [connection-options] --plugin_authentication_kerberos_client_mode=GSSAPI
```

Or:

```
mysql [connection-options] --plugin-authentication-kerberos-client-mode=GSSAPI
```

- Client users can select `GSSAPI` mode from MySQL Workbench and some MySQL connectors. On client hosts running Windows, you can override the default location of:
  - The Kerberos configuration file by setting the `KRB5_CONFIG` environment variable.
  - The default credential cache name with the `KRB5CCNAME` environment variable (for example, `KRB5CCNAME=DIR:/mydir/`).

For specific client-side plugin information, see the documentation at <https://dev.mysql.com/doc/>.

The appropriate client command for connecting to the MySQL server varies depending on whether the command authenticates using a TGT from the MIT Kerberos cache, or based on command options for the MySQL user name and the UPN password. GSSAPI support through the MIT library on Windows is similar to GSSAPI on Linux (see [Commands for Linux Clients](#)), with the following exceptions:

- Tickets are always retrieved from or placed into the MIT Kerberos cache on hosts running Windows.
- `kinit` runs with Functional Accounts on Windows that have narrow permissions and specific roles. The client user does not know the `kinit` password. For an overview, see <https://docs.oracle.com/en/java/javase/11/tools/kinit.html>.
- If the client user supplies a password, the MIT Kerberos library on Windows decides whether to use it or rely on the existing ticket.
- The `destroy_tickets` parameter, described in [Client Configuration Parameters for Kerberos Authentication](#), is not supported because the MIT Kerberos library on Windows does not support the required API member (`get_profile_boolean`) to read its value from configuration file.

## Client Configuration Parameters for Kerberos Authentication

This section applies only for client hosts running Linux, not client hosts running Windows.

### Note

A client host running Windows with the `authentication_kerberos_client` client-side Kerberos plugin set to `GSSAPI` mode does support client configuration parameters, in general, but the MIT Kerberos library on Windows does not support the `destroy_tickets` parameter described in this section.

If no valid ticket-granting ticket (TGT) exists at the time of MySQL client application invocation, the application itself may obtain and cache the TGT. If during the Kerberos authentication process the client application causes a TGT to be cached, any such TGT that was added can be destroyed after it is no longer needed, by setting the appropriate configuration parameter.

The `authentication_kerberos_client` client-side Kerberos plugin reads the local `/etc/krb5.conf` file. If this file is missing or inaccessible, an error occurs. Assuming that the file is accessible, it can include an optional `[appdefaults]` section to provide information used by the plugin. Place the information within the `mysql` part of the section. For example:

```
[appdefaults]
mysql = {
 destroy_tickets = true
}
```

The client-side plugin recognizes these parameters in the `mysql` section:

- The `destroy_tickets` value indicates whether the client-side plugin destroys the TGT after obtaining and using it. By default, `destroy_tickets` is `false`, but can be set to `true` to avoid TGT reuse. (This setting applies only to TGTs created by the client-side plugin, not TGTs created by other plugins or externally to MySQL.)

On the client host, a client keytab file may be used to obtain a TGT and TS without supplying a password. For information about keytab files, see [https://web.mit.edu/kerberos/krb5-latest/doc/basic/keytab\\_def.html](https://web.mit.edu/kerberos/krb5-latest/doc/basic/keytab_def.html).

## Kerberos Authentication Debugging

The `AUTHENTICATION_KERBEROS_CLIENT_LOG` environment variable enables or disables debug output for Kerberos authentication.

### Note

Despite `CLIENT` in the name `AUTHENTICATION_KERBEROS_CLIENT_LOG`, the same environment variable applies to the server-side plugin as well as the client-side plugin.

On the server side, the permitted values are 0 (off) and 1 (on). Log messages are written to the server error log, subject to the server error-logging verbosity level. For example, if you are using priority-based log filtering, the `log_error_verbosity` system variable controls verbosity, as described in [Section 7.4.2.5, “Priority-Based Error Log Filtering \(log\\_filter\\_internal\)”](#).

On the client side, the permitted values are from 1 to 5 and are written to the standard error output. The following table shows the meaning of each log-level value.

Log Level	Meaning
1 or not set	No logging
2	Error messages
3	Error and warning messages
4	Error, warning, and information messages
5	Error, warning, information, and debug messages

### 8.4.1.8 No-Login Pluggable Authentication

The `mysql_no_login` server-side authentication plugin prevents all client connections to any account that uses it. Use cases for this plugin include:

- Accounts that must be able to execute stored programs and views with elevated privileges without exposing those privileges to ordinary users.

- Proxied accounts that should never permit direct login but are intended to be accessed only through proxy accounts.

The following table shows the plugin and library file names. The file name suffix might differ on your system. The file must be located in the directory named by the `plugin_dir` system variable.

**Table 8.23 Plugin and Library Names for No-Login Authentication**

Plugin or File	Plugin or File Name
Server-side plugin	<code>mysql_no_login</code>
Client-side plugin	None
Library file	<code>mysql_no_login.so</code>

The following sections provide installation and usage information specific to no-login pluggable authentication:

- [Installing No-Login Pluggable Authentication](#)
- [Uninstalling No-Login Pluggable Authentication](#)
- [Using No-Login Pluggable Authentication](#)

For general information about pluggable authentication in MySQL, see [Section 8.2.17, “Pluggable Authentication”](#). For proxy user information, see [Section 8.2.19, “Proxy Users”](#).

## Installing No-Login Pluggable Authentication

This section describes how to install the no-login authentication plugin. For general information about installing plugins, see [Section 7.6.1, “Installing and Uninstalling Plugins”](#).

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

The plugin library file base name is `mysql_no_login`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

To load the plugin at server startup, use the `--plugin-load-add` option to name the library file that contains it. With this plugin-loading method, the option must be given each time the server starts. For example, put these lines in the server `my.cnf` file, adjusting the `.so` suffix for your platform as necessary:

```
[mysqld]
plugin-load-add=mysql_no_login.so
```

After modifying `my.cnf`, restart the server to cause the new settings to take effect.

Alternatively, to load the plugin at runtime, use this statement, adjusting the `.so` suffix for your platform as necessary:

```
INSTALL PLUGIN mysql_no_login SONAME 'mysql_no_login.so';
```

`INSTALL PLUGIN` loads the plugin immediately, and also registers it in the `mysql.plugins` system table to cause the server to load it for each subsequent normal startup without the need for `--plugin-load-add`.

To verify plugin installation, examine the Information Schema `PLUGINS` table or use the `SHOW PLUGINS` statement (see [Section 7.6.2, “Obtaining Server Plugin Information”](#)). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
FROM INFORMATION_SCHEMA.PLUGINS
WHERE PLUGIN_NAME LIKE '%login%';
```

PLUGIN_NAME	PLUGIN_STATUS
mysql_no_login	ACTIVE

If the plugin fails to initialize, check the server error log for diagnostic messages.

To associate MySQL accounts with the no-login plugin, see [Using No-Login Pluggable Authentication](#).

## Uninstalling No-Login Pluggable Authentication

The method used to uninstall the no-login authentication plugin depends on how you installed it:

- If you installed the plugin at server startup using a `--plugin-load-add` option, restart the server without the option.
- If you installed the plugin at runtime using an `INSTALL PLUGIN` statement, it remains installed across server restarts. To uninstall it, use `UNINSTALL PLUGIN`:

```
UNINSTALL PLUGIN mysql_no_login;
```

## Using No-Login Pluggable Authentication

This section describes how to use the no-login authentication plugin to prevent accounts from being used for connecting from MySQL client programs to the server. It is assumed that the server is running with the no-login plugin enabled, as described in [Installing No-Login Pluggable Authentication](#).

To refer to the no-login authentication plugin in the `IDENTIFIED WITH` clause of a `CREATE USER` statement, use the name `mysql_no_login`.

An account that authenticates using `mysql_no_login` may be used as the `DEFINER` for stored program and view objects. If such an object definition also includes `SQL SECURITY DEFINER`, it executes with that account's privileges. DBAs can use this behavior to provide access to confidential or sensitive data that is exposed only through well-controlled interfaces.

The following example illustrates these principles. It defines an account that does not permit client connections, and associates with it a view that exposes only certain columns of the `mysql.user` system table:

```
CREATE DATABASE nologindb;
CREATE USER 'nologin'@'localhost'
 IDENTIFIED WITH mysql_no_login;
GRANT ALL ON nologindb.*
 TO 'nologin'@'localhost';
GRANT SELECT ON mysql.user
 TO 'nologin'@'localhost';
CREATE DEFINER = 'nologin'@'localhost'
 SQL SECURITY DEFINER
 VIEW nologindb.myview
 AS SELECT User, Host FROM mysql.user;
```

To provide protected access to the view to an ordinary user, do this:

```
GRANT SELECT ON nologindb.myview
 TO 'ordinaryuser'@'localhost';
```

Now the ordinary user can use the view to access the limited information it presents:

```
SELECT * FROM nologindb.myview;
```

Attempts by the user to access columns other than those exposed by the view result in an error, as do attempts to select from the view by users not granted access to it.

#### Note

Because the `nologin` account cannot be used directly, the operations required to set up objects that it uses must be performed by `root` or similar account that has the privileges required to create the objects and set `DEFINER` values.

The `mysql_no_login` plugin is also useful in proxying scenarios. (For a discussion of concepts involved in proxying, see [Section 8.2.19, “Proxy Users”](#).) An account that authenticates using `mysql_no_login` may be used as a proxied user for proxy accounts:

```
-- create proxied account
CREATE USER 'proxied_user'@'localhost'
 IDENTIFIED WITH mysql_no_login;
-- grant privileges to proxied account
GRANT ...
 ON ...
 TO 'proxied_user'@'localhost';
-- permit proxy_user to be a proxy account for proxied account
GRANT PROXY
 ON 'proxied_user'@'localhost'
 TO 'proxy_user'@'localhost';
```

This enables clients to access MySQL through the proxy account (`proxy_user`) but not to bypass the proxy mechanism by connecting directly as the proxied user (`proxied_user`). A client who connects using the `proxy_user` account has the privileges of the `proxied_user` account, but `proxied_user` itself cannot be used to connect.

For alternative methods of protecting proxied accounts against direct use, see [Preventing Direct Login to Proxied Accounts](#).

### 8.4.1.9 OpenID Connect Pluggable Authentication

#### Note

OpenID Connect pluggable authentication is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see <https://www.mysql.com/products/>.

MySQL Enterprise Edition supports an authentication method that enables users to authenticate to MySQL Server using OpenID Connect, provided that appropriate OpenID Connect credentials and tokens are properly configured based on the OAuth 2.0 framework.

The following table shows the plugin and library file names. The file name suffix might differ on your system. The file must be located in the directory named by the `plugin_dir` system variable. For installation information, see [Installing OpenID Pluggable Authentication](#).

**Table 8.24 Plugin and Library Names for OpenID Connect Authentication**

Plugin or File	Plugin or File Name
Server-side plugin	<code>authentication_openid_connect</code>
Client-side plugin	<code>authentication_openid_connect_client</code>
Library file	<code>authentication_openid_connect.so</code> , <code>authentication_openid_connect_client.so</code>

The server-side OpenID Connect authentication plugin is included in MySQL Enterprise Edition. It is not included in MySQL community distributions. The client-side plugin is included in all distributions, including community distributions. This enables clients from any distribution to connect to a server that has the server-side plugin loaded.

The following sections provide installation and usage information specific to OpenID Connect pluggable authentication:

- [Prerequisites for OpenID Connect Pluggable Authentication](#)
- [OpenID Connect Process and Workflow](#)
- [Installing OpenID Pluggable Authentication](#)
- [Connecting with a Client](#)

For general information about pluggable authentication in MySQL, see [Section 8.2.17, “Pluggable Authentication”](#).

## Prerequisites for OpenID Connect Pluggable Authentication

To use OpenID Connect pluggable authentication for MySQL, these prerequisites must be satisfied:

- The *connecting user* must have an account in the Identity provider domain, and the means to obtain the [Identity Token](#).
- The *administrator* must have a list of token issuers to support along with their public signing keys. The administrator must also have the user's identifier from the Identity provider domain.

## OpenID Connect Process and Workflow

OpenID Connect authentication follows these steps, where the server-side and client-side parts are performed using the [authentication\\_openid\\_connect](#) and [authentication\\_openid\\_connect\\_client](#) authentication plugins, respectively:

1. The client reads the Identity token file. For example, the `mysql` command-line client uses the [authentication-openid-connect-client-id-token-file](#) option with a full filepath to the token file. The client does not accept a token with a size exceeding 10 KB. Each connector has a method to pass in this information.
2. The client checks if the connection is secure between the client and the server. Only TLS, socket, and shared memory connections are considered secure.
3. The client sends the token to the server after checking if it is a valid JSON Web Token (JWT).
4. The server checks if the connection is secure between the client and the server, and receives the token.
5. The server decodes and validates the token:
  - a. It checks if the token is a valid JWT.
  - b. The headers are extracted using the encryption algorithm, which uses the RS256 asymmetric algorithm.
  - c. The payload is decoded, and checks are performed to determine if the appropriate criteria is met for a successful login.

## 6. Criteria for a successful login:

- The Identity token's `sub` claim value must be the same as the user's value in the authentication string.
- The `identity_provider` value in the authentication string must be one of the `identity_provider` values set in the configuration.
- The Identity token's `iss` claim value must equal the `identity_provider` name's value set in the configuration.
- The Identity token expiration time must be greater than the current time.
- The Identity token's signature must be verified by the public key of the Identity token's issuer specified in the `authentication_openid_connect_configuration` option as set by the administrator.

## 7. Authentication is successful if all the required criteria are met, otherwise authentication fails and logs the appropriate information to the error log.

## Installing OpenID Pluggable Authentication

This section describes how to install the server-side OpenID Connect authentication plugin. For general information about installing plugins, see [Section 7.6.1, “Installing and Uninstalling Plugins”](#).

Install the server-side `authentication_openid_connect` plugin on the MySQL Server. For example, by using `INSTALL PLUGIN`:

```
INSTALL PLUGIN authentication_openid_connect SONAME 'authentication_openid_connect.so';
```

Next, configure the `authentication_openid_connect_configuration` MySQL server option. The administrator specifies the list of issuers and their corresponding Public Signing Keys used to validate the Identity token's signature. This is defined as a JSON string (with the `JSON://` prefix) or point to a JSON file (with the `file://` prefix). Only the Identity tokens issued by the list of issuers specified by the administrator are accepted for authentication. For example:

```
SET GLOBAL authentication_openid_connect_configuration = "file://full/path/to/file.json";
```

File `file.json` in this example looks similar to:

```
{
 "issuer1": "{ \"name\": \"issuer1_formal_name\", \"e\": \"AQAB\", \"use\": \"sig\", \"n\": \"oUriU8GqbRw-avcMn951\" }",
 "issuer2": "{ \"name\": \"issuer2_formal_name\", \"e\": \"AQAB\", \"use\": \"sig\", \"n\": \"oUriU8GqbRw-avcMn951\" }"
}
```

Alternatively, set `authentication_openid_connect_configuration` inline as a JSON string instead of a file:

```
SET GLOBAL authentication_openid_connect_configuration = "JSON://{ \"issuer1\" : \"{\\\"name\\\":\\\"issuer1\\\"}\" }";
```

One of the issuer names should match the authentication string's `identity_provider` value, and the corresponding `name` key value must match with Identity token's `iss` value.

A MySQL user is mapped to a user managed in an Identity provider domain to authenticate via the `authentication_openid_connect_client` client-side plugin, as in the example shown here:

```
CREATE USER
 'username'@'%'
IDENTIFIED WITH
 'authentication_openid_connect'
```

```
AS
'{"identity_provider" : "idp_name_here", "user" : "user_id_here"}';
```

Replace *idp\_name\_here* with the Identity provider name chosen by the administrator to match one of the allowed identity provider keys specified in the configuration. Replace *user\_id\_here* with the user's identifier in the Identity Provider' domain, which must match with the `sub` field in the Identity token.

## Connecting with a Client

A client with the `authentication_openid_connect_client` plugin enabled passes the required Identity token to authenticate with a mapped MySQL user, using the complete path to the Identity token file used when connecting to the MySQL server.

For example, the `mysql` command-line client passes in the `--authentication-openid-connect-client-id-token-file` option. For example:

```
mysql -h hostname --port port --authentication-openid-connect-client-id-token-file=/path/to/token/file -u user
```

### 8.4.1.10 Socket Peer-Credential Pluggable Authentication

The server-side `auth_socket` authentication plugin authenticates clients that connect from the local host through the Unix socket file. The plugin uses the `SO_PEERCREC` socket option to obtain information about the user running the client program. Thus, the plugin can be used only on systems that support the `SO_PEERCREC` option, such as Linux.

The source code for this plugin can be examined as a relatively simple example demonstrating how to write a loadable authentication plugin.

The following table shows the plugin and library file names. The file must be located in the directory named by the `plugin_dir` system variable.

**Table 8.25 Plugin and Library Names for Socket Peer-Credential Authentication**

Plugin or File	Plugin or File Name
Server-side plugin	<code>auth_socket</code>
Client-side plugin	None, see discussion
Library file	<code>auth_socket.so</code>

The following sections provide installation and usage information specific to socket pluggable authentication:

- [Installing Socket Pluggable Authentication](#)
- [Uninstalling Socket Pluggable Authentication](#)
- [Using Socket Pluggable Authentication](#)

For general information about pluggable authentication in MySQL, see [Section 8.2.17, “Pluggable Authentication”](#).

## Installing Socket Pluggable Authentication

This section describes how to install the socket authentication plugin. For general information about installing plugins, see [Section 7.6.1, “Installing and Uninstalling Plugins”](#).

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

To load the plugin at server startup, use the `--plugin-load-add` option to name the library file that contains it. With this plugin-loading method, the option must be given each time the server starts. For example, put these lines in the server `my.cnf` file:

```
[mysqld]
plugin-load-add=auth_socket.so
```

After modifying `my.cnf`, restart the server to cause the new settings to take effect.

Alternatively, to load the plugin at runtime, use this statement:

```
INSTALL PLUGIN auth_socket SONAME 'auth_socket.so';
```

`INSTALL PLUGIN` loads the plugin immediately, and also registers it in the `mysql.plugins` system table to cause the server to load it for each subsequent normal startup without the need for `--plugin-load-add`.

To verify plugin installation, examine the Information Schema `PLUGINS` table or use the `SHOW PLUGINS` statement (see [Section 7.6.2, “Obtaining Server Plugin Information”](#)). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
 FROM INFORMATION_SCHEMA.PLUGINS
 WHERE PLUGIN_NAME LIKE '%socket%';
+-----+-----+
| PLUGIN_NAME | PLUGIN_STATUS |
+-----+-----+
| auth_socket | ACTIVE |
+-----+-----+
```

If the plugin fails to initialize, check the server error log for diagnostic messages.

To associate MySQL accounts with the socket plugin, see [Using Socket Pluggable Authentication](#).

## Uninstalling Socket Pluggable Authentication

The method used to uninstall the socket authentication plugin depends on how you installed it:

- If you installed the plugin at server startup using a `--plugin-load-add` option, restart the server without the option.
- If you installed the plugin at runtime using an `INSTALL PLUGIN` statement, it remains installed across server restarts. To uninstall it, use `UNINSTALL PLUGIN`:

```
UNINSTALL PLUGIN auth_socket;
```

## Using Socket Pluggable Authentication

The socket plugin checks whether the socket user name (the operating system user name) matches the MySQL user name specified by the client program to the server. If the names do not match, the plugin checks whether the socket user name matches the name specified in the `authentication_string` column of the `mysql.user` system table row. If a match is found, the plugin permits the connection. The `authentication_string` value can be specified using an `IDENTIFIED ...AS` clause with `CREATE USER` or `ALTER USER`.

Suppose that a MySQL account is created for an operating system user named `valerie` who is to be authenticated by the `auth_socket` plugin for connections from the local host through the socket file:

```
CREATE USER 'valerie'@'localhost' IDENTIFIED WITH auth_socket;
```

If a user on the local host with a login name of `stefanie` invokes `mysql` with the option `--user=valerie` to connect through the socket file, the server uses `auth_socket` to authenticate the client. The plugin determines that the `--user` option value (`valerie`) differs from the client user's name (`stefanie`) and refuses the connection. If a user named `valerie` tries the same thing, the plugin finds that the user name and the MySQL user name are both `valerie` and permits the connection. However, the plugin refuses the connection even for `valerie` if the connection is made using a different protocol, such as TCP/IP.

To permit both the `valerie` and `stefanie` operating system users to access MySQL through socket file connections that use the account, this can be done two ways:

- Name both users at account-creation time, one following `CREATE USER`, and the other in the authentication string:

```
CREATE USER 'valerie'@'localhost' IDENTIFIED WITH auth_socket AS 'stefanie';
```

- If you have already used `CREATE USER` to create the account for a single user, use `ALTER USER` to add the second user:

```
CREATE USER 'valerie'@'localhost' IDENTIFIED WITH auth_socket;
ALTER USER 'valerie'@'localhost' IDENTIFIED WITH auth_socket AS 'stefanie';
```

To access the account, both `valerie` and `stefanie` specify `--user=valerie` at connect time.

#### 8.4.1.11 WebAuthn Pluggable Authentication

##### Note

WebAuthn authentication is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see <https://www.mysql.com/products/>.

MySQL Enterprise Edition supports an authentication method that enables users to authenticate to MySQL Server using WebAuthn authentication.

WebAuthn stands for Web Authentication, which is a web standard published by the World Wide Web Consortium (W3C) and web application APIs that add FIDO-based authentication to supported browsers and platforms.

WebAuthn pluggable authentication replaces FIDO pluggable authentication, which is deprecated. WebAuthn pluggable authentication supports both FIDO and FIDO2 devices.

WebAuthn pluggable authentication provides these capabilities:

- WebAuthn enables authentication to MySQL Server using devices such as smart cards, security keys, and biometric readers.
- Because authentication can occur other than by providing a password, WebAuthn enables passwordless authentication.
- On the other hand, device authentication is often used in conjunction with password authentication, so WebAuthn authentication can be used to good effect for MySQL accounts that use multifactor authentication; see [Section 8.2.18, “Multifactor Authentication”](#).

The following table shows the plugin and library file names. The file name suffix might differ on your system. Common suffixes are `.so` for Unix and Unix-like systems, and `.dll` for Windows. The file must be located in the directory named by the `plugin_dir` system variable. For installation information, see [Installing WebAuthn Pluggable Authentication](#).

**Table 8.26 Plugin and Library Names for WebAuthn Authentication**

Plugin or File	Plugin or File Name
Server-side plugin	<code>authentication_webauthn</code>
Client-side plugin	<code>authentication_webauthn_client</code>
Library file	<code>authentication_webauthn.so</code> , <code>authentication_webauthn_client.so</code>

**Note**

A `libfido2` library must be available on systems where either the server-side or client-side WebAuthn authentication plugin is used.

The server-side WebAuthn authentication plugin is included only in MySQL Enterprise Edition. It is not included in MySQL community distributions. The client-side plugin is included in all distributions, including community distributions, which enables clients from any distribution to connect to a server that has the server-side plugin loaded.

The following sections provide installation and usage information specific to WebAuthn pluggable authentication:

- [Installing WebAuthn Pluggable Authentication](#)
- [Using WebAuthn Authentication](#)
- [WebAuthn Passwordless Authentication](#)
- [Device Unregistration for WebAuthn](#)
- [How WebAuthn Authentication of MySQL Users Works](#)

For general information about pluggable authentication in MySQL, see [Section 8.2.17, “Pluggable Authentication”](#).

## Installing WebAuthn Pluggable Authentication

This section describes how to install the server-side WebAuthn authentication plugin. For general information about installing plugins, see [Section 7.6.1, “Installing and Uninstalling Plugins”](#).

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

The server-side plugin library file base name is `authentication_webauthn`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

Before installing the server-side plugin, define a unique name for the relying party ID (used for device registration and authentication), which is the MySQL server. Start the server using the `--loose-authentication-webauthn-rp-id=value` option. The example here specifies the value `mysql.com` as the relying party ID. Replace this value with one that satisfies your requirements.

```
$> mysqld [options] --loose-authentication-webauthn-rp-id=mysql.com
```

**Note**

For replication, use the same `authentication_webauthn_rp_id` value on all nodes if a user is expected to connect to multiple servers.

To define the relying party and load the plugin at server startup, use the `--plugin-load-add` option to name the library file that contains it, adjusting the `.so` suffix for your platform as necessary. With this plugin-loading method, the option must be given each time the server starts.

```
$> mysqld [options]
 --loose-authentication-webauthn-rp-id=mysql.com
 --plugin-load-add=authentication_webauthn.so
```

To define the relying party and load the plugin, put lines such as this in your `my.cnf` file, adjusting the `.so` suffix for your platform as necessary:

```
[mysqld]
plugin-load-add=authentication_webauthn.so
authentication_webauthn_rp_id=mysql.com
```

After modifying `my.cnf`, restart the server to cause the new setting to take effect.

Alternatively, to load the plugin at runtime, use this statement, adjusting the `.so` suffix for your platform as necessary:

```
INSTALL PLUGIN authentication_webauthn
 SONAME 'authentication_webauthn.so';
```

`INSTALL PLUGIN` loads the plugin immediately, and also registers it in the `mysql.plugins` system table to cause the server to load it for each subsequent normal startup without the need for `--plugin-load-add`.

To verify plugin installation, examine the Information Schema `PLUGINS` table or use the `SHOW PLUGINS` statement (see [Section 7.6.2, “Obtaining Server Plugin Information”](#)). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
 FROM INFORMATION_SCHEMA.PLUGINS
 WHERE PLUGIN_NAME = 'authentication_webauthn';
+-----+-----+
| PLUGIN_NAME | PLUGIN_STATUS |
+-----+-----+
| authentication_webauthn | ACTIVE |
+-----+-----+
```

If a plugin fails to initialize, check the server error log for diagnostic messages.

To associate MySQL accounts with the WebAuthn authentication plugin, see [Using WebAuthn Authentication](#).

## Using WebAuthn Authentication

WebAuthn authentication typically is used in the context of multifactor authentication (see [Section 8.2.18, “Multifactor Authentication”](#)). This section shows how to incorporate WebAuthn device-based authentication into a multifactor account, using the `authentication_webauthn` plugin.

It is assumed in the following discussion that the server is running with the server-side WebAuthn authentication plugin enabled, as described in [Installing WebAuthn Pluggable Authentication](#), and that the client-side WebAuthn plugin is available in the plugin directory on the client host.

### Note

On Windows, WebAuthn authentication only functions if the client process runs as a user with administrator privileges. It might also be necessary to add the location of your FIDO/FIDO2 device to the client host's `PATH` environment variable.

It is also assumed that WebAuthn authentication is used in conjunction with non-WebAuthn authentication (which implies a 2FA or 3FA account). WebAuthn can also be used by itself to create 1FA accounts that authenticate in a passwordless manner. In this case, the setup process differs somewhat. For instructions, see [WebAuthn Passwordless Authentication](#).

An account that is configured to use the `authentication_webauthn` plugin is associated with a Fast Identity Online (FIDO/FIDO2) device. Because of this, a one-time device registration step is required before WebAuthn authentication can occur. The device registration process has these characteristics:

- Any FIDO/FIDO2 device associated with an account must be registered before the account can be used.
- Registration requires that a FIDO/FIDO2 device be available on the client host, or registration fails.
- The user is expected to perform the appropriate FIDO/FIDO2 device action when prompted during registration (for example, touching the device or performing a biometric scan).
- To perform device registration, the client user must invoke the `mysql` client program and specify the `--register-factor` option to specify the factor or factors for which a device is being registered. For example, if the account is set to use WebAuthn as the second authentication factor, the user invokes `mysql` with the `--register-factor=2` option.
- If the user account is configured with the `authentication_webauthn` plugin set as the second or third factor, authentication for all preceding factors must succeed before the registration step can proceed.
- The server knows from the information in the user account whether the FIDO/FIDO2 device requires registration or has already been registered. When the client program connects, the server places the client session in sandbox mode if the device must be registered, so that registration must occur before anything else can be done. Sandbox mode used for FIDO/FIDO2 device registration is similar to that used for handling of expired passwords. See [Section 8.2.16, “Server Handling of Expired Passwords”](#).
- In sandbox mode, no statements other than `ALTER USER` are permitted. Registration is performed using forms of this statement. When invoked with the `--register-factor` option, the `mysql` client generates the `ALTER USER` statements required to perform registration. After registration has been accomplished, the server switches the session out of sandbox mode, and the client can proceed normally. For information about the generated `ALTER USER` statements, refer to the `--register-factor` description.
- When device registration has been performed for the account, the server updates the `mysql.user` system table row for that account to update the device registration status and to store the public key and credential ID. (The server does not retain the credential ID following FIDO2 device registration.)
- The registration step can be performed only by the user named by the account. If one user attempts to perform registration for another user, an error occurs.
- The user should use the same FIDO/FIDO2 device during registration and authentication. If, after registering a FIDO/FIDO2 device on the client host, the device is reset or a different device is inserted, authentication fails. In this case, the device associated with the account must be unregistered and registration must be done again.
- Windows Hello authentication support is available in MySQL 9.1.0 and later. The server plugin is available with MySQL Enterprise Edition only; the client plugin is available with MySQL Enterprise Edition and MySQL Community Edition. Windows 11 and later is supported.

The `authentication_webauthn` client plugin uses the `libfido` library, which supports the concept of a “device” which can be implemented as hardware (such as a Yubikey) or as software (for example, the Windows Hello passkey store). `libfido` uses such a device to communicate with the backend

passkey store and to interact with the passkeys which the store contains. Passkeys do not physically leave the backend store.

To specify a device, use the `mysql` client `--plugin-authentication-webauthn-device=#` option. The default is the first device (0). The client raises an error if the device specified does not exist. This occurs, for example, if there are only two devices and the user requests a third one. The client does not perform any checks for more active devices than are needed.

The client plugin prints the product and manufacturer names for the device prior to interacting with it.

Only passkeys stored in the Windows Hello passkey store are currently supported by the Windows Hello device; other nonlocal passkey stores (located on other devices, possibly accessible through Windows Hello by scanning a QR code) are not supported. Passkeys stored in HSM modules or Yubikeys need to be accessed directly, rather than using the Windows Hello device.

Stored passkey deletion from the Windows passkey store must be performed using system tools; the `mysql` client does not provide a way to delete a passkey.

Suppose that you want an account to authenticate first using the `caching_sha2_password` plugin, then using the `authentication_webauthn` plugin. Create a multifactor account using a statement like this:

```
CREATE USER 'u2'@'localhost'
 IDENTIFIED WITH caching_sha2_password
 BY 'sha2_password'
 AND IDENTIFIED WITH authentication_webauthn;
```

To connect, supply the factor 1 password to satisfy authentication for that factor, and to initiate registration of the FIDO/FIDO2 device, set the `--register-factor` to factor 2.

```
$> mysql --user=u2 --password1 --register-factor=2
Enter password: (enter factor 1 password)
Please insert FIDO device and follow the instruction. Depending on the device,
you may have to perform gesture action multiple times.
1. Perform gesture action (Skip this step if you are prompted to enter device PIN).
2. Enter PIN for token device:
3. Perform gesture action for registration to complete.
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 8
```

After the factor 1 password is accepted, the client session enters sandbox mode so that device registration can be performed for factor 2. During registration, you are prompted to perform the appropriate FIDO/FIDO2 device action, such as touching the device or performing a biometric scan.

Optionally, you can invoke the `mysql` client program and specify the `--plugin-authentication-webauthn-client-preserve-privacy` option. If the FIDO2 device contains multiple discoverable credentials (resident keys) for a given replying party (RP) ID, this option permits choosing a key to be used for assertion. By default, the option is set to `FALSE`, indicating that assertions are to be created using all resident keys for a given RP ID. When specified with this option, `mysql` prompts the you for a device PIN and lists all of the available credentials for given RP ID. Select one key and then perform the remaining online instructions to complete the authentication. The example here assumes that `mysql.com` is a valid RP ID:

```
$> mysql --user=u2 --password1 --register-factor=2
 --plugin-authentication-webauthn-client-preserve-privacy
Enter password: (enter factor 1 password)
Enter PIN for token device:
Found following credentials for RP ID: mysql.com
[1]`u2`@`127.0.0.1`
[2]`u2`@`%`
Please select one(1...N):
1
```

```
Please insert FIDO device and perform gesture action for authentication to complete.
+-----+
| CURRENT_USER() |
+-----+
| u2@127.0.0.1 |
+-----+
```

The `--plugin-authentication-webauthn-client-preserve-privacy` option has no effect on FIDO devices that do not support the resident-key feature.

When the registration process is complete, the connection to the server is permitted.

#### Note

The connection to the server is permitted following registration regardless of additional authentication factors in the account's authentication chain. For example, if the account in the preceding example was defined with a third authentication factor (using non-WebAuthn authentication), the connection would be permitted after a successful registration without authenticating the third factor. However, subsequent connections would require authenticating all three factors.

## WebAuthn Passwordless Authentication

This section describes how WebAuthn can be used by itself to create 1FA accounts that authenticate in a passwordless manner. In this context, “passwordless” means that authentication occurs but uses a method other than a password, such as a security key or biometric scan. It does not refer to an account that uses a password-based authentication plugin for which the password is empty. That kind of “passwordless” is completely insecure and is not recommended.

The following prerequisites apply when using the `authentication_webauthn` plugin to achieve passwordless authentication:

- The user that creates a passwordless-authentication account requires the `PASSWORDLESS_USER_ADMIN` privilege in addition to the `CREATE USER` privilege.
- The first element of the `authentication_policy` value must be an asterisk (\*) and not a plugin name. For example, the default `authentication_policy` value supports enabling passwordless authentication because the first element is an asterisk:

```
authentication_policy='*,','
```

For information about configuring the `authentication_policy` value, see [Configuring the Multifactor Authentication Policy](#).

To use `authentication_webauthn` as a passwordless authentication method, the account must be created with `authentication_webauthn` as the first factor authentication method. The `INITIAL AUTHENTICATION IDENTIFIED BY` clause must also be specified for the first factor (it is not supported with 2nd or 3rd factors). This clause specifies whether a randomly generated or user-specified password will be used for FIDO/FIDO2 device registration. After device registration, the server deletes the password and modifies the account to make `authentication_webauthn` the sole authentication method (the 1FA method).

The required `CREATE USER` syntax is as follows:

```
CREATE USER user
 IDENTIFIED WITH authentication_webauthn
 INITIAL AUTHENTICATION IDENTIFIED BY {RANDOM PASSWORD | 'auth_string'};
```

The following example uses the `RANDOM PASSWORD` syntax:

```
mysql> CREATE USER 'u1'@'localhost'
IDENTIFIED WITH authentication_webauthn
INITIAL AUTHENTICATION IDENTIFIED BY RANDOM PASSWORD;
```

user	host	generated password	auth_factor
u1	localhost	9XHK]M{l2rnD;VXyHzeF	1

To perform registration, the user must authenticate to the server with the password associated with the `INITIAL AUTHENTICATION IDENTIFIED BY` clause, either the randomly generated password, or the `'auth_string'` value. If the account was created as just shown, the user executes this command and pastes in the preceding randomly generated password (`9XHK]M{l2rnD;VXyHzeF`) at the prompt:

```
$> mysql --user=u1 --password --register-factor=2
Enter password:
Please insert FIDO device and follow the instruction. Depending on the device,
you may have to perform gesture action multiple times.
1. Perform gesture action (Skip this step if you are prompted to enter device PIN).
2. Enter PIN for token device:
3. Perform gesture action for registration to complete.
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 10
```

Alternatively, use the `--plugin-authentication-webauthn-client-preserve-privacy` option to select a discoverable credential for authentication.

```
$> mysql --user=u1 --password --register-factor=2
--plugin-authentication-webauthn-client-preserve-privacy
Enter password:
Enter PIN for token device:
Found following credentials for RP ID: mysql.com
[1]'u1'@'127.0.0.1'
[2]'u1'@'%'
Please select one(1...N):
1
Please insert FIDO device and perform gesture action for authentication to complete.
```

CURRENT_USER()
u1@127.0.0.1

The option `--register-factor=2` is used because the `INITIAL AUTHENTICATION IDENTIFIED BY` clause is currently acting as the first factor authentication method. The user must therefore provide the temporary password by using the second factor. On a successful registration, the server removes the temporary password and revises the account entry in the `mysql.user` system table to list `authentication_webauthn` as the sole (1FA) authentication method.

When creating a passwordless-authentication account, it is important to include the `INITIAL AUTHENTICATION IDENTIFIED BY` clause in the `CREATE USER` statement. The server accepts a statement without the clause, but the resulting account is unusable because there is no way to connect to the server to register the device. Suppose that you execute a statement like this:

```
CREATE USER 'u2'@'localhost'
IDENTIFIED WITH authentication_webauthn;
```

Subsequent attempts to use the account to connect fail like this:

```
$> mysql --user=u2 --skip-password
mysql: [Warning] Using a password on the command line can be insecure.
No FIDO device on client host.
ERROR 1 (HY000): Unknown MySQL error
```

**Note**

Passwordless authentication is achieved using the Universal 2nd Factor (U2F) protocol, which does not support additional security measures such as setting a PIN on the device to be registered. It is therefore the responsibility of the device holder to ensure the device is handled in a secure manner.

## Device Unregistration for WebAuthn

It is possible to unregister FIDO/FIDO2 devices associated with a MySQL account. This might be desirable or necessary under multiple circumstances:

- A FIDO/FIDO2 device is to be replaced with a different device. The previous device must be unregistered and the new device registered.

In this case, the account owner or any user who has the `CREATE USER` privilege can unregister the device. The account owner can register the new device.

- A FIDO/FIDO2 device is reset or lost. Authentication attempts will fail until the current device is unregistered and a new registration is performed.

In this case, the account owner, being unable to authenticate, cannot unregister the current device and must contact the DBA (or any user who has the `CREATE USER` privilege) to do so. Then the account owner can reregister the reset device or register a new device.

Unregistering a FIDO/FIDO2 device can be done by the account owner or by any user who has the `CREATE USER` privilege. Use this syntax:

```
ALTER USER user {2 | 3} FACTOR UNREGISTER;
```

To re-register a device or perform a new registration, refer to the instructions in [Using WebAuthn Authentication](#).

## How WebAuthn Authentication of MySQL Users Works

This section provides an overview of how MySQL and WebAuthn work together to authenticate MySQL users. For examples showing how to set up MySQL accounts to use the WebAuthn authentication plugins, see [Using WebAuthn Authentication](#).

An account that uses WebAuthn authentication must perform an initial device registration step before it can connect to the server. After the device has been registered, authentication can proceed. WebAuthn device registration process is as follows:

1. The server sends a random challenge, user ID, and relying party ID (which uniquely identifies a server) to the client in JSON format. The relying party ID is defined by the `authentication_webauthn_rp_id` system variable. The default value is `mysql.com`.
2. The client receives that information and sends it to the client-side WebAuthn authentication plugin, which in turn provides it to the FIDO/FIDO2 device. Client also sends 1-byte capability, with `RESIDENT_KEYS` bit set to `ON` (if it is FIDO2 device) or `OFF`.
3. After the user has performed the appropriate device action (for example, touching the device or performing a biometric scan) the FIDO/FIDO2 device generates a public/private key pair, a key handle, an X.509 certificate, and a signature, which is returned to the server.
4. The server-side WebAuthn authentication plugin verifies the signature. With successful verification, the server stores the credential ID (for FIDO devices only) and public key in the `mysql.user` system table.

After registration has been performed successfully, WebAuthn authentication follows this process:

1. The server sends a random challenge, user ID, relying party ID and credentials to the client. The challenge is converted to URL-safe Base64 format.
2. The client sends the same information to the device. The client queries the device to check if it supports Client-to-Authenticator Protocols (CTAP2) protocol. CTAP2 support indicates that the device is FIDO2-protocol aware.
3. The FIDO/FIDO2 device prompts the user to perform the appropriate device action, based on the selection made during registration.

If the device is FIDO2-protocol aware, the device signs with all private keys available in the device for a given RP ID. Optionally, it may prompt user to pick one from the list as well. If the device is not FIDO2 capable, it fetches the right private key.

4. This action unlocks the private key and the challenge is signed.
5. This signed challenge is returned to the server.
6. The server-side WebAuthn authentication plugin verifies the signature with the public key and responds to indicate authentication success or failure.

#### 8.4.1.12 Test Pluggable Authentication

MySQL includes a test plugin that checks account credentials and logs success or failure to the server error log. This is a loadable plugin (not built in) and must be installed prior to use.

The test plugin source code is separate from the server source, unlike the built-in native plugin, so it can be examined as a relatively simple example demonstrating how to write a loadable authentication plugin.

#### Note

This plugin is intended for testing and development purposes, and is not for use in production environments or on servers that are exposed to public networks.

The following table shows the plugin and library file names. The file name suffix might differ on your system. The file must be located in the directory named by the `plugin_dir` system variable.

**Table 8.27 Plugin and Library Names for Test Authentication**

Plugin or File	Plugin or File Name
Server-side plugin	<code>test_plugin_server</code>
Client-side plugin	<code>auth_test_plugin</code>
Library file	<code>auth_test_plugin.so</code>

The following sections provide installation and usage information specific to test pluggable authentication:

- [Installing Test Pluggable Authentication](#)
- [Uninstalling Test Pluggable Authentication](#)
- [Using Test Pluggable Authentication](#)

For general information about pluggable authentication in MySQL, see [Section 8.2.17, “Pluggable Authentication”](#).

## Installing Test Pluggable Authentication

This section describes how to install the server-side test authentication plugin. For general information about installing plugins, see [Section 7.6.1, “Installing and Uninstalling Plugins”](#).

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

To load the plugin at server startup, use the `--plugin-load-add` option to name the library file that contains it. With this plugin-loading method, the option must be given each time the server starts. For example, put these lines in the server `my.cnf` file, adjusting the `.so` suffix for your platform as necessary:

```
[mysqld]
plugin-load-add=auth_test_plugin.so
```

After modifying `my.cnf`, restart the server to cause the new settings to take effect.

Alternatively, to load the plugin at runtime, use this statement, adjusting the `.so` suffix for your platform as necessary:

```
INSTALL PLUGIN test_plugin_server SONAME 'auth_test_plugin.so';
```

`INSTALL PLUGIN` loads the plugin immediately, and also registers it in the `mysql.plugins` system table to cause the server to load it for each subsequent normal startup without the need for `--plugin-load-add`.

To verify plugin installation, examine the Information Schema `PLUGINS` table or use the `SHOW PLUGINS` statement (see [Section 7.6.2, “Obtaining Server Plugin Information”](#)). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
 FROM INFORMATION_SCHEMA.PLUGINS
 WHERE PLUGIN_NAME LIKE '%test_plugin%';
+-----+-----+
| PLUGIN_NAME | PLUGIN_STATUS |
+-----+-----+
| test_plugin_server | ACTIVE |
+-----+-----+
```

If the plugin fails to initialize, check the server error log for diagnostic messages.

To associate MySQL accounts with the test plugin, see [Using Test Pluggable Authentication](#).

## Uninstalling Test Pluggable Authentication

The method used to uninstall the test authentication plugin depends on how you installed it:

- If you installed the plugin at server startup using a `--plugin-load-add` option, restart the server without the option.
- If you installed the plugin at runtime using an `INSTALL PLUGIN` statement, it remains installed across server restarts. To uninstall it, use `UNINSTALL PLUGIN`:

```
UNINSTALL PLUGIN test_plugin_server;
```

## Using Test Pluggable Authentication

To use the test authentication plugin, create an account and name that plugin in the `IDENTIFIED WITH` clause:

```
CREATE USER 'testuser'@'localhost'
IDENTIFIED WITH test_plugin_server
BY 'testpassword';
```

The test authentication plugin also requires creating a proxy user as follows:

```
CREATE USER testpassword@localhost;
GRANT PROXY ON testpassword@localhost TO testuser@localhost;
```

Then provide the `--user` and `--password` options for that account when you connect to the server. For example:

```
$> mysql --user=testuser --password
Enter password: testpassword
```

The plugin fetches the password as received from the client and compares it with the value stored in the `authentication_string` column of the account row in the `mysql.user` system table. If the two values match, the plugin returns the `authentication_string` value as the new effective user ID.

You can look in the server error log for a message indicating whether authentication succeeded (notice that the password is reported as the “user”):

```
[Note] Plugin test_plugin_server reported:
'successfully authenticated user testpassword'
```

### 8.4.1.13 Pluggable Authentication System Variables

These variables are unavailable unless the appropriate server-side plugin is installed:

- `authentication_ldap_sasl` for system variables with names of the form `authentication_ldap_sasl_xxx`
- `authentication_ldap_simple` for system variables with names of the form `authentication_ldap_simple_xxx`

**Table 8.28 Authentication Plugin System Variable Summary**

Name	Cmd-Line	Option File	System Var	Status Var	Var Scope	Dynamic
<code>authentication_ldap_sasl_key_tab</code>	Yes	Yes	Yes		Global	No
<code>authentication_ldap_sasl_principal</code>	Yes	Yes	Yes		Global	Yes

- authentication\_kerberos\_service\_key\_tab

Command-Line Format	--authentication-kerberos-service-key-tab=file_name
System Variable	authentication_kerberos_service_key_tab
Scope	Global
Dynamic	No
SET_VAR Hint Applies	No
Type	File name
Default Value	datadir/mysql.keytab

The name of the server-side key-table (“keytab”) file containing Kerberos service keys to authenticate MySQL service tickets received from clients. The file name should be given as an absolute path name. If this variable is not set, the default is `mysql.keytab` in the data directory.

The file must exist and contain a valid key for the service principal name (SPN) or authentication of clients will fail. (The SPN and same key also must be created in the Kerberos server.) The file may contain multiple service principal names and their respective key combinations.

The file must be generated by the Kerberos server administrator and be copied to a location accessible by the MySQL server. The file can be validated to make sure that it is correct and was copied properly using this command:

```
klist -k file_name
```

For information about keytab files, see [https://web.mit.edu/kerberos/krb5-latest/doc/basic/keytab\\_def.html](https://web.mit.edu/kerberos/krb5-latest/doc/basic/keytab_def.html).

- `authentication_kerberos_service_principal`

Command-Line Format	<code>--authentication-kerberos-service-principal=name</code>
System Variable	<code>authentication_kerberos_service_principal</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value	<code>mysql/host_name@realm_name</code>

The Kerberos service principal name (SPN) that the MySQL server sends to clients.

The value is composed from the service name (`mysql`), a host name, and a realm name. The default value is `mysql/host_name@realm_name`. The realm in the service principal name enables retrieving the exact service key.

To use a nondefault value, set the value using the same format. For example, to use a host name of `krbauth.example.com` and a realm of `MYSQL.LOCAL`, set `authentication_kerberos_service_principal` to `mysql/krbauth.example.com@MYSQL.LOCAL`.

The service principal name and service key must already be present in the database managed by the KDC server.

There can be service principal names that differ only by realm name.

- `authentication_ldap_sasl_auth_method_name`

Command-Line Format	<code>--authentication-ldap-sasl-auth-method-name=value</code>
System Variable	<code>authentication_ldap_sasl_auth_method_name</code>
Scope	Global
Dynamic	Yes

<a href="#">SET_VAR</a> Hint Applies	No
Type	String
Default Value	<a href="#">SCRAM-SHA-1</a>
Valid Values	<a href="#">SCRAM-SHA-1</a> <a href="#">SCRAM-SHA-256</a> <a href="#">GSSAPI</a>

For SASL LDAP authentication, the authentication method name. Communication between the authentication plugin and the LDAP server occurs according to this authentication method to ensure password security.

These authentication method values are permitted:

- [SCRAM-SHA-1](#): Use a SASL challenge-response mechanism.

The client-side [authentication\\_ldap\\_sasl\\_client](#) plugin communicates with the SASL server, using the password to create a challenge and obtain a SASL request buffer, then passes this buffer to the server-side [authentication\\_ldap\\_sasl](#) plugin. The client-side and server-side SASL LDAP plugins use SASL messages for secure transmission of credentials within the LDAP protocol, to avoid sending the cleartext password between the MySQL client and server.

- [SCRAM-SHA-256](#): Use a SASL challenge-response mechanism.

This method is similar to [SCRAM-SHA-1](#), but is more secure. It requires an OpenLDAP server built using Cyrus SASL 2.1.27 or higher.

- [GSSAPI](#): Use Kerberos, a passwordless and ticket-based protocol.

GSSAPI/Kerberos is supported as an authentication method for MySQL clients and servers only on Linux. It is useful in Linux environments where applications access LDAP using Microsoft Active Directory, which has Kerberos enabled by default.

The client-side [authentication\\_ldap\\_sasl\\_client](#) plugin obtains a service ticket using the ticket-granting ticket (TGT) from Kerberos, but does not use LDAP services directly. The server-side [authentication\\_ldap\\_sasl](#) plugin routes Kerberos messages between the client-side plugin and the LDAP server. Using the credentials thus obtained, the server-side plugin then communicates with the LDAP server to interpret LDAP authentication messages and retrieve LDAP groups.

- [authentication\\_ldap\\_sasl\\_bind\\_base\\_dn](#)

Command-Line Format	<a href="#">--authentication-ldap-sasl-bind-base-dn=value</a>
System Variable	<a href="#">authentication_ldap_sasl_bind_base_dn</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	String

Default Value	NULL
---------------	------

For SASL LDAP authentication, the base distinguished name (DN). This variable can be used to limit the scope of searches by anchoring them at a certain location (the “base”) within the search tree.

Suppose that members of one set of LDAP user entries each have this form:

```
uid=user_name,ou=People,dc=example,dc=com
```

And that members of another set of LDAP user entries each have this form:

```
uid=user_name,ou=Admin,dc=example,dc=com
```

Then searches work like this for different base DN values:

- If the base DN is `ou=People,dc=example,dc=com`: Searches find user entries only in the first set.
- If the base DN is `ou=Admin,dc=example,dc=com`: Searches find user entries only in the second set.
- If the base DN is `ou=dc=example,dc=com`: Searches find user entries in the first or second set.

In general, more specific base DN values result in faster searches because they limit the search scope more.

- `authentication_ldap_sasl_bind_root_dn`

Command-Line Format	<code>--authentication-ldap-sasl-bind-root-dn=value</code>
System Variable	<code>authentication_ldap_sasl_bind_root_dn</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value	NULL

For SASL LDAP authentication, the root distinguished name (DN). This variable is used in conjunction with `authentication_ldap_sasl_bind_root_pwd` as the credentials for authenticating to the LDAP server for the purpose of performing searches. Authentication uses either one or two LDAP bind operations, depending on whether the MySQL account names an LDAP user DN:

- If the account does not name a user DN: `authentication_ldap_sasl` performs an initial LDAP binding using `authentication_ldap_sasl_bind_root_dn` and `authentication_ldap_sasl_bind_root_pwd`. (These are both empty by default, so if they are not set, the LDAP server must permit anonymous connections.) The resulting bind LDAP handle is used to search for the user DN, based on the client user name. `authentication_ldap_sasl` performs a second bind using the user DN and client-supplied password.
- If the account does name a user DN: The first bind operation is unnecessary in this case. `authentication_ldap_sasl` performs a single bind using the user DN and client-supplied password. This is faster than if the MySQL account does not specify an LDAP user DN.

- `authentication_ldap_sasl_bind_root_pwd`

Command-Line Format	<code>--authentication-ldap-sasl-bind-root-pwd=value</code>
System Variable	<code>authentication_ldap_sasl_bind_root_pwd</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value	<code>NULL</code>

For SASL LDAP authentication, the password for the root distinguished name. This variable is used in conjunction with `authentication_ldap_sasl_bind_root_dn`. See the description of that variable.

- `authentication_ldap_sasl_ca_path`

Command-Line Format	<code>--authentication-ldap-sasl-ca-path=value</code>
System Variable	<code>authentication_ldap_sasl_ca_path</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value	<code>NULL</code>

For SASL LDAP authentication, the absolute path of the certificate authority file. Specify this file if it is desired that the authentication plugin perform verification of the LDAP server certificate.

#### Note

In addition to setting the `authentication_ldap_sasl_ca_path` variable to the file name, you must add the appropriate certificate authority certificates to the file and enable the `authentication_ldap_sasl_tls` system variable. These variables can be set to override the default OpenLDAP TLS configuration; see [LDAP Pluggable Authentication and ldap.conf](#)

- `authentication_ldap_sasl_connect_timeout`

Command-Line Format	<code>--authentication-ldap-sasl-connect-timeout=#</code>
System Variable	<code>authentication_ldap_sasl_connect_timeout</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	<code>30</code>
Minimum Value	<code>0</code>

Maximum Value	31536000
Unit	seconds

Specifies the time (in seconds) that MySQL server waits to connect to the LDAP server using TCP.

When a MySQL account authenticates using LDAP, MySQL server attempts to establish a TCP connection with the LDAP server, which it uses to send an LDAP bind request over the connection. If the LDAP server does not respond to TCP handshake after a configured amount of time, MySQL abandons the TCP handshake attempt and emits an error message. If the timeout setting is zero, MySQL server ignores this system variable setting. For more information, see [Setting Timeouts for LDAP Pluggable Authentication](#).

#### Note

If you set this variable to a timeout value that is greater than the host system's default value, the shorter system timeout is used.

- [authentication\\_ldap\\_sasl\\_group\\_search\\_attr](#)

Command-Line Format	<code>--authentication-ldap-sasl-group-search-attr=value</code>
System Variable	<a href="#">authentication_ldap_sasl_group_search_attr</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	String
Default Value	<code>cn</code>

For SASL LDAP authentication, the name of the attribute that specifies group names in LDAP directory entries. If [authentication\\_ldap\\_sasl\\_group\\_search\\_attr](#) has its default value of `cn`, searches return the `cn` value as the group name. For example, if an LDAP entry with a `uid` value of `user1` has a `cn` attribute of `mygroup`, searches for `user1` return `mygroup` as the group name.

This variable should be the empty string if you want no group or proxy authentication.

If the group search attribute is `isMemberOf`, LDAP authentication directly retrieves the user attribute `isMemberOf` value and assigns it as group information. If the group search attribute is not `isMemberOf`, LDAP authentication searches for all groups where the user is a member. (The latter is the default behavior.) This behavior is based on how LDAP group information can be stored two ways: 1) A group entry can have an attribute named `memberUid` or `member` with a value that is a user name; 2) A user entry can have an attribute named `isMemberOf` with values that are group names.

- [authentication\\_ldap\\_sasl\\_group\\_search\\_filter](#)

Command-Line Format	<code>--authentication-ldap-sasl-group-search-filter=value</code>
System Variable	<a href="#">authentication_ldap_sasl_group_search_filter</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No

Type	String
Default Value	<code>(   (&amp;(objectClass=posixGroup) (memberUid=%s) (&amp;(objectClass=group) (member=%s)))</code>

For SASL LDAP authentication, the custom group search filter.

The search filter value can contain `{UA}` and `{UD}` notation to represent the user name and the full user DN. For example, `{UA}` is replaced with a user name such as `"admin"`, whereas `{UD}` is replaced with a use full DN such as `"uid=admin,ou=People,dc=example,dc=com"`. The following value is the default, which supports both OpenLDAP and Active Directory:

```
(| (&(objectClass=posixGroup)(memberUid={UA}))
(&(objectClass=group)(member={UD})))
```

In some cases for the user scenario, `memberOf` is a simple user attribute that holds no group information. For additional flexibility, an optional `{GA}` prefix can be used with the group search attribute. Any group attribute with a `{GA}` prefix is treated as a user attribute having group names. For example, with a value of `{GA}memberOf`, if the group value is the DN, the first attribute value from the group DN is returned as the group name.

- `authentication_ldap_sasl_init_pool_size`

Command-Line Format	<code>--authentication-ldap-sasl-init-pool-size=#</code>
System Variable	<code>authentication_ldap_sasl_init_pool_size</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	10
Minimum Value	0
Maximum Value	32767
Unit	connections

For SASL LDAP authentication, the initial size of the pool of connections to the LDAP server. Choose the value for this variable based on the average number of concurrent authentication requests to the LDAP server.

The plugin uses `authentication_ldap_sasl_init_pool_size` and `authentication_ldap_sasl_max_pool_size` together for connection-pool management:

- When the authentication plugin initializes, it creates `authentication_ldap_sasl_init_pool_size` connections, unless `authentication_ldap_sasl_max_pool_size=0` to disable pooling.
- If the plugin receives an authentication request when there are no free connections in the current connection pool, the plugin can create a new connection, up to the maximum connection pool size given by `authentication_ldap_sasl_max_pool_size`.

- If the plugin receives a request when the pool size is already at its maximum and there are no free connections, authentication fails.
- When the plugin unloads, it closes all pooled connections.

Changes to plugin system variable settings may have no effect on connections already in the pool. For example, modifying the LDAP server host, port, or TLS settings does not affect existing connections. However, if the original variable values were invalid and the connection pool could not be initialized, the plugin attempts to reinitialize the pool for the next LDAP request. In this case, the new system variable values are used for the reinitialization attempt.

If `authentication_ldap_sasl_max_pool_size=0` to disable pooling, each LDAP connection opened by the plugin uses the values the system variables have at that time.

- `authentication_ldap_sasl_log_status`

Command-Line Format	<code>--authentication-ldap-sasl-log-status=#</code>
System Variable	<code>authentication_ldap_sasl_log_status</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	1
Minimum Value	1
Maximum Value	6

For SASL LDAP authentication, the logging level for messages written to the error log. The following table shows the permitted level values and their meanings.

**Table 8.29 Log Levels for `authentication_ldap_sasl_log_status`**

Option Value	Types of Messages Logged
1	No messages
2	Error messages
3	Error and warning messages
4	Error, warning, and information messages
5	Same as previous level plus debugging messages from MySQL

Option Value	Types of Messages Logged
6	Same as previous level plus debugging messages from LDAP library

On the client side, messages can be logged to the standard output by setting the [AUTHENTICATION\\_LDAP\\_CLIENT\\_LOG](#) environment variable. The permitted and default values are the same as for [authentication\\_ldap\\_sasl\\_log\\_status](#).

The [AUTHENTICATION\\_LDAP\\_CLIENT\\_LOG](#) environment variable applies only to SASL LDAP authentication. It has no effect for simple LDAP authentication because the client plugin in that case is [mysql\\_clear\\_password](#), which knows nothing about LDAP operations.

- [authentication\\_ldap\\_sasl\\_max\\_pool\\_size](#)

Command-Line Format	<code>--authentication-ldap-sasl-max-pool-size=#</code>
System Variable	<a href="#">authentication_ldap_sasl_max_pool_size</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	1000
Minimum Value	0
Maximum Value	32767
Unit	connections

For SASL LDAP authentication, the maximum size of the pool of connections to the LDAP server. To disable connection pooling, set this variable to 0.

This variable is used in conjunction with [authentication\\_ldap\\_sasl\\_init\\_pool\\_size](#). See the description of that variable.

- [authentication\\_ldap\\_sasl\\_referral](#)

Command-Line Format	<code>--authentication-ldap-sasl-referral[={OFF ON}]</code>
System Variable	<a href="#">authentication_ldap_sasl_referral</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Boolean
Default Value	OFF

For SASL LDAP authentication, whether to enable LDAP search referral. See [LDAP Search Referral](#).

This variable can be set to override the default OpenLDAP referral configuration; see [LDAP Pluggable Authentication and ldap.conf](#)

- `authentication_ldap_sasl_response_timeout`

Command-Line Format	<code>--authentication-ldap-sasl-response-timeout=#</code>
System Variable	<code>authentication_ldap_sasl_response_timeout</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	30
Minimum Value	0
Maximum Value	31536000
Unit	seconds

Specifies the time (in seconds) that MySQL server waits for the LDAP server to response to an LDAP bind request.

When a MySQL account authenticates using LDAP, MySQL server sends an LDAP bind request to the LDAP server. If the LDAP server does not respond to the request after a configured amount of time, MySQL abandons the request and emits an error message. If the timeout setting is zero, MySQL server ignores this system variable setting. For more information, see [Setting Timeouts for LDAP Pluggable Authentication](#).

- `authentication_ldap_sasl_server_host`

Command-Line Format	<code>--authentication-ldap-sasl-server-host=host_name</code>
System Variable	<code>authentication_ldap_sasl_server_host</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String

For SASL LDAP authentication, the LDAP server host. The permitted values for this variable depend on the authentication method:

- For `authentication_ldap_sasl_auth_method_name=SCRAM-SHA-1`: The LDAP server host can be a host name or IP address.
- For `authentication_ldap_sasl_auth_method_name=SCRAM-SHA-256`: The LDAP server host can be a host name or IP address.
- `authentication_ldap_sasl_server_port`

Command-Line Format	<code>--authentication-ldap-sasl-server-port=port_num</code>
System Variable	<code>authentication_ldap_sasl_server_port</code>
Scope	Global

Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	389
Minimum Value	1
Maximum Value	32376

For SASL LDAP authentication, the LDAP server TCP/IP port number.

If the LDAP port number is configured as 636 or 3269, the plugin uses LDAPS (LDAP over SSL) instead of LDAP. (LDAPS differs from [startTLS](#).)

- [authentication\\_ldap\\_sasl\\_tls](#)

Command-Line Format	<code>--authentication-ldap-sasl-tls[={OFF ON}]</code>
System Variable	<a href="#">authentication_ldap_sasl_tls</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Boolean
Default Value	OFF

For SASL LDAP authentication, whether connections by the plugin to the LDAP server are secure. If this variable is enabled, the plugin uses TLS to connect securely to the LDAP server. This variable can be set to override the default OpenLDAP TLS configuration; see [LDAP Pluggable Authentication and ldap.conf](#). If you enable this variable, you may also wish to set the [authentication\\_ldap\\_sasl\\_ca\\_path](#) variable.

MySQL LDAP plugins support the StartTLS method, which initializes TLS on top of a plain LDAP connection.

LDAPS can be used by setting the [authentication\\_ldap\\_sasl\\_server\\_port](#) system variable.

- [authentication\\_ldap\\_sasl\\_user\\_search\\_attr](#)

Command-Line Format	<code>--authentication-ldap-sasl-user-search-attr=value</code>
System Variable	<a href="#">authentication_ldap_sasl_user_search_attr</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	String
Default Value	uid

For SASL LDAP authentication, the name of the attribute that specifies user names in LDAP directory entries. If a user distinguished name is not provided, the authentication plugin searches for the name

using this attribute. For example, if the `authentication_ldap_sasl_user_search_attr` value is `uid`, a search for the user name `user1` finds entries with a `uid` value of `user1`.

- `authentication_ldap_simple_auth_method_name`

Command-Line Format	<code>--authentication-ldap-simple-auth-method-name=value</code>
System Variable	<code>authentication_ldap_simple_auth_method_name</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value	<code>SIMPLE</code>
Valid Values	<code>SIMPLE</code> <code>AD-FOREST</code>

For simple LDAP authentication, the authentication method name. Communication between the authentication plugin and the LDAP server occurs according to this authentication method.

#### Note

For all simple LDAP authentication methods, it is recommended to also set TLS parameters to require that communication with the LDAP server take place over secure connections.

These authentication method values are permitted:

- `SIMPLE`: Use simple LDAP authentication. This method uses either one or two LDAP bind operations, depending on whether the MySQL account names an LDAP user distinguished name. See the description of `authentication_ldap_simple_bind_root_dn`.
- `AD-FOREST`: A variation on `SIMPLE`, such that authentication searches all domains in the Active Directory forest, performing an LDAP bind to each Active Directory domain until the user is found in some domain.
- `authentication_ldap_simple_bind_base_dn`

Command-Line Format	<code>--authentication-ldap-simple-bind-base-dn=value</code>
System Variable	<code>authentication_ldap_simple_bind_base_dn</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String

Default Value	NULL
---------------	------

For simple LDAP authentication, the base distinguished name (DN). This variable can be used to limit the scope of searches by anchoring them at a certain location (the “base”) within the search tree.

Suppose that members of one set of LDAP user entries each have this form:

```
uid=user_name,ou=People,dc=example,dc=com
```

And that members of another set of LDAP user entries each have this form:

```
uid=user_name,ou=Admin,dc=example,dc=com
```

Then searches work like this for different base DN values:

- If the base DN is `ou=People,dc=example,dc=com`: Searches find user entries only in the first set.
- If the base DN is `ou=Admin,dc=example,dc=com`: Searches find user entries only in the second set.
- If the base DN is `ou=dc=example,dc=com`: Searches find user entries in the first or second set.

In general, more specific base DN values result in faster searches because they limit the search scope more.

- `authentication_ldap_simple_bind_root_dn`

Command-Line Format	<code>--authentication-ldap-simple-bind-root-dn=value</code>
System Variable	<code>authentication_ldap_simple_bind_root_dn</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value	NULL

For simple LDAP authentication, the root distinguished name (DN). This variable is used in conjunction with `authentication_ldap_simple_bind_root_pwd` as the credentials for authenticating to the LDAP server for the purpose of performing searches. Authentication uses either one or two LDAP bind operations, depending on whether the MySQL account names an LDAP user DN:

- If the account does not name a user DN: `authentication_ldap_simple` performs an initial LDAP binding using `authentication_ldap_simple_bind_root_dn` and `authentication_ldap_simple_bind_root_pwd`. (These are both empty by default, so if they are not set, the LDAP server must permit anonymous connections.) The resulting bind LDAP handle is used to search for the user DN, based on the client user name. `authentication_ldap_simple` performs a second bind using the user DN and client-supplied password.
- If the account does name a user DN: The first bind operation is unnecessary in this case. `authentication_ldap_simple` performs a single bind using the user DN and client-supplied password. This is faster than if the MySQL account does not specify an LDAP user DN.

- `authentication_ldap_simple_bind_root_pwd`

Command-Line Format	<code>--authentication-ldap-simple-bind-root-pwd=value</code>
System Variable	<code>authentication_ldap_simple_bind_root_pwd</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value	<code>NULL</code>

For simple LDAP authentication, the password for the root distinguished name. This variable is used in conjunction with `authentication_ldap_simple_bind_root_dn`. See the description of that variable.

- `authentication_ldap_simple_ca_path`

Command-Line Format	<code>--authentication-ldap-simple-ca-path=value</code>
System Variable	<code>authentication_ldap_simple_ca_path</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value	<code>NULL</code>

For simple LDAP authentication, the absolute path of the certificate authority file. Specify this file if it is desired that the authentication plugin perform verification of the LDAP server certificate.

#### Note

In addition to setting the `authentication_ldap_simple_ca_path` variable to the file name, you must add the appropriate certificate authority certificates to the file and enable the `authentication_ldap_simple_tls` system variable. These variables can be set to override the default OpenLDAP TLS configuration; see [LDAP Pluggable Authentication and ldap.conf](#)

- `authentication_ldap_simple_connect_timeout`

Command-Line Format	<code>--authentication-ldap-simple-connect-timeout=#</code>
System Variable	<code>authentication_ldap_simple_connect_timeout</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	<code>30</code>

Minimum Value	0
Maximum Value	31536000
Unit	seconds

Specifies the time (in seconds) that MySQL server waits to connect to the LDAP server using TCP.

When a MySQL account authenticates using LDAP, MySQL server attempts to establish a TCP connection with the LDAP server, which it uses to send an LDAP bind request over the connection. If the LDAP server does not respond to TCP handshake after a configured amount of time, MySQL abandons the TCP handshake attempt and emits an error message. If the timeout setting is zero, MySQL server ignores this system variable setting. For more information, see [Setting Timeouts for LDAP Pluggable Authentication](#).

#### Note

If you set this variable to a timeout value that is greater than the host system's default value, the shorter system timeout is used.

- [authentication\\_ldap\\_simple\\_group\\_search\\_attr](#)

Command-Line Format	<code>--authentication-ldap-simple-group-search-attr=value</code>
System Variable	<a href="#">authentication_ldap_simple_group_search_attr</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	String
Default Value	<code>cn</code>

For simple LDAP authentication, the name of the attribute that specifies group names in LDAP directory entries. If [authentication\\_ldap\\_simple\\_group\\_search\\_attr](#) has its default value of `cn`, searches return the `cn` value as the group name. For example, if an LDAP entry with a `uid` value of `user1` has a `cn` attribute of `mygroup`, searches for `user1` return `mygroup` as the group name.

If the group search attribute is `isMemberOf`, LDAP authentication directly retrieves the user attribute `isMemberOf` value and assigns it as group information. If the group search attribute is not `isMemberOf`, LDAP authentication searches for all groups where the user is a member. (The latter is the default behavior.) This behavior is based on how LDAP group information can be stored two ways: 1) A group entry can have an attribute named `memberUid` or `member` with a value that is a user name; 2) A user entry can have an attribute named `isMemberOf` with values that are group names.

- [authentication\\_ldap\\_simple\\_group\\_search\\_filter](#)

Command-Line Format	<code>--authentication-ldap-simple-group-search-filter=value</code>
System Variable	<a href="#">authentication_ldap_simple_group_search_filt</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	String

Default Value	<code>(   (&amp;(objectClass=posixGroup) (memberUid=%s) (&amp;(objectClass=group) (member=%s) ) )</code>
---------------	----------------------------------------------------------------------------------------------------------

For simple LDAP authentication, the custom group search filter.

The search filter value can contain `{UA}` and `{UD}` notation to represent the user name and the full user DN. For example, `{UA}` is replaced with a user name such as "admin", whereas `{UD}` is replaced with a use full DN such as "uid=admin,ou=People,dc=example,dc=com". The following value is the default, which supports both OpenLDAP and Active Directory:

```
(| (&(objectClass=posixGroup) (memberUid={UA}))
 (&(objectClass=group) (member={UD})))
```

In some cases for the user scenario, `memberOf` is a simple user attribute that holds no group information. For additional flexibility, an optional `{GA}` prefix can be used with the group search attribute. Any group attribute with a `{GA}` prefix is treated as a user attribute having group names. For example, with a value of `{GA}MemberOf`, if the group value is the DN, the first attribute value from the group DN is returned as the group name.

- `authentication_ldap_simple_init_pool_size`

Command-Line Format	<code>--authentication-ldap-simple-init-pool-size=#</code>
System Variable	<code>authentication_ldap_simple_init_pool_size</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	10
Minimum Value	0
Maximum Value	32767
Unit	connections

For simple LDAP authentication, the initial size of the pool of connections to the LDAP server. Choose the value for this variable based on the average number of concurrent authentication requests to the LDAP server.

The plugin uses `authentication_ldap_simple_init_pool_size` and `authentication_ldap_simple_max_pool_size` together for connection-pool management:

- When the authentication plugin initializes, it creates `authentication_ldap_simple_init_pool_size` connections, unless `authentication_ldap_simple_max_pool_size=0` to disable pooling.
- If the plugin receives an authentication request when there are no free connections in the current connection pool, the plugin can create a new connection, up to the maximum connection pool size given by `authentication_ldap_simple_max_pool_size`.
- If the plugin receives a request when the pool size is already at its maximum and there are no free connections, authentication fails.

- When the plugin unloads, it closes all pooled connections.

Changes to plugin system variable settings may have no effect on connections already in the pool. For example, modifying the LDAP server host, port, or TLS settings does not affect existing connections. However, if the original variable values were invalid and the connection pool could not be initialized, the plugin attempts to reinitialize the pool for the next LDAP request. In this case, the new system variable values are used for the reinitialization attempt.

If `authentication_ldap_simple_max_pool_size=0` to disable pooling, each LDAP connection opened by the plugin uses the values the system variables have at that time.

- `authentication_ldap_simple_log_status`

Command-Line Format	<code>--authentication-ldap-simple-log-status=#</code>
System Variable	<code>authentication_ldap_simple_log_status</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	1
Minimum Value	1
Maximum Value	6

For simple LDAP authentication, the logging level for messages written to the error log. The following table shows the permitted level values and their meanings.

**Table 8.30 Log Levels for `authentication_ldap_simple_log_status`**

Option Value	Types of Messages Logged
1	No messages
2	Error messages
3	Error and warning messages
4	Error, warning, and information messages
5	Same as previous level plus debugging messages from MySQL
6	Same as previous level plus debugging messages from LDAP library

- `authentication_ldap_simple_max_pool_size`

Command-Line Format	<code>--authentication-ldap-simple-max-pool-size=#</code>
System Variable	<code>authentication_ldap_simple_max_pool_size</code>
Scope	Global
Dynamic	Yes

<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	1000
Minimum Value	0
Maximum Value	32767
Unit	connections

For simple LDAP authentication, the maximum size of the pool of connections to the LDAP server. To disable connection pooling, set this variable to 0.

This variable is used in conjunction with [authentication\\_ldap\\_simple\\_init\\_pool\\_size](#). See the description of that variable.

- [authentication\\_ldap\\_simple\\_referral](#)

Command-Line Format	<code>--authentication-ldap-simple-referral[={OFF ON}]</code>
System Variable	<a href="#">authentication_ldap_simple_referral</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Boolean
Default Value	OFF

For simple LDAP authentication, whether to enable LDAP search referral. See [LDAP Search Referral](#).

- [authentication\\_ldap\\_simple\\_response\\_timeout](#)

Command-Line Format	<code>--authentication-ldap-simple-response-timeout=#</code>
System Variable	<a href="#">authentication_ldap_simple_response_timeout</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Integer
Default Value	30
Minimum Value	0
Maximum Value	31536000
Unit	seconds

Specifies the time (in seconds) that MySQL server waits for the LDAP server to response to an LDAP bind request.

When a MySQL account authenticates using LDAP, MySQL server sends an LDAP bind request to the LDAP server. If the LDAP server does not respond to the request after a configured amount of time, MySQL abandons the request and emits an error message. If the timeout setting is zero, MySQL server

ignores this system variable setting. For more information, see [Setting Timeouts for LDAP Pluggable Authentication](#).

- `authentication_ldap_simple_server_host`

Command-Line Format	<code>--authentication-ldap-simple-server-host=host_name</code>
System Variable	<code>authentication_ldap_simple_server_host</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String

For simple LDAP authentication, the LDAP server host. The permitted values for this variable depend on the authentication method:

- For `authentication_ldap_simple_auth_method_name=SIMPLE`: The LDAP server host can be a host name or IP address.
- For `authentication_ldap_simple_auth_method_name=AD-FOREST`: The LDAP server host can be an Active Directory domain name. For example, for an LDAP server URL of `ldap://example.mem.local:389`, the domain name can be `mem.local`.

An Active Directory forest setup can have multiple domains (LDAP server IPs), which can be discovered using DNS. On Unix and Unix-like systems, some additional setup may be required to configure your DNS server with SRV records that specify the LDAP servers for the Active Directory domain. For information about DNS SRV, see [RFC 2782](#).

Suppose that your configuration has these properties:

- The name server that provides information about Active Directory domains has IP address `10.172.166.100`.
- The LDAP servers have names `ldap1.mem.local` through `ldap3.mem.local` and IP addresses `10.172.166.101` through `10.172.166.103`.

You want the LDAP servers to be discoverable using SRV searches. For example, at the command line, a command like this should list the LDAP servers:

```
host -t SRV _ldap._tcp.mem.local
```

Perform the DNS configuration as follows:

1. Add a line to `/etc/resolv.conf` to specify the name server that provides information about Active Directory domains:

```
nameserver 10.172.166.100
```

2. Configure the appropriate zone file for the name server with SRV records for the LDAP servers:

```
_ldap._tcp.mem.local. 86400 IN SRV 0 100 389 ldap1.mem.local.
_ldap._tcp.mem.local. 86400 IN SRV 0 100 389 ldap2.mem.local.
```

```
_ldap._tcp.mem.local. 86400 IN SRV 0 100 389 ldap3.mem.local.
```

- It may also be necessary to specify the IP address for the LDAP servers in `/etc/hosts` if the server host cannot be resolved. For example, add lines like this to the file:

```
10.172.166.101 ldap1.mem.local
10.172.166.102 ldap2.mem.local
10.172.166.103 ldap3.mem.local
```

With the DNS configured as just described, the server-side LDAP plugin can discover the LDAP servers and tries to authenticate in all domains until authentication succeeds or there are no more servers.

Windows needs no such settings as just described. Given the LDAP server host in the `authentication_ldap_simple_server_host` value, the Windows LDAP library searches all domains and attempts to authenticate.

- `authentication_ldap_simple_server_port`

Command-Line Format	<code>--authentication-ldap-simple-server-port=port_num</code>
System Variable	<code>authentication_ldap_simple_server_port</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	389
Minimum Value	1
Maximum Value	32376

For simple LDAP authentication, the LDAP server TCP/IP port number.

If the LDAP port number is configured as 636 or 3269, the plugin uses LDAPS (LDAP over SSL) instead of LDAP. (LDAPS differs from `startTLS`.)

- `authentication_ldap_simple_tls`

Command-Line Format	<code>--authentication-ldap-simple-tls[={OFF ON}]</code>
System Variable	<code>authentication_ldap_simple_tls</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	OFF

For simple LDAP authentication, whether connections by the plugin to the LDAP server are secure. If this variable is enabled, the plugin uses TLS to connect securely to the LDAP server. This variable can be set to override the default OpenLDAP TLS configuration; see [LDAP](#)

[Pluggable Authentication and ldap.conf](#) If you enable this variable, you may also wish to set the `authentication_ldap_simple_ca_path` variable.

MySQL LDAP plugins support the StartTLS method, which initializes TLS on top of a plain LDAP connection.

LDAPS can be used by setting the `authentication_ldap_simple_server_port` system variable.

- `authentication_ldap_simple_user_search_attr`

Command-Line Format	<code>--authentication-ldap-simple-user-search-attr=value</code>
System Variable	<code>authentication_ldap_simple_user_search_attr</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value	<code>uid</code>

For simple LDAP authentication, the name of the attribute that specifies user names in LDAP directory entries. If a user distinguished name is not provided, the authentication plugin searches for the name using this attribute. For example, if the `authentication_ldap_simple_user_search_attr` value is `uid`, a search for the user name `user1` finds entries with a `uid` value of `user1`.

- `authentication_webauthn_rp_id`

Command-Line Format	<code>--authentication-webauthn-rp-id=value</code>
System Variable	<code>authentication_webauthn_rp_id</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String

This variable specifies the relying party ID used for server-side plugin installation, device registration, and WebAuthn authentication. If WebAuthn authentication is attempted and this value is not the one expected by the device, the device assumes that it is not talking to the correct server and an error occurs. The maximum value length is 255 characters.

## 8.4.2 The Connection-Control Plugins

MySQL Server includes a plugin library that enables administrators to introduce an increasing delay in server response to connection attempts after a configurable number of consecutive failed attempts. This capability provides a deterrent that slows down brute force attacks against MySQL user accounts. The plugin library contains two plugins:

- `CONNECTION_CONTROL` checks incoming connection attempts and adds a delay to server responses as necessary. This plugin also exposes system variables that enable its operation to be configured and a status variable that provides rudimentary monitoring information.

The `CONNECTION_CONTROL` plugin uses the audit plugin interface (see [Writing Audit Plugins](#)). To collect information, it subscribes to the `MYSQL_AUDIT_CONNECTION_CLASSMASK` event class, and processes

`MYSQL_AUDIT_CONNECTION_CONNECT` and `MYSQL_AUDIT_CONNECTION_CHANGE_USER` subevents to check whether the server should introduce a delay before responding to connection attempts.

- `CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS` implements an `INFORMATION_SCHEMA` table that exposes more detailed monitoring information for failed connection attempts.

The following sections provide information about connection-control plugin installation and configuration. For information about the `CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS` table, see [Section 28.6.2, “The INFORMATION\\_SCHEMA CONNECTION\\_CONTROL\\_FAILED\\_LOGIN\\_ATTEMPTS Table”](#).

### 8.4.2.1 Connection-Control Plugin Installation

This section describes how to install the connection-control plugins, `CONNECTION_CONTROL` and `CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS`. For general information about installing plugins, see [Section 7.6.1, “Installing and Uninstalling Plugins”](#).

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

The plugin library file base name is `connection_control`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

To load the plugins at server startup, use the `--plugin-load-add` option to name the library file that contains them. With this plugin-loading method, the option must be given each time the server starts. For example, put these lines in the server `my.cnf` file, adjusting the `.so` suffix for your platform as necessary:

```
[mysqld]
plugin-load-add=connection_control.so
```

After modifying `my.cnf`, restart the server to cause the new settings to take effect.

Alternatively, to load the plugins at runtime, use these statements, adjusting the `.so` suffix for your platform as necessary:

```
INSTALL PLUGIN CONNECTION_CONTROL
 SONAME 'connection_control.so';
INSTALL PLUGIN CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS
 SONAME 'connection_control.so';
```

`INSTALL PLUGIN` loads the plugin immediately, and also registers it in the `mysql.plugins` system table to cause the server to load it for each subsequent normal startup without the need for `--plugin-load-add`.

To verify plugin installation, examine the Information Schema `PLUGINS` table or use the `SHOW PLUGINS` statement (see [Section 7.6.2, “Obtaining Server Plugin Information”](#)). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
FROM INFORMATION_SCHEMA.PLUGINS
WHERE PLUGIN_NAME LIKE 'connection%';
```

PLUGIN_NAME	PLUGIN_STATUS
CONNECTION_CONTROL	ACTIVE
CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS	ACTIVE

If a plugin fails to initialize, check the server error log for diagnostic messages.

If the plugins have been previously registered with `INSTALL PLUGIN` or are loaded with `--plugin-load-add`, you can use the `--connection-control` and `--connection-control-failed-login-`

`attempts` options at server startup to control plugin activation. For example, to load the plugins at startup and prevent them from being removed at runtime, use these options:

```
[mysqld]
plugin-load-add=connection_control.so
connection-control=FORCE_PLUS_PERMANENT
connection-control-failed-login-attempts=FORCE_PLUS_PERMANENT
```

If it is desired to prevent the server from running without a given connection-control plugin, use an option value of `FORCE` or `FORCE_PLUS_PERMANENT` to force server startup to fail if the plugin does not initialize successfully.

#### Note

It is possible to install one plugin without the other, but both must be installed for full connection-control capability. In particular, installing only the `CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS` plugin is of little use because, without the `CONNECTION_CONTROL` plugin to provide the data that populates the `CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS` table, the table is always empty.

- [Connection Delay Configuration](#)
- [Connection Failure Assessment](#)
- [Connection Failure Monitoring](#)

## Connection Delay Configuration

To enable configuring its operation, the `CONNECTION_CONTROL` plugin exposes these system variables:

- `connection_control_failed_connections_threshold`: The number of consecutive failed connection attempts permitted to accounts before the server adds a delay for subsequent connection attempts. To disable failed-connection counting, set `connection_control_failed_connections_threshold` to zero.
- `connection_control_min_connection_delay`: The minimum delay in milliseconds for connection failures above the threshold.
- `connection_control_max_connection_delay`: The maximum delay in milliseconds for connection failures above the threshold.

If `connection_control_failed_connections_threshold` is nonzero, failed-connection counting is enabled and has these properties:

- The delay is zero up through `connection_control_failed_connections_threshold` consecutive failed connection attempts.
- Thereafter, the server adds an increasing delay for subsequent consecutive attempts, until a successful connection occurs. The initial unadjusted delays begin at 1000 milliseconds (1 second) and increase by 1000 milliseconds per attempt. That is, once delay has been activated for an account, the unadjusted delays for subsequent failed attempts are 1000 milliseconds, 2000 milliseconds, 3000 milliseconds, and so forth.
- The actual delay experienced by a client is the unadjusted delay, adjusted to lie within the values of the `connection_control_min_connection_delay` and `connection_control_max_connection_delay` system variables, inclusive.

- Once delay has been activated for an account, the first successful connection thereafter by the account also experiences a delay, but failure counting is reset for subsequent connections.

For example, with the default `connection_control_failed_connections_threshold` value of 3, there is no delay for the first three consecutive failed connection attempts by an account. The actual adjusted delays experienced by the account for the fourth and subsequent failed connections depend on the `connection_control_min_connection_delay` and `connection_control_max_connection_delay` values:

- If `connection_control_min_connection_delay` and `connection_control_max_connection_delay` are 1000 and 20000, the adjusted delays are the same as the unadjusted delays, up to a maximum of 20000 milliseconds. The fourth and subsequent failed connections are delayed by 1000 milliseconds, 2000 milliseconds, 3000 milliseconds, and so forth.
- If `connection_control_min_connection_delay` and `connection_control_max_connection_delay` are 1500 and 20000, the adjusted delays for the fourth and subsequent failed connections are 1500 milliseconds, 2000 milliseconds, 3000 milliseconds, and so forth, up to a maximum of 20000 milliseconds.
- If `connection_control_min_connection_delay` and `connection_control_max_connection_delay` are 2000 and 3000, the adjusted delays for the fourth and subsequent failed connections are 2000 milliseconds, 2000 milliseconds, and 3000 milliseconds, with all subsequent failed connections also delayed by 3000 milliseconds.

You can set the `CONNECTION_CONTROL` system variables at server startup or runtime. Suppose that you want to permit four consecutive failed connection attempts before the server starts delaying its responses, with a minimum delay of 2000 milliseconds. To set the relevant variables at server startup, put these lines in the server `my.cnf` file:

```
[mysqld]
plugin-load-add=connection_control.so
connection_control_failed_connections_threshold=4
connection_control_min_connection_delay=2000
```

To set and persist the variables at runtime, use these statements:

```
SET PERSIST connection_control_failed_connections_threshold = 4;
SET PERSIST connection_control_min_connection_delay = 2000;
```

`SET PERSIST` sets a value for the running MySQL instance. It also saves the value, causing it to carry over to subsequent server restarts. To change a value for the running MySQL instance without having it carry over to subsequent restarts, use the `GLOBAL` keyword rather than `PERSIST`. See [Section 15.7.6.1, “SET Syntax for Variable Assignment”](#).

The `connection_control_min_connection_delay` and `connection_control_max_connection_delay` system variables both have minimum and maximum values of 1000 and 2147483647. In addition, the permitted range of values of each variable also depends on the current value of the other:

- `connection_control_min_connection_delay` cannot be set greater than the current value of `connection_control_max_connection_delay`.
- `connection_control_max_connection_delay` cannot be set less than the current value of `connection_control_min_connection_delay`.

Thus, to make the changes required for some configurations, you might need to set the variables in a specific order. Suppose that the current minimum and maximum delays are 1000 and 2000, and that you want to set them to 3000 and 5000. You cannot first set `connection_control_min_connection_delay` to 3000 because that is greater

than the current `connection_control_max_connection_delay` value of 2000. Instead, set `connection_control_max_connection_delay` to 5000, then set `connection_control_min_connection_delay` to 3000.

## Connection Failure Assessment

When the `CONNECTION_CONTROL` plugin is installed, it checks connection attempts and tracks whether they fail or succeed. For this purpose, a failed connection attempt is one for which the client user and host match a known MySQL account but the provided credentials are incorrect, or do not match any known account.

Failed-connection counting is based on the user/host combination for each connection attempt. Determination of the applicable user name and host name takes proxying into account and occurs as follows:

- If the client user proxies another user, the account for failed-connection counting is the proxying user, not the proxied user. For example, if `external_user@example.com` proxies `proxy_user@example.com`, connection counting uses the proxying user, `external_user@example.com`, rather than the proxied user, `proxy_user@example.com`. Both `external_user@example.com` and `proxy_user@example.com` must have valid entries in the `mysql.user` system table and a proxy relationship between them must be defined in the `mysql.proxies_priv` system table (see [Section 8.2.19, “Proxy Users”](#)).
- If the client user does not proxy another user, but does match a `mysql.user` entry, counting uses the `CURRENT_USER()` value corresponding to that entry. For example, if a user `user1` connecting from a host `host1.example.com` matches a `user1@host1.example.com` entry, counting uses `user1@host1.example.com`. If the user matches a `user1@%.example.com`, `user1@%.com`, or `user1@%` entry instead, counting uses `user1@%.example.com`, `user1@%.com`, or `user1@%`, respectively.

For the cases just described, the connection attempt matches some `mysql.user` entry, and whether the request succeeds or fails depends on whether the client provides the correct authentication credentials. For example, if the client presents an incorrect password, the connection attempt fails.

If the connection attempt matches no `mysql.user` entry, the attempt fails. In this case, no `CURRENT_USER()` value is available and connection-failure counting uses the user name provided by the client and the client host as determined by the server. For example, if a client attempts to connect as user `user2` from host `host2.example.com`, the user name part is available in the client request and the server determines the host information. The user/host combination used for counting is `user2@host2.example.com`.

### Note

The server maintains information about which client hosts can possibly connect to the server (essentially the union of host values for `mysql.user` entries). If a client attempts to connect from any other host, the server rejects the attempt at an early stage of connection setup:

```
ERROR 1130 (HY000): Host 'host_name' is not
allowed to connect to this MySQL server
```

Because this type of rejection occurs so early, `CONNECTION_CONTROL` does not see it, and does not count it.

## Connection Failure Monitoring

To monitor failed connections, use these information sources:

- The `Connection_control_delay_generated` status variable indicates the number of times the server added a delay to its response to a failed connection attempt. This does not count attempts that occur before reaching the threshold defined by the `connection_control_failed_connections_threshold` system variable.
- The `INFORMATION_SCHEMA CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS` table provides information about the current number of consecutive failed connection attempts per account (user/host combination). This counts all failed attempts, regardless of whether they were delayed.

Assigning a value to `connection_control_failed_connections_threshold` at runtime has these effects:

- All accumulated failed-connection counters are reset to zero.
- The `Connection_control_delay_generated` status variable is reset to zero.
- The `CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS` table becomes empty.

### 8.4.2.2 Connection-Control System and Status Variables

This section describes the system and status variables that the `CONNECTION_CONTROL` plugin provides to enable its operation to be configured and monitored.

- [Connection-Control System Variables](#)
- [Connection-Control Status Variables](#)

#### Connection-Control System Variables

If the `CONNECTION_CONTROL` plugin is installed, it exposes these system variables:

- `connection_control_failed_connections_threshold`

Command-Line Format	<code>--connection-control-failed-connections-threshold=#</code>
System Variable	<code>connection_control_failed_connections_threshold</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	3
Minimum Value	0
Maximum Value	2147483647

The number of consecutive failed connection attempts permitted to accounts before the server adds a delay for subsequent connection attempts:

- If the variable has a nonzero value `N`, the server adds a delay beginning with consecutive failed attempt `N+1`. If an account has reached the point where connection responses are delayed, a delay also occurs for the next subsequent successful connection.
- Setting this variable to zero disables failed-connection counting. In this case, the server never adds delays.

For information about how `connection_control_failed_connections_threshold` interacts with other connection-control system and status variables, see [Section 8.4.2.1, “Connection-Control Plugin Installation”](#).

- `connection_control_max_connection_delay`

Command-Line Format	<code>--connection-control-max-connection-delay=#</code>
System Variable	<code>connection_control_max_connection_delay</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	2147483647
Minimum Value	1000
Maximum Value	2147483647
Unit	milliseconds

The maximum delay in milliseconds for server response to failed connection attempts, if `connection_control_failed_connections_threshold` is greater than zero.

For information about how `connection_control_max_connection_delay` interacts with other connection-control system and status variables, see [Section 8.4.2.1, “Connection-Control Plugin Installation”](#).

- `connection_control_min_connection_delay`

Command-Line Format	<code>--connection-control-min-connection-delay=#</code>
System Variable	<code>connection_control_min_connection_delay</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	1000
Minimum Value	1000
Maximum Value	2147483647
Unit	milliseconds

The minimum delay in milliseconds for server response to failed connection attempts, if `connection_control_failed_connections_threshold` is greater than zero.

For information about how `connection_control_min_connection_delay` interacts with other connection-control system and status variables, see [Section 8.4.2.1, “Connection-Control Plugin Installation”](#).

## Connection-Control Status Variables

If the `CONNECTION_CONTROL` plugin is installed, it exposes this status variable:

- `Connection_control_delay_generated`

The number of times the server added a delay to its response to a failed connection attempt. This does not count attempts that occur before reaching the threshold defined by the `connection_control_failed_connections_threshold` system variable.

This variable provides a simple counter. For more detailed connection-control monitoring information, examine the `INFORMATION_SCHEMA CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS` table; see [Section 28.6.2, “The INFORMATION\\_SCHEMA CONNECTION\\_CONTROL\\_FAILED\\_LOGIN\\_ATTEMPTS Table”](#).

Assigning a value to `connection_control_failed_connections_threshold` at runtime resets `Connection_control_delay_generated` to zero.

### 8.4.3 The Password Validation Component

The `validate_password` component serves to improve security by requiring account passwords and enabling strength testing of potential passwords. This component exposes system variables that enable you to configure password policy, and status variables for component monitoring.

The `validate_password` component implements these capabilities:

- For SQL statements that assign a password supplied as a cleartext value, `validate_password` checks the password against the current password policy and rejects the password if it is weak (the statement returns an `ER_NOT_VALID_PASSWORD` error). This applies to the `ALTER USER`, `CREATE USER`, and `SET PASSWORD` statements.
- For `CREATE USER` statements, `validate_password` requires that a password be given, and that it satisfies the password policy. This is true even if an account is locked initially because otherwise unlocking the account later would cause it to become accessible without a password that satisfies the policy.
- `validate_password` implements a `VALIDATE_PASSWORD_STRENGTH()` SQL function that assesses the strength of potential passwords. This function takes a password argument and returns an integer from 0 (weak) to 100 (strong).

#### Note

For statements that assign or modify account passwords (`ALTER USER`, `CREATE USER`, and `SET PASSWORD`), the `validate_password` capabilities described here apply only to accounts that use an authentication plugin that stores credentials internally to MySQL. For accounts that use plugins that perform authentication against a credentials system external to MySQL, password management must be handled externally against that system as well. For more information about internal credentials storage, see [Section 8.2.15, “Password Management”](#).

The preceding restriction does not apply to use of the `VALIDATE_PASSWORD_STRENGTH()` function because it does not affect accounts directly.

Examples:

- `validate_password` checks the cleartext password in the following statement. Under the default password policy, which requires passwords to be at least 8 characters long, the password is weak and the statement produces an error:

```
mysql> ALTER USER USER() IDENTIFIED BY 'abc';
ERROR 1819 (HY000): Your password does not satisfy the current
policy requirements
```

- Passwords specified as hashed values are not checked because the original password value is not available for checking:

```
mysql> ALTER USER 'jeffrey'@'localhost'
IDENTIFIED WITH sha256_password
AS '*0D3CED9BEC10A777AEC23CCC353A8C08A633045E';
Query OK, 0 rows affected (0.01 sec)
```

- This account-creation statement fails, even though the account is locked initially, because it does not include a password that satisfies the current password policy:

```
mysql> CREATE USER 'juanita'@'localhost' ACCOUNT LOCK;
ERROR 1819 (HY000): Your password does not satisfy the current
policy requirements
```

- To check a password, use the `VALIDATE_PASSWORD_STRENGTH()` function:

```
mysql> SELECT VALIDATE_PASSWORD_STRENGTH('weak');
+-----+
| VALIDATE_PASSWORD_STRENGTH('weak') |
+-----+
| 25 |
+-----+
mysql> SELECT VALIDATE_PASSWORD_STRENGTH('lessweak$_@123');
+-----+
| VALIDATE_PASSWORD_STRENGTH('lessweak$_@123') |
+-----+
| 50 |
+-----+
mysql> SELECT VALIDATE_PASSWORD_STRENGTH('N0Tweak$_@123!');
+-----+
| VALIDATE_PASSWORD_STRENGTH('N0Tweak$_@123!') |
+-----+
| 100 |
+-----+
```

To configure password checking, modify the system variables having names of the form `validate_password.xxx`; these are the parameters that control password policy. See [Section 8.4.3.2, “Password Validation Options and Variables”](#).

If `validate_password` is not installed, the `validate_password.xxx` system variables are not available, passwords in statements are not checked, and the `VALIDATE_PASSWORD_STRENGTH()` function always returns 0. For example, without the plugin installed, accounts can be assigned passwords shorter than 8 characters, or no password at all.

Assuming that `validate_password` is installed, it implements three levels of password checking: `LOW`, `MEDIUM`, and `STRONG`. The default is `MEDIUM`; to change this, modify the value of `validate_password.policy`. The policies implement increasingly strict password tests. The following descriptions refer to default parameter values, which can be modified by changing the appropriate system variables.

- `LOW` policy tests password length only. Passwords must be at least 8 characters long. To change this length, modify `validate_password.length`.
- `MEDIUM` policy adds the conditions that passwords must contain at least 1 numeric character, 1 lowercase character, 1 uppercase character, and 1 special (nonalphanumeric)

character. To change these values, modify `validate_password.number_count`, `validate_password.mixed_case_count`, and `validate_password.special_char_count`.

- **STRONG** policy adds the condition that password substrings of length 4 or longer must not match words in the dictionary file, if one has been specified. To specify the dictionary file, modify `validate_password.dictionary_file`.

In addition, `validate_password` supports the capability of rejecting passwords that match the user name part of the effective user account for the current session, either forward or in reverse. To provide control over this capability, `validate_password` exposes a `validate_password.check_user_name` system variable, which is enabled by default.

### 8.4.3.1 Password Validation Component Installation and Uninstallation

This section describes how to install and uninstall the `validate_password` password-validation component. For general information about installing and uninstalling components, see [Section 7.5, “MySQL Components”](#).

#### Note

If you install MySQL 9.1 using the [MySQL Yum repository](#), [MySQL SLES Repository](#), or [RPM packages provided by Oracle](#), the `validate_password` component is enabled by default after you start your MySQL Server for the first time.

Upgrades to MySQL 9.1 from 9.0 using Yum or RPM packages leave the `validate_password` plugin in place. To make the transition from the `validate_password` plugin to the `validate_password` component, see [Section 8.4.3.3, “Transitioning to the Password Validation Component”](#).

To be usable by the server, the component library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

To install the `validate_password` component, use this statement:

```
INSTALL COMPONENT 'file://component_validate_password';
```

Component installation is a one-time operation that need not be done per server startup. `INSTALL COMPONENT` loads the component, and also registers it in the `mysql.component` system table to cause it to be loaded during subsequent server startups.

To uninstall the `validate_password` component, use this statement:

```
UNINSTALL COMPONENT 'file://component_validate_password';
```

`UNINSTALL COMPONENT` unloads the component, and unregisters it from the `mysql.component` system table to cause it not to be loaded during subsequent server startups.

### 8.4.3.2 Password Validation Options and Variables

This section describes the system and status variables that `validate_password` provides to enable its operation to be configured and monitored.

- [Password Validation Component System Variables](#)

- [Password Validation Component Status Variables](#)
- [Password Validation Plugin Options](#)
- [Password Validation Plugin System Variables](#)
- [Password Validation Plugin Status Variables](#)

## Password Validation Component System Variables

If the `validate_password` component is enabled, it exposes several system variables that enable configuration of password checking:

```
mysql> SHOW VARIABLES LIKE 'validate_password.%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| validate_password.changed_characters_percentage | 0 |
| validate_password.check_user_name | ON |
| validate_password.dictionary_file | |
| validate_password.length | 8 |
| validate_password.mixed_case_count | 1 |
| validate_password.number_count | 1 |
| validate_password.policy | MEDIUM |
| validate_password.special_char_count | 1 |
+-----+-----+
```

To change how passwords are checked, you can set these system variables at server startup or at runtime. The following list describes the meaning of each variable.

- `validate_password.changed_characters_percentage`

Command-Line Format	<code>--validate-password.changed-characters-percentage[=value]</code>
System Variable	<code>validate_password.changed_characters_percentage</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	0
Minimum Value	0
Maximum Value	100

Indicates the minimum number of characters, as a percentage of all characters, in a password that a user must change before `validate_password` accepts a new password for the user's own account. This applies only when changing an existing password, and has no effect when setting a user account's initial password.

This variable is not available unless `validate_password` is installed.

By default, `validate_password.changed_characters_percentage` permits all of the characters from the current password to be reused in the new password. The range of valid percentages is 0 to 100. If set to 100 percent, all of the characters from the current password are rejected, regardless of the casing. Characters `'abc'` and `'ABC'` are considered to be the same characters. If `validate_password` rejects the new password, it reports an error indicating the minimum number of characters that must differ.

If the `ALTER USER` statement does not provide the existing password in a `REPLACE` clause, this variable is not enforced. Whether the `REPLACE` clause is required is subject to the password verification policy as it applies to a given account. For an overview of the policy, see [Password Verification-Required Policy](#).

- `validate_password.check_user_name`

Command-Line Format	<code>--validate-password.check-user-name[={OFF ON}]</code>
System Variable	<code>validate_password.check_user_name</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>ON</code>

Whether `validate_password` compares passwords to the user name part of the effective user account for the current session and rejects them if they match. This variable is unavailable unless `validate_password` is installed.

By default, `validate_password.check_user_name` is enabled. This variable controls user name matching independent of the value of `validate_password.policy`.

When `validate_password.check_user_name` is enabled, it has these effects:

- Checking occurs in all contexts for which `validate_password` is invoked, which includes use of statements such as `ALTER USER` or `SET PASSWORD` to change the current user's password, and invocation of functions such as `VALIDATE_PASSWORD_STRENGTH()`.
  - The user names used for comparison are taken from the values of the `USER()` and `CURRENT_USER()` functions for the current session. An implication is that a user who has sufficient privileges to set another user's password can set the password to that user's name, and cannot set that user's password to the name of the user executing the statement. For example, `'root'@'localhost'` can set the password for `'jeffrey'@'localhost'` to `'jeffrey'`, but cannot set the password to `'root'`.
  - Only the user name part of the `USER()` and `CURRENT_USER()` function values is used, not the host name part. If a user name is empty, no comparison occurs.
  - If a password is the same as the user name or its reverse, a match occurs and the password is rejected.
  - User-name matching is case-sensitive. The password and user name values are compared as binary strings on a byte-by-byte basis.
  - If a password matches the user name, `VALIDATE_PASSWORD_STRENGTH()` returns 0 regardless of how other `validate_password` system variables are set.
- `validate_password.dictionary_file`

Command-Line Format	<code>--validate-password.dictionary-file=file_name</code>
System Variable	<code>validate_password.dictionary_file</code>

Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	File name

The path name of the dictionary file that `validate_password` uses for checking passwords. This variable is unavailable unless `validate_password` is installed.

By default, this variable has an empty value and dictionary checks are not performed. For dictionary checks to occur, the variable value must be nonempty. If the file is named as a relative path, it is interpreted relative to the server data directory. File contents should be lowercase, one word per line. Contents are treated as having a character set of `utf8mb3`. The maximum permitted file size is 1MB.

For the dictionary file to be used during password checking, the password policy must be set to 2 (`STRONG`); see the description of the `validate_password.policy` system variable. Assuming that is true, each substring of the password of length 4 up to 100 is compared to the words in the dictionary file. Any match causes the password to be rejected. Comparisons are not case-sensitive.

For `VALIDATE_PASSWORD_STRENGTH()`, the password is checked against all policies, including `STRONG`, so the strength assessment includes the dictionary check regardless of the `validate_password.policy` value.

`validate_password.dictionary_file` can be set at runtime and assigning a value causes the named file to be read without a server restart.

- `validate_password.length`

Command-Line Format	<code>--validate-password.length=#</code>
System Variable	<code>validate_password.length</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	8
Minimum Value	0

The minimum number of characters that `validate_password` requires passwords to have. This variable is unavailable unless `validate_password` is installed.

The `validate_password.length` minimum value is a function of several other related system variables. The value cannot be set less than the value of this expression:

```
validate_password.number_count
+ validate_password.special_char_count
+ (2 * validate_password.mixed_case_count)
```

If `validate_password` adjusts the value of `validate_password.length` due to the preceding constraint, it writes a message to the error log.

- `validate_password.mixed_case_count`

Command-Line Format	<code>--validate-password.mixed-case-count=#</code>
System Variable	<code>validate_password.mixed_case_count</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	1
Minimum Value	0

The minimum number of lowercase and uppercase characters that `validate_password` requires passwords to have if the password policy is `MEDIUM` or stronger. This variable is unavailable unless `validate_password` is installed.

For a given `validate_password.mixed_case_count` value, the password must have that many lowercase characters, and that many uppercase characters.

- `validate_password.number_count`

Command-Line Format	<code>--validate-password.number-count=#</code>
System Variable	<code>validate_password.number_count</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	1
Minimum Value	0

The minimum number of numeric (digit) characters that `validate_password` requires passwords to have if the password policy is `MEDIUM` or stronger. This variable is unavailable unless `validate_password` is installed.

- `validate_password.policy`

Command-Line Format	<code>--validate-password.policy=value</code>
System Variable	<code>validate_password.policy</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Enumeration
Default Value	1
Valid Values	0 1

The password policy enforced by `validate_password`. This variable is unavailable unless `validate_password` is installed.

`validate_password.policy` affects how `validate_password` uses its other policy-setting system variables, except for checking passwords against user names, which is controlled independently by `validate_password.check_user_name`.

The `validate_password.policy` value can be specified using numeric values 0, 1, 2, or the corresponding symbolic values `LOW`, `MEDIUM`, `STRONG`. The following table describes the tests performed for each policy. For the length test, the required length is the value of the `validate_password.length` system variable. Similarly, the required values for the other tests are given by other `validate_password.xxx` variables.

Policy	Tests Performed
0 or <code>LOW</code>	Length
1 or <code>MEDIUM</code>	Length; numeric, lowercase/uppercase, and special characters
2 or <code>STRONG</code>	Length; numeric, lowercase/uppercase, and special characters; dictionary file

- `validate_password.special_char_count`

Command-Line Format	<code>--validate-password.special-char-count=#</code>
System Variable	<code>validate_password.special_char_count</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	1
Minimum Value	0

The minimum number of nonalphanumeric characters that `validate_password` requires passwords to have if the password policy is `MEDIUM` or stronger. This variable is unavailable unless `validate_password` is installed.

## Password Validation Component Status Variables

If the `validate_password` component is enabled, it exposes status variables that provide operational information:

```
mysql> SHOW STATUS LIKE 'validate_password.%';
```

Variable_name	Value
<code>validate_password.dictionary_file_last_parsed</code>	2019-10-03 08:33:49
<code>validate_password.dictionary_file_words_count</code>	1902

The following list describes the meaning of each status variable.

- `validate_password.dictionary_file_last_parsed`

When the dictionary file was last parsed. This variable is unavailable unless `validate_password` is installed.

- `validate_password.dictionary_file_words_count`

The number of words read from the dictionary file. This variable is unavailable unless `validate_password` is installed.

## Password Validation Plugin Options

### Note

In MySQL 9.1, the `validate_password` plugin was reimplemented as the `validate_password` component. The `validate_password` plugin is deprecated; expect it to be removed in a future version of MySQL. Consequently, its options are also deprecated, and you should expect them to be removed as well. MySQL installations that use the plugin should make the transition to using the component instead. See [Section 8.4.3.3, “Transitioning to the Password Validation Component”](#).

To control activation of the `validate_password` plugin, use this option:

- `--validate-password[=value]`

Command-Line Format	<code>--validate-password[=value]</code>
Type	Enumeration
Default Value	ON
Valid Values	ON  OFF  FORCE  FORCE_PLUS_PERMANENT

This option controls how the server loads the deprecated `validate_password` plugin at startup. The value should be one of those available for plugin-loading options, as described in [Section 7.6.1, “Installing and Uninstalling Plugins”](#). For example, `--validate-password=FORCE_PLUS_PERMANENT` tells the server to load the plugin at startup and prevents it from being removed while the server is running.

This option is available only if the `validate_password` plugin has been previously registered with `INSTALL PLUGIN` or is loaded with `--plugin-load-add`. See [Section 8.4.3.1, “Password Validation Component Installation and Uninstallation”](#).

## Password Validation Plugin System Variables

### Note

In MySQL 9.1, the `validate_password` plugin was reimplemented as the `validate_password` component. The `validate_password` plugin is deprecated; expect it to be removed in a future version of MySQL. Consequently, its system variables are also deprecated and you should expect them to be removed as well. Use the corresponding system variables of the `validate_password`

component instead; see [Password Validation Component System Variables](#). MySQL installations that use the plugin should make the transition to using the component instead. See [Section 8.4.3.3, “Transitioning to the Password Validation Component”](#).

- `validate_password_check_user_name`

Command-Line Format	<code>--validate-password-check-user-name[={OFF ON}]</code>
System Variable	<code>validate_password_check_user_name</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	ON

This `validate_password` plugin system variable is deprecated; expect it to be removed in a future version of MySQL. Use the corresponding `validate_password.check_user_name` system variable of the `validate_password` component instead.

- `validate_password_dictionary_file`

Command-Line Format	<code>--validate-password-dictionary-file=file_name</code>
System Variable	<code>validate_password_dictionary_file</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	File name

This `validate_password` plugin system variable is deprecated; expect it to be removed in a future version of MySQL. Use the corresponding `validate_password.dictionary_file` system variable of the `validate_password` component instead.

- `validate_password_length`

Command-Line Format	<code>--validate-password-length=#</code>
System Variable	<code>validate_password_length</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	8
Minimum Value	0

This `validate_password` plugin system variable is deprecated; expect it to be removed in a future version of MySQL. Use the corresponding `validate_password.length` system variable of the `validate_password` component instead.

- `validate_password_mixed_case_count`

Command-Line Format	<code>--validate-password-mixed-case-count=#</code>
System Variable	<code>validate_password_mixed_case_count</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	1
Minimum Value	0

This `validate_password` plugin system variable is deprecated; expect it to be removed in a future version of MySQL. Use the corresponding `validate_password.mixed_case_count` system variable of the `validate_password` component instead.

- `validate_password_number_count`

Command-Line Format	<code>--validate-password-number-count=#</code>
System Variable	<code>validate_password_number_count</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	1
Minimum Value	0

This `validate_password` plugin system variable is deprecated; expect it to be removed in a future version of MySQL. Use the corresponding `validate_password.number_count` system variable of the `validate_password` component instead.

- `validate_password_policy`

Command-Line Format	<code>--validate-password-policy=value</code>
System Variable	<code>validate_password_policy</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Enumeration
Default Value	1
Valid Values	0 1

This `validate_password` plugin system variable is deprecated; expect it to be removed in a future version of MySQL. Use the corresponding `validate_password.policy` system variable of the `validate_password` component instead.

- `validate_password_special_char_count`

Command-Line Format	<code>--validate-password-special-char-count=#</code>
System Variable	<code>validate_password_special_char_count</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Integer
Default Value	1
Minimum Value	0

This `validate_password` plugin system variable is deprecated; expect it to be removed in a future version of MySQL. Use the corresponding `validate_password.special_char_count` system variable of the `validate_password` component instead.

## Password Validation Plugin Status Variables

### Note

In MySQL 9.1, the `validate_password` plugin was reimplemented as the `validate_password` component. The `validate_password` plugin is deprecated; expect it to be removed in a future version of MySQL. Consequently, its status variables are also deprecated; expect it to be removed. Use the corresponding status variables of the `validate_password` component; see [Password Validation Component Status Variables](#). MySQL installations that use the plugin should make the transition to using the component instead. See [Section 8.4.3.3, “Transitioning to the Password Validation Component”](#).

- `validate_password_dictionary_file_last_parsed`

This `validate_password` plugin status variable is deprecated; expect it to be removed in a future version of MySQL. Use the corresponding `validate_password.dictionary_file_last_parsed` status variable of the `validate_password` component instead.

- `validate_password_dictionary_file_words_count`

This `validate_password` plugin status variable is deprecated; expect it to be removed in a future version of MySQL. Use the corresponding `validate_password.dictionary_file_words_count` status variable of the `validate_password` component instead.

## 8.4.3.3 Transitioning to the Password Validation Component

**Note**

In MySQL 9.1, the `validate_password` plugin was reimplemented as the `validate_password` component. The `validate_password` plugin is deprecated; expect it to be removed in a future version of MySQL.

MySQL installations that currently use the `validate_password` plugin should make the transition to using the `validate_password` component instead. To do so, use the following procedure. The procedure installs the component before uninstalling the plugin, to avoid having a time window during which no password validation occurs. (The component and plugin can be installed simultaneously. In this case, the server attempts to use the component, falling back to the plugin if the component is unavailable.)

1. Install the `validate_password` component:

```
INSTALL COMPONENT 'file://component_validate_password';
```

2. Test the `validate_password` component to ensure that it works as expected. If you need to set any `validate_password.xxx` system variables, you can do so at runtime using `SET GLOBAL`. (Any option file changes that must be made are performed in the next step.)
3. Adjust any references to the plugin system and status variables to refer to the corresponding component system and status variables. Suppose that previously you had configured the plugin at startup using an option file like this:

```
[mysqld]
validate-password=FORCE_PLUS_PERMANENT
validate_password_dictionary_file=/usr/share/dict/words
validate_password_length=10
validate_password_number_count=2
```

Those settings are appropriate for the plugin, but must be modified to apply to the component. To adjust the option file, omit the `--validate-password` option (it applies only to the plugin, not the component), and modify the system variable references from no-dot names appropriate for the plugin to dotted names appropriate for the component:

```
[mysqld]
validate_password.dictionary_file=/usr/share/dict/words
validate_password.length=10
validate_password.number_count=2
```

Similar adjustments are needed for applications that refer at runtime to `validate_password` plugin system and status variables. Change the no-dot plugin variable names to the corresponding dotted component variable names.

4. Uninstall the `validate_password` plugin:

```
UNINSTALL PLUGIN validate_password;
```

If the `validate_password` plugin is loaded at server startup using a `--plugin-load` or `--plugin-load-add` option, omit that option from the server startup procedure. For example, if the option is listed in a server option file, remove it from the file.

5. Restart the server.

## 8.4.4 The MySQL Keyring

MySQL Server supports a keyring that enables internal server components and plugins to securely store sensitive information for later retrieval. The implementation comprises these elements:

- Keyring components and plugins that manage a backing store or communicate with a storage back end. Keyring use involves installing one from among the available components and plugins. Keyring components and plugins both manage keyring data but are configured differently and may have operational differences (see [Section 8.4.4.1, “Keyring Components Versus Keyring Plugins”](#)).

These keyring components are available:

- `component_keyring_file`: Stores keyring data in a file local to the server host. Available in MySQL Community Edition and MySQL Enterprise Edition distributions. See [Section 8.4.4.4, “Using the component\\_keyring\\_file File-Based Keyring Component”](#).
- `component_keyring_encrypted_file`: Stores keyring data in an encrypted, password-protected file local to the server host. Available in MySQL Enterprise Edition distributions. See [Section 8.4.4.5, “Using the component\\_keyring\\_encrypted\\_file Encrypted File-Based Keyring Component”](#).
- `component_keyring_oci`: Stores keyring data in the Oracle Cloud Infrastructure Vault. Available in MySQL Enterprise Edition distributions. See [Section 8.4.4.10, “Using the Oracle Cloud Infrastructure Vault Keyring Component”](#).
- `component_keyring_aws`: Communicates with the Amazon Web Services Key Management Service for key generation and uses a local file for key storage. Available in MySQL Enterprise Edition distributions. See [Section 8.4.4.8, “Using the component\\_keyring\\_aws AWS Keyring Component”](#).

These keyring plugins are available:

- `keyring_okv`: A KMIP 1.1 plugin for use with KMIP-compatible back end keyring storage products such as Oracle Key Vault and Gemalto SafeNet KeySecure Appliance. Available in MySQL Enterprise Edition distributions. See [Section 8.4.4.6, “Using the keyring\\_okv KMIP Plugin”](#).
- `keyring_aws`: Communicates with the Amazon Web Services Key Management Service for key generation and uses a local file for key storage. Available in MySQL Enterprise Edition distributions. See [Section 8.4.4.7, “Using the keyring\\_aws Amazon Web Services Keyring Plugin”](#).
- `keyring_hashicorp`: Communicates with HashiCorp Vault for back end storage. Available in MySQL Enterprise Edition distributions. See [Section 8.4.4.9, “Using the HashiCorp Vault Keyring Plugin”](#).
- A keyring service interface for keyring key management. This service is accessible at two levels:
  - SQL interface: In SQL statements, call the functions described in [Section 8.4.4.13, “General-Purpose Keyring Key-Management Functions”](#).
  - C interface: In C-language code, call the keyring service functions described in [Section 7.6.9.2, “The Keyring Service”](#).
- Key metadata access:
  - The Performance Schema `keyring_keys` table exposes metadata for keys in the keyring. Key metadata includes key IDs, key owners, and backend key IDs. The `keyring_keys` table does not expose any sensitive keyring data such as key contents. See [Section 29.12.18.2, “The keyring\\_keys table”](#).
  - The Performance Schema `keyring_component_status` table provides status information about the keyring component in use, if one is installed. See [Section 29.12.18.1, “The keyring\\_component\\_status Table”](#).

- A key migration capability. MySQL supports migration of keys between keystores, enabling DBAs to switch a MySQL installation from one keystore to another. See [Section 8.4.4.12, “Migrating Keys Between Keyring Keystores”](#).
- The implementation of keyring plugins is revised to use the component infrastructure. This is facilitated using the built-in plugin named `daemon_keyring_proxy_plugin` that acts as a bridge between the plugin and component service APIs. See [Section 7.6.8, “The Keyring Proxy Bridge Plugin”](#).

**Warning**

For encryption key management, the `component_keyring_file` and `component_keyring_encrypted_file` components are not intended as a regulatory compliance solution. Security standards such as PCI, FIPS, and others require use of key management systems to secure, manage, and protect encryption keys in key vaults or hardware security modules (HSMs).

Within MySQL, keyring service consumers include:

- The `InnoDB` storage engine uses the keyring to store its key for tablespace encryption. See [Section 17.13, “InnoDB Data-at-Rest Encryption”](#).
- MySQL Enterprise Audit uses the keyring to store the audit log file encryption password. See [Encrypting Audit Log Files](#).
- Binary log and relay log management supports keyring-based encryption of log files. With log file encryption activated, the keyring stores the keys used to encrypt passwords for the binary log files and relay log files. See [Section 19.3.2, “Encrypting Binary Log Files and Relay Log Files”](#).
- The master key to decrypt the file key that decrypts the persisted values of sensitive system variables is stored in the keyring. A keyring component must be enabled on the MySQL Server instance to support secure storage for persisted system variable values, rather than a keyring plugin, which do not support the function. See [Persisting Sensitive System Variables](#).

For general keyring installation instructions, see [Section 8.4.4.2, “Keyring Component Installation”](#), and [Section 8.4.4.3, “Keyring Plugin Installation”](#). For installation and configuration information specific to a given keyring component or plugin, see the section describing it.

For a general comparison of keyring components and keyring plugins, see [Section 8.4.4.1, “Keyring Components Versus Keyring Plugins”](#).

For information about using the keyring functions, see [Section 8.4.4.13, “General-Purpose Keyring Key-Management Functions”](#).

Keyring components, plugins, and functions access a keyring service that provides the interface to the keyring. For information about accessing this service and writing keyring plugins, see [Section 7.6.9.2, “The Keyring Service”](#), and [Writing Keyring Plugins](#).

### 8.4.4.1 Keyring Components Versus Keyring Plugins

The MySQL Keyring originally implemented keystore capabilities using server plugins, but began transitioning to use the component infrastructure. This section briefly compares keyring components and plugins to provide an overview of their differences. It may assist you in making the transition from plugins to components, or, if you are just beginning to use the keyring, assist you in choosing whether to use a component versus using a plugin.

- Keyring plugin loading uses the `--early-plugin-load` option. Keyring component loading uses a manifest.

- Keyring plugin configuration is based on plugin-specific system variables. For keyring components, no system variables are used. Instead, each component has its own configuration file.
- Keyring components have fewer restrictions than keyring plugins with respect to key types and lengths. See [Section 8.4.4.11, “Supported Keyring Key Types and Lengths”](#).

**Note**

`component_keyring_oci` can generate keys of type `AES` with a size of 16, 24, or 32 bytes only.

- Keyring components support secure storage for persisted system variable values, whereas keyring plugins do not support the function.

A keyring component must be enabled on the MySQL server instance to support secure storage for persisted system variable values. The sensitive data that can be protected in this way includes items such as private keys and passwords that appear in the values of system variables. In the operating system file where persisted system variables are stored, the names and values of sensitive system variables are stored in an encrypted format, along with a generated file key to decrypt them. The generated file key is in turn encrypted using a master key that is stored in a keyring. See [Persisting Sensitive System Variables](#).

#### 8.4.4.2 Keyring Component Installation

Keyring service consumers require that a keyring component or plugin be installed:

- To use a keyring component, begin with the instructions here.
- To use a keyring plugin instead, begin with [Section 8.4.4.3, “Keyring Plugin Installation”](#).
- If you intend to use keyring functions in conjunction with the chosen keyring component or plugin, install the functions after installing that component or plugin, using the instructions in [Section 8.4.4.13, “General-Purpose Keyring Key-Management Functions”](#).

**Note**

Only one keyring component or plugin should be enabled at a time. Enabling multiple keyring components or plugins is unsupported and results may not be as anticipated.

MySQL provides these keyring component choices:

- `component_keyring_file`: Stores keyring data in a file local to the server host. Available in MySQL Community Edition and MySQL Enterprise Edition distributions.
- `component_keyring_encrypted_file`: Stores keyring data in an encrypted, password-protected file local to the server host. Available in MySQL Enterprise Edition distributions.
- `component_keyring_oci`: Stores keyring data in the Oracle Cloud Infrastructure Vault. Available in MySQL Enterprise Edition distributions.
- `component_keyring_aws`: Communicates with the AWS Key Management Service for key generation and uses a local file for key storage. Available in MySQL Enterprise Edition distributions.

To be usable by the server, the component library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

A keyring component or plugin must be loaded early during the server startup sequence so that other components can access it as necessary during their own initialization. For example, the [InnoDB](#) storage engine uses the keyring for tablespace encryption, so a keyring component or plugin must be loaded and available prior to [InnoDB](#) initialization.

**Note**

A keyring component must be enabled on the MySQL server instance if you need to support secure storage for persisted system variable values. The keyring plugin does not support the function. See [Persisting Sensitive System Variables](#).

Unlike keyring plugins, keyring components are not loaded using the `--early-plugin-load` server option or configured using system variables. Instead, the server determines which keyring component to load during startup using a manifest, and the loaded component consults its own configuration file when it initializes. Therefore, to install a keyring component, you must:

1. Write a manifest that tells the server which keyring component to load.
2. Write a configuration file for that keyring component.

The first step in installing a keyring component is writing a manifest that indicates which component to load. During startup, the server reads either a global manifest file, or a global manifest file paired with a local manifest file:

- The server attempts to read its global manifest file from the directory where the server is installed.
- If the global manifest file indicates use of a local manifest file, the server attempts to read its local manifest file from the data directory.
- Although global and local manifest files are located in different directories, the file name is `mysqld.my` in both locations.
- It is not an error for a manifest file not to exist. In this case, the server attempts no component loading associated with the file.

Local manifest files permit setting up component loading for multiple instances of the server, such that loading instructions for each server instance are specific to a given data directory instance. This enables different MySQL instances to use different keyring components.

Server manifest files have these properties:

- A manifest file must be in valid JSON format.
- A manifest file permits these items:
  - `"read_local_manifest"`: This item is permitted only in the global manifest file. If the item is not present, the server uses only the global manifest file. If the item is present, its value is `true` or `false`, indicating whether the server should read component-loading information from the local manifest file.

If the `"read_local_manifest"` item is present in the global manifest file along with other items, the server checks the `"read_local_manifest"` item value first:

- If the value is `false`, the server processes the other items in the global manifest file and ignores the local manifest file.
- If the value is `true`, the server ignores the other items in the global manifest file and attempts to read the local manifest file.

- `"components"`: This item indicates which component to load. The item value is a string that specifies a valid component URN, such as `"file://component_keyring_file"`. A component URN begins with `file://` and indicates the base name of the library file located in the MySQL plugin directory that implements the component.
- Server access to a manifest file should be read only. For example, a `mysqld.my` server manifest file may be owned by `root` and be read/write to `root`, but should be read only to the account used to run the MySQL server. If the manifest file is found during startup to be read/write to that account, the server writes a warning to the error log suggesting that the file be made read only.
- The database administrator has the responsibility for creating any manifest files to be used, and for ensuring that their access mode and contents are correct. If an error occurs, server startup fails and the administrator must correct any issues indicated by diagnostics in the server error log.

Given the preceding manifest file properties, to configure the server to load `component_keyring_file`, create a global manifest file named `mysqld.my` in the `mysqld` installation directory, and optionally create a local manifest file, also named `mysqld.my`, in the data directory. The following instructions describe how to load `component_keyring_file`. To load a different keyring component, substitute its name for `component_keyring_file`.

- To use a global manifest file only, the file contents look like this:

```
{
 "components": "file://component_keyring_file"
}
```

Create this file in the directory where `mysqld` is installed.

- Alternatively, to use a global and local manifest file pair, the global file looks like this:

```
{
 "read_local_manifest": true
}
```

Create this file in the directory where `mysqld` is installed.

The local file looks like this:

```
{
 "components": "file://component_keyring_file"
}
```

Create this file in the data directory.

With the manifest in place, proceed to configuring the keyring component. To do this, check the notes for your chosen keyring component for configuration instructions specific to that component:

- `component_keyring_file`: [Section 8.4.4.4, “Using the component\\_keyring\\_file File-Based Keyring Component”](#).
- `component_keyring_encrypted_file`: [Section 8.4.4.5, “Using the component\\_keyring\\_encrypted\\_file Encrypted File-Based Keyring Component”](#).
- `component_keyring_oci`: [Section 8.4.4.10, “Using the Oracle Cloud Infrastructure Vault Keyring Component”](#).

After performing any component-specific configuration, start the server. Verify component installation by examining the Performance Schema `keyring_component_status` table:

```
mysql> SELECT * FROM performance_schema.keyring_component_status;
```

STATUS_KEY	STATUS_VALUE
Component_name	component_keyring_file
Author	Oracle Corporation
License	GPL
Implementation_name	component_keyring_file
Version	1.0
Component_status	Active
Data_file	/usr/local/mysql/keyring/component_keyring_file
Read_only	No

A `Component_status` value of `Active` indicates that the component initialized successfully.

If the component cannot be loaded, server startup fails. Check the server error log for diagnostic messages. If the component loads but fails to initialize due to configuration problems, the server starts but the `Component_status` value is `Disabled`. Check the server error log, correct the configuration issues, and use the `ALTER INSTANCE RELOAD KEYRING` statement to reload the configuration.

Keyring components should be loaded only by using a manifest file, not by using the `INSTALL COMPONENT` statement. Keyring components loaded using that statement may be available too late in the server startup sequence for certain components that use the keyring, such as `InnoDB`, because they are registered in the `mysql.component` system table and loaded automatically for subsequent server restarts. But `mysql.component` is an `InnoDB` table, so any components named in it can be loaded during startup only after `InnoDB` initialization.

If no keyring component or plugin is available when a component tries to access the keyring service, the service cannot be used by that component. As a result, the component may fail to initialize or may initialize with limited functionality. For example, if `InnoDB` finds that there are encrypted tablespaces when it initializes, it attempts to access the keyring. If the keyring is unavailable, `InnoDB` can access only unencrypted tablespaces.

#### 8.4.4.3 Keyring Plugin Installation

Keyring service consumers require that a keyring component or plugin be installed:

- To use a keyring plugin, begin with the instructions here. (Also, for general information about installing plugins, see [Section 7.6.1, “Installing and Uninstalling Plugins”](#).)
- To use a keyring component instead, begin with [Section 8.4.4.2, “Keyring Component Installation”](#).
- If you intend to use keyring functions in conjunction with the chosen keyring component or plugin, install the functions after installing that component or plugin, using the instructions in [Section 8.4.4.13, “General-Purpose Keyring Key-Management Functions”](#).

#### Note

Only one keyring component or plugin should be enabled at a time. Enabling multiple keyring components or plugins is unsupported and results may not be as anticipated.

A keyring component must be enabled on the MySQL Server instance if you need to support secure storage for persisted system variable values, rather than a keyring plugin, which do not support the function. See [Persisting Sensitive System Variables](#).

MySQL provides these keyring plugin choices:

- [keyring\\_okv](#): A KMIP 1.1 plugin for use with KMIP-compatible back end keyring storage products such as Oracle Key Vault and Gemalto SafeNet KeySecure Appliance. Available in MySQL Enterprise Edition distributions.
- [keyring\\_aws](#): Communicates with the Amazon Web Services Key Management Service as a back end for key generation and uses a local file for key storage. Available in MySQL Enterprise Edition distributions.
- [keyring\\_hashicorp](#): Communicates with HashiCorp Vault for back end storage. Available in MySQL Enterprise Edition distributions.

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the [plugin\\_dir](#) system variable). If necessary, configure the plugin directory location by setting the value of [plugin\\_dir](#) at server startup.

A keyring component or plugin must be loaded early during the server startup sequence so that other components can access it as necessary during their own initialization. For example, the [InnoDB](#) storage engine uses the keyring for tablespace encryption, so a keyring component or plugin must be loaded and available prior to [InnoDB](#) initialization.

Installation for each keyring plugin is similar. The following instructions describe how to install [keyring\\_okv](#). To use a different keyring plugin, substitute its name for [keyring\\_okv](#).

The [keyring\\_okv](#) plugin library file base name is [keyring\\_okv](#). The file name suffix differs per platform (for example, [.so](#) for Unix and Unix-like systems, [.dll](#) for Windows).

To load the plugin, use the [--early-plugin-load](#) option to name the plugin library file that contains it. For example, on platforms where the plugin library file suffix is [.so](#), use these lines in the server [my.cnf](#) file, adjusting the [.so](#) suffix for your platform as necessary:

```
[mysqld]
early-plugin-load=keyring_okv.so
```

Before starting the server, check the notes for your chosen keyring plugin for configuration instructions specific to that plugin:

- [keyring\\_okv](#): [Section 8.4.4.6, “Using the keyring\\_okv KMIP Plugin”](#).
- [keyring\\_aws](#): [Section 8.4.4.7, “Using the keyring\\_aws Amazon Web Services Keyring Plugin”](#)
- [keyring\\_hashicorp](#): [Section 8.4.4.9, “Using the HashiCorp Vault Keyring Plugin”](#)

After performing any plugin-specific configuration, start the server. Verify plugin installation by examining the Information Schema [PLUGINS](#) table or use the [SHOW PLUGINS](#) statement (see [Section 7.6.2, “Obtaining Server Plugin Information”](#)). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
 FROM INFORMATION_SCHEMA.PLUGINS
 WHERE PLUGIN_NAME LIKE 'keyring%';
+-----+-----+
| PLUGIN_NAME | PLUGIN_STATUS |
+-----+-----+
| keyring_okv | ACTIVE |
+-----+-----+
```

If the plugin fails to initialize, check the server error log for diagnostic messages.

Plugins can be loaded by methods other than [--early-plugin-load](#), such as the [--plugin-load](#) or [--plugin-load-add](#) option or the [INSTALL PLUGIN](#) statement. However, keyring plugins loaded using

those methods may be available too late in the server startup sequence for certain components that use the keyring, such as [InnoDB](#):

- Plugin loading using `--plugin-load` or `--plugin-load-add` occurs after [InnoDB](#) initialization.
- Plugins installed using `INSTALL PLUGIN` are registered in the `mysql.plugin` system table and loaded automatically for subsequent server restarts. However, because `mysql.plugin` is an [InnoDB](#) table, any plugins named in it can be loaded during startup only after [InnoDB](#) initialization.

If no keyring component or plugin is available when a component tries to access the keyring service, the service cannot be used by that component. As a result, the component may fail to initialize or may initialize with limited functionality. For example, if [InnoDB](#) finds that there are encrypted tablespaces when it initializes, it attempts to access the keyring. If the keyring is unavailable, [InnoDB](#) can access only unencrypted tablespaces. To ensure that [InnoDB](#) can access encrypted tablespaces as well, use `--early-plugin-load` to load the keyring plugin.

#### 8.4.4.4 Using the `component_keyring_file` File-Based Keyring Component

The `component_keyring_file` keyring component stores keyring data in a file local to the server host.

##### Warning

For encryption key management, the `component_keyring_file` and `component_keyring_encrypted_file` components are not intended as a regulatory compliance solution. Security standards such as PCI, FIPS, and others require use of key management systems to secure, manage, and protect encryption keys in key vaults or hardware security modules (HSMs).

To use `component_keyring_file` for keystore management, you must:

1. Write a manifest that tells the server to load `component_keyring_file`, as described in [Section 8.4.4.2, “Keyring Component Installation”](#).
2. Write a configuration file for `component_keyring_file`, as described here.

When it initializes, `component_keyring_file` reads either a global configuration file, or a global configuration file paired with a local configuration file:

- The component attempts to read its global configuration file from the directory where the component library file is installed (that is, the server plugin directory).
- If the global configuration file indicates use of a local configuration file, the component attempts to read its local configuration file from the data directory.
- Although global and local configuration files are located in different directories, the file name is `component_keyring_file.cnf` in both locations.
- It is an error for no configuration file to exist. `component_keyring_file` cannot initialize without a valid configuration.

Local configuration files permit setting up multiple server instances to use `component_keyring_file`, such that component configuration for each server instance is specific to a given data directory instance. This enables the same keyring component to be used with a distinct data file for each instance.

`component_keyring_file` configuration files have these properties:

- A configuration file must be in valid JSON format.
- A configuration file permits these configuration items:

- `"read_local_config"`: This item is permitted only in the global configuration file. If the item is not present, the component uses only the global configuration file. If the item is present, its value is `true` or `false`, indicating whether the component should read configuration information from the local configuration file.

If the `"read_local_config"` item is present in the global configuration file along with other items, the component checks the `"read_local_config"` item value first:

- If the value is `false`, the component processes the other items in the global configuration file and ignores the local configuration file.
- If the value is `true`, the component ignores the other items in the global configuration file and attempts to read the local configuration file.
- `"path"`: The item value is a string that names the file to use for storing keyring data. The file should be named using an absolute path, not a relative path. This item is mandatory in the configuration. If not specified, `component_keyring_file` initialization fails.
- `"read_only"`: The item value indicates whether the keyring data file is read only. The item value is `true` (read only) or `false` (read/write). This item is mandatory in the configuration. If not specified, `component_keyring_file` initialization fails.
- The database administrator has the responsibility for creating any configuration files to be used, and for ensuring that their contents are correct. If an error occurs, server startup fails and the administrator must correct any issues indicated by diagnostics in the server error log.

Given the preceding configuration file properties, to configure `component_keyring_file`, create a global configuration file named `component_keyring_file.cnf` in the directory where the `component_keyring_file` library file is installed, and optionally create a local configuration file, also named `component_keyring_file.cnf`, in the data directory. The following instructions assume that a keyring data file named `/usr/local/mysql/keyring/component_keyring_file` is to be used in read/write fashion.

- To use a global configuration file only, the file contents look like this:

```
{
 "path": "/usr/local/mysql/keyring/component_keyring_file",
 "read_only": false
}
```

Create this file in the directory where the `component_keyring_file` library file is installed.

This path must not point to or include the MySQL data directory.

- Alternatively, to use a global and local configuration file pair, the global file looks like this:

```
{
 "read_local_config": true
}
```

Create this file in the directory where the `component_keyring_file` library file is installed.

The local file looks like this:

```
{
 "path": "/usr/local/mysql/keyring/component_keyring_file",
 "read_only": false
}
```

This path must not point to or include the MySQL data directory.

Keyring operations are transactional: `component_keyring_file` uses a backup file during write operations to ensure that it can roll back to the original file if an operation fails. The backup file has the same name as the data file with a suffix of `.backup`.

`component_keyring_file` supports the functions that comprise the standard MySQL Keyring service interface. Keyring operations performed by those functions are accessible in SQL statements as described in [Section 8.4.4.13, “General-Purpose Keyring Key-Management Functions”](#).

Example:

```
SELECT keyring_key_generate('MyKey', 'AES', 32);
SELECT keyring_key_remove('MyKey');
```

For information about the characteristics of key values permitted by `component_keyring_file`, see [Section 8.4.4.11, “Supported Keyring Key Types and Lengths”](#).

### 8.4.4.5 Using the `component_keyring_encrypted_file` Encrypted File-Based Keyring Component

#### Note

`component_keyring_encrypted_file` is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see <https://www.mysql.com/products/>.

The `component_keyring_encrypted_file` keyring component stores keyring data in an encrypted, password-protected file local to the server host.

#### Warning

For encryption key management, the `component_keyring_file` and `component_keyring_encrypted_file` components are not intended as a regulatory compliance solution. Security standards such as PCI, FIPS, and others require use of key management systems to secure, manage, and protect encryption keys in key vaults or hardware security modules (HSMs).

To use `component_keyring_encrypted_file` for keystore management, you must:

1. Write a manifest that tells the server to load `component_keyring_encrypted_file`, as described in [Section 8.4.4.2, “Keyring Component Installation”](#).
2. Write a configuration file for `component_keyring_encrypted_file`, as described here.

When it initializes, `component_keyring_encrypted_file` reads either a global configuration file, or a global configuration file paired with a local configuration file:

- The component attempts to read its global configuration file from the directory where the component library file is installed (that is, the server plugin directory).
- If the global configuration file indicates use of a local configuration file, the component attempts to read its local configuration file from the data directory.
- Although global and local configuration files are located in different directories, the file name is `component_keyring_encrypted_file.cnf` in both locations.
- If `component_keyring_encrypted_file` cannot find the configuration file, an error results, and the component cannot initialize.

Local configuration files permit setting up multiple server instances to use `component_keyring_encrypted_file`, such that component configuration for each server instance is specific to a given data directory instance. This enables the same keyring component to be used with a distinct data file for each instance.

`component_keyring_encrypted_file` configuration files have these properties:

- A configuration file must be in valid JSON format.
- A configuration file permits these configuration items:
  - `"read_local_config"`: This item is permitted only in the global configuration file. If the item is not present, the component uses only the global configuration file. If the item is present, its value is `true` or `false`, indicating whether the component should read configuration information from the local configuration file.

If the `"read_local_config"` item is present in the global configuration file along with other items, the component checks the `"read_local_config"` item value first:

- If the value is `false`, the component processes the other items in the global configuration file and ignores the local configuration file.
- If the value is `true`, the component ignores the other items in the global configuration file and attempts to read the local configuration file.
- `"path"`: The item value is a string that names the file to use for storing keyring data. The file should be named using an absolute path, not a relative path. This item is mandatory in the configuration. If not specified, `component_keyring_encrypted_file` initialization fails.
- `"password"`: The item value is a string that specifies the password for accessing the data file. This item is mandatory in the configuration. If not specified, `component_keyring_encrypted_file` initialization fails.
- `"read_only"`: The item value indicates whether the keyring data file is read only. The item value is `true` (read only) or `false` (read/write). This item is mandatory in the configuration. If not specified, `component_keyring_encrypted_file` initialization fails.
- The database administrator has the responsibility for creating any configuration files to be used, and for ensuring that their contents are correct. If an error occurs, server startup fails and the administrator must correct any issues indicated by diagnostics in the server error log.
- Any configuration file that stores a password should have a restrictive mode and be accessible only to the account used to run the MySQL server.

Given the preceding configuration file properties, to configure `component_keyring_encrypted_file`, create a global configuration file named `component_keyring_encrypted_file.cnf` in the directory where the `component_keyring_encrypted_file` library file is installed, and optionally create a local configuration file, also named `component_keyring_encrypted_file.cnf`, in the data directory. The following instructions assume that a keyring data file named `/usr/local/mysql/keyring/component_keyring_encrypted_file` is to be used in read/write fashion. You must also choose a password.

- To use a global configuration file only, the file contents look like this:

```
{
 "path": "/usr/local/mysql/keyring/component_keyring_encrypted_file",
 "password": "password",
 "read_only": false
}
```

```
}
```

Create this file in the directory where the `component_keyring_encrypted_file` library file is installed.

This path must not point to or include the MySQL data directory.

- Alternatively, to use a global and local configuration file pair, the global file looks like this:

```
{
 "read_local_config": true
}
```

Create this file in the directory where the `component_keyring_encrypted_file` library file is installed.

The local file looks like this:

```
{
 "path": "/usr/local/mysql/keyring/component_keyring_encrypted_file",
 "password": "password",
 "read_only": false
}
```

This path must not point to or include the MySQL data directory.

Keyring operations are transactional: `component_keyring_encrypted_file` uses a backup file during write operations to ensure that it can roll back to the original file if an operation fails. The backup file has the same name as the data file with a suffix of `.backup`.

`component_keyring_encrypted_file` supports the functions that comprise the standard MySQL Keyring service interface. Keyring operations performed by those functions are accessible in SQL statements as described in [Section 8.4.4.13, “General-Purpose Keyring Key-Management Functions”](#).

Example:

```
SELECT keyring_key_generate('MyKey', 'AES', 32);
SELECT keyring_key_remove('MyKey');
```

For information about the characteristics of key values permitted by `component_keyring_encrypted_file`, see [Section 8.4.4.11, “Supported Keyring Key Types and Lengths”](#).

#### 8.4.4.6 Using the `keyring_okv` KMIP Plugin

##### Note

The `keyring_okv` plugin is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see <https://www.mysql.com/products/>.

The Key Management Interoperability Protocol (KMIP) enables communication of cryptographic keys between a key management server and its clients. The `keyring_okv` keyring plugin uses the KMIP 1.1 protocol to communicate securely as a client of a KMIP back end. Keyring material is generated exclusively by the back end, not by `keyring_okv`. The plugin works with these KMIP-compatible products:

- Oracle Key Vault
- Gemalto SafeNet KeySecure Appliance

- Townsend Alliance Key Manager
- Entrust KeyControl

Each MySQL Server instance must be registered separately as a client for KMIP. If two or more MySQL Server instances use the same set of credentials, they can interfere with each other's functioning.

The `keyring_okv` plugin supports the functions that comprise the standard MySQL Keyring service interface. Keyring operations performed by those functions are accessible at two levels:

- SQL interface: In SQL statements, call the functions described in [Section 8.4.4.13, “General-Purpose Keyring Key-Management Functions”](#).
- C interface: In C-language code, call the keyring service functions described in [Section 7.6.9.2, “The Keyring Service”](#).

Example (using the SQL interface):

```
SELECT keyring_key_generate('MyKey', 'AES', 32);
SELECT keyring_key_remove('MyKey');
```

For information about the characteristics of key values permitted by `keyring_okv`, [Section 8.4.4.11, “Supported Keyring Key Types and Lengths”](#).

To install `keyring_okv`, use the general instructions found in [Section 8.4.4.3, “Keyring Plugin Installation”](#), together with the configuration information specific to `keyring_okv` found here.

- [General keyring\\_okv Configuration](#)
- [Configuring keyring\\_okv for Oracle Key Vault](#)
- [Configuring keyring\\_okv for Gemalto SafeNet KeySecure Appliance](#)
- [Configuring keyring\\_okv for Townsend Alliance Key Manager](#)
- [Configuring keyring\\_okv for Entrust KeyControl](#)
- [Password-Protecting the keyring\\_okv Key File](#)

## General keyring\_okv Configuration

Regardless of which KMIP back end the `keyring_okv` plugin uses for keyring storage, the `keyring_okv_conf_dir` system variable configures the location of the directory used by `keyring_okv` for its support files. The default value is empty, so you must set the variable to name a properly configured directory before the plugin can communicate with the KMIP back end. Unless you do so, `keyring_okv` writes a message to the error log during server startup that it cannot communicate:

```
[Warning] Plugin keyring_okv reported: 'For keyring_okv to be
initialized, please point the keyring_okv_conf_dir variable to a directory
containing Oracle Key Vault configuration file and ssl materials'
```

The `keyring_okv_conf_dir` variable must name a directory that contains the following items:

- `okvclient.ora`: A file that contains details of the KMIP back end with which `keyring_okv` communicates.
- `ssl`: A directory that contains the certificate and key files required to establish a secure connection with the KMIP back end: `CA.pem`, `cert.pem`, and `key.pem`. If the key file is password-protected, the `ssl` directory can contain a single-line text file named `password.txt` containing the password needed to decrypt the key file.

Both the `okvclient.ora` file and `ssl` directory with the certificate and key files are required for `keyring_okv` to work properly. The procedure used to populate the configuration directory with these files depends on the KMIP back end used with `keyring_okv`, as described elsewhere.

The configuration directory used by `keyring_okv` as the location for its support files should have a restrictive mode and be accessible only to the account used to run the MySQL server. For example, on Unix and Unix-like systems, to use the `/usr/local/mysql/mysql-keyring-okv` directory, the following commands (executed as `root`) create the directory and set its mode and ownership:

```
cd /usr/local/mysql
mkdir mysql-keyring-okv
chmod 750 mysql-keyring-okv
chown mysql mysql-keyring-okv
chgrp mysql mysql-keyring-okv
```

To be usable during the server startup process, `keyring_okv` must be loaded using the `--early-plugin-load` option. Also, set the `keyring_okv_conf_dir` system variable to tell `keyring_okv` where to find its configuration directory. For example, use these lines in the server `my.cnf` file, adjusting the `.so` suffix and directory location for your platform as necessary:

```
[mysqld]
early-plugin-load=keyring_okv.so
keyring_okv_conf_dir=/usr/local/mysql/mysql-keyring-okv
```

For additional information about `keyring_okv_conf_dir`, see [Section 8.4.4.17, “Keyring System Variables”](#).

## Configuring `keyring_okv` for Oracle Key Vault

The discussion here assumes that you are familiar with Oracle Key Vault. Some pertinent information sources:

- [Oracle Key Vault site](#)
- [Oracle Key Vault documentation](#)

In Oracle Key Vault terminology, clients that use Oracle Key Vault to store and retrieve security objects are called endpoints. To communicate with Oracle Key Vault, it is necessary to register as an endpoint and enroll by downloading and installing endpoint support files. Note that you must register a separate endpoint for each MySQL Server instance. If two or more MySQL Server instances use the same endpoint, they can interfere with each other's functioning.

The following procedure briefly summarizes the process of setting up `keyring_okv` for use with Oracle Key Vault:

1. Create the configuration directory for the `keyring_okv` plugin to use.
2. Register an endpoint with Oracle Key Vault to obtain an enrollment token.
3. Use the enrollment token to obtain the `okvclient.jar` client software download.
4. Install the client software to populate the `keyring_okv` configuration directory that contains the Oracle Key Vault support files.

Use the following procedure to configure `keyring_okv` and Oracle Key Vault to work together. This description only summarizes how to interact with Oracle Key Vault. For details, visit the [Oracle Key Vault site](#) and consult the *Oracle Key Vault Administrator's Guide*.

1. Create the configuration directory that contains the Oracle Key Vault support files, and make sure that the `keyring_okv_conf_dir` system variable is set to name that directory (for details, see [General `keyring\_okv` Configuration](#)).

2. Log in to the Oracle Key Vault management console as a user who has the System Administrator role.
3. Select the Endpoints tab to arrive at the Endpoints page. On the Endpoints page, click Add.
4. Provide the required endpoint information and click Register. The endpoint type should be Other. Successful registration results in an enrollment token.
5. Log out from the Oracle Key Vault server.
6. Connect again to the Oracle Key Vault server, this time without logging in. Use the endpoint enrollment token to enroll and request the `okvclient.jar` software download. Save this file to your system.
7. Install the `okvclient.jar` file using the following command (you must have JDK 1.4 or higher):

```
java -jar okvclient.jar -d dir_name [-v]
```

The directory name following the `-d` option is the location in which to install extracted files. The `-v` option, if given, causes log information to be produced that may be useful if the command fails.

When the command asks for an Oracle Key Vault endpoint password, do not provide one. Instead, press **Enter**. (The result is that no password is required when the endpoint connects to Oracle Key Vault.)

The preceding command produces an `okvclient.ora` file, which should be in this location under the directory named by the `-d` option in the preceding `java -jar` command:

```
install_dir/conf/okvclient.ora
```

The expected file contents include lines that look like this:

```
SERVER=host_ip:port_num
STANDBY_SERVER=host_ip:port_num
```

The `SERVER` variable is mandatory, and the `STANDBY_SERVER` variable is optional. The `keyring_okv` plugin attempts to communicate with the server running on the host named by the `SERVER` variable and falls back to `STANDBY_SERVER` if that fails.

#### Note

If the existing file is not in this format, then create a new file with the lines shown in the previous example. Also, consider backing up the `okvclient.ora` file before you run the `okvutil` command. Restore the file as needed.

You can specify more than one standby server (up to a maximum of 64). If you do, the `keyring_okv` plugin iterates over them until it can establish a connection, and fails if it cannot. To add extra standby servers, edit the `okvclient.ora` file to specify the IP addresses and port numbers of the servers as a comma-separated list in the value of the `STANDBY_SERVER` variable. For example:

```
STANDBY_SERVER=host_ip:port_num,host_ip:port_num,host_ip:port_num,host_ip:port_num
```

Ensure that the list of standby servers is kept short, accurate, and up to date, and servers that are no longer valid are removed. There is a 20-second wait for each connection attempt, so the presence of a long list of invalid servers can significantly affect the `keyring_okv` plugin's connection time and therefore the server startup time.

8. Go to the Oracle Key Vault installer directory and test the setup by running this command:

```
okvutil/bin/okvutil list
```

The output should look something like this:

Unique ID	Type	Identifier
255AB8DE-C97F-482C-E053-0100007F28B9	Symmetric Key	-
264BF6E0-A20E-7C42-E053-0100007FB29C	Symmetric Key	-

For a fresh Oracle Key Vault server (a server without any key in it), the output looks like this instead, to indicate that there are no keys in the vault:

```
no objects found
```

9. Use this command to extract the `ssl` directory containing SSL materials from the `okvclient.jar` file:

```
jar xf okvclient.jar ssl
```

10. Copy the Oracle Key Vault support files (the `okvclient.ora` file and the `ssl` directory) into the configuration directory.
11. (Optional) If you wish to password-protect the key file, use the instructions in [Password-Protecting the keyring\\_okv Key File](#).

After completing the preceding procedure, restart the MySQL server. It loads the `keyring_okv` plugin and `keyring_okv` uses the files in its configuration directory to communicate with Oracle Key Vault.

## Configuring keyring\_okv for Gemalto SafeNet KeySecure Appliance

Gemalto SafeNet KeySecure Appliance uses the KMIP protocol (version 1.1 or 1.2). The `keyring_okv` keyring plugin (which supports KMIP 1.1) can use KeySecure as its KMIP back end for keyring storage.

Use the following procedure to configure `keyring_okv` and KeySecure to work together. The description only summarizes how to interact with KeySecure. For details, consult the section named Add a KMIP Server in the [KeySecure User Guide](#).

1. Create the configuration directory that contains the KeySecure support files, and make sure that the `keyring_okv_conf_dir` system variable is set to name that directory (for details, see [General keyring\\_okv Configuration](#)).
2. In the configuration directory, create a subdirectory named `ssl` to use for storing the required SSL certificate and key files.
3. In the configuration directory, create a file named `okvclient.ora`. It should have following format:

```
SERVER=host_ip:port_num
STANDBY_SERVER=host_ip:port_num
```

For example, if KeySecure is running on host 198.51.100.20 and listening on port 9002, and also running on alternative host 203.0.113.125 and listening on port 8041, the `okvclient.ora` file looks like this:

```
SERVER=198.51.100.20:9002
STANDBY_SERVER=203.0.113.125:8041
```

You can specify more than one standby server (up to a maximum of 64). If you do, the `keyring_okv` plugin iterates over them until it can establish a connection, and fails if it cannot. To add extra standby servers, edit the `okvclient.ora` file to specify the IP addresses and port numbers of the servers as a comma-separated list in the value of the `STANDBY_SERVER` variable. For example:

```
STANDBY_SERVER=host_ip:port_num,host_ip:port_num,host_ip:port_num,host_ip:port_num
```

Ensure that the list of standby servers is kept short, accurate, and up to date, and servers that are no longer valid are removed. There is a 20-second wait for each connection attempt, so the presence of a long list of invalid servers can significantly affect the `keyring_okv` plugin's connection time and therefore the server startup time.

4. Connect to the KeySecure Management Console as an administrator with credentials for Certificate Authorities access.
5. Navigate to Security >> Local CAs and create a local certificate authority (CA).
6. Go to Trusted CA Lists. Select Default and click on Properties. Then select Edit for Trusted Certificate Authority List and add the CA just created.
7. Download the CA and save it in the `ssl` directory as a file named `CA.pem`.
8. Navigate to Security >> Certificate Requests and create a certificate. Then you can download a compressed `tar` file containing certificate PEM files.
9. Extract the PEM files from in the downloaded file. For example, if the file name is `csr_w_pk_pkcs8.gz`, decompress and unpack it using this command:

```
tar zxvf csr_w_pk_pkcs8.gz
```

Two files result from the extraction operation: `certificate_request.pem` and `private_key_pkcs8.pem`.

10. Use this `openssl` command to decrypt the private key and create a file named `key.pem`:

```
openssl pkcs8 -in private_key_pkcs8.pem -out key.pem
```

11. Copy the `key.pem` file into the `ssl` directory.
12. Copy the certificate request in `certificate_request.pem` into the clipboard.
13. Navigate to Security >> Local CAs. Select the same CA that you created earlier (the one you downloaded to create the `CA.pem` file), and click Sign Request. Paste the Certificate Request from the clipboard, choose a certificate purpose of Client (the keyring is a client of KeySecure), and click Sign Request. The result is a certificate signed with the selected CA in a new page.
14. Copy the signed certificate to the clipboard, then save the clipboard contents as a file named `cert.pem` in the `ssl` directory.
15. (Optional) If you wish to password-protect the key file, use the instructions in [Password-Protecting the keyring\\_okv Key File](#).

After completing the preceding procedure, restart the MySQL server. It loads the `keyring_okv` plugin and `keyring_okv` uses the files in its configuration directory to communicate with KeySecure.

## Configuring `keyring_okv` for Townsend Alliance Key Manager

Townsend Alliance Key Manager uses the KMIP protocol. The `keyring_okv` keyring plugin can use Alliance Key Manager as its KMIP back end for keyring storage. For additional information, see [Alliance Key Manager for MySQL](#).

## Configuring `keyring_okv` for Entrust KeyControl

Entrust KeyControl uses the KMIP protocol. The `keyring_okv` keyring plugin can use Entrust KeyControl as its KMIP back end for keyring storage. For additional information, see the [Oracle MySQL and Entrust KeyControl with nShield HSM Integration Guide](#).

## Password-Protecting the `keyring_okv` Key File

You can optionally protect the key file with a password and supply a file containing the password to enable the key file to be decrypted. To do so, change location to the `ssl` directory and perform these steps:

1. Encrypt the `key.pem` key file. For example, use a command like this, and enter the encryption password at the prompts:

```
$> openssl rsa -des3 -in key.pem -out key.pem.new
Enter PEM pass phrase:
Verifying - Enter PEM pass phrase:
```

2. Save the encryption password in a single-line text file named `password.txt` in the `ssl` directory.
3. Verify that the encrypted key file can be decrypted using the following command. The decrypted file should display on the console:

```
$> openssl rsa -in key.pem.new -passin file:password.txt
```

4. Remove the original `key.pem` file and rename `key.pem.new` to `key.pem`.
5. Change the ownership and access mode of new `key.pem` file and `password.txt` file as necessary to ensure that they have the same restrictions as other files in the `ssl` directory.

### 8.4.4.7 Using the `keyring_aws` Amazon Web Services Keyring Plugin

#### Note

The `keyring_aws` plugin is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see <https://www.mysql.com/products/>.

#### Important

The `keyring_aws` keyring plugin is deprecated as of MySQL 9.1, and is being replaced by the AWS Keyring component (`component_aws_keyring`). Deprecation of the plugin means that you should expect the plugin to be removed in a future version of MySQL. For more information, including information about migrating from the `keyring_aws` plugin to `component_aws_keyring`, see [Section 8.4.4.8, “Using the component\\_aws\\_keyring AWS Keyring Component”](#).

The `keyring_aws` keyring plugin communicates with the Amazon Web Services Key Management Service (AWS KMS) as a back end for key generation and uses a local file for key storage. All keyring material is generated exclusively by the AWS server, not by `keyring_aws`.

MySQL Enterprise Edition can work with `keyring_aws` on Red Hat Enterprise Linux, SUSE Linux Enterprise Server, Debian, Ubuntu, macOS, and Windows. MySQL Enterprise Edition does not support the use of `keyring_aws` on these platforms:

- EL6
- Generic Linux (glibc2.12)
- SLES 12 (with versions after MySQL Server 5.7)
- Solaris

The discussion here assumes that you are familiar with AWS in general and KMS in particular. Some pertinent information sources:

- [AWS site](#)
- [KMS documentation](#)

The following sections provide configuration and usage information for the `keyring_aws` keyring plugin:

- [keyring\\_aws Configuration](#)
- [keyring\\_aws Operation](#)
- [keyring\\_aws Credential Changes](#)

## keyring\_aws Configuration

To install `keyring_aws`, use the general instructions found in [Section 8.4.4.3, “Keyring Plugin Installation”](#), together with the plugin-specific configuration information found here.

The plugin library file contains the `keyring_aws` plugin and two loadable functions, `keyring_aws_rotate_cmk()` and `keyring_aws_rotate_keys()`.

To configure `keyring_aws`, you must obtain a secret access key that provides credentials for communicating with AWS KMS and write it to a configuration file:

1. Create an AWS KMS account.
2. Use AWS KMS to create a secret access key ID and secret access key. The access key serves to verify your identity and that of your applications.
3. Use the AWS KMS account to create a KMS key ID. At MySQL startup, set the `keyring_aws_cmk_id` system variable to the CMK ID value. This variable is mandatory and there is no default. (Its value can be changed at runtime if desired using `SET GLOBAL`.)
4. If necessary, create the directory in which the configuration file should be located. The directory should have a restrictive mode and be accessible only to the account used to run the MySQL server. For example, on Unix and Unix-like systems, to use `/usr/local/mysql/mysql-keyring/keyring_aws_conf` as the file name, the following commands (executed as `root`) create its parent directory and set the directory mode and ownership:

```
$> cd /usr/local/mysql
$> mkdir mysql-keyring
$> chmod 750 mysql-keyring
$> chown mysql mysql-keyring
$> chgrp mysql mysql-keyring
```

At MySQL startup, set the `keyring_aws_conf_file` system variable to `/usr/local/mysql/mysql-keyring/keyring_aws_conf` to indicate the configuration file location to the server.

5. Prepare the `keyring_aws` configuration file, which should contain two lines:
  - Line 1: The secret access key ID
  - Line 2: The secret access key

For example, if the key ID is `wwwwwwwwwEXAMPLE` and the key is `xxxxxxxxxxxxx/yyyyyyy/zzzzzzzzEXAMPLEKEY`, the configuration file looks like this:

```
wwwwwwwwwEXAMPLE
```

```
xxxxxxxxxxxxx/yyyyyy/zzzzzzzEXAMPLEKEY
```

To be usable during the server startup process, `keyring_aws` must be loaded using the `--early-plugin-load` option. The `keyring_aws_cmek_id` system variable is mandatory and configures the KMS key ID obtained from the AWS KMS server. The `keyring_aws_conf_file` and `keyring_aws_data_file` system variables optionally configure the locations of the files used by the `keyring_aws` plugin for configuration information and data storage. The file location variable default values are platform specific. To configure the locations explicitly, set the variable values at startup. For example, use these lines in the server `my.cnf` file, adjusting the `.so` suffix and file locations for your platform as necessary:

```
[mysqld]
early-plugin-load=keyring_aws.so
keyring_aws_cmek_id='arn:aws:kms:us-west-2:111122223333:key/abcd1234-ef56-ab12-cd34-ef56abcd1234'
keyring_aws_conf_file=/usr/local/mysql/mysql-keyring/keyring_aws_conf
keyring_aws_data_file=/usr/local/mysql/mysql-keyring/keyring_aws_data
```

For the `keyring_aws` plugin to start successfully, the configuration file must exist and contain valid secret access key information, initialized as described previously. The storage file need not exist. If it does not, `keyring_aws` attempts to create it (as well as its parent directory, if necessary).

For additional information about the system variables used to configure the `keyring_aws` plugin, see [Section 8.4.4.17, “Keyring System Variables”](#).

Start the MySQL server and install the functions associated with the `keyring_aws` plugin. This is a one-time operation, performed by executing the following statements, adjusting the `.so` suffix for your platform as necessary:

```
CREATE FUNCTION keyring_aws_rotate_cmek RETURNS INTEGER
 SONAME 'keyring_aws.so';
CREATE FUNCTION keyring_aws_rotate_keys RETURNS INTEGER
 SONAME 'keyring_aws.so';
```

For additional information about the `keyring_aws` functions, see [Section 8.4.4.14, “Plugin-Specific Keyring Key-Management Functions”](#).

## keyring\_aws Operation

At plugin startup, the `keyring_aws` plugin reads the AWS secret access key ID and key from its configuration file. It also reads any encrypted keys contained in its storage file into its in-memory cache.

During operation, `keyring_aws` maintains encrypted keys in the in-memory cache and uses the storage file as local persistent storage. Each keyring operation is transactional: `keyring_aws` either successfully changes both the in-memory key cache and the keyring storage file, or the operation fails and the keyring state remains unchanged.

To ensure that keys are flushed only when the correct keyring storage file exists, `keyring_aws` stores a SHA-256 checksum of the keyring in the file. Before updating the file, the plugin verifies that it contains the expected checksum.

The `keyring_aws` plugin supports the functions that comprise the standard MySQL Keyring service interface. Keyring operations performed by these functions are accessible at two levels:

- SQL interface: In SQL statements, call the functions described in [Section 8.4.4.13, “General-Purpose Keyring Key-Management Functions”](#).
- C interface: In C-language code, call the keyring service functions described in [Section 7.6.9.2, “The Keyring Service”](#).

Example (using the SQL interface):

```
SELECT keyring_key_generate('MyKey', 'AES', 32);
SELECT keyring_key_remove('MyKey');
```

In addition, the `keyring_aws_rotate_cmk()` and `keyring_aws_rotate_keys()` functions “extend” the keyring plugin interface to provide AWS-related capabilities not covered by the standard keyring service interface. These capabilities are accessible only by calling these functions using SQL. There are no corresponding C-language key service functions.

For information about the characteristics of key values permitted by `keyring_aws`, see [Section 8.4.4.11, “Supported Keyring Key Types and Lengths”](#).

## keyring\_aws Credential Changes

Assuming that the `keyring_aws` plugin has initialized properly at server startup, it is possible to change the credentials used for communicating with AWS KMS:

1. Use AWS KMS to create a new secret access key ID and secret access key.
2. Store the new credentials in the configuration file (the file named by the `keyring_aws_conf_file` system variable). The file format is as described previously.
3. Reinitialize the `keyring_aws` plugin so that it re-reads the configuration file. Assuming that the new credentials are valid, the plugin should initialize successfully.

There are two ways to reinitialize the plugin:

- Restart the server. This is simpler and has no side effects, but is not suitable for installations that require minimal server downtime with as few restarts as possible.
- Reinitialize the plugin without restarting the server by executing the following statements, adjusting the `.so` suffix for your platform as necessary:

```
UNINSTALL PLUGIN keyring_aws;
INSTALL PLUGIN keyring_aws SONAME 'keyring_aws.so';
```

### Note

In addition to loading a plugin at runtime, `INSTALL PLUGIN` has the side effect of registering the plugin in the `mysql.plugin` system table. Because of this, if you decide to stop using `keyring_aws`, it is not sufficient to remove the `--early-plugin-load` option from the set of options used to start the server. That stops the plugin from loading early, but the server still attempts to load it when it gets to the point in the startup sequence where it loads the plugins registered in `mysql.plugin`.

Consequently, if you execute the `UNINSTALL PLUGIN` plus `INSTALL PLUGIN` sequence just described to change the AWS KMS credentials, then to stop using `keyring_aws`, it is necessary to execute `UNINSTALL PLUGIN` again to unregister the plugin in addition to removing the `--early-plugin-load` option.

## 8.4.4.8 Using the component\_keyring\_aws AWS Keyring Component

### Note

`component_keyring_aws` is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see <https://www.mysql.com/products/>.

The AWS Keyring component is intended to replace the AWS Keyring plugin, which is now deprecated. See [Migration from AWS keyring plugin](#).

The `component_keyring_aws` keyring component stores keyring data in an encrypted, password-protected file local to the server host.

`component_keyring_aws` supports the functions that comprise the standard MySQL Keyring service interface. Keyring operations performed by those functions are accessible in SQL statements as described in [Section 8.4.4.13, “General-Purpose Keyring Key-Management Functions”](#).

Example:

```
SELECT keyring_key_generate('MyKey', 'AES', 32);
SELECT keyring_key_remove('MyKey');
```

For information about the characteristics of key values permitted by `component_keyring_aws`, see [Section 8.4.4.11, “Supported Keyring Key Types and Lengths”](#).

To use `component_keyring_aws` for keystore management, you must:

1. Write a manifest that tells the server to load `component_keyring_aws`, as described in [Section 8.4.4.2, “Keyring Component Installation”](#).

For `component_keyring_aws`, the contents of the manifest file are shown here:

```
{
 "components": "file://component_aws_keyring"
}
```

2. Write a configuration file for `component_keyring_aws`, as described in [AWS Keyring Component Configuration](#).

The AWS keyring component supports two authentication modes, simple and native, as determined by the value of the `aws_authentication.mode` parameter specified in `component_keyring_aws.cnf`. This parameter is required. Configuration of the component for supporting each of these modes can be found in [Simple authentication mode](#), and [Native authentication mode](#), respectively.

- [AWS Keyring Component Configuration](#)
- [Simple authentication mode](#)
- [Native authentication mode](#)
- [Migration from AWS keyring plugin](#)

## AWS Keyring Component Configuration

When it initializes, `component_keyring_aws` read a component configuration file `~/.aws/component_keyring_aws.cnf` (Linux and MacOS) or `%USERPROFILE%.aws\component_keyring_aws.cnf` (Windows). You can override this by setting the `AWS_CONFIG_FILE` environment variable.

In some cases, additional information can be read from an AWS configuration file, a credentials file, or both. These files are described later in this section.

If `component_keyring_aws` cannot find the configuration file, an error results, and the component cannot initialize.

The `component_keyring_aws.cnf` component configuration file must be in valid JSON format. Configuration items supported in this file are shown in the following table:

**Table 8.31 component\_keyring\_aws.cnf Configuration Items**

Parameter	Parent	Description	Valid	Required	Default	Permitted values
<code>cmk_id</code>	—	Customer Master Key (CMK) identifier obtained from AWS KMS server	—	Yes	—	—
<code>data_file</code>	—	Location of component JSON storage file	—	Yes	—	—
<code>cache_keys</code>	—	<code>true</code> : Keys cached in memory in plaintext; <code>false</code> : Keys decrypted when accessed	—	No	<code>false</code>	<code>true</code> , <code>false</code>
<code>mode</code>	<code>aws_authentication</code>	AWS authentication mode	—	Yes	—	<code>native</code> , <code>simple</code>
<code>profile</code>	<code>aws_authentication</code>	Name of AWS profile used by AWS native authentication	When <code>aws_authentication.mode</code> is <code>native</code>	No	<code>default</code>	—
<code>region</code>	<code>aws_authentication</code>	AWS region	When <code>aws_authentication.mode</code> is <code>simple</code>	Yes, when <code>aws_authentication.mode</code> is <code>simple</code>	—	—
<code>access_key_id</code>	<code>aws_authentication</code>	AWS access key identifier	When <code>aws_authentication.mode</code> is <code>simple</code>	Yes, when <code>aws_authentication.mode</code> is <code>simple</code>	—	—
<code>access_key_secret</code>	<code>aws_authentication</code>	AWS access key secret	When <code>aws_authentication.mode</code> is <code>simple</code>	Yes, when <code>aws_authentication.mode</code> is <code>simple</code>	—	—
<code>connect_timeout</code>	<code>aws_connection</code>	Socket connection timeout	—	No	<code>1000</code>	—
<code>host</code>	<code>aws_connection</code>	Proxy host	—	No	—	—
<code>port</code>	<code>aws_connection</code>	Proxy port	—	No	—	—
<code>user</code>	<code>aws_connection</code>	Proxy user name	—	No	—	—
<code>password</code>	<code>aws_connection</code>	Proxy user password	—	No	—	—
<code>read_only</code>	—	When <code>true</code> , no operations which modify the keyring are allowed	—	No	<code>false</code>	<code>true</code> , <code>false</code>

Component configuration file parameters that are not valid are ignored. For example, `aws_authentication.access_key_id` and `aws_authentication.access_key_secret` have no effect when the `aws_authentication.mode` is `native`.

The database administrator has the responsibility for creating any configuration files to be used, and for ensuring that their contents are correct. If an error occurs, server startup fails; the administrator must correct any issues indicated by diagnostic messages in the server error log.

### Important

Any configuration file that stores a password should have a restrictive mode and be accessible only to the account used to run the MySQL server.

Given the preceding configuration file items, to configure `component_keyring_aws`, create a component configuration file named `component_keyring_aws.cnf` in the directory indicated previously.

A read/write keyring data file using JSON format, whose location is determined by the `data_file` configuration item, is also required; the following instructions assume that such a file exists at `/usr/local/mysql/keyring.json`. An example of its content is shown here:

```

 "extension": []
 }
]
}
```

### Note

Each of the `data` values just shown consists of a single line; the values have been wrapped here to fit within the confines of the viewing space.

Keyring operations are transactional: `component_keyring_aws` uses a backup file during write operations to ensure that it can roll back to the original file if an operation fails. The backup file has the same name as the data file with the added suffix `.backup`.

`component_keyring_aws` configuration files may not be placed anywhere within the MySQL server data directory.

You must also choose a password.

## Simple authentication mode

This mode provides ease of use when more advanced AWS mechanisms are not needed. (This also simplifies upgrading from the legacy AWS keyring plugin to the component; see [Migration from AWS keyring plugin](#).) The `config` and `credentials` files are not used in this case; the configuration is read from the global `component_keyring_aws.cnf` only. To enable simple authentication mode, set `aws_authentication.mode` to `simple` in this file.

In simple mode, the component uses the access key ID and secret obtained from AWS, which are also set in `component_keyring_aws.cnf`, as the values of the `aws_authentication.access_key_id` and `aws_authentication.access_key_secret` configuration items. In addition, you must specify a region using `aws_authentication.region`.

The contents of a sample `component_keyring_aws.cnf` that meets the requirements for enabling simple authentication mode are shown here:

```
{
 "cmk_id": "arn:aws:kms:us-east-1:79566666666:key/d0111111-1111-1111-1111-999999999abd",
 "data_file": "/usr/local/mysql/keyring.json",
 "cache_keys": "true",
 "aws_authentication": {
 {
 "mode": "simple",
 "region": "us-east-1",
 "access_key_id": "wwwwwwwwwwwwEXAMPLE",
 "access_key_secret": "xxxxxxxxxxxxx/yyyyyy/zzzzzzzzEXAMPLEKEY"
 }
 }
}
```

## Native authentication mode

When `aws_authentication.mode` is `native`, the AWS keyring component uses the standard AWS authentication configuration mechanism (see [AWS SDKs and Tools: Configuration](#)) and the AWS profile specified in the component configuration file. The source for AWS credentials in this case is the AWS default credentials provider chain (see [AWS SDKs and Tools: Standardized credential providers](#)).

Enabling AWS native authentication mode with the AWS Keyring component are more complex, but includes the following advantages:

- Conformance with standard AWS client behavior
- Support for authentication configuration methods other than storing long-term secrets in the same file as other configuration items.
- Possible to leverage the role connected to an AWS container or compute node, thus improving security.
- More flexible configuration, since a wider range of parameters—such as timeouts, proxying, and use of a CA—is available then with the alternative mode.

To enable AWS native authentication, `aws_authentication.mode` must be set to `native` in the `component_keyring_aws.cnf` file, as shown here:

```
{
 "cmk_id": "arn:aws:kms:us-east-1:79566666666:key/d0111111-1111-1111-1111-999999999abd",
```

```
"data_file": "/usr/local/mysql/keyring.json",
"cache_keys": true,
"aws_authentication":
{
 "mode": "native"
}
}
```

Configuration of the component for AWS native authentication is based on a chain of credentials providers. Each provider uses a different source for credentials; possible sources include files, environment variables, and external services. Credential providers are called in the order specified by the default providers chain described in the next few paragraphs.

**Default credentials provider chain.** A credentials provider chain consists of one or more credential providers. Each such provider provides credentials taken from a different source. Providers are called until credentials are provided and collected for further use. The default chain consists of the credential providers listed here together with the credentials each of them provides:

- [EnvironmentAWSCredentialsProvider](#): AWS access keys taken from environment variables (see [AWS SDKs and Tools: AWS access keys](#) for details). This is convenient in development or other short-term environments, but not recommended for production.
- [ProfileConfigFileAWSCredentialsProvider](#): AWS access keys taken from a credentials file \*default section (see [AWS SDKs and Tools: AWS access keys](#)). This is recommended for MySQL server running outside of AWS.
- [ProcessCredentialsProvider](#): AWS access keys taken from the output of an external command specified by the `credential_process` AWS configuration parameter. The output of this command must be in `JSON` format (see [AWS SDKs and Tools: Process credential provider](#)).
- [STSAssumeRoleWebIdentityCredentialsProvider](#): A set of temporary security credentials for a specific role (see [AWS SDKs and Tools: Assume role credential provider](#)).
- [SSOCredentialsProvider](#): Credentials from the AWS IAM Identity Center (see [AWS SDKs and Tools: IAM Identity Center credential provider](#)).
- [TaskRoleCredentialsProvider](#): Credentials for use within an AWS ECS container (see [AWS SDKs and Tools: Amazon ECS task role](#)). This is recommended when the MySQL server runs within an AWS ECS container.
- [InstanceProfileCredentialsProvider](#): Credentials loaded from the Amazon EC2 Instance Metadata Service (IMDS) (see [AWS SDKs and Tools: IMDS credential provider](#)). This is recommended when the MySQL server runs in an AWS EC2 node.

To use AWS native authentication, `aws_authentication.mode` must be set to `native` in the `component_keyring_aws.cnf` file, as shown here:

```
{
 "cmk_id": "arn:aws:kms:us-east-1:795666666666:key/d0111111-1111-1111-1111-999999999abd",
 "data_file": "/usr/local/mysql/keyring.json",
 "cache_keys": true,
 "aws_authentication":
 {
 "mode": "native"
 }
}
```

The AWS configuration file (`config`) uses INI format similar to that employed in the MySQL Server `my.cnf` file. You can specify a section of this file to be read by setting `aws_authentication.profile`.

For example, setting `aws_authentication.profile` to `mysql` causes the component to read the `[mysql]` section of `config`, as shown here:

```
{
 "cmk_id": "arn:aws:kms:us-east-1:795666666666:key/d0111111-1111-1111-1111-999999999abd",
 "data_file": "/usr/local/mysql/keyring.json",
 "cache_keys": true,
 "aws_authentication": {
 {
 "mode": "native",
 "profile": "mysql"
 }
 }
}
```

If `aws_authentication.profile` is not specified, the component tries to read the `config` file section labelled `[default]`.

The AWS keyring component also supports an AWS `credentials` file to act as a source of credentials for the provider `ProfileConfigFileAWSCredentialsProvider` as described later in this section's discussion of native authentication mode. This file's location is determined in the same way as that of the `component_keyring_aws.cnf` and `config` files. To override the default for the `credentials` file (`%USERPROFILE%\.aws\credentials` for Windows, `~/.aws/credentials` for Linux or MacOS), set the `AWS_SHARED_CREDENTIALS_FILE` environment variable to the desired location.

## Migration from AWS keyring plugin

To migrate from the AWS keyring plugin to the AWS keyring component, it is necessary to perform the following steps:

1. Create an equivalent configuration for the component:

- a. Write a local or global manifest file `mysqld.my` (see [Section 8.4.4.2, “Keyring Component Installation”](#)). The content of the file must match what is shown here:

```
{
 "components": "file://component_keyring_aws"
}
```

- b. Write a component configuration file `component_keyring_aws.cnf` as described in [Section 8.4.4.4, “Using the component\\_keyring\\_file File-Based Keyring Component”](#) (in the example for `component_keyring_file`). See also the instructions given for configuration simple configuration section. In particular, the value of the `cmk_id` configuration item used by the component must be set to the that of the `keyring_aws_cmk_id` used by the plugin; similarly, the `aws_region` item's value must be set to the value of `keyring_aws_region`. For example:

```
{
 "cmk_id": "arn:aws:kms:us-east-1:795666666666:key/d0111111-1111-1111-1111-999999999abd",
 "data_file": "/usr/local/mysql/keyring.json",
 "cache_keys": true,
 "aws_authentication": {
 {
 "mode": "simple",
 "region": "us-east-1",
 "access_key_id": "wwwwwwwwwEXAMPLE",
 "access_key_secret": "xxxxxxxxxxxxx/yyyyyy/zzzzzzzzEXAMPLEKEY"
 }
 }
}
```

Values of the access key ID and secret just shown must be copied from the `keyring_aws` configuration file used by the AWS keyring plugin (see [Section 8.4.4.7, “Using the keyring\\_aws Amazon Web Services Keyring Plugin”](#)).

2. Perform key migration as described in [Section 8.4.4.12, “Migrating Keys Between Keyring Keystores”](#).
3. Uninstall the plugin.

### 8.4.4.9 Using the HashiCorp Vault Keyring Plugin

#### Note

The `keyring_hashicorp` plugin is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see <https://www.mysql.com/products/>.

The `keyring_hashicorp` keyring plugin communicates with HashiCorp Vault for back end storage. The plugin supports HashiCorp Vault AppRole authentication. No key information is permanently stored in MySQL server local storage. (An optional in-memory key cache may be used as intermediate storage.) Random key generation is performed on the MySQL server side, with the keys subsequently stored to Hashicorp Vault.

The `keyring_hashicorp` plugin supports the functions that comprise the standard MySQL Keyring service interface. Keyring operations performed by those functions are accessible at two levels:

- SQL interface: In SQL statements, call the functions described in [Section 8.4.4.13, “General-Purpose Keyring Key-Management Functions”](#).
- C interface: In C-language code, call the keyring service functions described in [Section 7.6.9.2, “The Keyring Service”](#).

Example (using the SQL interface):

```
SELECT keyring_key_generate('MyKey', 'AES', 32);
SELECT keyring_key_remove('MyKey');
```

For information about the characteristics of key values permitted by `keyring_hashicorp`, see [Section 8.4.4.11, “Supported Keyring Key Types and Lengths”](#).

To install `keyring_hashicorp`, use the general instructions found in [Section 8.4.4.3, “Keyring Plugin Installation”](#), together with the configuration information specific to `keyring_hashicorp` found here. Plugin-specific configuration includes preparation of the certificate and key files needed for connecting to HashiCorp Vault, as well as configuring HashiCorp Vault itself. The following sections provide the necessary instructions.

- [Certificate and Key Preparation](#)
- [HashiCorp Vault Setup](#)
- [keyring\\_hashicorp Configuration](#)

### Certificate and Key Preparation

The `keyring_hashicorp` plugin requires a secure connection to the HashiCorp Vault server, employing the HTTPS protocol. A typical setup includes a set of certificate and key files:

- `company.crt`: A custom CA certificate belonging to the organization. This file is used both by HashiCorp Vault server and the `keyring_hashicorp` plugin.
- `vault.key`: The private key of the HashiCorp Vault server instance. This file is used by HashiCorp Vault server.
- `vault.crt`: The certificate of the HashiCorp Vault server instance. This file must be signed by the organization CA certificate.

The following instructions describe how to create the certificate and key files using OpenSSL. (If you already have those files, proceed to [HashiCorp Vault Setup](#).) The instructions as shown apply to Linux platforms and may require adjustment for other platforms.

### Important

Certificates generated by these instructions are self-signed, which may not be very secure. After you gain experience using such files, consider obtaining certificate/key material from a registered certificate authority.

1. Prepare the company and HashiCorp Vault server keys.

Use the following commands to generate the key files:

```
openssl genrsa -aes256 -out company.key 4096
openssl genrsa -aes256 -out vault.key 2048
```

The commands produce files holding the company private key ([company.key](#)) and the Vault server private key ([vault.key](#)). The keys are randomly generated RSA keys of 4,096 and 2,048 bits, respectively.

Each command prompts for a password. For testing purposes, the password is not required. To disable it, omit the `-aes256` argument.

The key files hold sensitive information and should be stored in a secure location. The password (also sensitive) is required later, so write it down and store it in a secure location.

(Optional) To check key file content and validity, use the following commands:

```
openssl rsa -in company.key -check
openssl rsa -in vault.key -check
```

2. Create the company CA certificate.

Use the following command to create a company CA certificate file named [company.crt](#) that is valid for 365 days (enter the command on a single line):

```
openssl req -x509 -new -nodes -key company.key
-sha256 -days 365 -out company.crt
```

If you used the `-aes256` argument to perform key encryption during key generation, you are prompted for the company key password during CA certificate creation. You are also prompted for information about the certificate holder (that is, you or your company), as shown here:

```
Country Name (2 letter code) [AU]:
State or Province Name (full name) [Some-State]:
Locality Name (eg, city) []:
Organization Name (eg, company) [Internet Widgits Pty Ltd]:
Organizational Unit Name (eg, section) []:
Common Name (e.g. server FQDN or YOUR name) []:
Email Address []:
```

Answer the prompts with appropriate values.

3. Create a certificate signing request.

To create a HashiCorp Vault server certificate, a Certificate Signing Request (CSR) must be prepared for the newly created server key. Create a configuration file named [request.conf](#) containing the following lines. If the HashiCorp Vault server does not run on the local host, substitute appropriate CN and IP values, and make any other changes required.

```
[req]
distinguished_name = vault
x509_extensions = v3_req
prompt = no

[vault]
C = US
ST = CA
L = RWC
O = Company
CN = 127.0.0.1

[v3_req]
subjectAltName = @alternatives
authorityKeyIdentifier = keyid,issuer
basicConstraints = CA:TRUE

[alternatives]
IP = 127.0.0.1
```

Use this command to create the signing request:

```
openssl req -new -key vault.key -config request.conf -out request.csr
```

The output file (`request.csr`) is an intermediate file that serves as input for creation of the server certificate.

#### 4. Create the HashiCorp Vault server certificate.

Sign the combined information from the HashiCorp Vault server key (`vault.key`) and the CSR (`request.csr`) with the company certificate (`company.crt`) to create the HashiCorp Vault server certificate (`vault.crt`). Use the following command to do this (enter the command on a single line):

```
openssl x509 -req -in request.csr
 -CA company.crt -CAkey company.key -CAcreateserial
 -out vault.crt -days 365 -sha256
```

To make the `vault.crt` server certificate useful, append the contents of the `company.crt` company certificate to it. This is required so that the company certificate is delivered along with the server certificate in requests.

```
cat company.crt >> vault.crt
```

If you display the contents of the `vault.crt` file, it should look like this:

```
-----BEGIN CERTIFICATE-----
... content of HashiCorp Vault server certificate ...
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
... content of company certificate ...
-----END CERTIFICATE-----
```

## HashiCorp Vault Setup

The following instructions describe how to create a HashiCorp Vault setup that facilitates testing the `keyring_hashicorp` plugin.

### Important

A test setup is similar to a production setup, but production use of HashiCorp Vault entails additional security considerations such as use of non-self-signed certificates and storing the company certificate in the system trust store. You must

implement whatever additional security steps are needed to satisfy your operational requirements.

These instructions assume availability of the certificate and key files created in [Certificate and Key Preparation](#). See that section if you do not have those files.

1. Fetch the HashiCorp Vault binary.

Download the HashiCorp Vault binary appropriate for your platform from <https://www.vaultproject.io/downloads.html>.

Extract the content of the archive to produce the executable `vault` command, which is used to perform HashiCorp Vault operations. If necessary, add the directory where you install the command to the system path.

(Optional) HashiCorp Vault supports autocomplete options that make it easier to use. For more information, see <https://learn.hashicorp.com/vault/getting-started/install#command-completion>.

2. Create the HashiCorp Vault server configuration file.

Prepare a configuration file named `config.hcl` with the following content. For the `tls_cert_file`, `tls_key_file`, and `path` values, substitute path names appropriate for your system.

```
listener "tcp" {
 address="127.0.0.1:8200"
 tls_cert_file="/home/username/certificates/vault.crt"
 tls_key_file="/home/username/certificates/vault.key"
}

storage "file" {
 path = "/home/username/vaultstorage/storage"
}

ui = true
```

3. Start the HashiCorp Vault server.

To start the Vault server, use the following command, where the `-config` option specifies the path to the configuration file just created:

```
vault server -config=config.hcl
```

During this step, you may be prompted for a password for the Vault server private key stored in the `vault.key` file.

The server should start, displaying some information on the console (IP, port, and so forth).

So that you can enter the remaining commands, put the `vault server` command in the background or open another terminal before continuing.

4. Initialize the HashiCorp Vault server.

**Note**

The operations described in this step are required only when starting Vault the first time, to obtain the unseal key and root token. Subsequent Vault instance restarts require only unsealing using the unseal key.

Issue the following commands (assuming Bourne shell syntax):

```
export VAULT_SKIP_VERIFY=1
vault operator init -n 1 -t 1
```

The first command enables the `vault` command to temporarily ignore the fact that no company certificate has been added to the system trust store. It compensates for the fact that our self-signed CA is not added to that store. (For production use, such a certificate should be added.)

The second command creates a single unseal key with a requirement for a single unseal key to be present for unsealing. (For production use, an instance would have multiple unseal keys with up to that many keys required to be entered to unseal it. The unseal keys should be delivered to key custodians within the company. Use of a single key might be considered a security issue because that permits the vault to be unsealed by a single key custodian.)

Vault should reply with information about the unseal key and root token, plus some additional text (the actual unseal key and root token values differ from those shown here):

```
...
Unseal Key 1: I2xwcFQc89200Nt2pBiRNlnkHdTUrWS+JybL39BjcOE=
Initial Root Token: s.vTvXeo3tPEYehfcd9WH7oUKz
...
```

Store the unseal key and root token in a secure location.

### 5. Unseal the HashiCorp Vault server.

Use this command to unseal the Vault server:

```
vault operator unseal
```

When prompted to enter the unseal key, use the key obtained previously during Vault initialization.

Vault should produce output indicating that setup is complete and the vault is unsealed.

### 6. Log in to the HashiCorp Vault server and verify its status.

Prepare the environment variables required for logging in as root:

```
vault login s.vTvXeo3tPEYehfcd9WH7oUKz
```

For the token value in that command, substitute the content of the root token obtained previously during Vault initialization.

Verify the Vault server status:

```
vault status
```

The output should contain these lines (among others):

```
...
Initialized true
Sealed false
...
```

## 7. Set up HashiCorp Vault authentication and storage.

**Note**

The operations described in this step are needed only the first time the Vault instance is run. They need not be repeated afterward.

Enable the AppRole authentication method and verify that it is in the authentication method list:

```
vault auth enable approle
vault auth list
```

Enable the Vault KeyValue storage engine:

```
vault secrets enable -version=1 kv
```

Create and set up a role for use with the `keyring_hashicorp` plugin (enter the command on a single line):

```
vault write auth/approle/role/mysql token_num_uses=0
token_ttl=20m token_max_ttl=30m secret_id_num_uses=0
```

## 8. Add an AppRole security policy.

**Note**

The operations described in this step are needed only the first time the Vault instance is run. They need not be repeated afterward.

Prepare a policy that to permit the previously created role to access appropriate secrets. Create a new file named `mysql.hcl` with the following content:

```
path "kv/mysql/*" {
 capabilities = ["create", "read", "update", "delete", "list"]
}
```

**Note**

`kv/mysql/` in this example may need adjustment per your local installation policies and security requirements. If so, make the same adjustment wherever else `kv/mysql/` appears in these instructions.

Import the policy file to the Vault server to create a policy named `mysql-policy`, then assign the policy to the new role:

```
vault policy write mysql-policy mysql.hcl
vault write auth/approle/role/mysql policies=mysql-policy
```

Obtain the ID of the newly created role and store it in a secure location:

```
vault read auth/approle/role/mysql/role-id
```

Generate a secret ID for the role and store it in a secure location:

```
vault write -f auth/approle/role/mysql/secret-id
```

After these AppRole role ID and secret ID credentials are generated, they are expected to remain valid indefinitely. They need not be generated again and the `keyring_hashicorp` plugin can be configured with them for use on an ongoing basis. For more information about AuthRole authentication, visit <https://www.vaultproject.io/docs/auth/approle.html>.

## keyring\_hashicorp Configuration

The plugin library file contains the `keyring_hashicorp` plugin and a loadable function, `keyring_hashicorp_update_config()`. When the plugin initializes and terminates, it automatically loads and unloads the function. There is no need to load and unload the function manually.

The `keyring_hashicorp` plugin supports the configuration parameters shown in the following table. To specify these parameters, assign values to the corresponding system variables.

Configuration Parameter	System Variable	Mandatory
HashiCorp Server URL	<code>keyring_hashicorp_server_url</code>	No
AppRole role ID	<code>keyring_hashicorp_role_id</code>	Yes
AppRole secret ID	<code>keyring_hashicorp_secret_id</code>	Yes
Store path	<code>keyring_hashicorp_store_path</code>	Yes
Authorization Path	<code>keyring_hashicorp_auth_path</code>	No
CA certificate file path	<code>keyring_hashicorp_ca_path</code>	No
Cache control	<code>keyring_hashicorp_caching</code>	No

To be usable during the server startup process, `keyring_hashicorp` must be loaded using the `--early-plugin-load` option. As indicated by the preceding table, several plugin-related system variables are mandatory and must also be set. For example, use these lines in the server `my.cnf` file, adjusting the `.so` suffix and file locations for your platform as necessary:

```
[mysqld]
early-plugin-load=keyring_hashicorp.so
keyring_hashicorp_role_id='ee3b495c-d0c9-11e9-8881-8444c71c32aa'
keyring_hashicorp_secret_id='0512af29-d0ca-11e9-95ee-0010e00dd718'
keyring_hashicorp_store_path='/v1/kv/mysql'
keyring_hashicorp_auth_path='/v1/auth/approle/login'
```

### Note

Per the [HashiCorp documentation](#), all API routes are prefixed with a protocol version (which you can see in the preceding example as `/v1/` in the `keyring_hashicorp_store_path` and `keyring_hashicorp_auth_path` values). If HashiCorp develops new protocol versions, it may be necessary to change `/v1/` to something else in your configuration.

MySQL Server authenticates against HashiCorp Vault using AppRole authentication. Successful authentication requires that two secrets be provided to Vault, a role ID and a secret ID, which are similar in concept to user name and password. The role ID and secret ID values to use are those obtained during the HashiCorp Vault setup procedure performed previously. To specify the two IDs, assign their respective values to the `keyring_hashicorp_role_id` and `keyring_hashicorp_secret_id` system variables. The setup procedure also results in a store path of `/v1/kv/mysql`, which is the value to assign to `keyring_hashicorp_commit_store_path`.

At plugin initialization time, `keyring_hashicorp` attempts to connect to the HashiCorp Vault server using the configuration values. If the connection is successful, the plugin stores the values in corresponding system variables that have `_commit_` in their name. For example, upon successful connection, the plugin stores the values of `keyring_hashicorp_role_id` and `keyring_hashicorp_store_path` in `keyring_hashicorp_commit_role_id` and `keyring_hashicorp_commit_store_path`.

Reconfiguration at runtime can be performed with the assistance of the `keyring_hashicorp_update_config()` function:

1. Use `SET` statements to assign the desired new values to the configuration system variables shown in the preceding table. These assignments in themselves have no effect on ongoing plugin operation.
2. Invoke `keyring_hashicorp_update_config()` to cause the plugin to reconfigure and reconnect to the HashiCorp Vault server using the new variable values.
3. If the connection is successful, the plugin stores the updated configuration values in corresponding system variables that have `_commit_` in their name.

For example, if you have reconfigured HashiCorp Vault to listen on port 8201 rather than the default 8200, reconfigure `keyring_hashicorp` like this:

```
mysql> SET GLOBAL keyring_hashicorp_server_url = 'https://127.0.0.1:8201';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT keyring_hashicorp_update_config();
+-----+
| keyring_hashicorp_update_config() |
+-----+
| Configuration update was successful. |
+-----+
1 row in set (0.03 sec)
```

If the plugin is not able to connect to HashiCorp Vault during initialization or reconfiguration and there was no existing connection, the `_commit_` system variables are set to `'Not committed'` for string-valued variables, and `OFF` for Boolean-valued variables. If the plugin is not able to connect but there was an existing connection, that connection remains active and the `_commit_` variables reflect the values used for it.

#### Note

If you do not set the mandatory system variables at server startup, or if some other plugin initialization error occurs, initialization fails. In this case, you can use the runtime reconfiguration procedure to initialize the plugin without restarting the server.

For additional information about the `keyring_hashicorp` plugin-specific system variables and function, see [Section 8.4.4.17, “Keyring System Variables”](#), and [Section 8.4.4.14, “Plugin-Specific Keyring Key-Management Functions”](#).

### 8.4.4.10 Using the Oracle Cloud Infrastructure Vault Keyring Component

#### Note

The Oracle Cloud Infrastructure Vault keyring component is included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see <https://www.mysql.com/products/>.

`component_keyring_oci` is part of the component infrastructure that communicates with Oracle Cloud Infrastructure Vault for back end storage. No key information is permanently stored in MySQL server local storage. All keys are stored in Oracle Cloud Infrastructure Vault, making this component well suited for Oracle Cloud Infrastructure MySQL customers for management of their MySQL Enterprise Edition keys.

MySQL Keyring began transitioning from plugins to use the component infrastructure. The introduction of `component_keyring_oci` is a continuation of that effort. For more information, see [Keyring Components Versus Keyring Plugins](#).

**Note**

Only one keyring component or plugin should be enabled at a time. Enabling multiple keyring components or plugins is unsupported and results may not be as anticipated.

To use `component_keyring_oci` for keystore management, you must:

1. Write a manifest that tells the server to load `component_keyring_oci`, as described in [Section 8.4.4.2, “Keyring Component Installation”](#).
2. Write a configuration file for `component_keyring_oci`, as described here.

- [Configuration Notes](#)
- [Verify the Component Installation](#)
- [Vault Keyring Component Usage](#)

## Configuration Notes

When it initializes, `component_keyring_oci` reads either a global configuration file, or a global configuration file paired with a local configuration file:

- The component attempts to read its global configuration file from the directory where the component library file is installed (that is, the server plugin directory).
- If the global configuration file indicates use of a local configuration file, the component attempts to read its local configuration file from the data directory.
- Although global and local configuration files are located in different directories, the file name is `component_keyring_oci.cnf` in both locations.
- It is an error for no configuration file to exist. `component_keyring_oci` cannot initialize without a valid configuration.

Local configuration files permit setting up multiple server instances to use `component_keyring_oci`, such that component configuration for each server instance is specific to a given data directory instance. This enables the same keyring component to be used with a distinct Oracle Cloud Infrastructure Vault for each instance.

You are assumed to be familiar with Oracle Cloud Infrastructure concepts, but the following documentation may be helpful when setting up resources to be used by `component_keyring_oci`:

- [Overview of Vault](#)
- [Required Keys and OCIDs](#)
- [Managing Keys](#)
- [Managing Compartments](#)
- [Managing Vaults](#)
- [Managing Secrets](#)

`component_keyring_oci` configuration files have these properties:

- A configuration file must be in valid JSON format.
- A configuration file permits these configuration items:

- `"read_local_config"`: This item is permitted only in the global configuration file. If the item is not present, the component uses only the global configuration file. If the item is present, its value is `true` or `false`, indicating whether the component should read configuration information from the local configuration file.

If the `"read_local_config"` item is present in the global configuration file along with other items, the component checks the `"read_local_config"` item value first:

- If the value is `false`, the component processes the other items in the global configuration file and ignores the local configuration file.
- If the value is `true`, the component ignores the other items in the global configuration file and attempts to read the local configuration file.
- `"user"`: The OCID of the Oracle Cloud Infrastructure user that `component_keyring_oci` uses for connections. Prior to using `component_keyring_oci`, the user account must exist and be granted access to use the configured Oracle Cloud Infrastructure tenancy, compartment, and vault resources. To obtain the user OCID from the Console, use the instructions at [Required Keys and OCIDs](#).

This value is mandatory.

- `"tenancy"`: The OCID of the Oracle Cloud Infrastructure tenancy that `component_keyring_oci` uses as the location of the MySQL compartment. Prior to using `component_keyring_oci`, you must create a tenancy if it does not exist. To obtain the tenancy OCID from the Console, use the instructions at [Required Keys and OCIDs](#).

This value is mandatory.

- `"compartment"`: The OCID of the tenancy compartment that `component_keyring_oci` uses as the location of the MySQL keys. Prior to using `component_keyring_oci`, you must create a MySQL compartment or subcompartment if it does not exist. This compartment should contain no vault keys or vault secrets. It should not be used by systems other than MySQL Keyring. For information about managing compartments and obtaining the OCID, see [Managing Compartments](#).

This value is mandatory.

- `"virtual_vault"`: The OCID of the Oracle Cloud Infrastructure Vault that `component_keyring_oci` uses for encryption operations. Prior to using `component_keyring_oci`, you must create a new vault in the MySQL compartment if it does not exist. (Alternatively, you can reuse an existing vault that is in a parent compartment of the MySQL compartment.) Compartment users can see and use only the keys in their respective compartments. For information about creating a vault and obtaining the vault OCID, see [Managing Vaults](#).

This value is mandatory.

- `"encryption_endpoint"`: The endpoint of the Oracle Cloud Infrastructure encryption server that `component_keyring_oci` uses for generating encrypted or encoded information (ciphertext) for new keys. The encryption endpoint is vault specific and Oracle Cloud Infrastructure assigns it at vault-creation time. To obtain the endpoint OCID, view the configuration details for your `keyring_oci` vault, using the instructions at [Managing Vaults](#).

This value is mandatory.

- `"management_endpoint"`: The endpoint of the Oracle Cloud Infrastructure key management server that `component_keyring_oci` uses for listing existing keys. The key management endpoint is vault

specific and Oracle Cloud Infrastructure assigns it at vault-creation time. To obtain the endpoint OCID, view the configuration details for your keyring\_oci vault, using the instructions at [Managing Vaults](#).

This value is mandatory.

- `"vaults_endpoint"`: The endpoint of the Oracle Cloud Infrastructure vaults server that `component_keyring_oci` uses for obtaining the value of secrets. The vaults endpoint is vault specific and Oracle Cloud Infrastructure assigns it at vault-creation time. To obtain the endpoint OCID, view the configuration details for your keyring\_oci vault, using the instructions at [Managing Vaults](#).

This value is mandatory.

- `"secrets_endpoint"`: The endpoint of the Oracle Cloud Infrastructure secrets server that `component_keyring_oci` uses for listing, creating, and retiring secrets. The secrets endpoint is vault specific and Oracle Cloud Infrastructure assigns it at vault-creation time. To obtain the endpoint OCID, view the configuration details for your keyring\_oci vault, using the instructions at [Managing Vaults](#).

This value is mandatory.

- `"master_key"`: The OCID of the Oracle Cloud Infrastructure master encryption key that `component_keyring_oci` uses for encryption of secrets. Prior to using `component_keyring_oci`, you must create a cryptographic key for the Oracle Cloud Infrastructure compartment if it does not exist. Provide a MySQL-specific name for the generated key and do not use it for other purposes. For information about key creation, see [Managing Keys](#).

This value is mandatory.

- `"key_file"`: The path name of the file containing the RSA private key that `component_keyring_oci` uses for Oracle Cloud Infrastructure authentication. You must also upload the corresponding RSA public key using the Console. The Console displays the key fingerprint value, which you can use to set the `"key_fingerprint"` value. For information about generating and uploading API keys, see [Required Keys and OCIDs](#).

This value is mandatory.

- `"key_fingerprint"`: The fingerprint of the RSA private key that `component_keyring_oci` uses for Oracle Cloud Infrastructure authentication. To obtain the key fingerprint while creating the API keys, execute this command:

```
openssl rsa -pubout -outform DER -in ~/.oci/oci_api_key.pem | openssl md5 -c
```

Alternatively, obtain the fingerprint from the Console, which automatically displays the fingerprint when you upload the RSA public key. For information about obtaining key fingerprints, see [Required Keys and OCIDs](#).

This value is mandatory.

- `"ca_certificate"`: The path name of the CA certificate bundle file that `component_keyring_oci` component uses for Oracle Cloud Infrastructure certificate verification. The file contains one or more certificates for peer verification. If no file is specified, the default CA bundle installed on the system is used. If the value is set to `disabled` (case-sensitive), `component_keyring_oci` performs no certificate verification.

Given the preceding configuration file properties, to configure `component_keyring_oci`, create a global configuration file named `component_keyring_oci.cnf` in the directory where the

`component_keyring_oci` library file is installed, and optionally create a local configuration file, also named `component_keyring_oci.cnf`, in the data directory.

## Verify the Component Installation

After performing any component-specific configuration, start the server. Verify component installation by examining the Performance Schema `keyring_component_status` table:

```
mysql> SELECT * FROM performance_schema.keyring_component_status;
```

STATUS_KEY	STATUS_VALUE
Component_name	component_keyring_oci
Author	Oracle Corporation
License	PROPRIETARY
Implementation_name	component_keyring_oci
Version	1.0
Component_status	Active
user	ocidl.user.oc1..aaaaaaaasqly<...>
tenancy	ocidl.tenancy.oc1..aaaaaaaai<...>
compartment	ocidl.compartment.oc1..aaaaaaaah2swh<...>
virtual_vault	ocidl.vault.oc1.iad.bbo5xyzkaaeuk.abuwcljtmvxp4r<...>
master_key	ocidl.key.oc1.iad.bbo5xyzkaaeuk.abuwcljrbsrewgap<...>
encryption_endpoint	bbo5xyzkaaeuk-crypto.kms.us-<...>
management_endpoint	bbo5xyzkaaeuk-management.kms.us-<...>
vaults_endpoint	vaults.us-<...>
secrets_endpoint	secrets.vaults.us-<...>
key_file	~/oci/oci_api_key.pem
key_fingerprint	ca:7c:el:fa:86:b6:40:af:39:d6<...>
ca_certificate	disabled

A `Component_status` value of `Active` indicates that the component initialized successfully.

If the component cannot be loaded, server startup fails. Check the server error log for diagnostic messages. If the component loads but fails to initialize due to configuration problems, the server starts but the `Component_status` value is `Disabled`. Check the server error log, correct the configuration issues, and use the `ALTER INSTANCE RELOAD KEYRING` statement to reload the configuration.

It is possible to query MySQL server for the list of existing keys. To see which keys exist, examine the Performance Schema `keyring_keys` table.

```
mysql> SELECT * FROM performance_schema.keyring_keys;
```

KEY_ID	KEY_OWNER	BACKEND_KEY_ID
audit_log-20210322T130749-1		
MyKey	me@localhost	
YourKey	me@localhost	

## Vault Keyring Component Usage

`component_keyring_oci` supports the functions that comprise the standard MySQL Keyring service interface. Keyring operations performed by those functions are accessible in SQL statements as described in [Section 8.4.4.13, “General-Purpose Keyring Key-Management Functions”](#).

Example:

```
SELECT keyring_key_generate('MyKey', 'AES', 32);
SELECT keyring_key_remove('MyKey');
```

For information about the characteristics of key values permitted by `component_keyring_oci`, see [Section 8.4.4.11, “Supported Keyring Key Types and Lengths”](#).

### 8.4.4.11 Supported Keyring Key Types and Lengths

MySQL Keyring supports keys of different types (encryption algorithms) and lengths:

- The available key types depend on which keyring plugin is installed.
- The permitted key lengths are subject to multiple factors:
  - General keyring loadable-function interface limits (for keys managed using one of the keyring functions described in [Section 8.4.4.13, “General-Purpose Keyring Key-Management Functions”](#)), or limits from back end implementations. These length limits can vary by key operation type.
  - In addition to the general limits, individual keyring plugins may impose restrictions on key lengths per key type.

[Table 8.32, “General Keyring Key Length Limits”](#) shows the general key-length limits. (The lower limits for `keyring_aws` are imposed by the AWS KMS interface, not the keyring functions.) For keyring plugins, [Table 8.33, “Keyring Plugin Key Types and Lengths”](#) shows the key types each keyring plugin permits, as well as any plugin-specific key-length restrictions. For most keyring components, the general key-length limits apply and there are no key-type restrictions.

#### Note

`component_keyring_oci` can generate keys of type `AES` with a size of 16, 24, or 32 bytes only.

**Table 8.32 General Keyring Key Length Limits**

Key Operation	Maximum Key Length
Generate key	16,384 bytes (2,048 previously); 1,024 for <code>keyring_aws</code>
Store key	16,384 bytes (2,048 previously); 4,096 for <code>keyring_aws</code>
Fetch key	16,384 bytes (2,048 previously); 4,096 for <code>keyring_aws</code>

**Table 8.33 Keyring Plugin Key Types and Lengths**

Plugin Name	Permitted Key Type	Plugin-Specific Length Restrictions
<code>keyring_aws</code>	<code>AES</code>	16, 24, or 32 bytes
	<code>SECRET</code>	None
<code>keyring_hashicorp</code>	<code>AES</code>	None
	<code>DSA</code>	None
	<code>RSA</code>	None
	<code>SECRET</code>	None
<code>keyring_okv</code>	<code>AES</code>	16, 24, or 32 bytes

Plugin Name	Permitted Key Type	Plugin-Specific Length Restrictions
	<a href="#">SECRET</a>	None

The [SECRET](#) key type is intended for general-purpose storage of sensitive data using the MySQL keyring, and is supported by most keyring components and keyring plugins. The keyring encrypts and decrypts [SECRET](#) data as a byte stream upon storage and retrieval.

Example keyring operations involving the [SECRET](#) key type:

```
SELECT keyring_key_generate('MySecret1', 'SECRET', 20);
SELECT keyring_key_remove('MySecret1');

SELECT keyring_key_store('MySecret2', 'SECRET', 'MySecretData');
SELECT keyring_key_fetch('MySecret2');
SELECT keyring_key_length_fetch('MySecret2');
SELECT keyring_key_type_fetch('MySecret2');
SELECT keyring_key_remove('MySecret2');
```

#### 8.4.4.12 Migrating Keys Between Keyring Keystores

A keyring migration copies keys from one keystore to another, enabling a DBA to switch a MySQL installation to a different keystore. A successful migration operation has this result:

- The destination keystore contains the keys it had prior to the migration, plus the keys from the source keystore.
- The source keystore remains the same before and after the migration (because keys are copied, not moved).

If a key to be copied already exists in the destination keystore, an error occurs and the destination keystore is restored to its premigration state.

The keyring manages keystores using keyring components and keyring plugins. This pertains to migration strategy because the way in which the source and destination keystores are managed determines the procedure for performing a given type of key migration:

- Migration from one keyring plugin to another: The MySQL server has an operational mode that provides this capability.
- Migration from a keyring plugin to a keyring component: The MySQL server has an operational mode that provides this capability.
- Migration from one keyring component to another: The [mysql\\_migrate\\_keyring](#) utility provides this capability.
- Migration from a keyring component to a keyring plugin: The MySQL server has an operational mode that provides this capability.

The following sections discuss the characteristics of offline and online migrations and describe how to perform migrations.

- [Offline and Online Key Migrations](#)
- [Key Migration Using a Migration Server](#)
- [Key Migration Using the mysql\\_migrate\\_keyring Utility](#)
- [Key Migration Involving Multiple Running Servers](#)

## Offline and Online Key Migrations

A key migration is either offline or online:

- Offline migration: For use when you are sure that no running server on the local host is using the source or destination keystore. In this case, the migration operation can copy keys from the source keystore to the destination without the possibility of a running server modifying keystore content during the operation.
- Online migration: For use when a running server on the local host is using the source keystore. In this case, care must be taken to prevent that server from updating keystores during the migration. This involves connecting to the running server and instructing it to pause keyring operations so that keys can be copied safely from the source keystore to the destination. When key copying is complete, the running server is permitted to resume keyring operations.

When you plan a key migration, use these points to decide whether it should be offline or online:

- Do not perform offline migration involving a keystore that is in use by a running server.
- Pausing keyring operations during an online migration is accomplished by connecting to the running server and setting its global `keyring_operations` system variable to `OFF` before key copying and `ON` after key copying. This has several implications:
  - `keyring_operations` was introduced in MySQL 5.7.21, so online migration is possible only if the running server is from MySQL 5.7.21 or higher. If the running server is older, you must stop it, perform an offline migration, and restart it. All migration instructions elsewhere that refer to `keyring_operations` are subject to this condition.
  - The account used to connect to the running server must have the privileges required to modify `keyring_operations`. These privileges are `ENCRYPTION_KEY_ADMIN` in addition to either `SYSTEM_VARIABLES_ADMIN` or the deprecated `SUPER` privilege.
  - If an online migration operation exits abnormally (for example, if it is forcibly terminated), it is possible for `keyring_operations` to remain disabled on the running server, leaving it unable to perform keyring operations. In this case, it may be necessary to connect to the running server and enable `keyring_operations` manually using this statement:

```
SET GLOBAL keyring_operations = ON;
```

- Online key migration provides for pausing keyring operations on a single running server. To perform a migration if multiple running servers are using the keystores involved, use the procedure described at [Key Migration Involving Multiple Running Servers](#).

## Key Migration Using a Migration Server

### Note

Online key migration using a migration server is only supported if the running server allows socket connections or TCP/IP connections using TLS; it is not supported when, for example, the server is running on a Windows platform and only allows shared memory connections.

A MySQL server becomes a migration server if invoked in a special operational mode that supports key migration. A migration server does not accept client connections. Instead, it runs only long enough to migrate keys, then exits. A migration server reports errors to the console (the standard error output).

A migration server supports these migration types:

- Migration from one keyring plugin to another.
- Migration from a keyring plugin to a keyring component.
- Migration from a keyring component to a keyring plugin.

A migration server does not support migration from one keyring component to another. For that type of migration, see [Key Migration Using the `mysql\_migrate\_keyring` Utility](#).

To perform a key migration operation using a migration server, determine the key migration options required to specify which keyring plugins or components are involved, and whether the migration is offline or online:

- To indicate the source keyring plugin and the destination keyring plugin or component, specify these options:
  - `--keyring-migration-source`: The source keyring component or plugin that manages the keys to be migrated.
  - `--keyring-migration-destination`: The destination keyring plugin or component to which the migrated keys are to be copied.
  - `--keyring-migration-to-component`: This option is required if the destination is a keyring component.
  - `--keyring-migration-from-component`: This option is required if the source is a keyring component.

The `--keyring-migration-source` and `--keyring-migration-destination` options signify to the server that it should run in key migration mode. For key migration operations, both options are mandatory. Each plugin or component is specified using the name of its library file, including any platform-specific extension such as `.so` or `.dll`. The source and destination must differ, and the migration server must support them both.

- For an offline migration, no additional key migration options are needed.
- For an online migration, some running server currently is using the source or destination keystore. To invoke the migration server, specify additional key migration options that indicate how to connect to the running server. This is necessary so that the migration server can connect to the running server and tell it to pause keyring use during the migration operation.

Use of any of the following options signifies an online migration:

- `--keyring-migration-host`: The host where the running server is located. This is always the local host because the migration server can migrate keys only between keystores managed by local plugins and components.
- `--keyring-migration-user`, `--keyring-migration-password`: The account credentials to use to connect to the running server.
- `--keyring-migration-port`: For TCP/IP connections, the port number to connect to on the running server.
- `--keyring-migration-socket`: For Unix socket file or Windows named pipe connections, the socket file or named pipe to connect to on the running server.

For additional details about the key migration options, see [Section 8.4.4.16, “Keyring Command Options”](#).

Start the migration server with key migration options indicating the source and destination keystores and whether the migration is offline or online, possibly with other options. Keep the following considerations in mind:

- Other server options might be required; other non-keyring options may be required as well. One way to specify these options is by using `--defaults-file` to name an option file that contains the required options.
- The migration server expects path name option values to be full paths. Relative path names may not be resolved as you expect.
- The user who invokes a server in key-migration mode must not be the `root` operating system user, unless the `--user` option is specified with a non-`root` user name to run the server as that user.
- The user a server in key-migration mode runs as must have permission to read and write any local keyring files, such as the data file for a file-based plugin.

If you invoke the migration server from a system account different from that normally used to run MySQL, it might create keyring directories or files that are inaccessible to the server during normal operation. Suppose that `mysqld` normally runs as the `mysql` operating system user, but you invoke the migration server while logged in as `isabel`. Any new directories or files created by the migration server are owned by `isabel`. Subsequent startup fails when a server run as the `mysql` operating system user attempts to access file system objects owned by `isabel`.

To avoid this issue, start the migration server as the `root` operating system user and provide a `--user=user_name` option, where `user_name` is the system account normally used to run MySQL. Alternatively, after the migration, examine the keyring-related file system objects and change their ownership and permissions if necessary using `chown`, `chmod`, or similar commands, so that the objects are accessible to the running server.

Example command line for offline migration between two keyring plugins (enter the command on a single line):

```
mysqld --defaults-file=/usr/local/mysql/etc/my.cnf
--keyring-migration-source=keyring_okv.so
--keyring-migration-destination=keyring_aws.so
```

Example command line for online migration between two keyring plugins:

```
mysqld --defaults-file=/usr/local/mysql/etc/my.cnf
--keyring-migration-source=keyring_okv.so
--keyring-migration-destination=keyring_aws.so
--keyring-migration-host=127.0.0.1
--keyring-migration-user=root
--keyring-migration-password=root_password
```

To perform a migration when the destination is a keyring component rather than a keyring plugin, specify the `--keyring-migration-to-component` option, and name the component as the value of the `--keyring-migration-destination` option.

Example command line for offline migration from a keyring plugin to a keyring component:

```
mysqld --defaults-file=/usr/local/mysql/etc/my.cnf
--keyring-migration-to-component
--keyring-migration-source=keyring_okv.so
--keyring-migration-destination=component_keyring_encrypted_file.so
```

Notice that in this case, no `keyring_encrypted_file_password` value is specified. The password for the component data file is listed in the component configuration file.

Example command line for online migration from a keyring plugin to a keyring component:

```
mysqld --defaults-file=/usr/local/mysql/etc/my.cnf
--keyring-migration-to-component
--keyring-migration-source=keyring_okv.so
--keyring-migration-destination=component_keyring_encrypted_file.so
--keyring-migration-host=127.0.0.1
--keyring-migration-user=root
--keyring-migration-password=root_password
```

To perform a migration when the source is a keyring component rather than a keyring plugin, specify the `--keyring-migration-from-component` option, and name the component as the value of the `--keyring-migration-source` option.

Example command line for offline migration from a keyring component to a keyring plugin:

```
mysqld --defaults-file=/usr/local/mysql/etc/my.cnf
--keyring-migration-from-component
--keyring-migration-source=component_keyring_file.so
--keyring-migration-destination=keyring_okv.so
--keyring-okv-conf-dir=/usr/local/mysql/mysql-keyring-okv
```

Example command line for online migration from a keyring component to a keyring plugin:

```
mysqld --defaults-file=/usr/local/mysql/etc/my.cnf
--keyring-migration-from-component
--keyring-migration-source=component_keyring_file.so
--keyring-migration-destination=keyring_okv.so
--keyring-okv-conf-dir=/usr/local/mysql/mysql-keyring-okv
--keyring-migration-host=127.0.0.1
--keyring-migration-user=root
--keyring-migration-password=root_password
```

The key migration server performs a migration operation as follows:

1. (Online migration only) Connect to the running server using the connection options.
2. (Online migration only) Disable `keyring_operations` on the running server.
3. Load the keyring plugin or component libraries for the source and destination keystores.
4. Copy keys from the source keystore to the destination.
5. Unload the keyring plugin or component libraries for the source and destination keystores.
6. (Online migration only) Enable `keyring_operations` on the running server.
7. (Online migration only) Disconnect from the running server.

If an error occurs during key migration, the destination keystore is restored to its premigration state.

After a successful online key migration operation, the running server might need to be restarted:

- If the running server was using the source keystore before the migration and should continue to use it after the migration, it need not be restarted after the migration.
- If the running server was using the destination keystore before the migration and should continue to use it after the migration, it should be restarted after the migration to load all keys migrated into the destination keystore.
- If the running server was using the source keystore before the migration but should use the destination keystore after the migration, it must be reconfigured to use the destination keystore and restarted. In this

case, be aware that although the running server is paused from modifying the source keystore during the migration itself, it is not paused during the interval between the migration and the subsequent restart. Care should be taken that the server does not modify the source keystore during this interval because any such changes will not be reflected in the destination keystore.

## Key Migration Using the `mysql_migrate_keyring` Utility

The `mysql_migrate_keyring` utility migrates keys from one keyring component to another. It does not support migrations involving keyring plugins. For that type of migration, use a MySQL server operating in key migration mode; see [Key Migration Using a Migration Server](#).

To perform a key migration operation using `mysql_migrate_keyring`, determine the key migration options required to specify which keyring components are involved, and whether the migration is offline or online:

- To indicate the source and destination keyring components and their location, specify these options:
  - `--source-keyring`: The source keyring component that manages the keys to be migrated.
  - `--destination-keyring`: The destination keyring component to which the migrated keys are to be copied.
  - `--component-dir`: The directory containing keyring component library files. This is typically the value of the `plugin_dir` system variable for the local MySQL server.

All three options are mandatory. Each keyring component name is a component library file name specified without any platform-specific extension such as `.so` or `.dll`. For example, to use the component for which the library file is `component_keyring_file.so`, specify the option as `--source-keyring=component_keyring_file`. The source and destination must differ, and `mysql_migrate_keyring` must support them both.

- For an offline migration, no additional options are needed.
- For an online migration, some running server currently is using the source or destination keystore. In this case, specify the `--online-migration` option to signify an online migration. In addition, specify connection options indicating how to connect to the running server, so that `mysql_migrate_keyring` can connect to it and tell it to pause keyring use during the migration operation.

The `--online-migration` option is commonly used in conjunction with connection options such as these:

- `--host`: The host where the running server is located. This is always the local host because `mysql_migrate_keyring` can migrate keys only between keystores managed by local components.
- `--user`, `--password`: The account credentials to use to connect to the running server.
- `--port`: For TCP/IP connections, the port number to connect to on the running server.
- `--socket`: For Unix socket file or Windows named pipe connections, the socket file or named pipe to connect to on the running server.

For descriptions of all available options, see [Section 6.6.8, “mysql\\_migrate\\_keyring — Keyring Key Migration Utility”](#).

Start `mysql_migrate_keyring` with options indicating the source and destination keystores and whether the migration is offline or online, possibly with other options. Keep the following considerations in mind:

- The user who invokes `mysql_migrate_keyring` must not be the `root` operating system user.
- The user who invokes `mysql_migrate_keyring` must have permission to read and write any local keyring files, such as the data file for a file-based plugin.

If you invoke `mysql_migrate_keyring` from a system account different from that normally used to run MySQL, it might create keyring directories or files that are inaccessible to the server during normal operation. Suppose that `mysqld` normally runs as the `mysql` operating system user, but you invoke `mysql_migrate_keyring` while logged in as `isabel`. Any new directories or files created by `mysql_migrate_keyring` are owned by `isabel`. Subsequent startup fails when a server run as the `mysql` operating system user attempts to access file system objects owned by `isabel`.

To avoid this issue, invoke `mysql_migrate_keyring` as the `mysql` operating system user. Alternatively, after the migration, examine the keyring-related file system objects and change their ownership and permissions if necessary using `chown`, `chmod`, or similar commands, so that the objects are accessible to the running server.

Suppose that you want to migrate keys from `component_keyring_file` to `component_keyring_encrypted_file`, and that the local server stores its keyring component library files in `/usr/local/mysql/lib/plugin`.

If no running server is using the keyring, an offline migration is permitted. Invoke `mysql_migrate_keyring` like this (enter the command on a single line):

```
mysql_migrate_keyring
--component-dir=/usr/local/mysql/lib/plugin
--source-keyring=component_keyring_file
--destination-keyring=component_keyring_encrypted_file
```

If a running server is using the keyring, you must perform an online migration instead. In this case, the `--online-migration` option must be given, along with any connection options required to specify which server to connect to and the MySQL account to use.

The following command performs an online migration. It connects to the local server using a TCP/IP connection and the `admin` account. The command prompts for a password, which you should enter when prompted:

```
mysql_migrate_keyring
--component-dir=/usr/local/mysql/lib/plugin
--source-keyring=component_keyring_file
--destination-keyring=component_keyring_encrypted_file
--online-migration --host=127.0.0.1 --user=admin --password
```

`mysql_migrate_keyring` performs a migration operation as follows:

1. (Online migration only) Connect to the running server using the connection options.
2. (Online migration only) Disable `keyring_operations` on the running server.
3. Load the keyring component libraries for the source and destination keystores.
4. Copy keys from the source keystore to the destination.
5. Unload the keyring component libraries for the source and destination keystores.
6. (Online migration only) Enable `keyring_operations` on the running server.
7. (Online migration only) Disconnect from the running server.

If an error occurs during key migration, the destination keystore is restored to its premigration state.

After a successful online key migration operation, the running server might need to be restarted:

- If the running server was using the source keystore before the migration and should continue to use it after the migration, it need not be restarted after the migration.
- If the running server was using the destination keystore before the migration and should continue to use it after the migration, it should be restarted after the migration to load all keys migrated into the destination keystore.
- If the running server was using the source keystore before the migration but should use the destination keystore after the migration, it must be reconfigured to use the destination keystore and restarted. In this case, be aware that although the running server is paused from modifying the source keystore during the migration itself, it is not paused during the interval between the migration and the subsequent restart. Care should be taken that the server does not modify the source keystore during this interval because any such changes will not be reflected in the destination keystore.

### Key Migration Involving Multiple Running Servers

Online key migration provides for pausing keyring operations on a single running server. To perform a migration if multiple running servers are using the keystores involved, use this procedure:

1. Connect to each running server manually and set `keyring_operations=OFF`. This ensures that no running server is using the source or destination keystore and satisfies the required condition for offline migration.
2. Use a migration server or `mysql_migrate_keyring` to perform an offline key migration for each paused server.
3. Connect to each running server manually and set `keyring_operations=ON`.

All running servers must support the `keyring_operations` system variable. Any server that does not must be stopped before the migration and restarted after.

#### 8.4.4.13 General-Purpose Keyring Key-Management Functions

MySQL Server supports a keyring service that enables internal components and plugins to store sensitive information securely for later retrieval.

MySQL Server also includes an SQL interface for keyring key management, implemented as a set of general-purpose functions that access the capabilities provided by the internal keyring service. The keyring functions are contained in a plugin library file, which also contains a `keyring_udf` plugin that must be enabled prior to function invocation. For these functions to be used, a keyring plugin such as `keyring_okv`, or a keyring component such as `component_keyring_file` or `component_keyring_encrypted_file`, must be enabled.

The functions described here are general-purpose and intended for use with any keyring component or plugin. A given keyring component or plugin may also provide functions of its own that are intended for use only with that component or plugin; see [Section 8.4.4.14, “Plugin-Specific Keyring Key-Management Functions”](#).

The following sections provide installation instructions for the keyring functions and demonstrate how to use them. For general keyring information, see [Section 8.4.4, “The MySQL Keyring”](#).

- [Installing or Uninstalling General-Purpose Keyring Functions](#)

- [Using General-Purpose Keyring Functions](#)
- [General-Purpose Keyring Function Reference](#)

## Installing or Uninstalling General-Purpose Keyring Functions

This section describes how to install or uninstall the keyring functions, which are implemented in a plugin library file that also contains a `keyring_udf` plugin. For general information about installing or uninstalling plugins and loadable functions, see [Section 7.6.1, “Installing and Uninstalling Plugins”](#), and [Section 7.7.1, “Installing and Uninstalling Loadable Functions”](#).

The keyring functions enable keyring key management operations, but the `keyring_udf` plugin must also be installed because the functions do not work correctly without it. Attempts to use the functions without the `keyring_udf` plugin result in an error.

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

The plugin library file base name is `keyring_udf`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

To install the `keyring_udf` plugin and the keyring functions, use the `INSTALL PLUGIN` and `CREATE FUNCTION` statements, adjusting the `.so` suffix for your platform as necessary:

```
INSTALL PLUGIN keyring_udf SONAME 'keyring_udf.so';
CREATE FUNCTION keyring_key_generate RETURNS INTEGER
 SONAME 'keyring_udf.so';
CREATE FUNCTION keyring_key_fetch RETURNS STRING
 SONAME 'keyring_udf.so';
CREATE FUNCTION keyring_key_length_fetch RETURNS INTEGER
 SONAME 'keyring_udf.so';
CREATE FUNCTION keyring_key_type_fetch RETURNS STRING
 SONAME 'keyring_udf.so';
CREATE FUNCTION keyring_key_store RETURNS INTEGER
 SONAME 'keyring_udf.so';
CREATE FUNCTION keyring_key_remove RETURNS INTEGER
 SONAME 'keyring_udf.so';
```

If the plugin and functions are used on a source replication server, install them on all replicas as well to avoid replication issues.

Once installed as just described, the plugin and functions remain installed until uninstalled. To remove them, use the `UNINSTALL PLUGIN` and `DROP FUNCTION` statements:

```
UNINSTALL PLUGIN keyring_udf;
DROP FUNCTION keyring_key_generate;
DROP FUNCTION keyring_key_fetch;
DROP FUNCTION keyring_key_length_fetch;
DROP FUNCTION keyring_key_type_fetch;
DROP FUNCTION keyring_key_store;
DROP FUNCTION keyring_key_remove;
```

## Using General-Purpose Keyring Functions

Before using the keyring general-purpose functions, install them according to the instructions provided in [Installing or Uninstalling General-Purpose Keyring Functions](#).

The keyring functions are subject to these constraints:

- To use any keyring function, the `keyring_udf` plugin must be enabled. Otherwise, an error occurs:

```
ERROR 1123 (HY000): Can't initialize function 'keyring_key_generate';
This function requires keyring_udf plugin which is not installed.
Please install
```

To install the `keyring_udf` plugin, see [Installing or Uninstalling General-Purpose Keyring Functions](#).

- The keyring functions invoke keyring service functions (see [Section 7.6.9.2, “The Keyring Service”](#)). The service functions in turn use whatever keyring plugin is installed (for example, `keyring_okv`). Therefore, to use any keyring function, some underlying keyring plugin must be enabled. Otherwise, an error occurs:

```
ERROR 3188 (HY000): Function 'keyring_key_generate' failed because
underlying keyring service returned an error. Please check if a
keyring plugin is installed and that provided arguments are valid
for the keyring you are using.
```

To install a keyring plugin, see [Section 8.4.4.3, “Keyring Plugin Installation”](#).

- A user must possess the global `EXECUTE` privilege to use any keyring function. Otherwise, an error occurs:

```
ERROR 1123 (HY000): Can't initialize function 'keyring_key_generate';
The user is not privileged to execute this function. User needs to
have EXECUTE
```

To grant the global `EXECUTE` privilege to a user, use this statement:

```
GRANT EXECUTE ON *.* TO user;
```

Alternatively, should you prefer to avoid granting the global `EXECUTE` privilege while still permitting users to access specific key-management operations, “wrapper” stored programs can be defined (a technique described later in this section).

- A key stored in the keyring by a given user can be manipulated later only by the same user. That is, the value of the `CURRENT_USER()` function at the time of key manipulation must have the same value as when the key was stored in the keyring. (This constraint rules out the use of the keyring functions for manipulation of instance-wide keys, such as those created by `InnoDB` to support tablespace encryption.)

To enable multiple users to perform operations on the same key, “wrapper” stored programs can be defined (a technique described later in this section).

- Keyring functions support the key types and lengths supported by the underlying keyring plugin. For information about keys specific to a particular keyring plugin, see [Section 8.4.4.11, “Supported Keyring Key Types and Lengths”](#).

To create a new random key and store it in the keyring, call `keyring_key_generate()`, passing to it an ID for the key, along with the key type (encryption method) and its length in bytes. The following call creates a 2,048-bit DSA-encrypted key named `MyKey`:

```
mysql> SELECT keyring_key_generate('MyKey', 'DSA', 256);
+-----+
| keyring_key_generate('MyKey', 'DSA', 256) |
+-----+
| 1 |
+-----+
```

A return value of 1 indicates success. If the key cannot be created, the return value is `NULL` and an error occurs. One reason this might be is that the underlying keyring plugin does not support the specified

combination of key type and key length; see [Section 8.4.4.11, “Supported Keyring Key Types and Lengths”](#).

To be able to check the return type regardless of whether an error occurs, use `SELECT ... INTO @var_name` and test the variable value:

```
mysql> SELECT keyring_key_generate('', '', -1) INTO @x;
ERROR 3188 (HY000): Function 'keyring_key_generate' failed because
underlying keyring service returned an error. Please check if a
keyring plugin is installed and that provided arguments are valid
for the keyring you are using.
mysql> SELECT @x;
+-----+
| @x |
+-----+
| NULL |
+-----+
mysql> SELECT keyring_key_generate('x', 'AES', 16) INTO @x;
mysql> SELECT @x;
+-----+
| @x |
+-----+
| 1 |
+-----+
```

This technique also applies to other keyring functions that for failure return a value and an error.

The ID passed to `keyring_key_generate()` provides a means by which to refer to the key in subsequent functions calls. For example, use the key ID to retrieve its type as a string or its length in bytes as an integer:

```
mysql> SELECT keyring_key_type_fetch('MyKey');
+-----+
| keyring_key_type_fetch('MyKey') |
+-----+
| DSA |
+-----+
mysql> SELECT keyring_key_length_fetch('MyKey');
+-----+
| keyring_key_length_fetch('MyKey') |
+-----+
| 256 |
+-----+
```

To retrieve a key value, pass the key ID to `keyring_key_fetch()`. The following example uses `HEX()` to display the key value because it may contain nonprintable characters. The example also uses a short key for brevity, but be aware that longer keys provide better security:

```
mysql> SELECT keyring_key_generate('MyShortKey', 'DSA', 8);
+-----+
| keyring_key_generate('MyShortKey', 'DSA', 8) |
+-----+
| 1 |
+-----+
mysql> SELECT HEX(keyring_key_fetch('MyShortKey'));
+-----+
| HEX(keyring_key_fetch('MyShortKey')) |
+-----+
| 1DB3B0FC3328A24C |
+-----+
```

Keyring functions treat key IDs, types, and values as binary strings, so comparisons are case-sensitive. For example, IDs of `MyKey` and `mykey` refer to different keys.

To remove a key, pass the key ID to `keyring_key_remove()`:

```
mysql> SELECT keyring_key_remove('MyKey');
+-----+
| keyring_key_remove('MyKey') |
+-----+
| 1 |
+-----+
```

To obfuscate and store a key that you provide, pass the key ID, type, and value to `keyring_key_store()`:

```
mysql> SELECT keyring_key_store('AES_key', 'AES', 'Secret string');
+-----+
| keyring_key_store('AES_key', 'AES', 'Secret string') |
+-----+
| 1 |
+-----+
```

As indicated previously, a user must have the global `EXECUTE` privilege to call keyring functions, and the user who stores a key in the keyring initially must be the same user who performs subsequent operations on the key later, as determined from the `CURRENT_USER()` value in effect for each function call. To permit key operations to users who do not have the global `EXECUTE` privilege or who may not be the key “owner,” use this technique:

1. Define “wrapper” stored programs that encapsulate the required key operations and have a `DEFINER` value equal to the key owner.
2. Grant the `EXECUTE` privilege for specific stored programs to the individual users who should be able to invoke them.
3. If the operations implemented by the wrapper stored programs do not include key creation, create any necessary keys in advance, using the account named as the `DEFINER` in the stored program definitions.

This technique enables keys to be shared among users and provides to DBAs more fine-grained control over who can do what with keys, without having to grant global privileges.

The following example shows how to set up a shared key named `SharedKey` that is owned by the DBA, and a `get_shared_key()` stored function that provides access to the current key value. The value can be retrieved by any user with the `EXECUTE` privilege for that function, which is created in the `key_schema` schema.

From a MySQL administrative account (`'root'@'localhost'` in this example), create the administrative schema and the stored function to access the key:

```
mysql> CREATE SCHEMA key_schema;

mysql> CREATE DEFINER = 'root'@'localhost'
FUNCTION key_schema.get_shared_key()
RETURNS BLOB READS SQL DATA
RETURN keyring_key_fetch('SharedKey');
```

From the administrative account, ensure that the shared key exists:

```
mysql> SELECT keyring_key_generate('SharedKey', 'DSA', 8);
+-----+
| keyring_key_generate('SharedKey', 'DSA', 8) |
+-----+
```

```
| 1 |
+-----+
```

From the administrative account, create an ordinary user account to which key access is to be granted:

```
mysql> CREATE USER 'key_user'@'localhost'
 IDENTIFIED BY 'key_user_pwd';
```

From the `key_user` account, verify that, without the proper `EXECUTE` privilege, the new account cannot access the shared key:

```
mysql> SELECT HEX(key_schema.get_shared_key());
ERROR 1370 (42000): execute command denied to user 'key_user'@'localhost'
for routine 'key_schema.get_shared_key'
```

From the administrative account, grant `EXECUTE` to `key_user` for the stored function:

```
mysql> GRANT EXECUTE ON FUNCTION key_schema.get_shared_key
 TO 'key_user'@'localhost';
```

From the `key_user` account, verify that the key is now accessible:

```
mysql> SELECT HEX(key_schema.get_shared_key());
+-----+
| HEX(key_schema.get_shared_key()) |
+-----+
| 9BAFB9E75CEE013 |
+-----+
```

## General-Purpose Keyring Function Reference

For each general-purpose keyring function, this section describes its purpose, calling sequence, and return value. For information about the conditions under which these functions can be invoked, see [Using General-Purpose Keyring Functions](#).

- `keyring_key_fetch(key_id)`

Given a key ID, deobfuscates and returns the key value.

Arguments:

- `key_id`: A string that specifies the key ID.

Return value:

Returns the key value as a string for success, `NULL` if the key does not exist, or `NULL` and an error for failure.

### Note

Key values retrieved using `keyring_key_fetch()` are subject to the general keyring function limits described in [Section 8.4.4.11, “Supported Keyring Key Types and Lengths”](#). A key value longer than that length can be stored using a keyring service function (see [Section 7.6.9.2, “The Keyring Service”](#)), but if retrieved using `keyring_key_fetch()` is truncated to the general keyring function limit.

Example:

```
mysql> SELECT keyring_key_generate('RSA_key', 'RSA', 16);
+-----+
| keyring_key_generate('RSA_key', 'RSA', 16) |
+-----+
| 1 |
+-----+
mysql> SELECT HEX(keyring_key_fetch('RSA_key'));
+-----+
| HEX(keyring_key_fetch('RSA_key')) |
+-----+
| 91C2253B696064D3556984B6630F891A |
+-----+
mysql> SELECT keyring_key_type_fetch('RSA_key');
+-----+
| keyring_key_type_fetch('RSA_key') |
+-----+
| RSA |
+-----+
mysql> SELECT keyring_key_length_fetch('RSA_key');
+-----+
| keyring_key_length_fetch('RSA_key') |
+-----+
| 16 |
+-----+
```

The example uses `HEX()` to display the key value because it may contain nonprintable characters. The example also uses a short key for brevity, but be aware that longer keys provide better security.

- `keyring_key_generate(key_id, key_type, key_length)`

Generates a new random key with a given ID, type, and length, and stores it in the keyring. The type and length values must be consistent with the values supported by the underlying keyring plugin. See [Section 8.4.4.11, “Supported Keyring Key Types and Lengths”](#).

Arguments:

- `key_id`: A string that specifies the key ID.
- `key_type`: A string that specifies the key type.
- `key_length`: An integer that specifies the key length in bytes.

Return value:

Returns 1 for success, or `NULL` and an error for failure.

Example:

```
mysql> SELECT keyring_key_generate('RSA_key', 'RSA', 384);
+-----+
| keyring_key_generate('RSA_key', 'RSA', 384) |
+-----+
| 1 |
+-----+
```

- `keyring_key_length_fetch(key_id)`

Given a key ID, returns the key length.

Arguments:

- `key_id`: A string that specifies the key ID.

Return value:

Returns the key length in bytes as an integer for success, `NULL` if the key does not exist, or `NULL` and an error for failure.

Example:

See the description of `keyring_key_fetch()`.

- `keyring_key_remove(key_id)`

Removes the key with a given ID from the keyring.

Arguments:

- `key_id`: A string that specifies the key ID.

Return value:

Returns 1 for success, or `NULL` for failure.

Example:

```
mysql> SELECT keyring_key_remove('AES_key');
+-----+
| keyring_key_remove('AES_key') |
+-----+
| 1 |
+-----+
```

- `keyring_key_store(key_id, key_type, key)`

Obfuscates and stores a key in the keyring.

Arguments:

- `key_id`: A string that specifies the key ID.
- `key_type`: A string that specifies the key type.
- `key`: A string that specifies the key value.

Return value:

Returns 1 for success, or `NULL` and an error for failure.

Example:

```
mysql> SELECT keyring_key_store('new key', 'DSA', 'My key value');
+-----+
| keyring_key_store('new key', 'DSA', 'My key value') |
+-----+
| 1 |
+-----+
```

- `keyring_key_type_fetch(key_id)`

Given a key ID, returns the key type.

Arguments:

- `key_id`: A string that specifies the key ID.

Return value:

Returns the key type as a string for success, `NULL` if the key does not exist, or `NULL` and an error for failure.

Example:

See the description of `keyring_key_fetch()`.

#### 8.4.4.14 Plugin-Specific Keyring Key-Management Functions

For each keyring plugin-specific function, this section describes its purpose, calling sequence, and return value. For information about general-purpose keyring functions, see [Section 8.4.4.13, “General-Purpose Keyring Key-Management Functions”](#).

- `keyring_aws_rotate_cmk()`

Associated keyring plugin: `keyring_aws`

##### Note

`keyring_aws_rotate_cmk()` is not provided by the AWS keyring component. For this reason, the function should be considered deprecated and thus subject to removal in a future version of MySQL.

`keyring_aws_rotate_cmk()` rotates the AWS KMS key. Rotation changes only the key that AWS KMS uses for subsequent data key-encryption operations. AWS KMS maintains previous CMK versions, so keys generated using previous CMKs remain decryptable after rotation.

Rotation changes the CMK value used inside AWS KMS but does not change the ID used to refer to it, so there is no need to change the `keyring_aws_cmk_id` system variable after calling `keyring_aws_rotate_cmk()`.

This function requires the `SUPER` privilege.

Arguments:

None.

Return value:

Returns 1 for success, or `NULL` and an error for failure.

- `keyring_aws_rotate_keys()`

Associated keyring plugin: `keyring_aws`

`keyring_aws_rotate_keys()` rotates keys stored in the `keyring_aws` storage file named by the `keyring_aws_data_file` system variable. Rotation sends each key stored in the file to AWS KMS for re-encryption using the value of the `keyring_aws_cmk_id` system variable as the CMK value, and stores the new encrypted keys in the file.

`keyring_aws_rotate_keys()` is useful for key re-encryption under these circumstances:

- After rotating the CMK; that is, after invoking the `keyring_aws_rotate_cmk()` function.

- After changing the `keyring_aws_cmk_id` system variable to a different key value.

This function requires the `SUPER` privilege.

Arguments:

None.

Return value:

Returns 1 for success, or `NULL` and an error for failure.

- `keyring_hashicorp_update_config()`

Associated keyring plugin: `keyring_hashicorp`

When invoked, the `keyring_hashicorp_update_config()` function causes `keyring_hashicorp` to perform a runtime reconfiguration, as described in [keyring\\_hashicorp Configuration](#).

This function requires the `SYSTEM_VARIABLES_ADMIN` privilege because it modifies global system variables.

Arguments:

None.

Return value:

Returns the string `'Configuration update was successful.'` for success, or `'Configuration update failed.'` for failure.

#### 8.4.4.15 Keyring Metadata

This section describes sources of information about keyring use.

To see whether a keyring plugin is loaded, check the Information Schema `PLUGINS` table or use the `SHOW PLUGINS` statement (see [Section 7.6.2, “Obtaining Server Plugin Information”](#)). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
 FROM INFORMATION_SCHEMA.PLUGINS
 WHERE PLUGIN_NAME LIKE 'keyring%';
```

PLUGIN_NAME	PLUGIN_STATUS
keyring_okv	ACTIVE

To see which keys exist, check the Performance Schema `keyring_keys` table:

```
mysql> SELECT * FROM performance_schema.keyring_keys;
```

KEY_ID	KEY_OWNER	BACKEND_KEY_ID
audit_log-20210322T130749-1		
MyKey	me@localhost	
YourKey	me@localhost	

To see whether a keyring component is loaded, check the Performance Schema `keyring_component_status` table. For example:

```
mysql> SELECT * FROM performance_schema.keyring_component_status;
```

STATUS_KEY	STATUS_VALUE
Component_name	component_keyring_file
Author	Oracle Corporation
License	GPL
Implementation_name	component_keyring_file
Version	1.0
Component_status	Active
Data_file	/usr/local/mysql/keyring/component_keyring_file
Read_only	No

A `Component_status` value of `Active` indicates that the component initialized successfully. If the component loaded but failed to initialize, the value is `Disabled`.

### 8.4.4.16 Keyring Command Options

MySQL supports the following keyring-related command-line options:

- `--keyring-migration-destination=plugin`

Command-Line Format	<code>--keyring-migration-destination=plugin_name</code>
Type	String

The destination keyring plugin or component for key migration. See [Section 8.4.4.12, “Migrating Keys Between Keyring Keystores”](#). The option value interpretation depends on whether `--keyring-migration-to-component` or `--keyring-migration-from-component` is specified:

- If `--keyring-migration-to-component` is used, the option value is a keyring plugin, interpreted the same way as for `--keyring-migration-source`.
- If `--keyring-migration-to-component` is used, the option value is a keyring component, specified as the component library name in the plugin directory, including any platform-specific extension such as `.so` or `.dll`.

#### Note

`--keyring-migration-source` and `--keyring-migration-destination` are mandatory for all keyring migration operations. The source and destination must differ, and the migration server must support both.

- `--keyring-migration-from-component`

Command-Line Format	<code>--keyring-migration-from-component[={OFF ON}]</code>
Type	Boolean
Default Value	<code>OFF</code>

Indicates that a key migration is from a keyring component to a keyring plugin. This option makes it possible to migrate keys from a keyring component to a keyring plugin.

For migration from a keyring plugin to a keyring component, use the `--keyring-migration-to-component` option. For key migration from one keyring component to another, use the `mysql_migrate_keyring` utility. See [Section 8.4.4.12, “Migrating Keys Between Keyring Keystores”](#).

- `--keyring-migration-host=host_name`

Command-Line Format	<code>--keyring-migration-host=host_name</code>
Type	String
Default Value	<code>localhost</code>

The host location of the running server that is currently using one of the key migration keystores. See [Section 8.4.4.12, “Migrating Keys Between Keyring Keystores”](#). Migration always occurs on the local host, so the option always specifies a value for connecting to a local server, such as `localhost`, `127.0.0.1`, `::1`, or the local host IP address or host name.

- `--keyring-migration-password[=password]`

Command-Line Format	<code>--keyring-migration-password[=password]</code>
Type	String

The password of the MySQL account used for connecting to the running server that is currently using one of the key migration keystores. See [Section 8.4.4.12, “Migrating Keys Between Keyring Keystores”](#).

The password value is optional. If not given, the server prompts for one. If given, there must be *no space* between `--keyring-migration-password=` and the password following it. If no password option is specified, the default is to send no password.

Specifying a password on the command line should be considered insecure. See [Section 8.1.2.1, “End-User Guidelines for Password Security”](#). You can use an option file to avoid giving the password on the command line. In this case, the file should have a restrictive mode and be accessible only to the account used to run the migration server.

- `--keyring-migration-port=port_num`

Command-Line Format	<code>--keyring-migration-port=port_num</code>
Type	Numeric
Default Value	<code>3306</code>

For TCP/IP connections, the port number for connecting to the running server that is currently using one of the key migration keystores. See [Section 8.4.4.12, “Migrating Keys Between Keyring Keystores”](#).

- `--keyring-migration-socket=path`

Command-Line Format	<code>--keyring-migration-socket={file_name pipe_name}</code>
Type	String

For Unix socket file or Windows named pipe connections, the socket file or named pipe for connecting to the running server that is currently using one of the key migration keystores. See [Section 8.4.4.12, “Migrating Keys Between Keyring Keystores”](#).

- `--keyring-migration-source=plugin`

Command-Line Format	<code>--keyring-migration-source=plugin_name</code>
---------------------	-----------------------------------------------------

Type	String
------	--------

The source keyring plugin for key migration. See [Section 8.4.4.12, “Migrating Keys Between Keyring Keystores”](#).

The option value is similar to that for `--plugin-load`, except that only one plugin library can be specified. The value is given as `plugin_library` or `name=plugin_library`, where `plugin_library` is the name of a library file that contains plugin code, and `name` is the name of a plugin to load. If a plugin library is named without any preceding plugin name, the server loads all plugins in the library. With a preceding plugin name, the server loads only the named plugin from the library. The server looks for plugin library files in the directory named by the `plugin_dir` system variable.

#### Note

`--keyring-migration-source` and `--keyring-migration-destination` are mandatory for all keyring migration operations. The source and destination plugins must differ, and the migration server must support both plugins.

- `--keyring-migration-to-component`

Command-Line Format	<code>--keyring-migration-to-component[={OFF ON}]</code>
Type	Boolean
Default Value	OFF

Indicates that a key migration is from a keyring plugin to a keyring component. This option makes it possible to migrate keys from a keyring plugin to a keyring component.

For migration from a keyring component to a keyring plugin, use the `--keyring-migration-from-component` option. For key migration from one keyring component to another, use the `mysql_migrate_keyring` utility. See [Section 8.4.4.12, “Migrating Keys Between Keyring Keystores”](#).

- `--keyring-migration-user=user_name`

Command-Line Format	<code>--keyring-migration-user=user_name</code>
Type	String

The user name of the MySQL account used for connecting to the running server that is currently using one of the key migration keystores. See [Section 8.4.4.12, “Migrating Keys Between Keyring Keystores”](#).

### 8.4.4.17 Keyring System Variables

MySQL Keyring plugins support the following system variables. Use them to configure keyring plugin operation. These variables are unavailable unless the appropriate keyring plugin is installed (see [Section 8.4.4.3, “Keyring Plugin Installation”](#)).

- `keyring_aws_cmk_id`

Command-Line Format	<code>--keyring-aws-cmk-id=value</code>
System Variable	<code>keyring_aws_cmk_id</code>
Scope	Global
Dynamic	Yes

<code>SET_VAR</code> Hint Applies	No
Type	String

The KMS key ID obtained from the AWS KMS server and used by the `keyring_aws` plugin. This variable is unavailable unless that plugin is installed.

This variable is mandatory. If not specified, `keyring_aws` initialization fails.

- `keyring_aws_conf_file`

Command-Line Format	<code>--keyring-aws-conf-file=file_name</code>
System Variable	<code>keyring_aws_conf_file</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	File name
Default Value	<code>platform specific</code>

The location of the configuration file for the `keyring_aws` plugin. This variable is unavailable unless that plugin is installed.

At plugin startup, `keyring_aws` reads the AWS secret access key ID and key from the configuration file. For the `keyring_aws` plugin to start successfully, the configuration file must exist and contain valid secret access key information, initialized as described in [Section 8.4.4.7, “Using the keyring\\_aws Amazon Web Services Keyring Plugin”](#).

The default file name is `keyring_aws_conf`, located in the default keyring file directory.

- `keyring_aws_data_file`

Command-Line Format	<code>--keyring-aws-data-file</code>
System Variable	<code>keyring_aws_data_file</code>
Scope	Global
Dynamic	No
<code>SET_VAR</code> Hint Applies	No
Type	File name
Default Value	<code>platform specific</code>

The location of the storage file for the `keyring_aws` plugin. This variable is unavailable unless that plugin is installed.

At plugin startup, if the value assigned to `keyring_aws_data_file` specifies a file that does not exist, the `keyring_aws` plugin attempts to create it (as well as its parent directory, if necessary). If the file does exist, `keyring_aws` reads any encrypted keys contained in the file into its in-memory cache. `keyring_aws` does not cache unencrypted keys in memory.

The default file name is `keyring_aws_data`, located in the default keyring file directory.

- `keyring_aws_region`

Command-Line Format	<code>--keyring-aws-region=value</code>
System Variable	<code>keyring_aws_region</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Enumeration
Default Value	<code>us-east-1</code>
Valid Values	<code>af-south-1</code> <code>ap-east-1</code> <code>ap-northeast-1</code> <code>ap-northeast-2</code> <code>ap-northeast-3</code> <code>ap-south-1</code> <code>ap-southeast-1</code> <code>ap-southeast-2</code> <code>ca-central-1</code> <code>cn-north-1</code> <code>cn-northwest-1</code> <code>eu-central-1</code> <code>eu-north-1</code> <code>eu-south-1</code> <code>eu-west-1</code> <code>eu-west-2</code> <code>eu-west-3</code> <code>me-south-1</code> <code>sa-east-1</code> <code>us-east-1</code> <code>us-east-2</code> <code>us-gov-east-1</code> <code>us-iso-east-1</code>

	us-iso-west-1
	us-isob-east-1
	us-west-1
	us-west-2

The AWS region for the `keyring_aws` plugin. This variable is unavailable unless that plugin is installed.

- `keyring_hashicorp_auth_path`

Command-Line Format	<code>--keyring-hashicorp-auth-path=value</code>
System Variable	<code>keyring_hashicorp_auth_path</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	String
Default Value	<code>/v1/auth/approle/login</code>

The authentication path where AppRole authentication is enabled within the HashiCorp Vault server, for use by the `keyring_hashicorp` plugin. This variable is unavailable unless that plugin is installed.

- `keyring_hashicorp_ca_path`

Command-Line Format	<code>--keyring-hashicorp-ca-path=file_name</code>
System Variable	<code>keyring_hashicorp_ca_path</code>
Scope	Global
Dynamic	Yes
SET_VAR Hint Applies	No
Type	File name
Default Value	<code>empty string</code>

The absolute path name of a local file accessible to the MySQL server that contains a properly formatted TLS certificate authority for use by the `keyring_hashicorp` plugin. This variable is unavailable unless that plugin is installed.

If this variable is not set, the `keyring_hashicorp` plugin opens an HTTPS connection without using server certificate verification, and trusts any certificate delivered by the HashiCorp Vault server. For this to be safe, it must be assumed that the Vault server is not malicious and that no man-in-the-middle attack is possible. If those assumptions are invalid, set `keyring_hashicorp_ca_path` to the path of a trusted CA certificate. (For example, for the instructions in [Certificate and Key Preparation](#), this is the `company.crt` file.)

- `keyring_hashicorp_caching`

Command-Line Format	<code>--keyring-hashicorp-caching[={OFF ON} ]</code>
System Variable	<code>keyring_hashicorp_caching</code>

Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Boolean
Default Value	<a href="#">OFF</a>

Whether to enable the optional in-memory key cache used by the [keyring\\_hashicorp](#) plugin to cache keys from the HashiCorp Vault server. This variable is unavailable unless that plugin is installed. If the cache is enabled, the plugin populates it during initialization. Otherwise, the plugin populates only the key list during initialization.

Enabling the cache is a compromise: It improves performance, but maintains a copy of sensitive key information in memory, which may be undesirable for security purposes.

- [keyring\\_hashicorp\\_commit\\_auth\\_path](#)

System Variable	<a href="#">keyring_hashicorp_commit_auth_path</a>
Scope	Global
Dynamic	No
<a href="#">SET_VAR</a> Hint Applies	No
Type	String

This variable is associated with [keyring\\_hashicorp\\_auth\\_path](#), from which it takes its value during [keyring\\_hashicorp](#) plugin initialization. This variable is unavailable unless that plugin is installed. It reflects the “committed” value actually used for plugin operation if initialization succeeds. For additional information, see [keyring\\_hashicorp Configuration](#).

- [keyring\\_hashicorp\\_commit\\_ca\\_path](#)

System Variable	<a href="#">keyring_hashicorp_commit_ca_path</a>
Scope	Global
Dynamic	No
<a href="#">SET_VAR</a> Hint Applies	No
Type	String

This variable is associated with [keyring\\_hashicorp\\_ca\\_path](#), from which it takes its value during [keyring\\_hashicorp](#) plugin initialization. This variable is unavailable unless that plugin is installed. It reflects the “committed” value actually used for plugin operation if initialization succeeds. For additional information, see [keyring\\_hashicorp Configuration](#).

- [keyring\\_hashicorp\\_commit\\_caching](#)

System Variable	<a href="#">keyring_hashicorp_commit_caching</a>
Scope	Global
Dynamic	No
<a href="#">SET_VAR</a> Hint Applies	No

Type	String
------	--------

This variable is associated with [keyring\\_hashicorp\\_caching](#), from which it takes its value during [keyring\\_hashicorp](#) plugin initialization. This variable is unavailable unless that plugin is installed. It reflects the “committed” value actually used for plugin operation if initialization succeeds. For additional information, see [keyring\\_hashicorp Configuration](#).

- [keyring\\_hashicorp\\_commit\\_role\\_id](#)

System Variable	<a href="#">keyring_hashicorp_commit_role_id</a>
Scope	Global
Dynamic	No
<a href="#">SET_VAR</a> Hint Applies	No
Type	String

This variable is associated with [keyring\\_hashicorp\\_role\\_id](#), from which it takes its value during [keyring\\_hashicorp](#) plugin initialization. This variable is unavailable unless that plugin is installed. It reflects the “committed” value actually used for plugin operation if initialization succeeds. For additional information, see [keyring\\_hashicorp Configuration](#).

- [keyring\\_hashicorp\\_commit\\_server\\_url](#)

System Variable	<a href="#">keyring_hashicorp_commit_server_url</a>
Scope	Global
Dynamic	No
<a href="#">SET_VAR</a> Hint Applies	No
Type	String

This variable is associated with [keyring\\_hashicorp\\_server\\_url](#), from which it takes its value during [keyring\\_hashicorp](#) plugin initialization. This variable is unavailable unless that plugin is installed. It reflects the “committed” value actually used for plugin operation if initialization succeeds. For additional information, see [keyring\\_hashicorp Configuration](#).

- [keyring\\_hashicorp\\_commit\\_store\\_path](#)

System Variable	<a href="#">keyring_hashicorp_commit_store_path</a>
Scope	Global
Dynamic	No
<a href="#">SET_VAR</a> Hint Applies	No
Type	String

This variable is associated with [keyring\\_hashicorp\\_store\\_path](#), from which it takes its value during [keyring\\_hashicorp](#) plugin initialization. This variable is unavailable unless that plugin is installed. It reflects the “committed” value actually used for plugin operation if initialization succeeds. For additional information, see [keyring\\_hashicorp Configuration](#).

- [keyring\\_hashicorp\\_role\\_id](#)

Command-Line Format	<a href="#">--keyring-hashicorp-role-id=value</a> 1521
---------------------	--------------------------------------------------------

System Variable	<code>keyring_hashicorp_role_id</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value	<code>empty string</code>

The HashiCorp Vault AppRole authentication role ID, for use by the `keyring_hashicorp` plugin. This variable is unavailable unless that plugin is installed. The value must be in UUID format.

This variable is mandatory. If not specified, `keyring_hashicorp` initialization fails.

- `keyring_hashicorp_secret_id`

Command-Line Format	<code>--keyring-hashicorp-secret-id=value</code>
System Variable	<code>keyring_hashicorp_secret_id</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value	<code>empty string</code>

The HashiCorp Vault AppRole authentication secret ID, for use by the `keyring_hashicorp` plugin. This variable is unavailable unless that plugin is installed. The value must be in UUID format.

This variable is mandatory. If not specified, `keyring_hashicorp` initialization fails.

The value of this variable is sensitive, so its value is masked by \* characters when displayed.

- `keyring_hashicorp_server_url`

Command-Line Format	<code>--keyring-hashicorp-server-url=value</code>
System Variable	<code>keyring_hashicorp_server_url</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	String
Default Value	<code>https://127.0.0.1:8200</code>

The HashiCorp Vault server URL, for use by the `keyring_hashicorp` plugin. This variable is unavailable unless that plugin is installed. The value must begin with `https://`.

- `keyring_hashicorp_store_path`

Command-Line Format	<code>--keyring-hashicorp-store-path=value</code>
System Variable	<code>keyring_hashicorp_store_path</code>
Scope	Global

Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	String
Default Value	<code>empty string</code>

A store path within the HashiCorp Vault server that is writeable when appropriate AppRole credentials are provided by the [keyring\\_hashicorp](#) plugin. This variable is unavailable unless that plugin is installed. To specify the credentials, set the [keyring\\_hashicorp\\_role\\_id](#) and [keyring\\_hashicorp\\_secret\\_id](#) system variables (for example, as shown in [keyring\\_hashicorp Configuration](#)).

This variable is mandatory. If not specified, [keyring\\_hashicorp](#) initialization fails.

- [keyring\\_okv\\_conf\\_dir](#)

Command-Line Format	<code>--keyring-okv-conf-dir=dir_name</code>
System Variable	<a href="#">keyring_okv_conf_dir</a>
Scope	Global
Dynamic	Yes
<a href="#">SET_VAR</a> Hint Applies	No
Type	Directory name
Default Value	<code>empty string</code>

The path name of the directory that stores configuration information used by the [keyring\\_okv](#) plugin. This variable is unavailable unless that plugin is installed. The location should be a directory considered for use only by the [keyring\\_okv](#) plugin. For example, do not locate the directory under the data directory.

The default [keyring\\_okv\\_conf\\_dir](#) value is empty. For the [keyring\\_okv](#) plugin to be able to access Oracle Key Vault, the value must be set to a directory that contains Oracle Key Vault configuration and SSL materials. For instructions on setting up this directory, see [Section 8.4.4.6, “Using the keyring\\_okv KMIP Plugin”](#).

The directory should have a restrictive mode and be accessible only to the account used to run the MySQL server. For example, on Unix and Unix-like systems, to use the [/usr/local/mysql/mysql-keyring-okv](#) directory, the following commands (executed as [root](#)) create the directory and set its mode and ownership:

```
cd /usr/local/mysql
mkdir mysql-keyring-okv
chmod 750 mysql-keyring-okv
chown mysql mysql-keyring-okv
chgrp mysql mysql-keyring-okv
```

If the value assigned to [keyring\\_okv\\_conf\\_dir](#) specifies a directory that does not exist, or that does not contain configuration information that enables a connection to Oracle Key Vault to be established, [keyring\\_okv](#) writes an error message to the error log. If an attempted runtime assignment to [keyring\\_okv\\_conf\\_dir](#) results in an error, the variable value and keyring operation remain unchanged.

- `keyring_operations`

System Variable	<code>keyring_operations</code>
Scope	Global
Dynamic	Yes
<code>SET_VAR</code> Hint Applies	No
Type	Boolean
Default Value	<code>ON</code>

Whether keyring operations are enabled. This variable is used during key migration operations. See [Section 8.4.4.12, “Migrating Keys Between Keyring Keystores”](#). The privileges required to modify this variable are `ENCRYPTION_KEY_ADMIN` in addition to either `SYSTEM_VARIABLES_ADMIN` or the deprecated `SUPER` privilege.

## 8.4.5 MySQL Enterprise Audit

### Note

MySQL Enterprise Audit is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see <https://www.mysql.com/products/>.

MySQL Enterprise Edition includes MySQL Enterprise Audit, implemented using a server plugin named `audit_log`. MySQL Enterprise Audit uses the open MySQL Audit API to enable standard, policy-based monitoring, logging, and blocking of connection and query activity executed on specific MySQL servers. Designed to meet the Oracle audit specification, MySQL Enterprise Audit provides an out of box, easy to use auditing and compliance solution for applications that are governed by both internal and external regulatory guidelines.

When installed, the audit plugin enables MySQL Server to produce a log file containing an audit record of server activity. The log contents include when clients connect and disconnect, and what actions they perform while connected, such as which databases and tables they access. You can add statistics for the time and size of each query to detect outliers.

By default, MySQL Enterprise Audit uses tables in the `mysql` system database for persistent storage of filter and user account data. To use a different database, set the `audit_log_database` system variable at server startup.

After you install the audit plugin (see [Section 8.4.5.2, “Installing or Uninstalling MySQL Enterprise Audit”](#)), it writes an audit log file. By default, the file is named `audit.log` in the server data directory. To change the name of the file, set the `audit_log_file` system variable at server startup.

By default, audit log file contents are written in new-style XML format, without compression or encryption. To select the file format, set the `audit_log_format` system variable at server startup. For details on file format and contents, see [Section 8.4.5.4, “Audit Log File Formats”](#).

For more information about controlling how logging occurs, including audit log file naming and format selection, see [Section 8.4.5.5, “Configuring Audit Logging Characteristics”](#). To perform filtering of audited events, see [Section 8.4.5.7, “Audit Log Filtering”](#). For descriptions of the parameters used to configure the audit log plugin, see [Audit Log Options and Variables](#).

If the audit log plugin is enabled, the Performance Schema (see [Chapter 29, MySQL Performance Schema](#)) has instrumentation for it. To identify the relevant instruments, use this query:

```
SELECT NAME FROM performance_schema.setup_instruments
```

```
WHERE NAME LIKE '%/alog/%';
```

### 8.4.5.1 Elements of MySQL Enterprise Audit

MySQL Enterprise Audit is based on the audit log plugin and related elements:

- A server-side plugin named `audit_log` examines auditable events and determines whether to write them to the audit log.
- A set of functions enables manipulation of filtering definitions that control logging behavior, the encryption password, and log file reading.
- Tables in the `mysql` system database provide persistent storage of filter and user account data, unless you set the `audit_log_database` system variable at server startup to specify a different database.
- System variables enable audit log configuration and status variables provide runtime operational information.
- The `AUDIT_ADMIN` privilege enable users to administer the audit log, and the `AUDIT_ABORT_EXEMPT` privilege enables system users to execute queries that would otherwise be blocked by an “abort” item in the audit log filter.

### 8.4.5.2 Installing or Uninstalling MySQL Enterprise Audit

This section describes how to install or uninstall MySQL Enterprise Audit, which is implemented using the audit log plugin and related elements described in [Section 8.4.5.1, “Elements of MySQL Enterprise Audit”](#). For general information about installing plugins, see [Section 7.6.1, “Installing and Uninstalling Plugins”](#).

Plugin upgrades are not automatic when you upgrade a MySQL installation and some plugin loadable functions must be loaded manually (see [Installing Loadable Functions](#)). Alternatively, you can reinstall the plugin after upgrading MySQL to load new functions.

#### Important

Read this entire section before following its instructions. Parts of the procedure differ depending on your environment.

#### Note

If installed, the `audit_log` plugin involves some minimal overhead even when disabled. To avoid this overhead, do not install MySQL Enterprise Audit unless you plan to use it.

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

To install MySQL Enterprise Audit, look in the `share` directory of your MySQL installation and choose the script that is appropriate for your platform. The available scripts differ in the file name used to refer to the script:

- `audit_log_filter_win_install.sql`
- `audit_log_filter_linux_install.sql`

Run the script as follows. The example here uses the Linux installation script and the default `mysql` system database. Make the appropriate substitution for your system.

```
$> mysql -u root -p -D mysql < audit_log_filter_linux_install.sql
Enter password: (enter root password here)
```

It is possible to specify a custom database for storing JSON filter tables when you run the installation script. Create the database first; its name should not exceed 64 characters. For example:

```
mysql> CREATE DATABASE IF NOT EXISTS database-name;
```

Next, run the script using the alternative database name.

```
$> mysql -u root -p -D database-name < audit_log_filter_linux_install.sql
Enter password: (enter root password here)
```

### Note

Some MySQL versions have introduced changes to the structure of the MySQL Enterprise Audit tables. To ensure that your tables are up to date for upgrades from earlier versions of MySQL, perform the MySQL upgrade procedure, making sure to use the option that forces an update (see [Chapter 3, Upgrading MySQL](#)). If you prefer to run the update statements only for the MySQL Enterprise Audit tables, see the following discussion.

For new MySQL installations, the `USER` and `HOST` columns in the `audit_log_user` table used by MySQL Enterprise Audit have definitions that better correspond to the definitions of the `User` and `Host` columns in the `mysql.user` system table. For upgrades to an installation for which MySQL Enterprise Audit is already installed, it is recommended that you alter the table definitions as follows:

```
ALTER TABLE mysql.audit_log_user
 DROP FOREIGN KEY audit_log_user_ibfk_1;
ALTER TABLE mysql.audit_log_filter
 CONVERT TO CHARACTER SET utf8mb4 COLLATE utf8mb4_0900_as_ci;
ALTER TABLE mysql.audit_log_user
 CONVERT TO CHARACTER SET utf8mb4 COLLATE utf8mb4_0900_as_ci;
ALTER TABLE mysql.audit_log_user
 MODIFY COLUMN USER VARCHAR(32);
ALTER TABLE mysql.audit_log_user
 ADD FOREIGN KEY (FILTERNAME) REFERENCES mysql.audit_log_filter(NAME);
```

### Note

To use MySQL Enterprise Audit in the context of source/replica replication, Group Replication, or InnoDB Cluster, you must prepare the replica nodes prior to running the installation script on the source node. This is necessary because the `INSTALL PLUGIN` statement in the script is not replicated.

1. On each replica node, extract the `INSTALL PLUGIN` statement from the installation script and execute it manually.
2. On the source node, run the installation script as described previously.

To verify plugin installation, examine the Information Schema `PLUGINS` table or use the `SHOW PLUGINS` statement (see [Section 7.6.2, “Obtaining Server Plugin Information”](#)). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
FROM INFORMATION_SCHEMA.PLUGINS
WHERE PLUGIN_NAME LIKE 'audit%';
```

```
+-----+-----+
| PLUGIN_NAME | PLUGIN_STATUS |
+-----+-----+
| audit_log | ACTIVE |
+-----+-----+
```

If the plugin fails to initialize, check the server error log for diagnostic messages.

After MySQL Enterprise Audit is installed, you can use the `--audit-log` option for subsequent server startups to control `audit_log` plugin activation. For example, to prevent the plugin from being removed at runtime, use this option:

```
[mysqld]
audit-log=FORCE_PLUS_PERMANENT
```

If it is desired to prevent the server from running without the audit plugin, use `--audit-log` with a value of `FORCE` or `FORCE_PLUS_PERMANENT` to force server startup to fail if the plugin does not initialize successfully.

### Important

By default, rule-based audit log filtering logs no auditable events for any users. This differs from legacy audit log behavior, which logs all auditable events for all users (see [Section 8.4.5.10, “Legacy Mode Audit Log Filtering”](#)). Should you wish to produce log-everything behavior with rule-based filtering, create a simple filter to enable logging and assign it to the default account:

```
SELECT audit_log_filter_set_filter('log_all', '{ "filter": { "log": true } }');
SELECT audit_log_filter_set_user('%', 'log_all');
```

The filter assigned to `%` is used for connections from any account that has no explicitly assigned filter (which initially is true for all accounts).

When installed as just described, MySQL Enterprise Audit remains installed until uninstalled. To remove it, run the uninstall script located in the `share` directory of your MySQL installation. The example here specifies the default system database, `mysql`. Make the appropriate substitution for your system.

```
$> mysql -u root -p -D mysql < audit_log_filter_uninstall.sql
Enter password: (enter root password here)
```

## 8.4.5.3 MySQL Enterprise Audit Security Considerations

By default, contents of audit log files produced by the audit log plugin are not encrypted and may contain sensitive information, such as the text of SQL statements. For security reasons, audit log files should be written to a directory accessible only to the MySQL server and to users with a legitimate reason to view the log. The default file name is `audit.log` in the data directory. This can be changed by setting the `audit_log_file` system variable at server startup. Other audit log files may exist due to log rotation.

For additional security, enable audit log file encryption. See [Encrypting Audit Log Files](#).

## 8.4.5.4 Audit Log File Formats

The MySQL server calls the audit log plugin to write an audit record to its log file whenever an auditable event occurs. Typically the first audit record written after plugin startup contains the server description and startup options. Elements following that one represent events such as client connect and disconnect events, executed SQL statements, and so forth. Only top-level statements are logged, not statements within stored programs such as triggers or stored procedures. Contents of files referenced by statements such as `LOAD DATA` are not logged.

To select the log format that the audit log plugin uses to write its log file, set the `audit_log_format` system variable at server startup. These formats are available:

- New-style XML format (`audit_log_format=NEW`): An XML format that has better compatibility with Oracle Audit Vault than old-style XML format. MySQL 9.1 uses new-style XML format by default.

- Old-style XML format (`audit_log_format=OLD`): The original audit log format used by default in older MySQL series.
- JSON format (`audit_log_format=JSON`): Writes the audit log as a JSON array. Only this format supports the optional query time and size statistics.

By default, audit log file contents are written in new-style XML format, without compression or encryption.

If you change `audit_log_format`, it is recommended that you also change `audit_log_file`. For example, if you set `audit_log_format` to `JSON`, set `audit_log_file` to `audit.json`. Otherwise, newer log files will have a different format than older files, but they will all have the same base name with nothing to indicate when the format changed.

- [New-Style XML Audit Log File Format](#)
- [Old-Style XML Audit Log File Format](#)
- [JSON Audit Log File Format](#)

## New-Style XML Audit Log File Format

Here is a sample log file in new-style XML format (`audit_log_format=NEW`), reformatted slightly for readability:

```
<?xml version="1.0" encoding="utf-8"?>
<AUDIT>
 <AUDIT_RECORD>
 <TIMESTAMP>2019-10-03T14:06:33 UTC</TIMESTAMP>
 <RECORD_ID>1_2019-10-03T14:06:33</RECORD_ID>
 <NAME>Audit</NAME>
 <SERVER_ID>1</SERVER_ID>
 <VERSION>1</VERSION>
 <STARTUP_OPTIONS>/usr/local/mysql/bin/mysqld
 --socket=/usr/local/mysql/mysql.sock
 --port=3306</STARTUP_OPTIONS>
 <OS_VERSION>i686-Linux</OS_VERSION>
 <MYSQL_VERSION>5.7.21-log</MYSQL_VERSION>
 </AUDIT_RECORD>
 <AUDIT_RECORD>
 <TIMESTAMP>2019-10-03T14:09:38 UTC</TIMESTAMP>
 <RECORD_ID>2_2019-10-03T14:06:33</RECORD_ID>
 <NAME>Connect</NAME>
 <CONNECTION_ID>5</CONNECTION_ID>
 <STATUS>0</STATUS>
 <STATUS_CODE>0</STATUS_CODE>
 <USER>root</USER>
 <OS_LOGIN/>
 <HOST>localhost</HOST>
 <IP>127.0.0.1</IP>
 <COMMAND_CLASS>connect</COMMAND_CLASS>
 <CONNECTION_TYPE>SSL/TLS</CONNECTION_TYPE>
 <CONNECTION_ATTRIBUTES>
 <ATTRIBUTE>
 <NAME>_pid</NAME>
 <VALUE>42794</VALUE>
 </ATTRIBUTE>
 ...

 <HOST>localhost</HOST>
 <IP>127.0.0.1</IP>
 <COMMAND_CLASS>drop_table</COMMAND_CLASS>
 <SQLTEXT>DROP TABLE IF EXISTS t</SQLTEXT>
</AUDIT_RECORD>

...

<AUDIT_RECORD>
 <TIMESTAMP>2019-10-03T14:09:39 UTC</TIMESTAMP>
 <RECORD_ID>8_2019-10-03T14:06:33</RECORD_ID>
 <NAME>Quit</NAME>
 <CONNECTION_ID>5</CONNECTION_ID>
 <STATUS>0</STATUS>
 <STATUS_CODE>0</STATUS_CODE>
 <USER>root</USER>
 <OS_LOGIN/>
 <HOST>localhost</HOST>
 <IP>127.0.0.1</IP>
 <COMMAND_CLASS>connect</COMMAND_CLASS>
 <CONNECTION_TYPE>SSL/TLS</CONNECTION_TYPE>
</AUDIT_RECORD>

...

<AUDIT_RECORD>
 <TIMESTAMP>2019-10-03T14:09:43 UTC</TIMESTAMP>
 <RECORD_ID>11_2019-10-03T14:06:33</RECORD_ID>
 <NAME>Quit</NAME>
 <CONNECTION_ID>6</CONNECTION_ID>
 <STATUS>0</STATUS>
 <STATUS_CODE>0</STATUS_CODE>
 <USER>root</USER>
 <OS_LOGIN/>
 <HOST>localhost</HOST>
 <IP>127.0.0.1</IP>
 <COMMAND_CLASS>connect</COMMAND_CLASS>
 <CONNECTION_TYPE>SSL/TLS</CONNECTION_TYPE>
</AUDIT_RECORD>
<AUDIT_RECORD>
 <TIMESTAMP>2019-10-03T14:09:45 UTC</TIMESTAMP>
 <RECORD_ID>12_2019-10-03T14:06:33</RECORD_ID>
 <NAME>NoAudit</NAME>
 <SERVER_ID>1</SERVER_ID>
</AUDIT_RECORD>
</AUDIT>

```

The audit log file is written as XML, using UTF-8 (up to 4 bytes per character). The root element is `<AUDIT>`. The root element contains `<AUDIT_RECORD>` elements, each of which provides information about an audited event. When the audit log plugin begins writing a new log file, it writes the XML declaration and opening `<AUDIT>` root element tag. When the plugin closes a log file, it writes the closing `</AUDIT>` root element tag. The closing tag is not present while the file is open.

Elements within `<AUDIT_RECORD>` elements have these characteristics:

- Some elements appear in every `<AUDIT_RECORD>` element. Others are optional and may appear depending on the audit record type.
- Order of elements within an `<AUDIT_RECORD>` element is not guaranteed.
- Element values are not fixed length. Long values may be truncated as indicated in the element descriptions given later.
- The `<`, `>`, `"`, and `&` characters are encoded as `&lt;`, `&gt;`, `&quot;`, and `&amp;`, respectively. NUL bytes (U+00) are encoded as the `?` character.
- Characters not valid as XML characters are encoded using numeric character references. Valid XML characters are:

```
#x9 | #xA | #xD | [#x20-#xD7FF] | [#xE000-#xFFFD] | [#x10000-#x10FFFF]
```

The following elements are mandatory in every `<AUDIT_RECORD>` element:

- `<NAME>`

A string representing the type of instruction that generated the audit event, such as a command that the server received from a client.

Example:

```
<NAME>Query</NAME>
```

Some common `<NAME>` values:

Audit	When auditing starts, which may be server startup time
Connect	When a client connects, also known as logging in
Query	An SQL statement (executed directly)
Prepare	Preparation of an SQL statement; usually followed by Execute
Execute	Execution of an SQL statement; usually follows Prepare
Shutdown	Server shutdown
Quit	When a client disconnects
NoAudit	Auditing has been turned off

The possible values are `Audit`, `Binlog Dump`, `Change user`, `Close stmt`, `Connect Out`, `Connect`, `Create DB`, `Daemon`, `Debug`, `Delayed insert`, `Drop DB`, `Execute`, `Fetch`, `Field List`, `Init DB`, `Kill`, `Long Data`, `NoAudit`, `Ping`, `Prepare`, `Processlist`, `Query`, `Quit`, `Refresh`, `Register Slave`, `Reset stmt`, `Set option`, `Shutdown`, `Sleep`, `Statistics`, `Table Dump`, `TableDelete`, `TableInsert`, `TableRead`, `TableUpdate`, `Time`.

Many of these values correspond to the `COM_xxx` command values listed in the `my_command.h` header file. For example, `Create DB` and `Change user` correspond to `COM_CREATE_DB` and `COM_CHANGE_USER`, respectively.

Events having `<NAME>` values of `TableXXX` accompany `Query` events. For example, the following statement generates one `Query` event, two `TableRead` events, and a `TableInsert` events:

```
INSERT INTO t3 SELECT t1.* FROM t1 JOIN t2;
```

Each `TableXXX` event contains `<TABLE>` and `<DB>` elements to identify the table to which the event refers and the database that contains the table.

- `<RECORD_ID>`

A unique identifier for the audit record. The value is composed from a sequence number and timestamp, in the format `SEQ_TIMESTAMP`. When the audit log plugin opens the audit log file, it initializes the sequence number to the size of the audit log file, then increments the sequence by 1 for each record logged. The timestamp is a UTC value in `YYYY-MM-DDThh:mm:ss` format indicating the date and time when the audit log plugin opened the file.

Example:

```
<RECORD_ID>12_2019-10-03T14:06:33</RECORD_ID>
```

- `<TIMESTAMP>`

A string representing a UTC value in `YYYY-MM-DDThh:mm:ss UTC` format indicating the date and time when the audit event was generated. For example, the event corresponding to execution of an SQL statement received from a client has a `<TIMESTAMP>` value occurring after the statement finishes, not when it was received.

Example:

```
<TIMESTAMP>2019-10-03T14:09:45 UTC</TIMESTAMP>
```

The following elements are optional in `<AUDIT_RECORD>` elements. Many of them occur only with specific `<NAME>` element values.

- `<COMMAND_CLASS>`

A string that indicates the type of action performed.

Example:

```
<COMMAND_CLASS>drop_table</COMMAND_CLASS>
```

The values correspond to the `statement/sql/xxx` command counters. For example, `xxx` is `drop_table` and `select` for `DROP TABLE` and `SELECT` statements, respectively. The following statement displays the possible names:

```
SELECT REPLACE(EVENT_NAME, 'statement/sql/', '') AS name
FROM performance_schema.events_statements_summary_global_by_event_name
WHERE EVENT_NAME LIKE 'statement/sql/%'
ORDER BY name;
```

- `<CONNECTION_ATTRIBUTES>`

Events with a `<COMMAND_CLASS>` value of `connect` may include a `<CONNECTION_ATTRIBUTES>` element to display the connection attributes passed by the client at connect time. (For information about these attributes, which are also exposed in Performance Schema tables, see [Section 29.12.9, “Performance Schema Connection Attribute Tables”](#).)

The `<CONNECTION_ATTRIBUTES>` element contains one `<ATTRIBUTE>` element per attribute, each of which contains `<NAME>` and `<VALUE>` elements to indicate the attribute name and value, respectively.

Example:

```
<CONNECTION_ATTRIBUTES>
 <ATTRIBUTE>
 <NAME>_pid</NAME>
 <VALUE>42794</VALUE>
 </ATTRIBUTE>
 <ATTRIBUTE>
```

```

<NAME>_os</NAME>
<VALUE>macos0.14</VALUE>
</ATTRIBUTE>
<ATTRIBUTE>
 <NAME>_platform</NAME>
 <VALUE>x86_64</VALUE>
</ATTRIBUTE>
<ATTRIBUTE>
 <NAME>_client_version</NAME>
 <VALUE>8.4.0</VALUE>
</ATTRIBUTE>
<ATTRIBUTE>
 <NAME>_client_name</NAME>
 <VALUE>libmysql</VALUE>
</ATTRIBUTE>
<ATTRIBUTE>
 <NAME>program_name</NAME>
 <VALUE>mysqladmin</VALUE>
</ATTRIBUTE>
</CONNECTION_ATTRIBUTES>

```

If no connection attributes are present in the event, none are logged and no `<CONNECTION_ATTRIBUTES>` element appears. This can occur if the connection attempt is unsuccessful, the client passes no attributes, or the connection occurs internally such as during server startup or when initiated by a plugin.

- `<CONNECTION_ID>`

An unsigned integer representing the client connection identifier. This is the same as the value returned by the `CONNECTION_ID()` function within the session.

Example:

```
<CONNECTION_ID>127</CONNECTION_ID>
```

- `<CONNECTION_TYPE>`

The security state of the connection to the server. Permitted values are `TCP/IP` (TCP/IP connection established without encryption), `SSL/TLS` (TCP/IP connection established with encryption), `Socket` (Unix socket file connection), `Named Pipe` (Windows named pipe connection), and `Shared Memory` (Windows shared memory connection).

Example:

```
<CONNECTION_TYPE>SSL/TLS</CONNECTION_TYPE>
```

- `<DB>`

A string representing a database name.

Example:

```
<DB>test</DB>
```

For connect events, this element indicates the default database; the element is empty if there is no default database. For table-access events, the element indicates the database to which the accessed table belongs.

- `<HOST>`

A string representing the client host name.

Example:

```
<HOST>localhost</HOST>
```

- `<IP>`

A string representing the client IP address.

Example:

```
<IP>127.0.0.1</IP>
```

- `<MYSQL_VERSION>`

A string representing the MySQL server version. This is the same as the value of the `VERSION()` function or `version` system variable.

Example:

```
<MYSQL_VERSION>5.7.21-log</MYSQL_VERSION>
```

- `<OS_LOGIN>`

A string representing the external user name used during the authentication process, as set by the plugin used to authenticate the client. With native (built-in) MySQL authentication, or if the plugin does not set the value, this element is empty. The value is the same as that of the `external_user` system variable (see [Section 8.2.19, “Proxy Users”](#)).

Example:

```
<OS_LOGIN>jeffrey</OS_LOGIN>
```

- `<OS_VERSION>`

A string representing the operating system on which the server was built or is running.

Example:

```
<OS_VERSION>x86_64-Linux</OS_VERSION>
```

- `<PRIV_USER>`

A string representing the user that the server authenticated the client as. This is the user name that the server uses for privilege checking, and may differ from the `<USER>` value.

Example:

```
<PRIV_USER>jeffrey</PRIV_USER>
```

- `<PROXY_USER>`

A string representing the proxy user (see [Section 8.2.19, “Proxy Users”](#)). The value is empty if user proxying is not in effect.

Example:

```
<PROXY_USER>developer</PROXY_USER>
```

- `<SERVER_ID>`

An unsigned integer representing the server ID. This is the same as the value of the `server_id` system variable.

Example:

```
<SERVER_ID>1</SERVER_ID>
```

- `<SQLTEXT>`

A string representing the text of an SQL statement. The value can be empty. Long values may be truncated. The string, like the audit log file itself, is written using UTF-8 (up to 4 bytes per character), so the value may be the result of conversion. For example, the original statement might have been received from the client as an SJIS string.

Example:

```
<SQLTEXT>DELETE FROM t1</SQLTEXT>
```

- `<STARTUP_OPTIONS>`

A string representing the options that were given on the command line or in option files when the MySQL server was started. The first option is the path to the server executable.

Example:

```
<STARTUP_OPTIONS>/usr/local/mysql/bin/mysqld
--port=3306 --log_output=FILE</STARTUP_OPTIONS>
```

- `<STATUS>`

An unsigned integer representing the command status: 0 for success, nonzero if an error occurred. This is the same as the value of the `mysql_errno()` C API function. See the description for `<STATUS_CODE>` for information about how it differs from `<STATUS>`.

The audit log does not contain the SQLSTATE value or error message. To see the associations between error codes, SQLSTATE values, and messages, see [Server Error Message Reference](#).

Warnings are not logged.

Example:

```
<STATUS>1051</STATUS>
```

- `<STATUS_CODE>`

An unsigned integer representing the command status: 0 for success, 1 if an error occurred.

The `STATUS_CODE` value differs from the `STATUS` value: `STATUS_CODE` is 0 for success and 1 for error, which is compatible with the EZ\_collector consumer for Audit Vault. `STATUS` is the value of the

`mysql_errno()` C API function. This is 0 for success and nonzero for error, and thus is not necessarily 1 for error.

Example:

```
<STATUS_CODE>0</STATUS_CODE>
```

- **<TABLE>**

A string representing a table name.

Example:

```
<TABLE>t3</TABLE>
```

- **<USER>**

A string representing the user name sent by the client. This may differ from the `<PRIV_USER>` value.

Example:

```
<USER>root[root] @ localhost [127.0.0.1]</USER>
```

- **<VERSION>**

An unsigned integer representing the version of the audit log file format.

Example:

```
<VERSION>1</VERSION>
```

## Old-Style XML Audit Log File Format

Here is a sample log file in old-style XML format (`audit_log_format=OLD`), reformatted slightly for readability:

```
<?xml version="1.0" encoding="utf-8"?>
<AUDIT>
 <AUDIT_RECORD
 TIMESTAMP="2019-10-03T14:25:00 UTC"
 RECORD_ID="1_2019-10-03T14:25:00"
 NAME="Audit"
 SERVER_ID="1"
 VERSION="1"
 STARTUP_OPTIONS="--port=3306"
 OS_VERSION="i686-Linux"
 MYSQL_VERSION="5.7.21-log"/>
 <AUDIT_RECORD
 TIMESTAMP="2019-10-03T14:25:24 UTC"
 RECORD_ID="2_2019-10-03T14:25:00"
 NAME="Connect"
 CONNECTION_ID="4"
 STATUS="0"
 STATUS_CODE="0"
 USER="root"
 OS_LOGIN=""
 HOST="localhost"
 IP="127.0.0.1"
 COMMAND_CLASS="connect"
 CONNECTION_TYPE="SSL/TLS"
 PRIV_USER="root"
 PROXY_USER=""
 DB="test"/>
```

```

...

<AUDIT_RECORD
 TIMESTAMP="2019-10-03T14:25:24 UTC"
 RECORD_ID="6_2019-10-03T14:25:00"
 NAME="Query"
 CONNECTION_ID="4"
 STATUS="0"
 STATUS_CODE="0"
 USER="root[root] @ localhost [127.0.0.1]"
 OS_LOGIN=""
 HOST="localhost"
 IP="127.0.0.1"
 COMMAND_CLASS="drop_table"
 SQLTEXT="DROP TABLE IF EXISTS t"/>

...

<AUDIT_RECORD
 TIMESTAMP="2019-10-03T14:25:24 UTC"
 RECORD_ID="8_2019-10-03T14:25:00"
 NAME="Quit"
 CONNECTION_ID="4"
 STATUS="0"
 STATUS_CODE="0"
 USER="root"
 OS_LOGIN=""
 HOST="localhost"
 IP="127.0.0.1"
 COMMAND_CLASS="connect"
 CONNECTION_TYPE="SSL/TLS" />
<AUDIT_RECORD
 TIMESTAMP="2019-10-03T14:25:32 UTC"
 RECORD_ID="12_2019-10-03T14:25:00"
 NAME="NoAudit"
 SERVER_ID="1" />
</AUDIT>

```

The audit log file is written as XML, using UTF-8 (up to 4 bytes per character). The root element is `<AUDIT>`. The root element contains `<AUDIT_RECORD>` elements, each of which provides information about an audited event. When the audit log plugin begins writing a new log file, it writes the XML declaration and opening `<AUDIT>` root element tag. When the plugin closes a log file, it writes the closing `</AUDIT>` root element tag. The closing tag is not present while the file is open.

Attributes of `<AUDIT_RECORD>` elements have these characteristics:

- Some attributes appear in every `<AUDIT_RECORD>` element. Others are optional and may appear depending on the audit record type.
- Order of attributes within an `<AUDIT_RECORD>` element is not guaranteed.
- Attribute values are not fixed length. Long values may be truncated as indicated in the attribute descriptions given later.
- The `<`, `>`, `"`, and `&` characters are encoded as `&lt;`, `&gt;`, `&quot;`, and `&amp;`, respectively. NUL bytes (U+00) are encoded as the `?` character.
- Characters not valid as XML characters are encoded using numeric character references. Valid XML characters are:

```
#x9 | #xA | #xD | [#x20-#xD7FF] | [#xE000-#xFFFF] | [#x10000-#x10FFFF]
```

The following attributes are mandatory in every `<AUDIT_RECORD>` element:

- **NAME**

A string representing the type of instruction that generated the audit event, such as a command that the server received from a client.

Example: `NAME="Query"`

Some common **NAME** values:

Audit	When auditing starts, which may be server startup time
Connect	When a client connects, also known as logging in
Query	An SQL statement (executed directly)
Prepare	Preparation of an SQL statement; usually followed by Execute
Execute	Execution of an SQL statement; usually follows Prepare
Shutdown	Server shutdown
Quit	When a client disconnects
NoAudit	Auditing has been turned off

The possible values are `Audit`, `Binlog Dump`, `Change user`, `Close stmt`, `Connect Out`, `Connect`, `Create DB`, `Daemon`, `Debug`, `Delayed insert`, `Drop DB`, `Execute`, `Fetch`, `Field List`, `Init DB`, `Kill`, `Long Data`, `NoAudit`, `Ping`, `Prepare`, `Processlist`, `Query`, `Quit`, `Refresh`, `Register Slave`, `Reset stmt`, `Set option`, `Shutdown`, `Sleep`, `Statistics`, `Table Dump`, `TableDelete`, `TableInsert`, `TableRead`, `TableUpdate`, `Time`.

Many of these values correspond to the `COM_xxx` command values listed in the `my_command.h` header file. For example, `"Create DB"` and `"Change user"` correspond to `COM_CREATE_DB` and `COM_CHANGE_USER`, respectively.

Events having **NAME** values of `TableXXX` accompany `Query` events. For example, the following statement generates one `Query` event, two `TableRead` events, and a `TableInsert` events:

```
INSERT INTO t3 SELECT t1.* FROM t1 JOIN t2;
```

Each `TableXXX` event has `TABLE` and `DB` attributes to identify the table to which the event refers and the database that contains the table.

`Connect` events for old-style XML audit log format do not include connection attributes.

- **RECORD\_ID**

A unique identifier for the audit record. The value is composed from a sequence number and timestamp, in the format `SEQ_TIMESTAMP`. When the audit log plugin opens the audit log file, it initializes the sequence number to the size of the audit log file, then increments the sequence by 1 for each record logged. The timestamp is a UTC value in `YYYY-MM-DDThh:mm:ss` format indicating the date and time when the audit log plugin opened the file.

Example: `RECORD_ID="12_2019-10-03T14:25:00"`

- **TIMESTAMP**

A string representing a UTC value in `YYYY-MM-DDThh:mm:ss UTC` format indicating the date and time when the audit event was generated. For example, the event corresponding to execution of an SQL statement received from a client has a **TIMESTAMP** value occurring after the statement finishes, not when it was received.

Example: `TIMESTAMP="2019-10-03T14:25:32 UTC"`

The following attributes are optional in `<AUDIT_RECORD>` elements. Many of them occur only for elements with specific values of the **NAME** attribute.

- `COMMAND_CLASS`

A string that indicates the type of action performed.

Example: `COMMAND_CLASS="drop_table"`

The values correspond to the `statement/sql/xxx` command counters. For example, `xxx` is `drop_table` and `select` for `DROP TABLE` and `SELECT` statements, respectively. The following statement displays the possible names:

```
SELECT REPLACE(EVENT_NAME, 'statement/sql/', '') AS name
FROM performance_schema.events_statements_summary_global_by_event_name
WHERE EVENT_NAME LIKE 'statement/sql/%'
ORDER BY name;
```

- `CONNECTION_ID`

An unsigned integer representing the client connection identifier. This is the same as the value returned by the `CONNECTION_ID()` function within the session.

Example: `CONNECTION_ID="127"`

- `CONNECTION_TYPE`

The security state of the connection to the server. Permitted values are `TCP/IP` (TCP/IP connection established without encryption), `SSL/TLS` (TCP/IP connection established with encryption), `Socket` (Unix socket file connection), `Named Pipe` (Windows named pipe connection), and `Shared Memory` (Windows shared memory connection).

Example: `CONNECTION_TYPE="SSL/TLS"`

- `DB`

A string representing a database name.

Example: `DB="test"`

For connect events, this attribute indicates the default database; the attribute is empty if there is no default database. For table-access events, the attribute indicates the database to which the accessed table belongs.

- `HOST`

A string representing the client host name.

Example: `HOST="localhost"`

- `IP`

A string representing the client IP address.

Example: `IP="127.0.0.1"`

- `MYSQL_VERSION`

A string representing the MySQL server version. This is the same as the value of the `VERSION()` function or `version` system variable.

Example: `MYSQL_VERSION="5.7.21-log"`

- `OS_LOGIN`

A string representing the external user name used during the authentication process, as set by the plugin used to authenticate the client. With native (built-in) MySQL authentication, or if the plugin does not set the value, this attribute is empty. The value is the same as that of the `external_user` system variable (see [Section 8.2.19, “Proxy Users”](#)).

Example: `OS_LOGIN="jeffrey"`

- `OS_VERSION`

A string representing the operating system on which the server was built or is running.

Example: `OS_VERSION="x86_64-Linux"`

- `PRIV_USER`

A string representing the user that the server authenticated the client as. This is the user name that the server uses for privilege checking, and it may differ from the `USER` value.

Example: `PRIV_USER="jeffrey"`

- `PROXY_USER`

A string representing the proxy user (see [Section 8.2.19, “Proxy Users”](#)). The value is empty if user proxying is not in effect.

Example: `PROXY_USER="developer"`

- `SERVER_ID`

An unsigned integer representing the server ID. This is the same as the value of the `server_id` system variable.

Example: `SERVER_ID="1"`

- `SQLTEXT`

A string representing the text of an SQL statement. The value can be empty. Long values may be truncated. The string, like the audit log file itself, is written using UTF-8 (up to 4 bytes per character), so the value may be the result of conversion. For example, the original statement might have been received from the client as an SJIS string.

Example: `SQLTEXT="DELETE FROM t1"`

- `STARTUP_OPTIONS`

A string representing the options that were given on the command line or in option files when the MySQL server was started.

Example: `STARTUP_OPTIONS="--port=3306 --log_output=FILE"`

- [STATUS](#)

An unsigned integer representing the command status: 0 for success, nonzero if an error occurred. This is the same as the value of the `mysql_errno()` C API function. See the description for [STATUS\\_CODE](#) for information about how it differs from [STATUS](#).

The audit log does not contain the SQLSTATE value or error message. To see the associations between error codes, SQLSTATE values, and messages, see [Server Error Message Reference](#).

Warnings are not logged.

Example: `STATUS="1051"`

- [STATUS\\_CODE](#)

An unsigned integer representing the command status: 0 for success, 1 if an error occurred.

The [STATUS\\_CODE](#) value differs from the [STATUS](#) value: [STATUS\\_CODE](#) is 0 for success and 1 for error, which is compatible with the EZ\_collector consumer for Audit Vault. [STATUS](#) is the value of the `mysql_errno()` C API function. This is 0 for success and nonzero for error, and thus is not necessarily 1 for error.

Example: `STATUS_CODE="0"`

- [TABLE](#)

A string representing a table name.

Example: `TABLE="t3"`

- [USER](#)

A string representing the user name sent by the client. This may differ from the [PRIV\\_USER](#) value.

- [VERSION](#)

An unsigned integer representing the version of the audit log file format.

Example: `VERSION="1"`

## JSON Audit Log File Format

For JSON-format audit logging (`audit_log_format=JSON`), the log file contents form a [JSON](#) array with each array element representing an audited event as a [JSON](#) hash of key-value pairs. Examples of complete event records appear later in this section. The following is an excerpt of partial events:

```
[
 {
 "timestamp": "2019-10-03 13:50:01",
 "id": 0,
 "class": "audit",
 "event": "startup",
 ...
 },
 {
 "timestamp": "2019-10-03 15:02:32",
 "id": 0,
 "class": "connection",
 "event": "connect",
 ...
 },
]
```

```

...
{
 "timestamp": "2019-10-03 17:37:26",
 "id": 0,
 "class": "table_access",
 "event": "insert",
 ...
}
...
]

```

The audit log file is written using UTF-8 (up to 4 bytes per character). When the audit log plugin begins writing a new log file, it writes the opening `[` array marker. When the plugin closes a log file, it writes the closing `]` array marker. The closing marker is not present while the file is open.

Items within audit records have these characteristics:

- Some items appear in every audit record. Others are optional and may appear depending on the audit record type.
- Order of items within an audit record is not guaranteed.
- Item values are not fixed length. Long values may be truncated as indicated in the item descriptions given later.
- The `"` and `\` characters are encoded as `\"` and `\\`, respectively.

JSON format is the only audit log file format that supports the optional query time and size statistics. This data is available in the slow query log for qualifying queries, and in the context of the audit log it similarly helps to detect outliers for activity analysis.

To add the query statistics to the log file, you must set them up as a filter using the `audit_log_filter_set_filter()` audit log function as the service element of the JSON filtering syntax. For instructions to do this, see [Adding Query Statistics for Outlier Detection](#). For the `bytes_sent` and `bytes_received` fields to be populated, the system variable `log_slow_extra` must be set to ON.

The following examples show the JSON object formats for different event types (as indicated by the `class` and `event` items), reformatted slightly for readability:

Auditing startup event:

```

{ "timestamp": "2019-10-03 14:21:56",
 "id": 0,
 "class": "audit",
 "event": "startup",
 "connection_id": 0,
 "startup_data": { "server_id": 1,
 "os_version": "i686-Linux",
 "mysql_version": "5.7.21-log",
 "args": ["/usr/local/mysql/bin/mysqld",
 "--loose-audit-log-format=JSON",
 "--log-error=log.err",
 "--pid-file=mysqld.pid",
 "--port=3306"] } }

```

When the audit log plugin starts as a result of server startup (as opposed to being enabled at runtime), `connection_id` is set to 0, and `account` and `login` are not present.

Auditing shutdown event:

```

{ "timestamp": "2019-10-03 14:28:20",
 "id": 3,
 "class": "audit",
 "event": "shutdown",

```

```
"connection_id": 0,
"shutdown_data": { "server_id": 1 } }
```

When the audit log plugin is uninstalled as a result of server shutdown (as opposed to being disabled at runtime), `connection_id` is set to 0, and `account` and `login` are not present.

Connect or change-user event:

```
{ "timestamp": "2019-10-03 14:23:18",
 "id": 1,
 "class": "connection",
 "event": "connect",
 "connection_id": 5,
 "account": { "user": "root", "host": "localhost" },
 "login": { "user": "root", "os": "", "ip": "::1", "proxy": "" },
 "connection_data": { "connection_type": "ssl",
 "status": 0,
 "db": "test",
 "connection_attributes": {
 "_pid": "43236",
 ...
 "program_name": "mysqldadmin"
 }
 }
}
```

Disconnect event:

```
{ "timestamp": "2019-10-03 14:24:45",
 "id": 3,
 "class": "connection",
 "event": "disconnect",
 "connection_id": 5,
 "account": { "user": "root", "host": "localhost" },
 "login": { "user": "root", "os": "", "ip": "::1", "proxy": "" },
 "connection_data": { "connection_type": "ssl" } }
```

Query event:

```
{ "timestamp": "2019-10-03 14:23:35",
 "id": 2,
 "class": "general",
 "event": "status",
 "connection_id": 5,
 "account": { "user": "root", "host": "localhost" },
 "login": { "user": "root", "os": "", "ip": "::1", "proxy": "" },
 "general_data": { "command": "Query",
 "sql_command": "show_variables",
 "query": "SHOW VARIABLES",
 "status": 0 } }
```

Query event with optional query statistics for outlier detection:

```
{ "timestamp": "2022-01-28 13:09:30",
 "id": 0,
 "class": "general",
 "event": "status",
 "connection_id": 46,
 "account": { "user": "user", "host": "localhost" },
 "login": { "user": "user", "os": "", "ip": "127.0.0.1", "proxy": "" },
 "general_data": { "command": "Query",
 "sql_command": "insert",
 "query": "INSERT INTO audit_table VALUES(4)",
 "status": 1146 }
 "query_statistics": { "query_time": 0.116250,
 "bytes_sent": 18384,
 "bytes_received": 78858,
 "rows_sent": 3,

```

```
"rows_examined": 20878 } }
```

Table access event (read, delete, insert, update):

```
{ "timestamp": "2019-10-03 14:23:41",
 "id": 0,
 "class": "table_access",
 "event": "insert",
 "connection_id": 5,
 "account": { "user": "root", "host": "localhost" },
 "login": { "user": "root", "os": "", "ip": "127.0.0.1", "proxy": "" },
 "table_access_data": { "db": "test",
 "table": "t1",
 "query": "INSERT INTO t1 (i) VALUES(1),(2),(3)",
 "sql_command": "insert" } }
```

The items in the following list appear at the top level of JSON-format audit records: Each item value is either a scalar or a [JSON](#) hash. For items that have a hash value, the description lists only the item names within that hash. For more complete descriptions of second-level hash items, see later in this section.

- [account](#)

The MySQL account associated with the event. The value is a hash containing these items equivalent to the value of the [CURRENT\\_USER\(\)](#) function within the section: [user](#), [host](#).

Example:

```
"account": { "user": "root", "host": "localhost" }
```

- [class](#)

A string representing the event class. The class defines the type of event, when taken together with the [event](#) item that specifies the event subclass.

Example:

```
"class": "connection"
```

The following table shows the permitted combinations of [class](#) and [event](#) values.

**Table 8.34 Audit Log Class and Event Combinations**

Class Value	Permitted Event Values
<a href="#">audit</a>	<a href="#">startup</a> , <a href="#">shutdown</a>
<a href="#">connection</a>	<a href="#">connect</a> , <a href="#">change_user</a> , <a href="#">disconnect</a>
<a href="#">general</a>	<a href="#">status</a>
<a href="#">table_access_data</a>	<a href="#">read</a> , <a href="#">delete</a> , <a href="#">insert</a> , <a href="#">update</a>

- [connection\\_data](#)

Information about a client connection. The value is a hash containing these items: [connection\\_type](#), [status](#), [db](#), and possibly [connection\\_attributes](#). This item occurs only for audit records with a [class](#) value of [connection](#).

Example:

```
"connection_data": { "connection_type": "ssl",
 "status": 0,
 "db": "test" }
```

Events with a `class` value of `connection` and `event` value of `connect` may include a `connection_attributes` item to display the connection attributes passed by the client at connect time. (For information about these attributes, which are also exposed in Performance Schema tables, see [Section 29.12.9, “Performance Schema Connection Attribute Tables”](#).)

The `connection_attributes` value is a hash that represents each attribute by its name and value.

Example:

```
"connection_attributes": {
 "_pid": "43236",
 "_os": "macos0.14",
 "_platform": "x86_64",
 "_client_version": "8.4.0",
 "_client_name": "libmysql",
 "program_name": "mysqladmin"
}
```

If no connection attributes are present in the event, none are logged and no `connection_attributes` item appears. This can occur if the connection attempt is unsuccessful, the client passes no attributes, or the connection occurs internally such as during server startup or when initiated by a plugin.

- `connection_id`

An unsigned integer representing the client connection identifier. This is the same as the value returned by the `CONNECTION_ID()` function within the session.

Example:

```
"connection_id": 5
```

- `event`

A string representing the subclass of the event class. The subclass defines the type of event, when taken together with the `class` item that specifies the event class. For more information, see the `class` item description.

Example:

```
"event": "connect"
```

- `general_data`

Information about an executed statement or command. The value is a hash containing these items: `command`, `sql_command`, `query`, `status`. This item occurs only for audit records with a `class` value of `general`.

Example:

```
"general_data": { "command": "Query",
 "sql_command": "show_variables",
 "query": "SHOW VARIABLES",
 "status": 0 }
```

- `id`

An unsigned integer representing an event ID.

Example:

```
"id": 2
```

For audit records that have the same `timestamp` value, their `id` values distinguish them and form a sequence. Within the audit log, `timestamp/id` pairs are unique. These pairs are bookmarks that identify event locations within the log.

- `login`

Information indicating how a client connected to the server. The value is a hash containing these items: `user`, `os`, `ip`, `proxy`.

Example:

```
"login": { "user": "root", "os": "", "ip": "::1", "proxy": "" }
```

- `query_statistics`

Optional query statistics for outlier detection. The value is a hash containing these items: `query_time`, `rows_sent`, `rows_examined`, `bytes_received`, `bytes_sent`. For instructions to set up the query statistics, see [Adding Query Statistics for Outlier Detection](#).

Example:

```
"query_statistics": { "query_time": 0.116250,
 "bytes_sent": 18384,
 "bytes_received": 78858,
 "rows_sent": 3,
 "rows_examined": 20878 }
```

- `shutdown_data`

Information pertaining to audit log plugin termination. The value is a hash containing these items: `server_id`. This item occurs only for audit records with `class` and `event` values of `audit` and `shutdown`, respectively.

Example:

```
"shutdown_data": { "server_id": 1 }
```

- `startup_data`

Information pertaining to audit log plugin initialization. The value is a hash containing these items: `server_id`, `os_version`, `mysql_version`, `args`. This item occurs only for audit records with `class` and `event` values of `audit` and `startup`, respectively.

Example:

```
"startup_data": { "server_id": 1,
 "os_version": "i686-Linux",
 "mysql_version": "5.7.21-log",
 "args": ["/usr/local/mysql/bin/mysqld",
 "--loose-audit-log-format=JSON",
 "--log-error=log.err",
 "--pid-file=mysqld.pid",
 "--port=3306"] }
```

- `table_access_data`

Information about an access to a table. The value is a hash containing these items: `db`, `table`, `query`, `sql_command`. This item occurs only for audit records with a `class` value of `table_access`.

Example:

```
"table_access_data": { "db": "test",
 "table": "t1",
 "query": "INSERT INTO t1 (i) VALUES(1),(2),(3)",
 "sql_command": "insert" }
```

- `time`

This field is similar to that in the `timestamp` field, but the value is an integer and represents the UNIX timestamp value indicating the date and time when the audit event was generated.

Example:

```
"time" : 1618498687
```

The `time` field occurs in JSON-format log files only if the `audit_log_format_unix_timestamp` system variable is enabled.

- `timestamp`

A string representing a UTC value in `YYYY-MM-DD hh:mm:ss` format indicating the date and time when the audit event was generated. For example, the event corresponding to execution of an SQL statement received from a client has a `timestamp` value occurring after the statement finishes, not when it was received.

Example:

```
"timestamp": "2019-10-03 13:50:01"
```

For audit records that have the same `timestamp` value, their `id` values distinguish them and form a sequence. Within the audit log, `timestamp/id` pairs are unique. These pairs are bookmarks that identify event locations within the log.

These items appear within hash values associated with top-level items of JSON-format audit records:

- `args`

An array of options that were given on the command line or in option files when the MySQL server was started. The first option is the path to the server executable.

Example:

```
"args": ["/usr/local/mysql/bin/mysqld",
 "--loose-audit-log-format=JSON",
 "--log-error=log.err",
 "--pid-file=mysqld.pid",
 "--port=3306"]
```

- `bytes_received`

The number of bytes received from the client. This item is part of the optional query statistics. For this field to be populated, the system variable `log_slow_extra` must be set to `ON`.

Example:

```
"bytes_received": 78858
```

- `bytes_sent`

The number of bytes sent to the client. This item is part of the optional query statistics. For this field to be populated, the system variable `log_slow_extra` must be set to `ON`.

Example:

```
"bytes_sent": 18384
```

- `command`

A string representing the type of instruction that generated the audit event, such as a command that the server received from a client.

Example:

```
"command": "Query"
```

- `connection_type`

The security state of the connection to the server. Permitted values are `tcp/ip` (TCP/IP connection established without encryption), `ssl` (TCP/IP connection established with encryption), `socket` (Unix socket file connection), `named_pipe` (Windows named pipe connection), and `shared_memory` (Windows shared memory connection).

Example:

```
"connection_type": "tcp/tcp"
```

- `db`

A string representing a database name. For `connection_data`, it is the default database. For `table_access_data`, it is the table database.

Example:

```
"db": "test"
```

- `host`

A string representing the client host name.

Example:

```
"host": "localhost"
```

- `ip`

A string representing the client IP address.

Example:

```
"ip": ":::1"
```

- `mysql_version`

A string representing the MySQL server version. This is the same as the value of the `VERSION()` function or `version` system variable.

Example:

```
"mysql_version": "5.7.21-log"
```

- `os`

A string representing the external user name used during the authentication process, as set by the plugin used to authenticate the client. With native (built-in) MySQL authentication, or if the plugin does not set the value, this attribute is empty. The value is the same as that of the `external_user` system variable. See [Section 8.2.19, “Proxy Users”](#).

Example:

```
"os": "jeffrey"
```

- `os_version`

A string representing the operating system on which the server was built or is running.

Example:

```
"os_version": "i686-Linux"
```

- `proxy`

A string representing the proxy user (see [Section 8.2.19, “Proxy Users”](#)). The value is empty if user proxying is not in effect.

Example:

```
"proxy": "developer"
```

- `query`

A string representing the text of an SQL statement. The value can be empty. Long values may be truncated. The string, like the audit log file itself, is written using UTF-8 (up to 4 bytes per character), so the value may be the result of conversion. For example, the original statement might have been received from the client as an SJIS string.

Example:

```
"query": "DELETE FROM t1"
```

- `query_time`

The query execution time in microseconds (if the `longlong` data type is selected) or seconds (if the `double` data type is selected). This item is part of the optional query statistics.

Example:

```
"query_time": 0.116250
```

- `rows_examined`

The number of rows accessed during the query. This item is part of the optional query statistics.

Example:

```
"rows_examined": 20878
```

- `rows_sent`

The number of rows sent to the client as a result. This item is part of the optional query statistics.

Example:

```
"rows_sent": 3
```

- `server_id`

An unsigned integer representing the server ID. This is the same as the value of the `server_id` system variable.

Example:

```
"server_id": 1
```

- `sql_command`

A string that indicates the SQL statement type.

Example:

```
"sql_command": "insert"
```

The values correspond to the `statement/sql/xxx` command counters. For example, `xxx` is `drop_table` and `select` for `DROP TABLE` and `SELECT` statements, respectively. The following statement displays the possible names:

```
SELECT REPLACE(EVENT_NAME, 'statement/sql/', '') AS name
FROM performance_schema.events_statements_summary_global_by_event_name
WHERE EVENT_NAME LIKE 'statement/sql/%'
ORDER BY name;
```

- `status`

An unsigned integer representing the command status: 0 for success, nonzero if an error occurred. This is the same as the value of the `mysql_errno()` C API function.

The audit log does not contain the SQLSTATE value or error message. To see the associations between error codes, SQLSTATE values, and messages, see [Server Error Message Reference](#).

Warnings are not logged.

Example:

```
"status": 1051
```

- `table`

A string representing a table name.

Example:

```
"table": "t1"
```

- `user`

A string representing a user name. The meaning differs depending on the item within which `user` occurs:

- Within `account` items, `user` is a string representing the user that the server authenticated the client as. This is the user name that the server uses for privilege checking.
- Within `login` items, `user` is a string representing the user name sent by the client.

Example:

```
"user": "root"
```

### 8.4.5.5 Configuring Audit Logging Characteristics

This section describes how to configure audit logging characteristics, such as the file to which the audit log plugin writes events, the format of written events, whether to enable log file compression and encryption, and space management.

- [Naming Conventions for Audit Log Files](#)
- [Selecting Audit Log File Format](#)
- [Enabling the Audit Log Flush Task](#)
- [Adding Query Statistics for Outlier Detection](#)
- [Compressing Audit Log Files](#)
- [Encrypting Audit Log Files](#)
- [Manually Uncompressing and Decrypting Audit Log Files](#)
- [Space Management of Audit Log Files](#)
- [Write Strategies for Audit Logging](#)

For additional information about the functions and system variables that affect audit logging, see [Audit Log Functions](#), and [Audit Log Options and Variables](#).

The audit log plugin can also control which audited events are written to the audit log file, based on event content or the account from which events originate. See [Section 8.4.5.7, “Audit Log Filtering”](#).

#### Naming Conventions for Audit Log Files

To configure the audit log file name, set the `audit_log_file` system variable at server startup. The default name is `audit.log` in the server data directory. For best security, write the audit log to a directory accessible only to the MySQL server and to users with a legitimate reason to view the log.

The plugin interprets the `audit_log_file` value as composed of an optional leading directory name, a base name, and an optional suffix. If compression or encryption are enabled, the effective file name (the name actually used to create the log file) differs from the configured file name because it has additional suffixes:

- If compression is enabled, the plugin adds a suffix of `.gz`.
- If encryption is enabled, the plugin adds a suffix of `.pwd_id.enc`, where `pwd_id` indicates which encryption password to use for log file operations. The audit log plugin stores encryption passwords in the keyring; see [Encrypting Audit Log Files](#).

The effective audit log file name is the name resulting from the addition of applicable compression and encryption suffixes to the configured file name. For example, if the configured `audit_log_file` value is `audit.log`, the effective file name is one of the values shown in the following table.

Enabled Features	Effective File Name
No compression or encryption	<code>audit.log</code>
Compression	<code>audit.log.gz</code>
Encryption	<code>audit.log.pwd_id.enc</code>
Compression, encryption	<code>audit.log.gz.pwd_id.enc</code>

`pwd_id` indicates the ID of the password used to encrypt or decrypt a file. `pwd_id` format is `pwd_timestamp-seq`, where:

- `pwd_timestamp` is a UTC value in `YYYYMMDDThhmmss` format indicating when the password was created.
- `seq` is a sequence number. Sequence numbers start at 1 and increase for passwords that have the same `pwd_timestamp` value.

Here are some example `pwd_id` password ID values:

```
20190403T142359-1
20190403T142400-1
20190403T142400-2
```

To construct the corresponding keyring IDs for storing passwords in the keyring, the audit log plugin adds a prefix of `audit_log-` to the `pwd_id` values. For the example password IDs just shown, the corresponding keyring IDs are:

```
audit_log-20190403T142359-1
audit_log-20190403T142400-1
audit_log-20190403T142400-2
```

The ID of the password currently used for encryption by the audit log plugin is the one having the largest `pwd_timestamp` value. If multiple passwords have that `pwd_timestamp` value, the current password ID is the one with the largest sequence number. For example, in the preceding set of password IDs, two of them have the largest timestamp, `20190403T142400`, so the current password ID is the one with the largest sequence number (2).

The audit log plugin performs certain actions during initialization and termination based on the effective audit log file name:

- During initialization, the plugin checks whether a file with the audit log file name already exists and renames it if so. (In this case, the plugin assumes that the previous server invocation exited unexpectedly with the audit log plugin running.) The plugin then writes to a new empty audit log file.
- During termination, the plugin renames the audit log file.
- File renaming (whether during plugin initialization or termination) occurs according to the usual rules for automatic size-based log file rotation; see [Manual Audit Log File Rotation](#).

## Selecting Audit Log File Format

To configure the audit log file format, set the `audit_log_format` system variable at server startup. These formats are available:

- **NEW**: New-style XML format. This is the default.
- **OLD**: Old-style XML format.

- **JSON:** JSON format. Writes the audit log as a JSON array. Only this format supports the optional query time and size statistics.

For details about each format, see [Section 8.4.5.4, “Audit Log File Formats”](#).

## Enabling the Audit Log Flush Task

MySQL Enterprise Audit provides the capability of setting a refresh interval to dispose of the in-memory cache automatically. A flush task configured using the `audit_log_flush_interval_seconds` system variable has a value of zero by default, which means the task is not scheduled to run.

When the task is configured to run (the value is non-zero), MySQL Enterprise Audit attempts to call the `scheduler` component at its initialization and configure a regular, recurring flush of its memory cache:

- If the audit log cannot find an implementation of the scheduler registration service, it does not schedule the flush and continue loading.
- Audit log implements the `dynamic_loader_services_loaded_notification` service and listens for new registrations of `mysql_scheduler` so that audit log can register its scheduled task into the newly loaded scheduler.
- Audit log only registers itself into the first scheduler implementation loaded.

Similarly, MySQL Enterprise Audit calls the `scheduler` component at its deinitialization and unconfigures the recurring flush that it has scheduled. It keeps an active reference to the scheduler registration service until the scheduled task is unregistered, ensuring that the `scheduler` component cannot be unloaded while there are active scheduled jobs. All of the results from executing the scheduler and its tasks are written to the server error log.

To schedule an audit log flush task:

1. Confirm that the `scheduler` component is loaded and enabled. The component is enabled (**ON**) by default (see `component_scheduler.enabled`).

```
SELECT * FROM mysql.components;
+-----+-----+-----+
| component_id | component_group_id | component_urn |
+-----+-----+-----+
| 1 | 1 | file://component_scheduler |
+-----+-----+-----+
```

2. Install the `audit_log` plugin, if it is not installed already (see [Section 8.4.5.2, “Installing or Uninstalling MySQL Enterprise Audit”](#)).
3. Start the server using `audit_log_flush_interval_seconds` and set the value to a number greater than 59. The upper limit of the value varies by platform. For example, to configure the flush task to recur every two minutes:

```
$> mysqld --audit_log_flush_interval_seconds=120
```

For more information, see the `audit_log_flush_interval_seconds` system variable.

## Adding Query Statistics for Outlier Detection

In MySQL 9.1, you can extend log files in JSON format with optional data fields to show the query time, the number of bytes sent and received, the number of rows returned to the client, and the number of rows examined. This data is available in the slow query log for qualifying queries, and in the context of the audit log it similarly helps to detect outliers for activity analysis. The extended data fields can be added only when the audit log is in JSON format (`audit_log_format=JSON`), which is not the default setting.

The query statistics are delivered to the audit log through component services that you set up as an audit log filtering function. The services are named `mysql_audit_print_service_longlong_data_source` and `mysql_audit_print_service_double_data_source`. You can choose either data type for each output item. For the query time, `longlong` outputs the value in microseconds, and `double` outputs the value in seconds.

You add the query statistics using the `audit_log_filter_set_filter()` audit log function, as the `service` element of the JSON filtering syntax, as follows:

```
SELECT audit_log_filter_set_filter('QueryStatistics',
 '{ "filter": { "class": { "name": "general", "event": { "name": "general", "service": { "implementation": "mysql_server", "tag": "query_time", "name": "query_time", "type": "double" }, "name": "bytes_sent", "type": "longlong" }, "name": "bytes_received", "type": "longlong" }, "name": "rows_sent", "type": "longlong" }, "name": "rows_examined", "type": "longlong" }] } } } } }
```

For the `bytes_sent` and `bytes_received` fields to be populated, the system variable `log_slow_extra` must be set to `ON`. If the system variable is value is `OFF`, a null value is written to the log file for these fields.

If you want to stop collecting the query statistics, use the `audit_log_filter_set_filter()` audit log function to remove the filter, for example:

```
SELECT audit_log_filter_remove_filter('QueryStatistics');
```

## Compressing Audit Log Files

Audit log file compression can be enabled for any logging format.

To configure audit log file compression, set the `audit_log_compression` system variable at server startup. Permitted values are `NONE` (no compression; the default) and `GZIP` (GNU Zip compression).

If both compression and encryption are enabled, compression occurs before encryption. To recover the original file manually, first decrypt it, then uncompress it. See [Manually Uncompressing and Decrypting Audit Log Files](#).

## Encrypting Audit Log Files

Audit log file encryption can be enabled for any logging format. Encryption is based on user-defined passwords (with the exception of the initial password that the audit log plugin generates). To use this feature, the MySQL keyring must be enabled because audit logging uses it for password storage. Any keyring component or plugin can be used; for instructions, see [Section 8.4.4, “The MySQL Keyring”](#).

To configure audit log file encryption, set the `audit_log_encryption` system variable at server startup. Permitted values are `NONE` (no encryption; the default) and `AES` (AES-256-CBC cipher encryption).

To set or get an encryption password at runtime, use these audit log functions:

- To set the current encryption password, invoke `audit_log_encryption_password_set()`. This function stores the new password in the keyring. If encryption is enabled, it also performs a log file rotation operation that renames the current log file, and begins a new log file encrypted with the password. File renaming occurs according to the usual rules for automatic size-based log file rotation; see [Manual Audit Log File Rotation](#).

If the `audit_log_password_history_keep_days` system variable is nonzero, invoking `audit log encryption password set()` also causes expiration of old archived audit log

encryption passwords. For information about audit log password history, including password archiving and expiration, see the description of that variable.

- To get the current encryption password, invoke `audit_log_encryption_password_get()` with no argument. To get a password by ID, pass an argument that specifies the keyring ID of the current password or an archived password.

To determine which audit log keyring IDs exist, query the Performance Schema `keyring_keys` table:

```
mysql> SELECT KEY_ID FROM performance_schema.keyring_keys
 WHERE KEY_ID LIKE 'audit_log%'
 ORDER BY KEY_ID;
+-----+
| KEY_ID |
+-----+
| audit_log-20190415T152248-1 |
| audit_log-20190415T153507-1 |
| audit_log-20190416T125122-1 |
| audit_log-20190416T141608-1 |
+-----+
```

For additional information about audit log encryption functions, see [Audit Log Functions](#).

When the audit log plugin initializes, if it finds that log file encryption is enabled, it checks whether the keyring contains an audit log encryption password. If not, the plugin automatically generates a random initial encryption password and stores it in the keyring. To discover this password, invoke `audit_log_encryption_password_get()`.

If both compression and encryption are enabled, compression occurs before encryption. To recover the original file manually, first decrypt it, then uncompress it. See [Manually Uncompressing and Decrypting Audit Log Files](#).

## Manually Uncompressing and Decrypting Audit Log Files

Audit log files can be uncompressed and decrypted using standard tools. This should be done only for log files that have been closed (archived) and are no longer in use, not for the log file that the audit log plugin is currently writing. You can recognize archived log files because they have been renamed by the audit log plugin to include a timestamp in the file name just after the base name.

For this discussion, assume that `audit_log_file` is set to `audit.log`. In that case, an archived audit log file has one of the names shown in the following table.

Enabled Features	Archived File Name
No compression or encryption	<code>audit.timestamp.log</code>
Compression	<code>audit.timestamp.log.gz</code>
Encryption	<code>audit.timestamp.log.pwd_id.enc</code>
Compression, encryption	<code>audit.timestamp.log.gz.pwd_id.enc</code>

As discussed in [Naming Conventions for Audit Log Files](#), `pwd_id` format is `pwd_timestamp-seq`. Thus, the names of archived encrypted log files actually contain two timestamps. The first indicates file rotation time, and the second indicates when the encryption password was created.

Consider the following set of archived encrypted log file names:

```
audit.20190410T205827.log.20190403T185337-1.enc
audit.20190410T210243.log.20190403T185337-1.enc
```

```
audit.20190415T145309.log.20190414T223342-1.enc
audit.20190415T151322.log.20190414T223342-2.enc
```

Each file name has a unique rotation-time timestamp. By contrast, the password timestamps are not unique:

- The first two files have the same password ID and sequence number (`20190403T185337-1`). They have the same encryption password.
- The second two files have the same password ID (`20190414T223342`) but different sequence numbers (`1`, `2`). These files have different encryption passwords.

To uncompress a compressed log file manually, use `gunzip`, `gzip -d`, or equivalent command. For example:

```
gunzip -c audit.timestamp.log.gz > audit.timestamp.log
```

To decrypt an encrypted log file manually, use the `openssl` command. For example:

```
openssl enc -d -aes-256-cbc -pass pass:password -md sha256
-in audit.timestamp.log.pwd_id.enc
-out audit.timestamp.log
```

To execute that command, you must obtain `password`, the encryption password. To do this, use `audit_log_encryption_password_get()`. For example, if the audit log file name is `audit.20190415T151322.log.20190414T223342-2.enc`, the password ID is `20190414T223342-2` and the keyring ID is `audit-log-20190414T223342-2`. Retrieve the keyring password like this:

```
SELECT audit_log_encryption_password_get('audit-log-20190414T223342-2');
```

If both compression and encryption are enabled for audit logging, compression occurs before encryption. In this case, the file name has `.gz` and `.pwd_id.enc` suffixes added, corresponding to the order in which those operations occur. To recover the original file manually, perform the operations in reverse. That is, first decrypt the file, then uncompress it:

```
openssl enc -d -aes-256-cbc -pass pass:password -md sha256
-in audit.timestamp.log.gz.pwd_id.enc
-out audit.timestamp.log.gz
gunzip -c audit.timestamp.log.gz > audit.timestamp.log
```

## Space Management of Audit Log Files

The audit log file has the potential to grow quite large and consume a great deal of disk space. If you are collecting the optional query time and size statistics, this increases the space requirements. The query statistics are only supported with JSON format.

To manage the space used, employ these methods:

- Log file rotation. This involves rotating the current log file by renaming it, then opening a new current log file using the original name. Rotation can be performed manually, or configured to occur automatically.
- Pruning of rotated JSON-format log files, if automatic rotation is enabled. Pruning can be performed based on log file age or combined log file size.

To configure audit log file space management, use the following system variables:

- If `audit_log_rotate_on_size` is 0 (the default), automatic log file rotation is disabled.

- No rotation occurs unless performed manually.
- To rotate the current file, use one of the following methods:
  - Run `SELECT audit_log_rotate();` to rename the file and open a new audit log file using the original name.

With this file rotation method, pruning of rotated JSON-format log files occurs if `audit_log_max_size` or `audit_log_prune_seconds` has a value greater than 0.

- Manually rename the file, then enable `audit_log_flush` to close it and open a new current log file using the original name. This file rotation method and the `audit_log_flush` variable are deprecated.

With this file rotation method, pruning of rotated JSON-format log files does not occur; `audit_log_max_size` and `audit_log_prune_seconds` have no effect.

See [Manual Audit Log File Rotation](#), for more information.

- If `audit_log_rotate_on_size` is greater than 0, automatic audit log file rotation is enabled:
  - Automatic rotation occurs when a write to the current log file causes its size to exceed the `audit_log_rotate_on_size` value, as well as under certain other conditions; see [Automatic Audit Log File Rotation](#). When automatic rotation occurs, the audit log plugin renames the current log file and opens a new current log file using the original name.
  - Pruning of rotated JSON-format log files occurs if `audit_log_max_size` or `audit_log_prune_seconds` has a value greater than 0.
  - `audit_log_flush` has no effect.

**Note**

For JSON-format log files, rotation also occurs when the value of the `audit_log_format_unix_timestamp` system variable is changed at runtime. However, this does not occur for space-management purposes, but rather so that, for a given JSON-format log file, all records in the file either do or do not include the `time` field.

**Note**

Rotated (renamed) log files are not removed automatically. For example, with size-based log file rotation, renamed log files have unique names and accumulate indefinitely. They do not rotate off the end of the name sequence. To avoid excessive use of space:

- For JSON-format log files: Enable log file pruning as described in [Audit Log File Pruning](#).
- Otherwise: Remove old files periodically, backing them up first as necessary. If backed-up log files are encrypted, also back up the corresponding encryption passwords to a safe place, should you need to decrypt the files later.

The following sections describe log file rotation and pruning in greater detail.

- [Manual Audit Log File Rotation](#)

- [Manual Audit Log File Rotation \(Old Method\)](#)
- [Automatic Audit Log File Rotation](#)
- [Audit Log File Pruning](#)

## Manual Audit Log File Rotation

If `audit_log_rotate_on_size` is 0 (the default), no log rotation occurs unless performed manually.

To rotate the audit log file manually, run `SELECT audit_log_rotate();` to rename the current audit log file and open a new audit log file. Files are renamed according to the conventions described in [Naming Conventions for Audit Log Files](#).

The `AUDIT_ADMIN` privilege is required to use the `audit_log_rotate()` function.

Managing the number of archived log files (the files that have been renamed) and the space they use is a manual task that involves removing archived audit log files that are no longer needed from your file system.

The content of audit log files that are renamed using the `audit_log_rotate()` function can be read by `audit_log_read()` function.

## Manual Audit Log File Rotation (Old Method)

### Note

The `audit_log_flush` variable and this method of audit log file rotation are deprecated; expect support to be removed in a future version of MySQL.

If `audit_log_rotate_on_size` is 0 (the default), no log rotation occurs unless performed manually. In this case, the audit log plugin closes and reopens the log file when the `audit_log_flush` value changes from disabled to enabled. Log file renaming must be done externally to the server. Suppose that the log file name is `audit.log` and you want to maintain the three most recent log files, cycling through the names `audit.log.1` through `audit.log.3`. On Unix, perform rotation manually like this:

1. From the command line, rename the current log files:

```
mv audit.log.2 audit.log.3
mv audit.log.1 audit.log.2
mv audit.log audit.log.1
```

This strategy overwrites the current `audit.log.3` contents, placing a bound on the number of archived log files and the space they use.

2. At this point, the plugin is still writing to the current log file, which has been renamed to `audit.log.1`. Connect to the server and flush the log file so the plugin closes it and reopens a new `audit.log` file:

```
SET GLOBAL audit_log_flush = ON;
```

`audit_log_flush` is special in that its value remains `OFF` so that you need not disable it explicitly before enabling it again to perform another flush.

### Note

If compression or encryption are enabled, log file names include suffixes that signify the enabled features, as well as a password ID if encryption is enabled. If file names include a password ID, be sure to retain the ID in the name of any files

you rename manually so that the password to use for decryption operations can be determined.

#### Note

For JSON-format logging, renaming audit log files manually makes them unavailable to the log-reading functions because the audit log plugin can no longer determine that they are part of the log file sequence (see [Section 8.4.5.6, “Reading Audit Log Files”](#)). Consider setting `audit_log_rotate_on_size` greater than 0 to use size-based rotation instead.

### Automatic Audit Log File Rotation

If `audit_log_rotate_on_size` is greater than 0, setting `audit_log_flush` has no effect. Instead, whenever a write to the current log file causes its size to exceed the `audit_log_rotate_on_size` value, the audit log plugin automatically renames the current log file and opens a new current log file using the original name.

Automatic size-based rotation also occurs under these conditions:

- During plugin initialization, if a file with the audit log file name already exists (see [Naming Conventions for Audit Log Files](#)).
- During plugin termination.
- When the `audit_log_encryption_password_set()` function is called to set the encryption password, if encryption is enabled. (Rotation does not occur if encryption is disabled.)

The plugin renames the original file by inserting a timestamp just after its base name. For example, if the file name is `audit.log`, the plugin renames it to a value such as `audit.20210115T140633.log`. The timestamp is a UTC value in `YYYYMMDDThhmmss` format. For XML logging, the timestamp indicates rotation time. For JSON logging, the timestamp is that of the last event written to the file.

If log files are encrypted, the original file name already contains a timestamp indicating the encryption password creation time (see [Naming Conventions for Audit Log Files](#)). In this case, the file name after rotation contains two timestamps. For example, an encrypted log file named `audit.log.20210110T130749-1.enc` is renamed to a value such as `audit.20210115T140633.log.20210110T130749-1.enc`.

### Audit Log File Pruning

The audit log plugin supports pruning of rotated JSON-format audit log files, if automatic log file rotation is enabled. To use this capability:

- Set `audit_log_format` to `JSON`. (In addition, consider also changing `audit_log_file`; see [Selecting Audit Log File Format](#).)
- Set `audit_log_rotate_on_size` greater than 0 to specify the size in bytes at which automatic log file rotation occurs.
- By default, no pruning of automatically rotated JSON-format log files occurs. To enable pruning, set one of these system variables to a value greater than 0:
  - Set `audit_log_max_size` greater than 0 to specify the limit in bytes on the combined size of rotated log files above which the files become subject to pruning.
  - Set `audit_log_prune_seconds` greater than 0 to specify the number of seconds after which rotated log files become subject to pruning.

Nonzero values of `audit_log_max_size` take precedence over nonzero values of `audit_log_prune_seconds`. If both are set greater than 0 at plugin initialization, a warning is written to the server error log. If a client sets both greater than 0 at runtime, a warning is returned to the client.

**Note**

Warnings to the error log are written as Notes, which are information messages. To ensure that such messages appear in the error log and are not discarded, make sure that error-logging verbosity is sufficient to include information messages. For example, if you are using priority-based log filtering, as described in [Section 7.4.2.5, “Priority-Based Error Log Filtering \(log\\_filter\\_internal\)”](#), set the `log_error_verbosity` system variable to a value of 3.

Pruning of JSON-format log files, if enabled, occurs as follows:

- When automatic rotation takes place; for the conditions under which this happens, see [Automatic Audit Log File Rotation](#).
- When the global `audit_log_max_size` or `audit_log_prune_seconds` system variable is set at runtime.

For pruning based on combined rotated log file size, if the combined size is greater than the limit specified by `audit_log_max_size`, the audit log plugin removes the oldest files until their combined size does not exceed the limit.

For pruning based on rotated log file age, the pruning point is the current time minus the value of `audit_log_prune_seconds`. In rotated JSON-format log files, the timestamp part of each file name indicates the timestamp of the last event written to the file. The audit log plugin uses file name timestamps to determine which files contain only events older than the pruning point, and removes them.

## Write Strategies for Audit Logging

The audit log plugin can use any of several strategies for log writes. Regardless of strategy, logging occurs on a best-effort basis, with no guarantee of consistency.

To specify a write strategy, set the `audit_log_strategy` system variable at server startup. By default, the strategy value is `ASYNCHRONOUS` and the plugin logs asynchronously to a buffer, waiting if the buffer is full. You can tell the plugin not to wait (`PERFORMANCE`) or to log synchronously, either using file system caching (`SEMISYNCHRONOUS`) or forcing output with a `sync()` call after each write request (`SYNCHRONOUS`).

In many cases, the plugin writes directly to a JSON-format audit log if the current query is too large for the buffer. The write strategy determines how the plugin increments the direct write count. You can track the number direct writes with the `Audit_log_direct_writes` status variable.

For asynchronous write strategy, the `audit_log_buffer_size` system variable is the buffer size in bytes. Set this variable at server startup to change the buffer size. The plugin uses a single buffer, which it allocates when it initializes and removes when it terminates. The plugin does not allocate this buffer for nonasynchronous write strategies.

Asynchronous logging strategy has these characteristics:

- Minimal impact on server performance and scalability.
- Blocking of threads that generate audit events for the shortest possible time; that is, time to allocate the buffer plus time to copy the event to the buffer.

- Output goes to the buffer. A separate thread handles writes from the buffer to the log file.

With asynchronous logging, the integrity of the log file may be compromised if a problem occurs during a write to the file or if the plugin does not shut down cleanly (for example, in the event that the server host exits unexpectedly). To reduce this risk, set `audit_log_strategy` to use synchronous logging.

A disadvantage of `PERFORMANCE` strategy is that it drops events when the buffer is full. For a heavily loaded server, the audit log may have events missing.

### 8.4.5.6 Reading Audit Log Files

The audit log plugin supports functions that provide an SQL interface for reading JSON-format audit log files. (This capability does not apply to log files written in other formats.)

When the audit log plugin initializes and is configured for JSON logging, it uses the directory containing the current audit log file as the location to search for readable audit log files. The plugin determines the file location, base name, and suffix from the value of the `audit_log_file` system variable, then looks for files with names that match the following pattern, where `[...]` indicates optional file name parts:

```
basename[.timestamp].suffix[.gz][[.pwd_id].enc]
```

If a file name ends with `.enc`, the file is encrypted and reading its unencrypted contents requires a decryption password obtained from the keyring. The audit log plugin determines the keyring ID of the decryption password as follows:

- If `.enc` is preceded by `pwd_id`, the keyring ID is `audit_log-pwd_id`.
- If `.enc` is not preceded by `pwd_id`, the file has an old name from before audit log encryption password history was implemented. The keyring ID is `audit_log`.

For more information about encrypted audit log files, see [Encrypting Audit Log Files](#).

The plugin ignores files that have been renamed manually and do not match the pattern, and files that were encrypted with a password no longer available in the keyring. The plugin opens each remaining candidate file, verifies that the file actually contains `JSON` audit events, and sorts the files using the timestamps from the first event of each file. The result is a sequence of files that are subject to access using the log-reading functions:

- `audit_log_read()` reads events from the audit log or closes the reading process.
- `audit_log_read_bookmark()` returns a bookmark for the most recently written audit log event. This bookmark is suitable for passing to `audit_log_read()` to indicate where to begin reading.

`audit_log_read()` takes an optional `JSON` string argument, and the result returned from a successful call to either function is a `JSON` string.

To use the functions to read the audit log, follow these principles:

- Call `audit_log_read()` to read events beginning from a given position or the current position, or to close reading:
  - To initialize an audit log read sequence, pass an argument that indicates the position at which to begin. One way to do so is to pass the bookmark returned by `audit_log_read_bookmark()`:

```
SELECT audit_log_read(audit_log_read_bookmark());
```

- To continue reading from the current position in the sequence, call `audit_log_read()` with no position specified:

```
SELECT audit_log_read();
```

- To explicitly close the read sequence, pass a `JSON null` argument:

```
SELECT audit_log_read('null');
```

It is unnecessary to close reading explicitly. Reading is closed implicitly when the session ends or a new read sequence is initialized by calling `audit_log_read()` with an argument that indicates the position at which to begin.

- A successful call to `audit_log_read()` to read events returns a `JSON` string containing an array of audit events:
- If the final value of the returned array is not a `JSON null` value, there are more events following those just read and `audit_log_read()` can be called again to read more of them.
- If the final value of the returned array is a `JSON null` value, there are no more events left to be read in the current read sequence.

Each non-`null` array element is an event represented as a `JSON` hash. For example:

```
[
 {
 "timestamp": "2020-05-18 13:39:33", "id": 0,
 "class": "connection", "event": "connect",
 ...
 },
 {
 "timestamp": "2020-05-18 13:39:33", "id": 1,
 "class": "general", "event": "status",
 ...
 },
 {
 "timestamp": "2020-05-18 13:39:33", "id": 2,
 "class": "connection", "event": "disconnect",
 ...
 },
 null
]
```

For more information about the content of `JSON`-format audit events, see [JSON Audit Log File Format](#).

- An `audit_log_read()` call to read events that does not specify a position produces an error under any of these conditions:
  - A read sequence has not yet been initialized by passing a position to `audit_log_read()`.
  - There are no more events left to be read in the current read sequence; that is, `audit_log_read()` previously returned an array ending with a `JSON null` value.
  - The most recent read sequence has been closed by passing a `JSON null` value to `audit_log_read()`.

To read events under those conditions, it is necessary to first initialize a read sequence by calling `audit_log_read()` with an argument that specifies a position.

To specify a position to `audit_log_read()`, include an argument that indicates where to begin reading. For example, pass a bookmark, which is a `JSON` hash containing `timestamp` and `id` elements that uniquely identify a particular event. Here is an example bookmark, obtained by calling the `audit_log_read_bookmark()` function:

```
mysql> SELECT audit_log_read_bookmark();
+-----+
| audit_log_read_bookmark() |
+-----+
| { "timestamp": "2020-05-18 21:03:44", "id": 0 } |
+-----+
```

Passing the current bookmark to `audit_log_read()` initializes event reading beginning at the bookmark position:

```
mysql> SELECT audit_log_read(audit_log_read_bookmark());
+-----+
| audit_log_read(audit_log_read_bookmark()) |
+-----+
| [{ "timestamp": "2020-05-18 22:41:24", "id": 0, "class": "connection", ... } |
+-----+
```

The argument to `audit_log_read()` is optional. If present, it can be a `JSON null` value to close the read sequence, or a `JSON` hash.

Within a hash argument to `audit_log_read()`, items are optional and control aspects of the read operation such as the position at which to begin reading or how many events to read. The following items are significant (other items are ignored):

- `start`: The position within the audit log of the first event to read. The position is given as a timestamp and the read starts from the first event that occurs on or after the timestamp value. The `start` item has this format, where *value* is a literal timestamp value:

```
"start": { "timestamp": "value" }
```

- `timestamp`, `id`: The position within the audit log of the first event to read. The `timestamp` and `id` items together comprise a bookmark that uniquely identify a particular event. If an `audit_log_read()` argument includes either item, it must include both to completely specify a position or an error occurs.
- `max_array_length`: The maximum number of events to read from the log. If this item is omitted, the default is to read to the end of the log or until the read buffer is full, whichever comes first.

To specify a starting position to `audit_log_read()`, pass a hash argument that includes either a `start` item or a bookmark consisting of `timestamp` and `id` items. If a hash argument includes both a `start` item and a bookmark, an error occurs.

If a hash argument specifies no starting position, reading continues from the current position.

If a timestamp value includes no time part, a time part of `00:00:00` is assumed.

Example arguments accepted by `audit_log_read()`:

- Read events starting with the first event that occurs on or after the given timestamp:

```
audit_log_read('{ "start": { "timestamp": "2020-05-24 12:30:00" } }')
```

- Like the previous example, but read at most 3 events:

```
audit_log_read('{ "start": { "timestamp": "2020-05-24 12:30:00" }, "max_array_length": 3 }')
```

- Read events starting with the first event that occurs on or after `2020-05-24 00:00:00` (the timestamp includes no time part, so `00:00:00` is assumed):

```
audit_log_read('{ "start": { "timestamp": "2020-05-24" } }')
```

- Read events starting with the event that has the exact timestamp and event ID:

```
audit_log_read('{ "timestamp": "2020-05-24 12:30:00", "id": 0 }')
```

- Like the previous example, but read at most 3 events:

```
audit_log_read('{ "timestamp": "2020-05-24 12:30:00", "id": 0, "max_array_length": 3 }')
```

- Read events from the current position in the read sequence:

```
audit_log_read()
```

- Read at most 5 events beginning at the current position in the read sequence:

```
audit_log_read('{ "max_array_length": 5 }')
```

- Close the current read sequence:

```
audit_log_read('null')
```

A [JSON](#) string returned from either log-reading function can be manipulated as necessary. Suppose that a call to obtain a bookmark produces this value:

```
mysql> SET @mark := audit_log_read_bookmark();
mysql> SELECT @mark;
+-----+
| @mark |
+-----+
| { "timestamp": "2020-05-18 16:10:28", "id": 2 } |
+-----+
```

Calling `audit_log_read()` with that argument can return multiple events. To limit `audit_log_read()` to reading at most *N* events, add to the string a `max_array_length` item with that value. For example, to read a single event, modify the string as follows:

```
mysql> SET @mark := JSON_SET(@mark, '$.max_array_length', 1);
mysql> SELECT @mark;
+-----+
| @mark |
+-----+
| {"id": 2, "timestamp": "2020-05-18 16:10:28", "max_array_length": 1} |
+-----+
```

The modified string, when passed to `audit_log_read()`, produces a result containing at most one event, no matter how many are available.

If an audit log function is invoked from within the `mysql` client, binary string results display using hexadecimal notation, depending on the value of the `--binary-as-hex`. For more information about that option, see [Section 6.5.1, “mysql — The MySQL Command-Line Client”](#).

To set a limit on the number of bytes that `audit_log_read()` reads, set the `audit_log_read_buffer_size` system variable. This variable has a default of 32KB and can be set at runtime. Each client should set its session value of `audit_log_read_buffer_size` appropriately for its use of `audit_log_read()`.

Each call to `audit_log_read()` returns as many available events as fit within the buffer size. Events that do not fit within the buffer size are skipped and generate warnings. Given this behavior, consider these factors when assessing the proper buffer size for an application:

- There is a tradeoff between number of calls to `audit_log_read()` and events returned per call:
  - With a smaller buffer size, calls return fewer events, so more calls are needed.

- With a larger buffer size, calls return more events, so fewer calls are needed.
- With a smaller buffer size, such as the default size of 32KB, there is a greater chance for events to exceed the buffer size and thus to be skipped.

For additional information about audit log-reading functions, see [Audit Log Functions](#).

### 8.4.5.7 Audit Log Filtering

#### Note

For audit log filtering to work as described here, the audit log plugin *and the accompanying audit tables and functions* must be installed. If the plugin is installed without the accompanying audit tables and functions needed for rule-based filtering, the plugin operates in legacy filtering mode, described in [Section 8.4.5.10, “Legacy Mode Audit Log Filtering”](#). Legacy mode (deprecated) is filtering behavior as it was prior to MySQL 5.7.13; that is, before the introduction of rule-based filtering.

- [Properties of Audit Log Filtering](#)
- [Constraints on Audit Log Filtering Functions](#)
- [Using Audit Log Filtering Functions](#)

### Properties of Audit Log Filtering

The audit log plugin has the capability of controlling logging of audited events by filtering them:

- Audited events can be filtered using these characteristics:
  - User account
  - Audit event class
  - Audit event subclass
  - Audit event fields such as those that indicate operation status or SQL statement executed
- Audit filtering is rule based:
  - A filter definition creates a set of auditing rules. Definitions can be configured to include or exclude events for logging based on the characteristics just described.
  - Filter rules have the capability of blocking (aborting) execution of qualifying events, in addition to existing capabilities for event logging.
  - Multiple filters can be defined, and any given filter can be assigned to any number of user accounts.
  - It is possible to define a default filter to use with any user account that has no explicitly assigned filter.

Audit log filtering is used to implement component services. To get the optional query statistics available from that release, you set them up as a filter using the service component, which implements the services that write the statistics to the audit log. For instructions to set this filter up, see [Adding Query Statistics for Outlier Detection](#).

For information about writing filtering rules, see [Section 8.4.5.8, “Writing Audit Log Filter Definitions”](#).

- Audit log filters can be defined and modified using an SQL interface based on function calls. By default, audit log filter definitions are stored in the `mysql` system database, and you can display audit filters by querying the `mysql.audit_log_filter` table. It is possible to use a different database for this purpose, in which case you should query the `database_name.audit_log_filter` table instead. See [Section 8.4.5.2, “Installing or Uninstalling MySQL Enterprise Audit”](#), for more information.
- Within a given session, the value of the read-only `audit_log_filter_id` system variable indicates whether a filter is assigned to the session.

#### Note

By default, rule-based audit log filtering logs no auditable events for any users. To log all auditable events for all users, use the following statements, which create a simple filter to enable logging and assign it to the default account:

```
SELECT audit_log_filter_set_filter('log_all', '{ "filter": { "log": true } }');
SELECT audit_log_filter_set_user('%', 'log_all');
```

The filter assigned to `%` is used for connections from any account that has no explicitly assigned filter (which initially is true for all accounts).

As previously mentioned, the SQL interface for audit filtering control is function based. The following list briefly summarizes these functions:

- `audit_log_filter_set_filter()`: Define a filter.
- `audit_log_filter_remove_filter()`: Remove a filter.
- `audit_log_filter_set_user()`: Start filtering a user account.
- `audit_log_filter_remove_user()`: Stop filtering a user account.
- `audit_log_filter_flush()`: Flush manual changes to the filter tables to affect ongoing filtering.

For usage examples and complete details about the filtering functions, see [Using Audit Log Filtering Functions](#), and [Audit Log Functions](#).

## Constraints on Audit Log Filtering Functions

Audit log filtering functions are subject to these constraints:

- To use any filtering function, the `audit_log` plugin must be enabled or an error occurs. In addition, the audit tables must exist or an error occurs. To install the `audit_log` plugin and its accompanying functions and tables, see [Section 8.4.5.2, “Installing or Uninstalling MySQL Enterprise Audit”](#).
- To use any filtering function, a user must possess the `AUDIT_ADMIN SUPER` privilege or an error occurs. To grant one of these privileges to a user account, use this statement:

```
GRANT privilege ON *.* TO user;
```

Alternatively, should you prefer to avoid granting the `AUDIT_ADMIN` or `SUPER` privilege while still permitting users to access specific filtering functions, “wrapper” stored programs can be defined. This technique is described in the context of keyring functions in [Using General-Purpose Keyring Functions](#); it can be adapted for use with filtering functions.

- The `audit_log` plugin operates in legacy mode if it is installed but the accompanying audit tables and functions are not created. The plugin writes these messages to the error log at server startup:

```
[Warning] Plugin audit_log reported: 'Failed to open the audit log filter tables.'
```

```
[Warning] Plugin audit_log reported: 'Audit Log plugin supports a filtering,
which has not been installed yet. Audit Log plugin will run in the legacy
mode, which will be disabled in the next release.'
```

In legacy mode, which is deprecated, filtering can be done based only on event account or status. For details, see [Section 8.4.5.10, “Legacy Mode Audit Log Filtering”](#).

- It is theoretically possible for a user with sufficient permissions to mistakenly create an “abort” item in the audit log filter that prevents themselves and other administrators from accessing the system. The `AUDIT_ABORT_EXEMPT` privilege is available to permit a user account’s queries to always be executed even if an “abort” item would block them. Accounts with this privilege can therefore be used to regain access to a system following an audit misconfiguration. The query is still logged in the audit log, but instead of being rejected, it is permitted due to the privilege.

Accounts created with the `SYSTEM_USER` privilege have the `AUDIT_ABORT_EXEMPT` privilege assigned automatically when they are created. The `AUDIT_ABORT_EXEMPT` privilege is also assigned to existing accounts with the `SYSTEM_USER` privilege when you carry out an upgrade procedure, if no existing accounts have that privilege assigned.

## Using Audit Log Filtering Functions

Before using the audit log functions, install them according to the instructions provided in [Section 8.4.5.2, “Installing or Uninstalling MySQL Enterprise Audit”](#). The `AUDIT_ADMIN` or `SUPER` privilege is required to use any of these functions.

The audit log filtering functions enable filtering control by providing an interface to create, modify, and remove filter definitions and assign filters to user accounts.

Filter definitions are `JSON` values. For information about using `JSON` data in MySQL, see [Section 13.5, “The JSON Data Type”](#). This section shows some simple filter definitions. For more information about filter definitions, see [Section 8.4.5.8, “Writing Audit Log Filter Definitions”](#).

When a connection arrives, the audit log plugin determines which filter to use for the new session by searching for the user account name in the current filter assignments:

- If a filter is assigned to the user, the audit log uses that filter.
- Otherwise, if no user-specific filter assignment exists, but there is a filter assigned to the default account (`%`), the audit log uses the default filter.
- Otherwise, the audit log selects no audit events from the session for processing.

If a change-user operation occurs during a session (see `mysql_change_user()`), filter assignment for the session is updated using the same rules but for the new user.

By default, no accounts have a filter assigned, so no processing of auditable events occurs for any account.

Suppose that you want to change the default to be to log only connection-related activity (for example, to see connect, change-user, and disconnect events, but not the SQL statements users execute while connected). To achieve this, define a filter (shown here named `log_conn_events`) that enables logging only of events in the `connection` class, and assign that filter to the default account, represented by the `%` account name:

```
SET @f = '{ "filter": { "class": { "name": "connection" } } }';
SELECT audit_log_filter_set_filter('log_conn_events', @f);
SELECT audit_log_filter_set_user('%', 'log_conn_events');
```

Now the audit log uses this default account filter for connections from any account that has no explicitly defined filter.

To assign a filter explicitly to a particular user account or accounts, define the filter, then assign it to the relevant accounts:

```
SELECT audit_log_filter_set_filter('log_all', '{ "filter": { "log": true } }');
SELECT audit_log_filter_set_user('user1@localhost', 'log_all');
SELECT audit_log_filter_set_user('user2@localhost', 'log_all');
```

Now full logging is enabled for `user1@localhost` and `user2@localhost`. Connections from other accounts continue to be filtered using the default account filter.

To disassociate a user account from its current filter, either unassign the filter or assign a different filter:

- To unassign the filter from the user account:

```
SELECT audit_log_filter_remove_user('user1@localhost');
```

Filtering of current sessions for the account remains unaffected. Subsequent connections from the account are filtered using the default account filter if there is one, and are not logged otherwise.

- To assign a different filter to the user account:

```
SELECT audit_log_filter_set_filter('log_nothing', '{ "filter": { "log": false } }');
SELECT audit_log_filter_set_user('user1@localhost', 'log_nothing');
```

Filtering of current sessions for the account remains unaffected. Subsequent connections from the account are filtered using the new filter. For the filter shown here, that means no logging for new connections from `user1@localhost`.

For audit log filtering, user name and host name comparisons are case-sensitive. This differs from comparisons for privilege checking, for which host name comparisons are not case-sensitive.

To remove a filter, do this:

```
SELECT audit_log_filter_remove_filter('log_nothing');
```

Removing a filter also unassigns it from any users to whom it is assigned, including any current sessions for those users.

The filtering functions just described affect audit filtering immediately and update the audit log tables in the `mysql` system database that store filters and user accounts (see [Audit Log Tables](#)). It is also possible to modify the audit log tables directly using statements such as `INSERT`, `UPDATE`, and `DELETE`, but such changes do not affect filtering immediately. To flush your changes and make them operational, call `audit_log_filter_flush()`:

```
SELECT audit_log_filter_flush();
```

### Warning

`audit_log_filter_flush()` should be used only after modifying the audit tables directly, to force reloading all filters. Otherwise, this function should be avoided. It is, in effect, a simplified version of unloading and reloading the `audit_log` plugin with `UNINSTALL PLUGIN` plus `INSTALL PLUGIN`.

`audit_log_filter_flush()` affects all current sessions and detaches them from their previous filters. Current sessions are no longer logged unless they disconnect and reconnect, or execute a change-user operation.

To determine whether a filter is assigned to the current session, check the session value of the read-only `audit_log_filter_id` system variable. If the value is 0, no filter is assigned. A nonzero value indicates the internally maintained ID of the assigned filter:

```
mysql> SELECT @@audit_log_filter_id;
+-----+
| @@audit_log_filter_id |
+-----+
| 2 |
+-----+
```

### 8.4.5.8 Writing Audit Log Filter Definitions

Filter definitions are `JSON` values. For information about using `JSON` data in MySQL, see [Section 13.5, “The JSON Data Type”](#).

Filter definitions have this form, where *actions* indicates how filtering takes place:

```
{ "filter": actions }
```

The following discussion describes permitted constructs in filter definitions.

- [Logging All Events](#)
- [Logging Specific Event Classes](#)
- [Logging Specific Event Subclasses](#)
- [Inclusive and Exclusive Logging](#)
- [Testing Event Field Values](#)
- [Blocking Execution of Specific Events](#)
- [Logical Operators](#)
- [Referencing Predefined Variables](#)
- [Referencing Predefined Functions](#)
- [Replacement of Event Field Values](#)
- [Replacing a User Filter](#)

#### Logging All Events

To explicitly enable or disable logging of all events, use a `log` item in the filter:

```
{
 "filter": { "log": true }
}
```

The `log` value can be either `true` or `false`.

The preceding filter enables logging of all events. It is equivalent to:

```
{
 "filter": { }
}
```

Logging behavior depends on the `log` value and whether `class` or `event` items are specified:

- With `log` specified, its given value is used.
- Without `log` specified, logging is `true` if no `class` or `event` item is specified, and `false` otherwise (in which case, `class` or `event` can include their own `log` item).

## Logging Specific Event Classes

To log events of a specific class, use a `class` item in the filter, with its `name` field denoting the name of the class to log:

```
{
 "filter": {
 "class": { "name": "connection" }
 }
}
```

The `name` value can be `connection`, `general`, or `table_access` to log connection, general, or table-access events, respectively.

The preceding filter enables logging of events in the `connection` class. It is equivalent to the following filter with `log` items made explicit:

```
{
 "filter": {
 "log": false,
 "class": { "log": true,
 "name": "connection" }
 }
}
```

To enable logging of multiple classes, define the `class` value as a `JSON` array element that names the classes:

```
{
 "filter": {
 "class": [
 { "name": "connection" },
 { "name": "general" },
 { "name": "table_access" }
]
 }
}
```

### Note

When multiple instances of a given item appear at the same level within a filter definition, the item values can be combined into a single instance of that item within an array value. The preceding definition can be written like this:

```
{
 "filter": {
 "class": [
 { "name": ["connection", "general", "table_access"] }
]
 }
}
```

## Logging Specific Event Subclasses

To select specific event subclasses, use an `event` item containing a `name` item that names the subclasses. The default action for events selected by an `event` item is to log them. For example, this filter enables logging for the named event subclasses:

```
{
 "filter": {
 "class": [
 {
 "name": "connection",
 "event": [
 { "name": "connect" },
 { "name": "disconnect" }
]
 },
 { "name": "general" },
 {
 "name": "table_access",
 "event": [
 { "name": "insert" },
 { "name": "delete" },
 { "name": "update" }
]
 }
]
 }
}
```

The `event` item can also contain explicit `log` items to indicate whether to log qualifying events. This `event` item selects multiple events and explicitly indicates logging behavior for them:

```
"event": [
 { "name": "read", "log": false },
 { "name": "insert", "log": true },
 { "name": "delete", "log": true },
 { "name": "update", "log": true }
]
```

The `event` item can also indicate whether to block qualifying events, if it contains an `abort` item. For details, see [Blocking Execution of Specific Events](#).

[Table 8.35, “Event Class and Subclass Combinations”](#) describes the permitted subclass values for each event class.

**Table 8.35 Event Class and Subclass Combinations**

Event Class	Event Subclass	Description
<code>connection</code>	<code>connect</code>	Connection initiation (successful or unsuccessful)
<code>connection</code>	<code>change_user</code>	User re-authentication with different user/password during session
<code>connection</code>	<code>disconnect</code>	Connection termination
<code>general</code>	<code>status</code>	General operation information
<code>message</code>	<code>internal</code>	Internally generated message
<code>message</code>	<code>user</code>	Message generated by <code>audit_api_message_emit_udf()</code>
<code>table_access</code>	<code>read</code>	Table read statements, such as <code>SELECT</code> or <code>INSERT INTO ... SELECT</code>
<code>table_access</code>	<code>delete</code>	Table delete statements, such as <code>DELETE</code> or <code>TRUNCATE TABLE</code>

Event Class	Event Subclass	Description
<code>table_access</code>	<code>insert</code>	Table insert statements, such as <code>INSERT</code> or <code>REPLACE</code>
<code>table_access</code>	<code>update</code>	Table update statements, such as <code>UPDATE</code>

Table 8.36, “Log and Abort Characteristics Per Event Class and Subclass Combination” describes for each event subclass whether it can be logged or aborted.

**Table 8.36 Log and Abort Characteristics Per Event Class and Subclass Combination**

Event Class	Event Subclass	Can be Logged	Can be Aborted
<code>connection</code>	<code>connect</code>	Yes	No
<code>connection</code>	<code>change_user</code>	Yes	No
<code>connection</code>	<code>disconnect</code>	Yes	No
<code>general</code>	<code>status</code>	Yes	No
<code>message</code>	<code>internal</code>	Yes	Yes
<code>message</code>	<code>user</code>	Yes	Yes
<code>table_access</code>	<code>read</code>	Yes	Yes
<code>table_access</code>	<code>delete</code>	Yes	Yes
<code>table_access</code>	<code>insert</code>	Yes	Yes
<code>table_access</code>	<code>update</code>	Yes	Yes

## Inclusive and Exclusive Logging

A filter can be defined in inclusive or exclusive mode:

- Inclusive mode logs only explicitly specified items.
- Exclusive mode logs everything but explicitly specified items.

To perform inclusive logging, disable logging globally and enable logging for specific classes. This filter logs `connect` and `disconnect` events in the `connection` class, and events in the `general` class:

```
{
 "filter": {
 "log": false,
 "class": [
 {
 "name": "connection",
 "event": [
 { "name": "connect", "log": true },
 { "name": "disconnect", "log": true }
]
 },
 { "name": "general", "log": true }
]
 }
}
```

To perform exclusive logging, enable logging globally and disable logging for specific classes. This filter logs everything except events in the `general` class:

```
{
 "filter": {
```

```

 "log": true,
 "class": {
 { "name": "general", "log": false }
 }
 }
}

```

This filter logs `change_user` events in the `connection` class, `message` events, and `table_access` events, by virtue of *not* logging everything else:

```

{
 "filter": {
 "log": true,
 "class": [
 {
 "name": "connection",
 "event": [
 { "name": "connect", "log": false },
 { "name": "disconnect", "log": false }
]
 },
 { "name": "general", "log": false }
]
 }
}

```

## Testing Event Field Values

To enable logging based on specific event field values, specify a `field` item within the `log` item that indicates the field name and its expected value:

```

{
 "filter": {
 "class": {
 "name": "general",
 "event": {
 "name": "status",
 "log": {
 "field": { "name": "general_command.str", "value": "Query" }
 }
 }
 }
 }
}

```

Each event contains event class-specific fields that can be accessed from within a filter to perform custom filtering.

An event in the `connection` class indicates when a connection-related activity occurs during a session, such as a user connecting to or disconnecting from the server. [Table 8.37, “Connection Event Fields”](#) indicates the permitted fields for `connection` events.

**Table 8.37 Connection Event Fields**

Field Name	Field Type	Description
<code>status</code>	integer	Event status:  0: OK  Otherwise: Failed
<code>connection_id</code>	unsigned integer	Connection ID
<code>user.str</code>	string	User name specified during authentication

Field Name	Field Type	Description
<code>user.length</code>	unsigned integer	User name length
<code>priv_user.str</code>	string	Authenticated user name (account user name)
<code>priv_user.length</code>	unsigned integer	Authenticated user name length
<code>external_user.str</code>	string	External user name (provided by third-party authentication plugin)
<code>external_user.length</code>	unsigned integer	External user name length
<code>proxy_user.str</code>	string	Proxy user name
<code>proxy_user.length</code>	unsigned integer	Proxy user name length
<code>host.str</code>	string	Connected user host
<code>host.length</code>	unsigned integer	Connected user host length
<code>ip.str</code>	string	Connected user IP address
<code>ip.length</code>	unsigned integer	Connected user IP address length
<code>database.str</code>	string	Database name specified at connect time
<code>database.length</code>	unsigned integer	Database name length
<code>connection_type</code>	integer	Connection type:  0 or " <code>:::undefined</code> ": Undefined  1 or " <code>:::tcp/ip</code> ": TCP/IP  2 or " <code>:::socket</code> ": Socket  3 or " <code>:::named_pipe</code> ": Named pipe  4 or " <code>:::ssl</code> ": TCP/IP with encryption  5 or " <code>:::shared_memory</code> ": Shared memory

The "`:::xxx`" values are symbolic pseudo-constants that may be given instead of the literal numeric values. They must be quoted as strings and are case-sensitive.

An event in the `general` class indicates the status code of an operation and its details. [Table 8.38, "General Event Fields"](#) indicates the permitted fields for `general` events.

**Table 8.38 General Event Fields**

Field Name	Field Type	Description
<code>general_error_code</code>	integer	Event status:  0: OK  Otherwise: Failed
<code>general_thread_id</code>	unsigned integer	Connection/thread ID

Field Name	Field Type	Description
<code>general_user.str</code>	string	User name specified during authentication
<code>general_user.length</code>	unsigned integer	User name length
<code>general_command.str</code>	string	Command name
<code>general_command.length</code>	unsigned integer	Command name length
<code>general_query.str</code>	string	SQL statement text
<code>general_query.length</code>	unsigned integer	SQL statement text length
<code>general_host.str</code>	string	Host name
<code>general_host.length</code>	unsigned integer	Host name length
<code>general_sql_command.str</code>	string	SQL command type name
<code>general_sql_command.length</code>	unsigned integer	SQL command type name length
<code>general_external_user.str</code>	string	External user name (provided by third-party authentication plugin)
<code>general_external_user.length</code>	unsigned integer	External user name length
<code>general_ip.str</code>	string	Connected user IP address
<code>general_ip.length</code>	unsigned integer	Connection user IP address length

`general_command.str` indicates a command name: `Query`, `Execute`, `Quit`, or `Change user`.

A `general` event with the `general_command.str` field set to `Query` or `Execute` contains `general_sql_command.str` set to a value that specifies the type of SQL command: `alter_db`, `alter_db_upgrade`, `admin_commands`, and so forth. The available `general_sql_command.str` values can be seen as the last components of the Performance Schema instruments displayed by this statement:

```
mysql> SELECT NAME FROM performance_schema.setup_instruments
 WHERE NAME LIKE 'statement/sql/%' ORDER BY NAME;
+-----+
| NAME |
+-----+
| statement/sql/alter_db |
| statement/sql/alter_db_upgrade |
| statement/sql/alter_event |
| statement/sql/alter_function |
| statement/sql/alter_instance |
| statement/sql/alter_procedure |
| statement/sql/alter_server |
| ... |
```

An event in the `table_access` class provides information about a specific type of access to a table. Table 8.39, “Table-Access Event Fields” indicates the permitted fields for `table_access` events.

**Table 8.39 Table-Access Event Fields**

Field Name	Field Type	Description
<code>connection_id</code>	unsigned integer	Event connection ID
<code>sql_command_id</code>	integer	SQL command ID
<code>query.str</code>	string	SQL statement text
<code>query.length</code>	unsigned integer	SQL statement text length

Field Name	Field Type	Description
<code>table_database.str</code>	string	Database name associated with event
<code>table_database.length</code>	unsigned integer	Database name length
<code>table_name.str</code>	string	Table name associated with event
<code>table_name.length</code>	unsigned integer	Table name length

The following list shows which statements produce which table-access events:

- `read` event:
  - `SELECT`
  - `INSERT ... SELECT` (for tables referenced in `SELECT` clause)
  - `REPLACE ... SELECT` (for tables referenced in `SELECT` clause)
  - `UPDATE ... WHERE` (for tables referenced in `WHERE` clause)
  - `HANDLER ... READ`
- `delete` event:
  - `DELETE`
  - `TRUNCATE TABLE`
- `insert` event:
  - `INSERT`
  - `INSERT ... SELECT` (for table referenced in `INSERT` clause)
  - `REPLACE`
  - `REPLACE ... SELECT` (for table referenced in `REPLACE` clause)
  - `LOAD DATA`
  - `LOAD XML`
- `update` event:
  - `UPDATE`
  - `UPDATE ... WHERE` (for tables referenced in `UPDATE` clause)

## Blocking Execution of Specific Events

`event` items can include an `abort` item that indicates whether to prevent qualifying events from executing. `abort` enables rules to be written that block execution of specific SQL statements.

### Important

It is theoretically possible for a user with sufficient permissions to mistakenly create an `abort` item in the audit log filter that prevents themselves and other

administrators from accessing the system. The `AUDIT_ABORT_EXEMPT` privilege is available to permit a user account's queries to always be executed even if an `abort` item would block them. Accounts with this privilege can therefore be used to regain access to a system following an audit misconfiguration. The query is still logged in the audit log, but instead of being rejected, it is permitted due to the privilege.

Accounts created with the `SYSTEM_USER` privilege have the `AUDIT_ABORT_EXEMPT` privilege assigned automatically when they are created. The `AUDIT_ABORT_EXEMPT` privilege is also assigned to existing accounts with the `SYSTEM_USER` privilege when you carry out an upgrade procedure, if no existing accounts have that privilege assigned.

The `abort` item must appear within an `event` item. For example:

```
"event": {
 "name": qualifying event subclass names
 "abort": condition
}
```

For event subclasses selected by the `name` item, the `abort` action is true or false, depending on `condition` evaluation. If the condition evaluates to true, the event is blocked. Otherwise, the event continues executing.

The `condition` specification can be as simple as `true` or `false`, or it can be more complex such that evaluation depends on event characteristics.

This filter blocks `INSERT`, `UPDATE`, and `DELETE` statements:

```
{
 "filter": {
 "class": {
 "name": "table_access",
 "event": {
 "name": ["insert", "update", "delete"],
 "abort": true
 }
 }
 }
}
```

This more complex filter blocks the same statements, but only for a specific table (`finances.bank_account`):

```
{
 "filter": {
 "class": {
 "name": "table_access",
 "event": {
 "name": ["insert", "update", "delete"],
 "abort": {
 "and": [
 { "field": { "name": "table_database.str", "value": "finances" } },
 { "field": { "name": "table_name.str", "value": "bank_account" } }
]
 }
 }
 }
 }
}
```

Statements matched and blocked by the filter return an error to the client:

```
ERROR 1045 (28000): Statement was aborted by an audit log filter
```

Not all events can be blocked (see [Table 8.36, “Log and Abort Characteristics Per Event Class and Subclass Combination”](#)). For an event that cannot be blocked, the audit log writes a warning to the error log rather than blocking it.

For attempts to define a filter in which the `abort` item appears elsewhere than in an `event` item, an error occurs.

## Logical Operators

Logical operators (`and`, `or`, `not`) permit construction of complex conditions, enabling more advanced filtering configurations to be written. The following `log` item logs only `general` events with `general_command` fields having a specific value and length:

```
{
 "filter": {
 "class": {
 "name": "general",
 "event": {
 "name": "status",
 "log": {
 "or": [
 {
 "and": [
 { "field": { "name": "general_command.str", "value": "Query" } },
 { "field": { "name": "general_command.length", "value": 5 } }
]
 },
 {
 "and": [
 { "field": { "name": "general_command.str", "value": "Execute" } },
 { "field": { "name": "general_command.length", "value": 7 } }
]
 }
]
 }
 }
 }
 }
}
```

## Referencing Predefined Variables

To refer to a predefined variable in a `log` condition, use a `variable` item, which takes `name` and `value` items and tests equality of the named variable against a given value:

```
"variable": {
 "name": "variable_name",
 "value": comparison_value
}
```

This is true if `variable_name` has the value `comparison_value`, false otherwise.

Example:

```
{
 "filter": {
 "class": {
 "name": "general",
 "event": {
 "name": "status",
 "log": {
 "variable": {
```

```
 "name": "audit_log_connection_policy_value",
 "value": "::none"
 }
}

}
}
```

Each predefined variable corresponds to a system variable. By writing a filter that tests a predefined variable, you can modify filter operation by setting the corresponding system variable, without having to redefine the filter. For example, by writing a filter that tests the value of the `audit_log_connection_policy_value` predefined variable, you can modify filter operation by changing the value of the `audit_log_connection_policy` system variable.

The `audit_log_xxx_policy` system variables are used for the deprecated legacy mode audit log (see [Section 8.4.5.10, “Legacy Mode Audit Log Filtering”](#)). With rule-based audit log filtering, those variables remain visible (for example, using `SHOW VARIABLES`), but changes to them have no effect unless you write filters containing constructs that refer to them.

The following list describes the permitted predefined variables for `variable` items:

- audit\_log\_connection\_policy\_value

This variable corresponds to the value of the `audit_log_connection_policy` system variable. The value is an unsigned integer. Table 8.40, “`audit_log_connection_policy_value` Values” shows the permitted values and the corresponding `audit_log_connection_policy` values.

### Table 8.40 audit\_log\_connection\_policy\_value Values

Value	Corresponding audit_log_connection_policy Value
0 or "::none"	NONE
1 or "::errors"	ERRORS
2 or "::all"	ALL

The " :xxx " values are symbolic pseudo-constants that may be given instead of the literal numeric values. They must be quoted as strings and are case-sensitive.

- audit log policy value

This variable corresponds to the value of the `audit_log_policy` system variable. The value is an unsigned integer. Table 8.41, “`audit_log_policy_value` Values” shows the permitted values and the corresponding `audit_log_policy` values.

### Table 8.41 audit\_log\_policy\_value Values

Value	Corresponding audit_log_policy Value
0 or ":: <none"< td=""><td>NONE</td></none"<>	NONE
1 or ":: <logins"< td=""><td>LOGINS</td></logins"<>	LOGINS
2 or ":: <all"< td=""><td>ALL</td></all"<>	ALL
3 or ":: <queries"< td=""><td>QUERIES</td></queries"<>	QUERIES

The `::xxx` values are symbolic pseudo-constants that may be given instead of the literal numeric values. They must be quoted as strings and are case-sensitive.

- `audit_log_statement_policy_value`

This variable corresponds to the value of the `audit_log_statement_policy` system variable. The value is an unsigned integer. Table 8.42, “`audit_log_statement_policy_value` Values” shows the permitted values and the corresponding `audit_log_statement_policy` values.

**Table 8.42 `audit_log_statement_policy_value` Values**

Value	Corresponding <code>audit_log_statement_policy</code> Value
0 or <code>::none</code>	NONE
1 or <code>::errors</code>	ERRORS
2 or <code>::all</code>	ALL

The `::xxx` values are symbolic pseudo-constants that may be given instead of the literal numeric values. They must be quoted as strings and are case-sensitive.

## Referencing Predefined Functions

To refer to a predefined function in a `log` condition, use a `function` item, which takes `name` and `args` items to specify the function name and its arguments, respectively:

```
"function": {
 "name": "function_name",
 "args": arguments
}
```

The `name` item should specify the function name only, without parentheses or the argument list.

The `args` item must satisfy these conditions:

- If the function takes no arguments, no `args` item should be given.
- If the function does take arguments, an `args` item is needed, and the arguments must be given in the order listed in the function description. Arguments can refer to predefined variables, event fields, or string or numeric constants.

If the number of arguments is incorrect or the arguments are not of the correct data types required by the function an error occurs.

Example:

```
{
 "filter": {
 "class": {
 "name": "general",
 "event": {
 "name": "status",
 "log": {
 "function": {
 "name": "find_in_include_list",
 "args": [{ "string": [{ "field": "user.str" },
 { "string": "@" },
 { "field": "host.str" }] }]
 }
 }
 }
 }
 }
}
```

The preceding filter determines whether to log `general` class `status` events depending on whether the current user is found in the `audit_log_include_accounts` system variable. That user is constructed using fields in the event.

The following list describes the permitted predefined functions for `function` items:

- `audit_log_exclude_accounts_is_null()`

Checks whether the `audit_log_exclude_accounts` system variable is `NULL`. This function can be helpful when defining filters that correspond to the legacy audit log implementation.

Arguments:

None.

- `audit_log_include_accounts_is_null()`

Checks whether the `audit_log_include_accounts` system variable is `NULL`. This function can be helpful when defining filters that correspond to the legacy audit log implementation.

Arguments:

None.

- `debug_sleep(millisec)`

Sleeps for the given number of milliseconds. This function is used during performance measurement.

`debug_sleep()` is available for debug builds only.

Arguments:

- `millisec`: An unsigned integer that specifies the number of milliseconds to sleep.

- `find_in_exclude_list(account)`

Checks whether an account string exists in the audit log exclude list (the value of the `audit_log_exclude_accounts` system variable).

Arguments:

- `account`: A string that specifies the user account name.

- `find_in_include_list(account)`

Checks whether an account string exists in the audit log include list (the value of the `audit_log_include_accounts` system variable).

Arguments:

- `account`: A string that specifies the user account name.

- `query_digest([str])`

This function has differing behavior depending on whether an argument is given:

- With no argument, `query_digest` returns the statement digest value corresponding to the statement literal text in the current event.

- With an argument, `query_digest` returns a Boolean indicating whether the argument is equal to the current statement digest.

Arguments:

- `str`: This argument is optional. If given, it specifies a statement digest to be compared against the digest for the statement in the current event.

Examples:

This `function` item includes no argument, so `query_digest` returns the current statement digest as a string:

```
"function": {
 "name": "query_digest"
}
```

This `function` item includes an argument, so `query_digest` returns a Boolean indicating whether the argument equals the current statement digest:

```
"function": {
 "name": "query_digest",
 "args": "SELECT ?"
}
```

- `string_find(text, substr)`

Checks whether the `substr` value is contained in the `text` value. This search is case-sensitive.

Arguments:

- `text`: The text string to search.
- `substr`: The substring to search for in `text`.

## Replacement of Event Field Values

Audit filter definitions support replacement of certain audit event fields, so that logged events contain the replacement value rather than the original value. This capability enables logged audit records to include statement digests rather than literal statements, which can be useful for MySQL deployments for which statements may expose sensitive values.

Field replacement in audit events works like this:

- Field replacements are specified in audit filter definitions, so audit log filtering must be enabled as described in [Section 8.4.5.7, “Audit Log Filtering”](#).
- Not all fields can be replaced. [Table 8.43, “Event Fields Subject to Replacement”](#) shows which fields are replaceable in which event classes.

**Table 8.43 Event Fields Subject to Replacement**

Event Class	Field Name
<code>general</code>	<code>general_query.str</code>
<code>table_access</code>	<code>query.str</code>

- Replacement is conditional. Each replacement specification in a filter definition includes a condition, enabling a replaceable field to be changed, or left unchanged, depending on the condition result.

- If replacement occurs, the replacement specification indicates the replacement value using a function that is permitted for that purpose.

As [Table 8.43, “Event Fields Subject to Replacement”](#) shows, currently the only replaceable fields are those that contain statement text (which occurs in events of the [general](#) and [table\\_access](#) classes). In addition, the only function permitted for specifying the replacement value is [query\\_digest](#). This means that the only permitted replacement operation is to replace statement literal text by its corresponding digest.

Because field replacement occurs at an early auditing stage (during filtering), the choice of whether to write statement literal text or digest values applies regardless of log format written later (that is, whether the audit log plugin produces XML or JSON output).

Field replacement can take place at differing levels of event granularity:

- To perform field replacement for all events in a class, filter events at the class level.
- To perform replacement on a more fine-grained basis, include additional event-selection items. For example, you can perform field replacement only for specific subclasses of a given event class, or only in events for which fields have certain characteristics.

Within a filter definition, specify field replacement by including a [print](#) item, which has this syntax:

```
"print": {
 "field": {
 "name": "field_name",
 "print": condition,
 "replace": replacement_value
 }
}
```

Within the [print](#) item, its [field](#) item takes these three items to indicate how whether and how replacement occurs:

- [name](#): The field for which replacement (potentially) occurs. [field\\_name](#) must be one of those shown in [Table 8.43, “Event Fields Subject to Replacement”](#).
- [print](#): The condition that determines whether to retain the original field value or replace it:
  - If [condition](#) evaluates to [true](#), the field remains unchanged.
  - If [condition](#) evaluates to [false](#), replacement occurs, using the value of the [replace](#) item.

To unconditionally replace a field, specify the condition like this:

```
"print": false
```

- [replace](#): The replacement value to use when the [print](#) condition evaluates to [false](#). Specify [replacement\\_value](#) using a [function](#) item.

For example, this filter definition applies to all events in the [general](#) class, replacing the statement literal text with its digest:

```
{
 "filter": {
 "class": {
 "name": "general",
 "print": {
 "field": {
 "name": "general_query.str",
 "print": false,

```

```

 "replace": {
 "function": {
 "name": "query_digest"
 }
 }
 }
}

```

The preceding filter uses this `print` item to unconditionally replace the statement literal text contained in `general_query.str` by its digest value:

```

"print": {
 "field": {
 "name": "general_query.str",
 "print": false,
 "replace": {
 "function": {
 "name": "query_digest"
 }
 }
 }
}

```

`print` items can be written different ways to implement different replacement strategies. The `replace` item just shown specifies the replacement text using this `function` construct to return a string representing the current statement digest:

```

"function": {
 "name": "query_digest"
}

```

The `query_digest` function can also be used in another way, as a comparator that returns a Boolean, which enables its use in the `print` condition. To do this, provide an argument that specifies a comparison statement digest:

```

"function": {
 "name": "query_digest",
 "args": "digest"
}

```

In this case, `query_digest` returns `true` or `false` depending on whether the current statement digest is the same as the comparison digest. Using `query_digest` this way enables filter definitions to detect statements that match particular digests. The condition in the following construct is true only for statements that have a digest equal to `SELECT ?`, thus effecting replacement only for statements that do not match the digest:

```

"print": {
 "field": {
 "name": "general_query.str",
 "print": {
 "function": {
 "name": "query_digest",
 "args": "SELECT ?"
 }
 },
 "replace": {
 "function": {
 "name": "query_digest"
 }
 }
 }
}

```

To perform replacement only for statements that do match the digest, use `not` to invert the condition:

```
"print": {
 "field": {
 "name": "general_query.str",
 "print": {
 "not": {
 "function": {
 "name": "query_digest",
 "args": "SELECT ?"
 }
 }
 }
 },
 "replace": {
 "function": {
 "name": "query_digest"
 }
 }
}
```

Suppose that you want the audit log to contain only statement digests and not literal statements. To achieve this, you must perform replacement on all events that contain statement text; that is, events in the `general` and `table_access` classes. An earlier filter definition showed how to unconditionally replace statement text for `general` events. To do the same for `table_access` events, use a filter that is similar but changes the class from `general` to `table_access` and the field name from `general_query.str` to `query.str`:

```
{
 "filter": {
 "class": {
 "name": "table_access",
 "print": {
 "field": {
 "name": "query.str",
 "print": false,
 "replace": {
 "function": {
 "name": "query_digest"
 }
 }
 }
 }
 }
 }
}
```

Combining the `general` and `table_access` filters results in a single filter that performs replacement for all statement text-containing events:

```
{
 "filter": {
 "class": [
 {
 "name": "general",
 "print": {
 "field": {
 "name": "general_query.str",
 "print": false,
 "replace": {
 "function": {
 "name": "query_digest"
 }
 }
 }
 }
 }
]
 }
}
```

```

 },
 {
 "name": "table_access",
 "print": {
 "field": {
 "name": "query.str",
 "print": false,
 "replace": {
 "function": {
 "name": "query_digest"
 }
 }
 }
 }
 }
]
}

```

To perform replacement on only some events within a class, add items to the filter that indicate more specifically when replacement occurs. The following filter applies to events in the `table_access` class, but performs replacement only for `insert` and `update` events (leaving `read` and `delete` events unchanged):

```

{
 "filter": {
 "class": {
 "name": "table_access",
 "event": {
 "name": [
 "insert",
 "update"
],
 "print": {
 "field": {
 "name": "query.str",
 "print": false,
 "replace": {
 "function": {
 "name": "query_digest"
 }
 }
 }
 }
 }
 }
 }
}

```

This filter performs replacement for `general` class events corresponding to the listed account-management statements (the effect being to hide credential and data values in the statements):

```

{
 "filter": {
 "class": {
 "name": "general",
 "event": {
 "name": "status",
 "print": {
 "field": {
 "name": "general_query.str",
 "print": false,
 "replace": {
 "function": {
 "name": "query_digest"
 }
 }
 }
 }
 }
 }
 }
}

```

```

 }
 },
 "log": {
 "or": [
 {
 "field": {
 "name": "general_sql_command.str",
 "value": "alter_user"
 }
 },
 {
 "field": {
 "name": "general_sql_command.str",
 "value": "alter_user_default_role"
 }
 },
 {
 "field": {
 "name": "general_sql_command.str",
 "value": "create_role"
 }
 },
 {
 "field": {
 "name": "general_sql_command.str",
 "value": "create_user"
 }
 }
]
 }
}

```

For information about the possible `general_sql_command.str` values, see [Testing Event Field Values](#).

## Replacing a User Filter

In some cases, the filter definition can be changed dynamically. To do this, define a `filter` configuration within an existing `filter`. For example:

```

{
 "filter": {
 "id": "main",
 "class": {
 "name": "table_access",
 "event": {
 "name": ["update", "delete"],
 "log": false,
 "filter": {
 "class": {
 "name": "general",
 "event": {
 "name": "status",
 "filter": { "ref": "main" }
 }
 }
 },
 "activate": {
 "or": [
 { "field": { "name": "table_name.str", "value": "temp_1" } },
 { "field": { "name": "table_name.str", "value": "temp_2" } }
]
 }
 }
 }
 }
}

```

```
}
```

A new filter is activated when the `activate` item within a subfilter evaluates to `true`. Using `activate` in a top-level `filter` is not permitted.

A new filter can be replaced with the original one by using a `ref` item inside the subfilter to refer to the original filter `id`.

The filter shown operates like this:

- The `main` filter waits for `table_access` events, either `update` or `delete`.
- If the `update` or `delete table_access` event occurs on the `temp_1` or `temp_2` table, the filter is replaced with the internal one (without an `id`, since there is no need to refer to it explicitly).
- If the end of the command is signalled (`general` / `status` event), an entry is written to the audit log file and the filter is replaced with the `main` filter.

The filter is useful to log statements that update or delete anything from the `temp_1` or `temp_2` tables, such as this one:

```
UPDATE temp_1, temp_3 SET temp_1.a=21, temp_3.a=23;
```

The statement generates multiple `table_access` events, but the audit log file contains only `general` / `status` entries.

#### Note

Any `id` values used in the definition are evaluated with respect only to that definition. They have nothing to do with the value of the `audit_log_filter_id` system variable.

### 8.4.5.9 Disabling Audit Logging

The `audit_log_disable` variable permits disabling audit logging for all connecting and connected sessions. The `audit_log_disable` variable can be set in a MySQL Server option file, in a command-line startup string, or at runtime using a `SET` statement; for example:

```
SET GLOBAL audit_log_disable = true;
```

Setting `audit_log_disable` to `true` disables the audit log plugin. The plugin is re-enabled when `audit_log_disable` is set back to `false`, which is the default setting.

Starting the audit log plugin with `audit_log_disable = true` generates a warning (`ER_WARN_AUDIT_LOG_DISABLED`) with the following message: `Audit Log is disabled. Enable it with audit_log_disable = false`. Setting `audit_log_disable` to `false` also generates a warning. When `audit_log_disable` is set to `true`, audit log function calls and variable changes generate a session warning.

Setting the runtime value of `audit_log_disable` requires the `AUDIT_ADMIN` privilege, in addition to the `SYSTEM_VARIABLES_ADMIN` privilege (or the deprecated `SUPER` privilege) normally required to set a global system variable runtime value.

### 8.4.5.10 Legacy Mode Audit Log Filtering

#### Note

This section describes legacy audit log filtering, which applies if the `audit_log` plugin is installed without the accompanying audit tables and functions needed for rule-based filtering.

## Legacy Mode Audit Log Filtering is deprecated.

The audit log plugin can filter audited events. This enables you to control whether audited events are written to the audit log file based on the account from which events originate or event status. Status filtering occurs separately for connection events and statement events.

- [Legacy Event Filtering by Account](#)
- [Legacy Event Filtering by Status](#)

### Legacy Event Filtering by Account

To filter audited events based on the originating account, set one (not both) of the following system variables at server startup or runtime. These deprecated variables apply only for legacy audit log filtering.

- `audit_log_include_accounts`: The accounts to include in audit logging. If this variable is set, only these accounts are audited.
- `audit_log_exclude_accounts`: The accounts to exclude from audit logging. If this variable is set, all but these accounts are audited.

The value for either variable can be `NULL` or a string containing one or more comma-separated account names, each in `user_name@host_name` format. By default, both variables are `NULL`, in which case, no account filtering is done and auditing occurs for all accounts.

Modifications to `audit_log_include_accounts` or `audit_log_exclude_accounts` affect only connections created subsequent to the modification, not existing connections.

Example: To enable audit logging only for the `user1` and `user2` local host accounts, set the `audit_log_include_accounts` system variable like this:

```
SET GLOBAL audit_log_include_accounts = 'user1@localhost,user2@localhost';
```

Only one of `audit_log_include_accounts` or `audit_log_exclude_accounts` can be non-`NULL` at a time:

- If you set `audit_log_include_accounts`, the server sets `audit_log_exclude_accounts` to `NULL`.
- If you attempt to set `audit_log_exclude_accounts`, an error occurs unless `audit_log_include_accounts` is `NULL`. In this case, you must first clear `audit_log_include_accounts` by setting it to `NULL`.

```
-- This sets audit_log_exclude_accounts to NULL
SET GLOBAL audit_log_include_accounts = value;

-- This fails because audit_log_include_accounts is not NULL
SET GLOBAL audit_log_exclude_accounts = value;

-- To set audit_log_exclude_accounts, first set
-- audit_log_include_accounts to NULL
SET GLOBAL audit_log_include_accounts = NULL;
SET GLOBAL audit_log_exclude_accounts = value;
```

If you inspect the value of either variable, be aware that `SHOW VARIABLES` displays `NULL` as an empty string. To display `NULL` as `NULL`, use `SELECT` instead:

```
mysql> SHOW VARIABLES LIKE 'audit_log_include_accounts';
+-----+-----+
| Variable_name | Value |
+-----+-----+
```

```

| audit_log_include_accounts | |
+-----+-----+
mysql> SELECT @@audit_log_include_accounts;
+-----+-----+
| @@audit_log_include_accounts |
+-----+-----+
| NULL |
+-----+-----+

```

If a user name or host name requires quoting because it contains a comma, space, or other special character, quote it using single quotes. If the variable value itself is quoted with single quotes, double each inner single quote or escape it with a backslash. The following statements each enable audit logging for the local `root` account and are equivalent, even though the quoting styles differ:

```

SET GLOBAL audit_log_include_accounts = 'root@localhost';
SET GLOBAL audit_log_include_accounts = ''root''@''localhost'';
SET GLOBAL audit_log_include_accounts = '\root\'@\localhost\';
SET GLOBAL audit_log_include_accounts = "'root'@'localhost'";

```

The last statement does not work if the `ANSI_QUOTES` SQL mode is enabled because in that mode double quotes signify identifier quoting, not string quoting.

## Legacy Event Filtering by Status

To filter audited events based on status, set the following system variables at server startup or runtime. These deprecated variables apply only for legacy audit log filtering. For JSON audit log filtering, different status variables apply; see [Audit Log Options and Variables](#).

- `audit_log_connection_policy`: Logging policy for connection events
- `audit_log_statement_policy`: Logging policy for statement events

Each variable takes a value of `ALL` (log all associated events; this is the default), `ERRORS` (log only failed events), or `NONE` (do not log events). For example, to log all statement events but only failed connection events, use these settings:

```

SET GLOBAL audit_log_statement_policy = ALL;
SET GLOBAL audit_log_connection_policy = ERRORS;

```

Another policy system variable, `audit_log_policy`, is available but does not afford as much control as `audit_log_connection_policy` and `audit_log_statement_policy`. It can be set only at server startup.

### Note

The `audit_log_policy` legacy-mode system variable is deprecated.

At runtime, it is a read-only variable. It takes a value of `ALL` (log all events; this is the default), `LOGINS` (log connection events), `QUERIES` (log statement events), or `NONE` (do not log events). For any of those values, the audit log plugin logs all selected events without distinction as to success or failure. Use of `audit_log_policy` at startup works as follows:

- If you do not set `audit_log_policy` or set it to its default of `ALL`, any explicit settings for `audit_log_connection_policy` or `audit_log_statement_policy` apply as specified. If not specified, they default to `ALL`.
- If you set `audit_log_policy` to a non-`ALL` value, that value takes precedence over and is used to set `audit_log_connection_policy` and `audit_log_statement_policy`, as indicated in the following table. If you also set either of those variables to a value other than their default of `ALL`, the server writes a message to the error log to indicate that their values are being overridden.

Startup <code>audit_log_policy</code> Value	Resulting <code>audit_log_connection_policy</code> Value	Resulting <code>audit_log_statement_policy</code> Value
LOGINS	ALL	NONE
QUERIES	NONE	ALL
NONE	NONE	NONE

### 8.4.5.11 Audit Log Reference

The following sections provide a reference to MySQL Enterprise Audit elements:

- [Audit Log Tables](#)
- [Audit Log Functions](#)
- [Audit Log Option and Variable Reference](#)
- [Audit Log Options and Variables](#)
- [Audit Log Status Variables](#)

To install the audit log tables and functions, use the instructions provided in [Section 8.4.5.2, “Installing or Uninstalling MySQL Enterprise Audit”](#). Unless those objects are installed, the `audit_log` plugin operates in (deprecated) legacy mode. See [Section 8.4.5.10, “Legacy Mode Audit Log Filtering”](#).

#### Audit Log Tables

MySQL Enterprise Audit uses tables in the `mysql` system database for persistent storage of filter and user account data. The tables can be accessed only by users who have privileges for that database. To use a different database, set the `audit_log_database` system variable at server startup. The tables use the `InnoDB` storage engine.

If these tables are missing, the `audit_log` plugin operates in (deprecated) legacy mode. See [Section 8.4.5.10, “Legacy Mode Audit Log Filtering”](#).

The `audit_log_filter` table stores filter definitions. The table has these columns:

- `NAME`

The filter name.

- `FILTER`

The filter definition associated with the filter name. Definitions are stored as `JSON` values.

The `audit_log_user` table stores user account information. The table has these columns:

- `USER`

The user name part of an account. For an account `user1@localhost`, the `USER` part is `user1`.

- `HOST`

The host name part of an account. For an account `user1@localhost`, the `HOST` part is `localhost`.

- `FILTERNAME`

The name of the filter assigned to the account. The filter name associates the account with a filter defined in the `audit_log_filter` table.

## Audit Log Functions

This section describes, for each audit log function, its purpose, calling sequence, and return value. For information about the conditions under which these functions can be invoked, see [Section 8.4.5.7, “Audit Log Filtering”](#).

Each audit log function returns a string that indicates whether the operation succeeded. `OK` indicates success. `ERROR: message` indicates failure.

Audit log functions convert string arguments to `utf8mb4` and string return values are `utf8mb4` strings. Previously, audit log functions treated string arguments as binary strings (which means they did not distinguish lettercase), and string return values were binary strings.

If an audit log function is invoked from within the `mysql` client, binary string results display using hexadecimal notation, depending on the value of the `--binary-as-hex`. For more information about that option, see [Section 6.5.1, “mysql — The MySQL Command-Line Client”](#).

These audit log functions are available:

- `audit_log_encryption_password_get([keyring_id])`

This function fetches an audit log encryption password from the MySQL keyring, which must be enabled or an error occurs. Any keyring component or plugin can be used; for instructions, see [Section 8.4.4, “The MySQL Keyring”](#).

With no argument, the function retrieves the current encryption password as a binary string. An argument may be given to specify which audit log encryption password to retrieve. The argument must be the keyring ID of the current password or an archived password.

For additional information about audit log encryption, see [Encrypting Audit Log Files](#).

Arguments:

*keyring\_id*: This optional argument indicates the keyring ID of the password to retrieve. The maximum permitted length is 766 bytes. If omitted, the function retrieves the current password.

Return value:

The password string for success (up to 766 bytes), or `NULL` and an error for failure.

Example:

Retrieve the current password:

```
mysql> SELECT audit_log_encryption_password_get();
+-----+
| audit_log_encryption_password_get() |
+-----+
| secret |
+-----+
```

To retrieve a password by ID, you can determine which audit log keyring IDs exist by querying the Performance Schema `keyring_keys` table:

```
mysql> SELECT KEY_ID FROM performance_schema.keyring_keys
WHERE KEY_ID LIKE 'audit_log%'
```

```

ORDER BY KEY_ID;
+-----+
| KEY_ID |
+-----+
| audit_log-20190415T152248-1 |
| audit_log-20190415T153507-1 |
| audit_log-20190416T125122-1 |
| audit_log-20190416T141608-1 |
+-----+
mysql> SELECT audit_log_encryption_password_get('audit_log-20190416T125122-1');
+-----+
| audit_log_encryption_password_get('audit_log-20190416T125122-1') |
+-----+
| segreto |
+-----+

```

- `audit_log_encryption_password_set(password)`

Sets the current audit log encryption password to the argument and stores the password in the MySQL keyring. The password is stored as a `utf8mb4` string. Previously, the password was stored in binary form.

If encryption is enabled, this function performs a log file rotation operation that renames the current log file, and begins a new log file encrypted with the password. The keyring must be enabled or an error occurs. Any keyring component or plugin can be used; for instructions, see [Section 8.4.4, “The MySQL Keyring”](#).

For additional information about audit log encryption, see [Encrypting Audit Log Files](#).

Arguments:

*password*: The password string. The maximum permitted length is 766 bytes.

Return value:

1 for success, 0 for failure.

Example:

```

mysql> SELECT audit_log_encryption_password_set(password);
+-----+
| audit_log_encryption_password_set(password) |
+-----+
| 1 |
+-----+

```

- `audit_log_filter_flush()`

Calling any of the other filtering functions affects operational audit log filtering immediately and updates the audit log tables. If instead you modify the contents of those tables directly using statements such as `INSERT`, `UPDATE`, and `DELETE`, the changes do not affect filtering immediately. To flush your changes and make them operational, call `audit_log_filter_flush()`.

### Warning

`audit_log_filter_flush()` should be used only after modifying the audit tables directly, to force reloading all filters. Otherwise, this function should

be avoided. It is, in effect, a simplified version of unloading and reloading the `audit_log` plugin with `UNINSTALL PLUGIN` plus `INSTALL PLUGIN`.

`audit_log_filter_flush()` affects all current sessions and detaches them from their previous filters. Current sessions are no longer logged unless they disconnect and reconnect, or execute a change-user operation.

If this function fails, an error message is returned and the audit log is disabled until the next successful call to `audit_log_filter_flush()`.

Arguments:

None.

Return value:

A string that indicates whether the operation succeeded. `OK` indicates success. `ERROR: message` indicates failure.

Example:

```
mysql> SELECT audit_log_filter_flush();
+-----+
| audit_log_filter_flush() |
+-----+
| OK |
+-----+
```

- `audit_log_filter_remove_filter(filter_name)`

Given a filter name, removes the filter from the current set of filters. It is not an error for the filter not to exist.

If a removed filter is assigned to any user accounts, those users stop being filtered (they are removed from the `audit_log_user` table). Termination of filtering includes any current sessions for those users: They are detached from the filter and no longer logged.

Arguments:

- `filter_name`: A string that specifies the filter name.

Return value:

A string that indicates whether the operation succeeded. `OK` indicates success. `ERROR: message` indicates failure.

Example:

```
mysql> SELECT audit_log_filter_remove_filter('SomeFilter');
+-----+
| audit_log_filter_remove_filter('SomeFilter') |
+-----+
| OK |
+-----+
```

- `audit_log_filter_remove_user(user_name)`

Given a user account name, cause the user to be no longer assigned to a filter. It is not an error if the user has no filter assigned. Filtering of current sessions for the user remains unaffected. New

connections for the user are filtered using the default account filter if there is one, and are not logged otherwise.

If the name is `%`, the function removes the default account filter that is used for any user account that has no explicitly assigned filter.

Arguments:

- `user_name`: The user account name as a string in `user_name@host_name` format, or `%` to represent the default account.

Return value:

A string that indicates whether the operation succeeded. `OK` indicates success. `ERROR: message` indicates failure.

Example:

```
mysql> SELECT audit_log_filter_remove_user('user1@localhost');
+-----+
| audit_log_filter_remove_user('user1@localhost') |
+-----+
| OK |
+-----+
```

- `audit_log_filter_set_filter(filter_name, definition)`

Given a filter name and definition, adds the filter to the current set of filters. If the filter already exists and is used by any current sessions, those sessions are detached from the filter and are no longer logged. This occurs because the new filter definition has a new filter ID that differs from its previous ID.

Arguments:

- `filter_name`: A string that specifies the filter name.
- `definition`: A `JSON` value that specifies the filter definition.

Return value:

A string that indicates whether the operation succeeded. `OK` indicates success. `ERROR: message` indicates failure.

Example:

```
mysql> SET @f = '{ "filter": { "log": false } }';
mysql> SELECT audit_log_filter_set_filter('SomeFilter', @f);
+-----+
| audit_log_filter_set_filter('SomeFilter', @f) |
+-----+
| OK |
+-----+
```

- `audit_log_filter_set_user(user_name, filter_name)`

Given a user account name and a filter name, assigns the filter to the user. A user can be assigned only one filter, so if the user was already assigned a filter, the assignment is replaced. Filtering of current sessions for the user remains unaffected. New connections are filtered using the new filter.

As a special case, the name `%` represents the default account. The filter is used for connections from any user account that has no explicitly assigned filter.

**Arguments:**

- `user_name`: The user account name as a string in `user_name@host_name` format, or `%` to represent the default account.
- `filter_name`: A string that specifies the filter name.

**Return value:**

A string that indicates whether the operation succeeded. `OK` indicates success. `ERROR: message` indicates failure.

**Example:**

```
mysql> SELECT audit_log_filter_set_user('user1@localhost', 'SomeFilter');
+-----+
| audit_log_filter_set_user('user1@localhost', 'SomeFilter') |
+-----+
| OK |
+-----+
```

- `audit_log_read([arg])`

Reads the audit log and returns a `JSON` string result. If the audit log format is not `JSON`, an error occurs.

With no argument or a `JSON` hash argument, `audit_log_read()` reads events from the audit log and returns a `JSON` string containing an array of audit events. Items in the hash argument influence how reading occurs, as described later. Each element in the returned array is an event represented as a `JSON` hash, with the exception that the last element may be a `JSON null` value to indicate no following events are available to read.

With an argument consisting of a `JSON null` value, `audit_log_read()` closes the current read sequence.

For additional details about the audit log-reading process, see [Section 8.4.5.6, “Reading Audit Log Files”](#).

**Arguments:**
